8.4.7.1 ISS SIMCOP ROT Overview

The rotation accelerator (ROT) module is intended to be used in the still-image coprocessor (SIMCOP) to perform block data rotation and data shifting from one SIMCOP local memory to another SIMCOP local memory. The following formats and operations are supported:

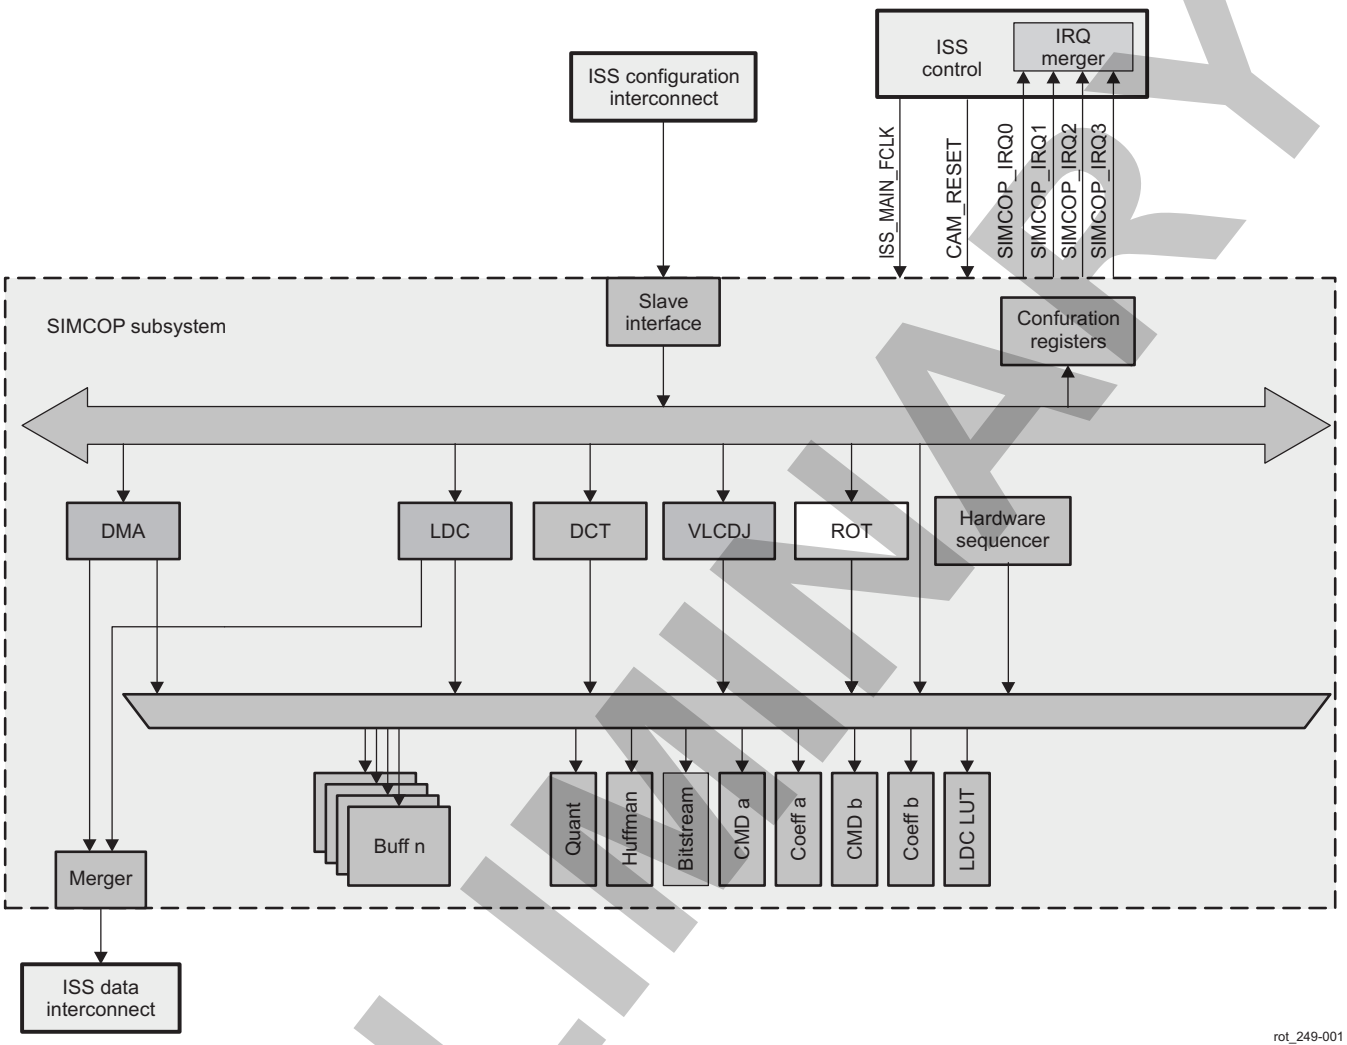
- YUV4:2:2 and generic 8-/16-/32-bit data block rotation by 90, 180, and 270 degrees
- YUV4:2:0 rotation by 90, 180, and 270 degrees
- Multiple-block rotation
- Data block shifting
- Data block horizontal circular shifting

The ROT supports a simple 1-block-per-initiation interaction, and includes a microcontroller unit (MCU) software-writable enable bit and hardware trigger signal to start the processing (see Section 8.4.7.3.7, *ISS SIMCOP ROT Synchronization*). It relies on external direct memory access (DMA) for transfers, and can work with the MCU or hardware sequencer to coordinate between transfer and computation.

The ROT has an input and output memory interface (see Figure 8-298). The rotation and horizontal-shifting operations read from the input memory and write to the output memory. The module connects to an input memory of up to 16 KiB (2048 × 64-bit), and an output memory of up to 16 KiB (2048 × 64-bit) using synchronous single-port memory interface.

Figure 8-296 is an overview of the ROT.

Figure 8-296. ISS SIMCOP ROT Module Overview



8.4.7.2 ISS SIMCOP ROT Integration

The ROT is part of the SIMCOP subsystem in the imaging subsystem (ISS). Figure 8-297 shows the integration of the ROT in the SIMCOP subsystem.

Figure 8-297. ISS SIMCOP ROT Engine Integration

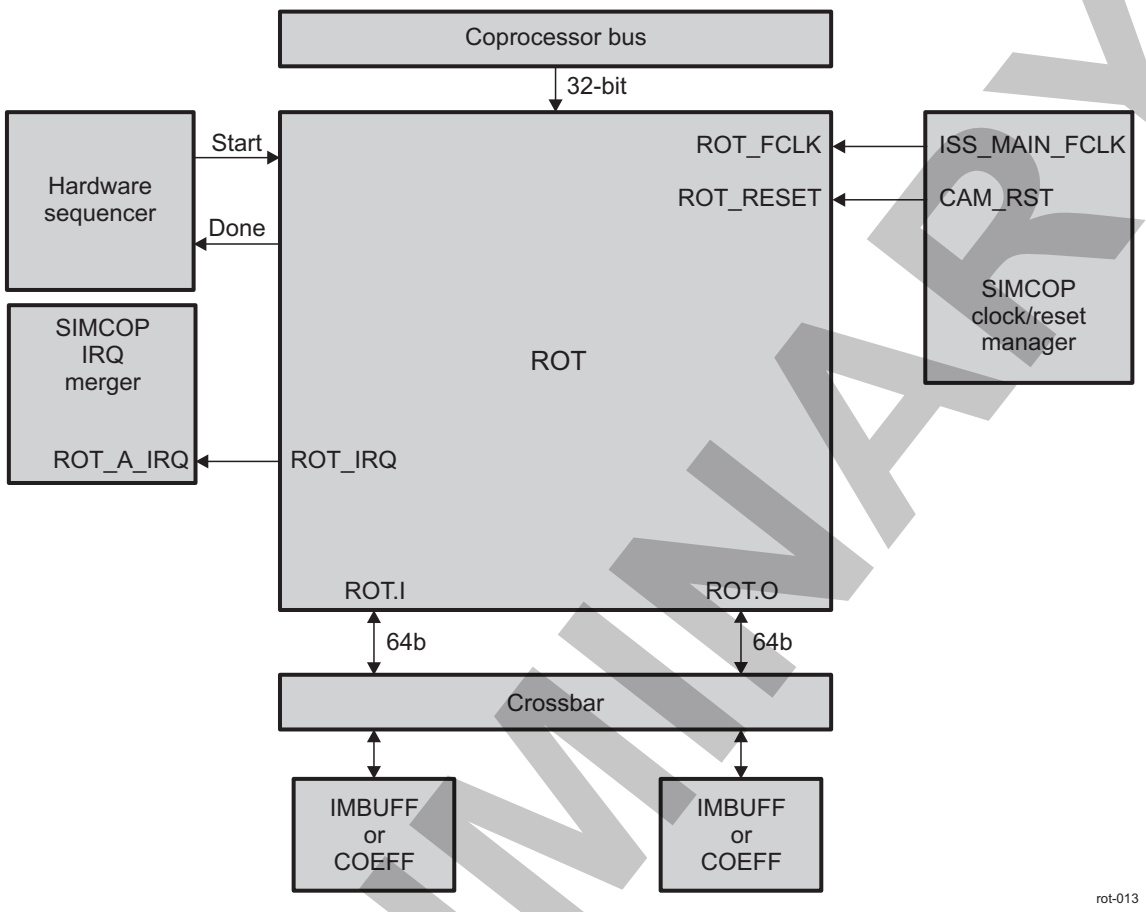


Table 8-1532 through Table 8-1534 list the integration attributes, clocks and resets, and hardware requests, respectively, of the SIMCOP ROT.

Table 8-1532. ISS SIMCOP ROT Integration Attributes

Module Instance	Attributes
	Power Domain
ROT	PD_CAM

Table 8-1533. ISS SIMCOP ROT Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
ROT	ROT_FCLK	ISS_MAIN_FCLK	ISS	Functional clock provided by CORE_ISS_MAIN_CLK from the power, reset, and clock management (PRCM) module. It is used by all ISS submodules and ISS top-level resources.
Resets				
ROT	ROT_RESET	CAM_RST	PRCM	ISS and SIMCOP global reset

For information about clock and reset management, see Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management*.

Table 8-1534. ISS SIMCOP ROT Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ROT	ROT_IRQ	ROT_A_IRQ	SIMCOP IRQ merger	Event triggered by the ROT engine.

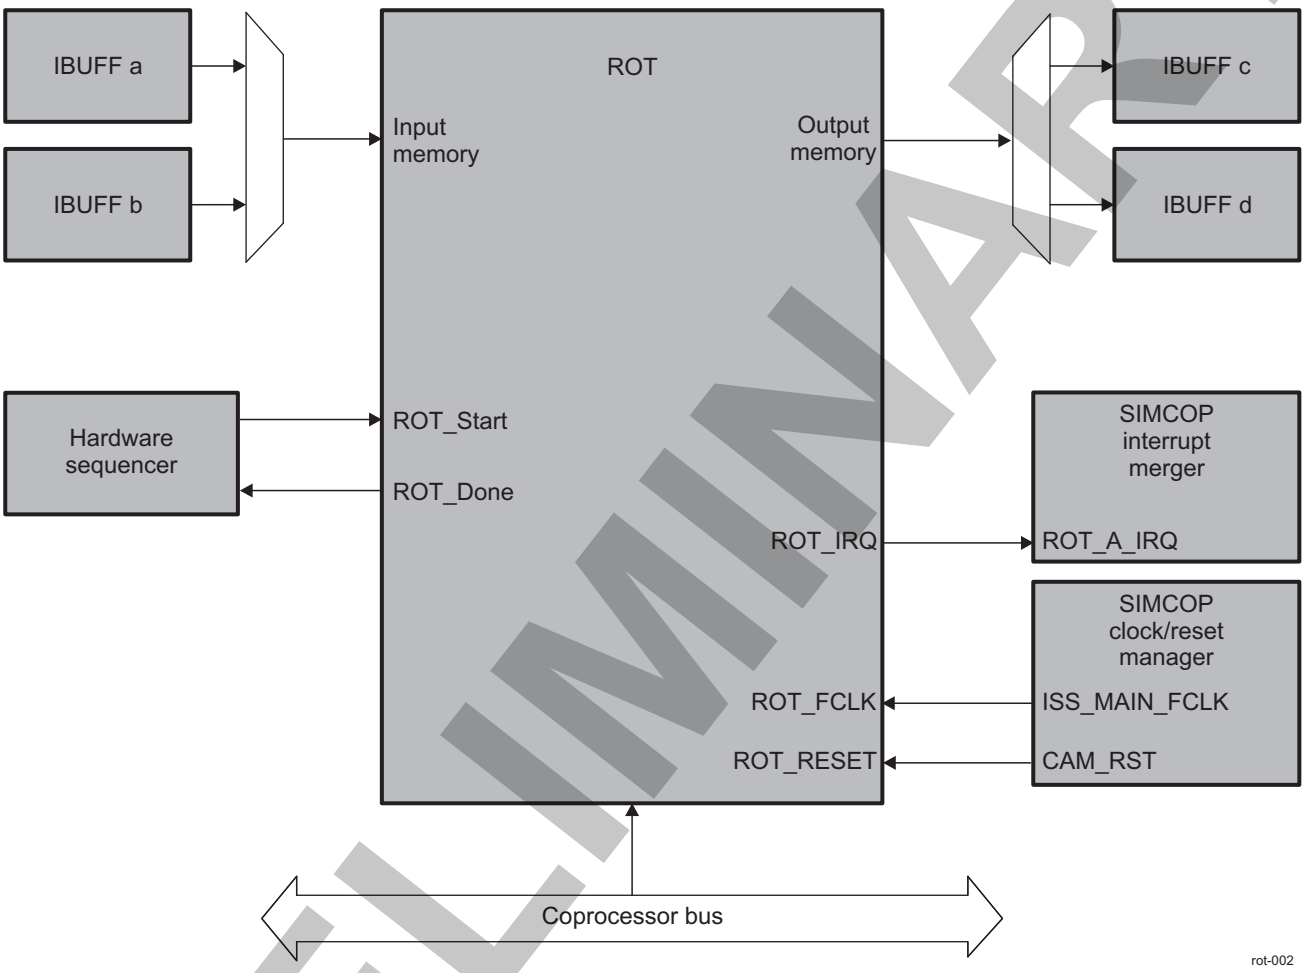
For more information about interrupt requests, see Section 8.4.1.2.3, *Interrupt Merger*.

8.4.7.3 ISS SIMCOP ROT Module Functional Description

8.4.7.3.1 ISS SIMCOP ROT Module Block Diagram

Figure 8-298 shows the block diagram of the ROT.

Figure 8-298. ISS SIMCOP ROT Module Block Diagram



8.4.7.3.2 ISS SIMCOP ROT Module Clock Configuration

The ROT receives a functional clock (ISS_MAIN_FCLK) from the ISS SIMCOP. The configuration clock is derived from the functional clock and interconnect clock enable signal (the ROT_CFG[9] AUTOGATING bit).

8.4.7.3.3 ISS SIMCOP ROT Module Reset

The ROT receives an asynchronous hardware reset signal (CAM_RST) from the ISS SIMCOP.

8.4.7.3.4 ISS SIMCOP ROT Module Power Management

The ROT uses clock autogating to conserve power. When a subblock is not in use, the corresponding clock tree is gated. The ROT_CFG[9] AUTOGATING bit controls whether autogating is enabled.

8.4.7.3.5 ISS SIMCOP ROT Module Interrupt Requests

One interrupt output line, ROT_A_IRQ, is used as a sideband signal of the interconnect slave port. This signal is connected to the SIMCOP interrupt merger. See Section 8.1.2.1.1, *Interrupt Merger*.

8.4.7.3.6 ISS SIMCOP ROT Module DMA Requests

The ROT has no DMA requests from the module.

8.4.7.3.7 ISS SIMCOP ROT Synchronization

The ROT has a simple one-block-per-task interaction with outside logic/microprocessor unit (MPU). The module can be started by setting the ROT_CTRL[0] EN bit to 0x1, or through the ROT_START signal of the hardware sequencer interface. When the ROT completes the specified rotation or data shift task, it sends a pulse on the ROT_DONE signal and, when the interrupt is enabled, sends a pulse on the ROT_A_IRQ interrupt output.

The ROT_CFG[8] TRIG_SRC bit specifies to which source the hardware must respond:

- When the module is idle and the ROT_CFG[8] TRIG_SRC bit is set to 0x0, hardware responds to the memory mapped register (MMR) mechanism, and any pulses on the start signal are ignored.
- When the module is idle and the ROT_CFG[8] TRIG_SRC bit is set to 0x1, hardware responds to the hardware start signal, and any write operation to the enable bit field is ignored.

When the module is busy, both triggering mechanisms are ignored.

8.4.7.3.8 ISS SIMCOP ROT Module Formats and Operations

The ROT module supports the formats and operations described in the following sections.

8.4.7.3.8.1 ISS SIMCOP ROT YUV4:2:0 and Generic 8-/16-/32-Bit Data Block Rotation

Rotation of YUV4:2:0 and generic 8-bit, 16-bit, 32-bit data blocks is straightforward. None of the data points are altered; each data point is copied to an appropriate address location. Zero-degree rotation is included for completeness of the programming model, and involves only data copy.

When YUV4:2:0 data have separate Y and UV processing and must be separately rotated, Y data can use generic 8-bit data rotation, and UV data can use generic 16-bit data rotation.

8.4.7.3.8.2 ISS SIMCOP ROT YUV4:2:2 Rotation

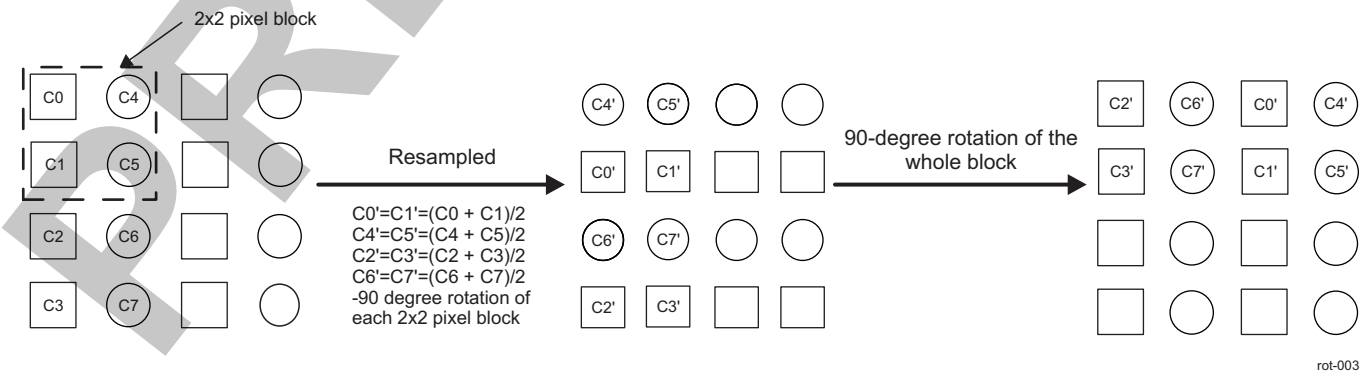
Various rotation cases of YUV4:2:2 data are described in the following and shown in Figure 8-299 through Figure 8-301 using 4 × 4-pixel block as an example.

The degree of rotation is defined as rotating clockwise. For 90-degree rotation:

- The two U samples in each 2 × 2-pixel input block are averaged and then replicated to provide the two U samples in the 2 × 2-pixel output block
- V samples - processed in the same way.

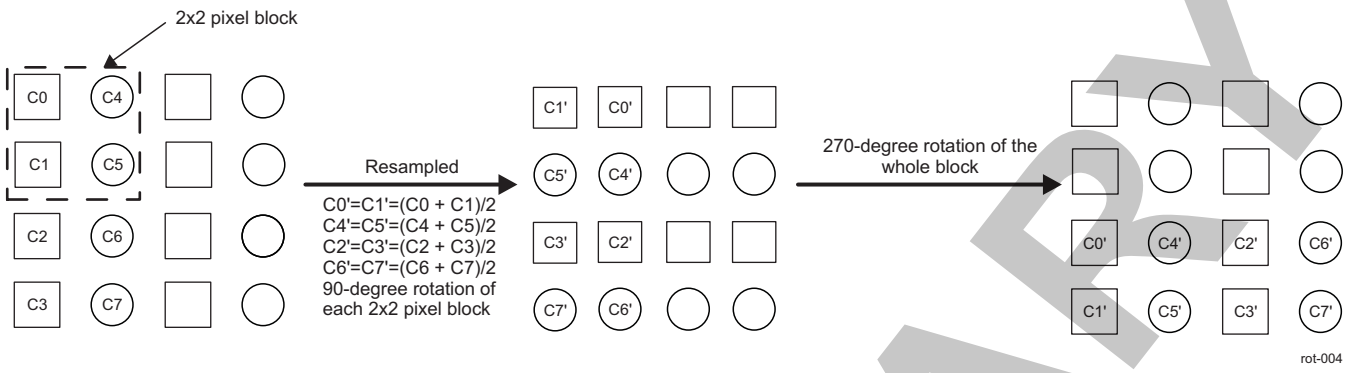
Thus, each 2N × 2N-pixel output block depends on only one 2N × 2N-pixel input block. After resampling every 2 × 2-pixel block, it is rotated –90 degrees, and then the whole 2N × 2N block is rotated 90 degrees.

Figure 8-299. ISS SIMCOP ROT 90-Degree Rotation of YUV4:2:2 Data



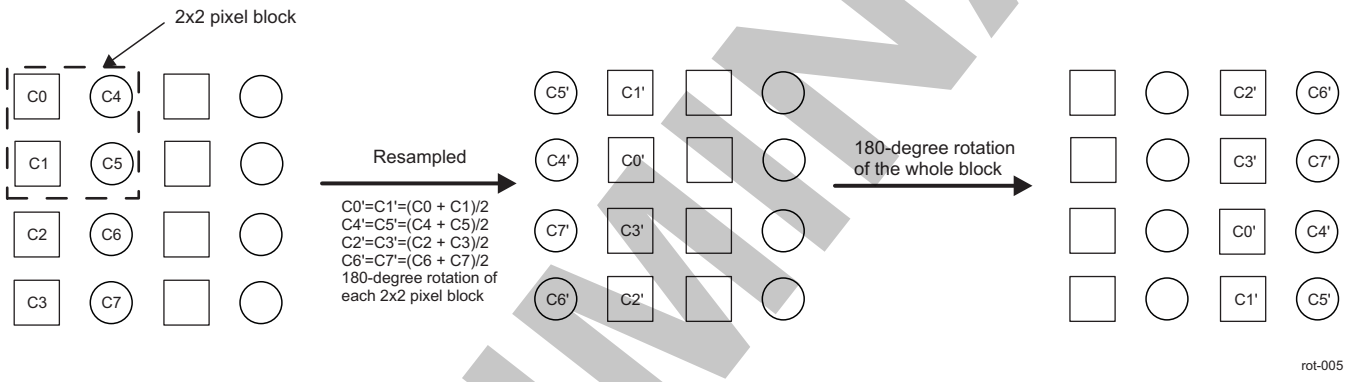
The same algorithm is used for 270-degree rotation.

Figure 8-300. ISS SIMCOP ROT 270-Degree Rotation of YUV4:2:2 Data



For 180-degree rotation, there is no arithmetic operation; chroma values are simply shifted horizontally before being rotated.

Figure 8-301. ISS SIMCOP ROT 180-Degree Rotation of YUV4:2:2 Data



NOTE: The intermediate process of 2 × 2 pixel block rotation, represented in the middle section in Figure 8-299 through Figure 8-301, does not involve data storage and reading into memory. That middle section is for better visualization of the process. The whole process is performed with a single memory reading and writing.

Zero-degree rotation is included for completeness of programming model, and involves only data copy.

8.4.7.3.8.3 ISS SIMCOP ROT Multiple-Block Rotation

For generic 8-/16-/32-bit data rotation and YUV4:2:0/4:2:2 rotation, multiple-block operation per hardware task is supported.

Figure 8-302 through Figure 8-305 show the multiple-block rotation feature.

The multiple blocks are in the horizontal dimension, and the blocks are horizontally adjacent to one another. In other words, in the source data and 180-degree rotated data, address offset between blocks is the source block width times the data size.

In the 90-degree and 270-degree rotated data, address offset is the source block height times the data size. The source/destination line offsets must be sufficiently large to accommodate the multiple blocks.

Figure 8-302. ISS SIMCOP ROT Block Representation Before Rotation

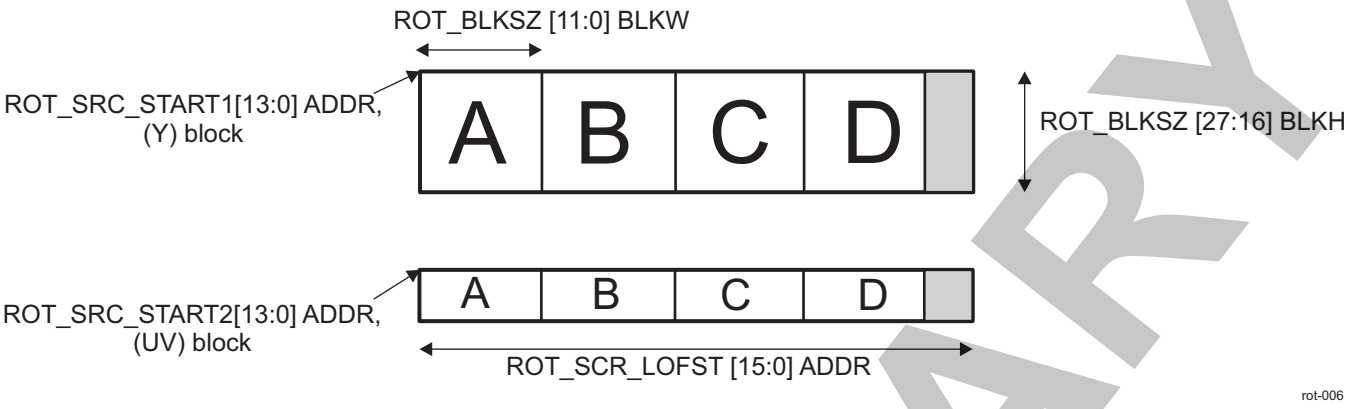


Figure 8-303. ISS SIMCOP ROT 90-Degree Block Rotation

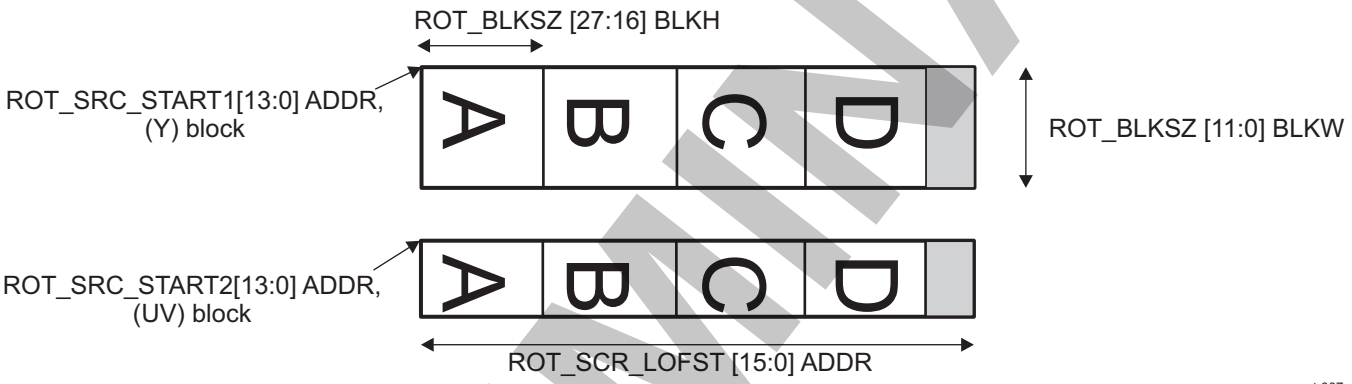

Figure 8-304. ISS SIMCOP ROT 180-Degree Block Rotation

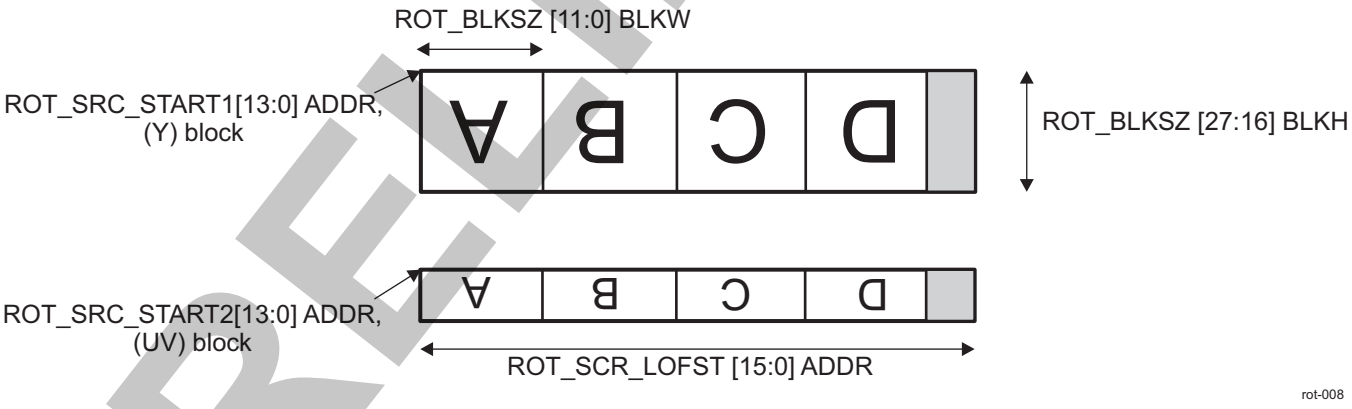

Figure 8-305. ISS SIMCOP ROT 270-Degree Block Rotation

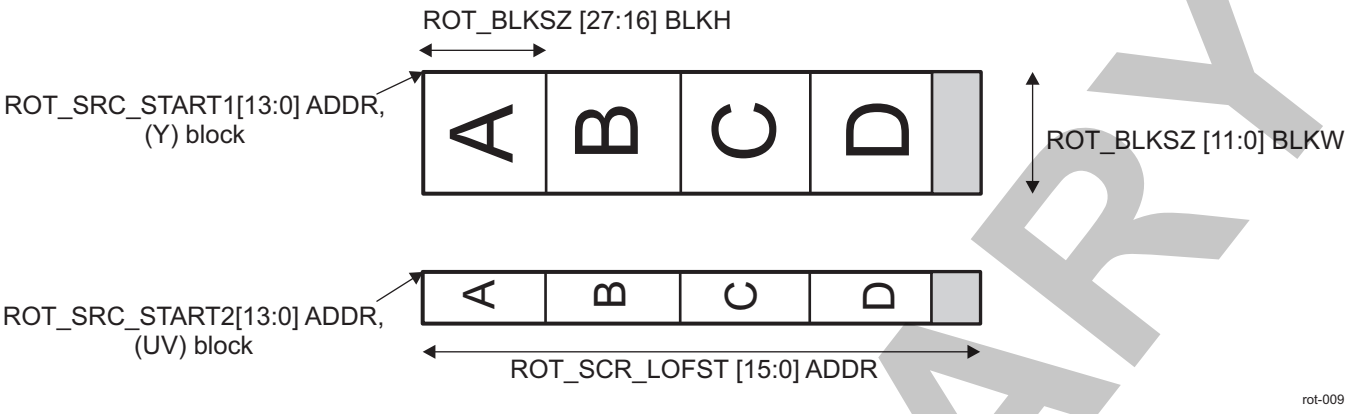


The operation is configured with these parameters:

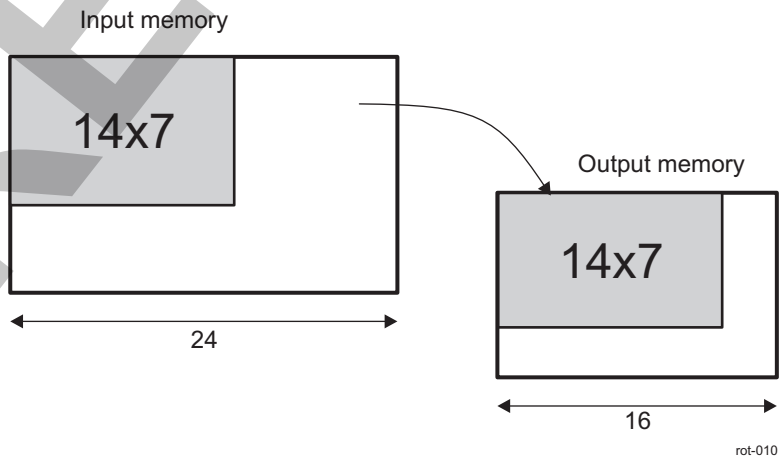
- ROT_CFG[2:0] OP (rotation orientation)
- ROT_CFG[6:4] FMT (data format)
- ROT_CFG[15:12] NBLKS (number of blocks minus 1; register value of 0 means one block, etc.)
- ROT_BLKSZ[11:0] BLKW (width of each block; all blocks are of the same width/height)
- ROT_BLKSZ[27:16] BLKH (height of each block)
- ROT_SRC_START1[13:0] ADDR (starting address of the first input block)
- ROT_SRC_LOFST[15:0] LOFST (line offset of input block)
- ROT_DST_START1[13:0] ADDR (starting address of the first output block)
- ROT_DST_LOFST[15:0]LOFST (line offset of output block)
- ROT_SRC_START2[13:0] ADDR (starting address of the first input UV block, if format is YUV4:2:0)
- ROT_DST_START2[13:0] ADDR (starting address of the first output UV block, if format is YUV4:2:0)

8.4.7.3.8.4 ISS SIMCOP ROT Data-Block Shifting

The ROT supports shifting of 2-dimensional (2D) data blocks in 8-bit granularity. This function is intended to supplement the SIMCOP DMA module, which operates on 128-bit alignment.

Figure 8-306 is an example of a 14 × 7-byte data block copied from one location in input memory to another location in output memory.

Figure 8-306. ISS SIMCOP ROT Data-Block Shifting Example



The following parameters are specified:

- ROT_BLKSZ[11:0] BLKW = 14 (in bytes)
- ROT_BLKSZ[27:16] BLKH = 7 (in rows)
- ROT_SRC_LOFST[15:0] LOFST = 24 (in bytes)
- ROT_DST_LOFST[15:0] LOFST = 16 (in bytes)

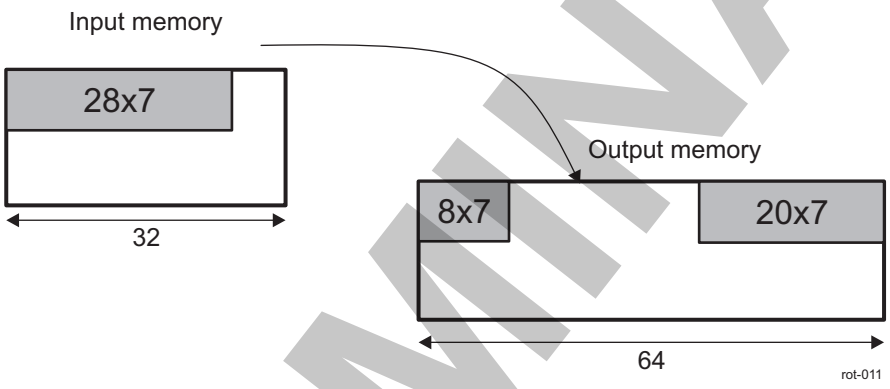
NOTE: This can be used to shift horizontally as well as vertically.

8.4.7.3.8.5 ISS SIMCOP ROT Data-Block Horizontal Circular Shifting

The ROT supports shifting of 2D data blocks in 8-bit granularity, with horizontal circular buffer addressing. This function is intended to supplement the SIMCOP DMA module, which operates on 128-bit alignment.

Figure 8-307 is an example of a 28 x 7-byte data block copied from one location in input memory to another location in output memory, and horizontal wrap-around occurs in the output memory.

Figure 8-307. ISS SIMCOP ROT Horizontal Circular Shifting Example



The following parameters are specified:

- ROT_BLKSZ[11:0] BLKW = 28 (in bytes)
- ROT_BLKSZ[27:16] BLKH = 7 (in rows)
- ROT_SRC_LOFST[15:0] LOFST = 32 (in bytes)
- ROT_DST_LOFST[15:0] LOFST = 64 (in bytes)

Wrapping around is allowed in the input memory, in the output memory, or in both. For this mode of operation, the line offset of the source and destination must be a power of 2, and at least 32 bytes. Source and destination line offsets can be different. This function is used to handle misaligned SDRAM data. The example that follows in this section shows that the line offset is at least the minimal transfer width, or the SDRAM burst. For target applications, 32 bytes is the minimal burst size to support.

NOTE: This can be used to shift horizontally as well as vertically. Input and output blocks can also have different line offsets.

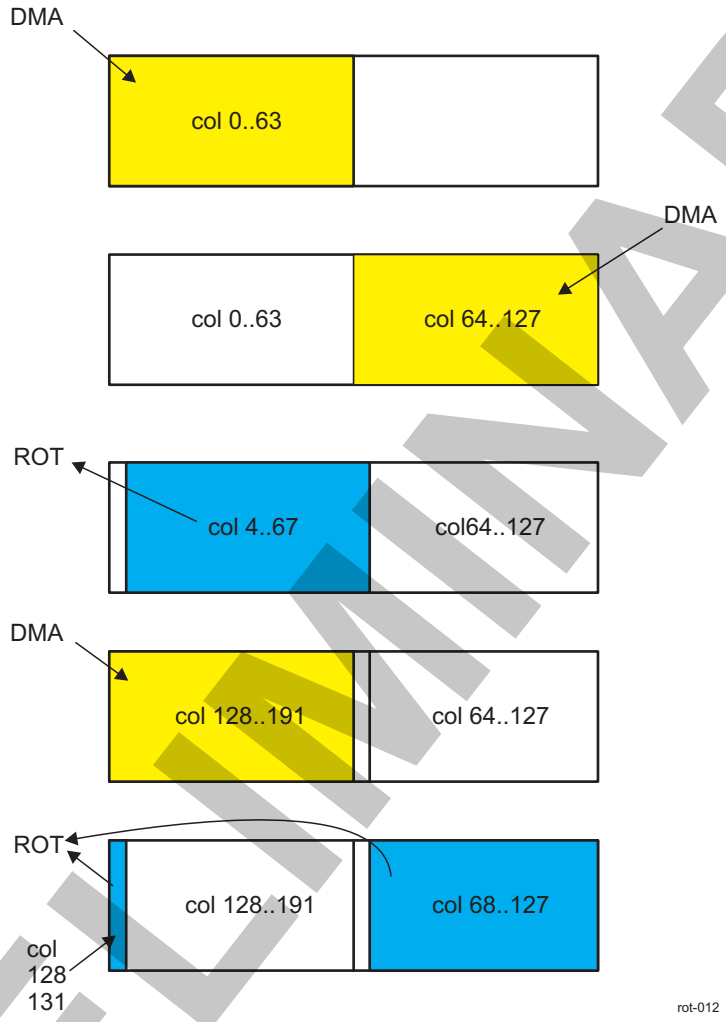
This mode of operation is intended to be used to manage 2D data blocks that are out of SDRAM alignment (for example, to crop out the left-most 2 pixels of the ISP YUV4:2:2 output image before JPEG compression). Assume that the ISP output is 64-byte SDRAM burst-aligned; thus, the starting address for JPEG input is 4 bytes out of alignment. Without the horizontal circular shifting function, the best solution is to use wide data blocks (for example, 128 pixels = 256 bytes wide) to reduce the bandwidth penalty of misalignment (costing five bursts to get four bursts worth of data). With horizontal circular shifting, the bandwidth penalty can be eliminated. In this example, the SIMCOP DMA is configured to transfer aligned data, and the ROT is used to perform the crop-out. A memory transaction log would be:

- The DMA writes columns 0–63, starting at byte address 0.
- The DMA writes columns 64–127, starting at byte address 64.
- The ROT module reads columns 4–67, starting at byte address 4.

- The DMA writes columns 128–191, starting at byte address 0.
- The ROT module reads columns 68–131, starting at byte address 68, and so on.

Figure 8-308 shows the data movement by the DMA and the ROT.

Figure 8-308. ISS SIMCOP ROT Using Horizontal Circular Shifting to Manage Misaligned Data



8.4.7.4 ISS SIMCOP ROT Module Programming Guide

8.4.7.4.1 ISS SIMCOP ROT Module Low-Level Programming Models

This section describes the low-level programming sequences for configuration and use of the ROT.

8.4.7.4.1.1 ISS SIMCOP ROT Global Initialization

8.4.7.4.1.1.1 ISS SIMCOP ROT Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the ROT is to be used for the first time after a device reset. Initialization of surrounding modules is based on the integration and environment of the module.

Table 8-1535 describes the global initialization of the surrounding modules.

Table 8-1535. ISS SIMCOP ROT Global Initialization of Surrounding Modules

Surrounding Modules	Comments
SIMCOP (clock management)	The ROT functional clock must be enabled. See Section 8.4.7.3.2, *ISS SIMCOP ROT Module Clock Configuration*.
SIMCOP (power management)	The ROT must be enabled (SIMCOP_CLKCTRL[7] ROT_A). See Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management* .
Buffers	Configure the ROT access to the image buffer inside the SIMCOP_HWSEQ_STEP_SWITCH_i register. See Section 8.4.2, *ISS SIMCOP Hardware Sequencer and Buffers Module*.
SIMCOP IRQ merger	Configure SIMCOP to handle the ROT interrupts. See Section 8.1.2.1.1, *Interrupt Merger*
SIMCOP hardware sequencer	Configure the hardware sequencer to activate the ROT. See Section 8.4.2,*ISS SIMCOP Hardware Sequencer and Buffers Module*.

8.4.7.4.1.1.2 ISS SIMCOP ROT Global Initialization

Table 8-1536 describes the global initialization of the ROT.

Table 8-1536. ISS SIMCOP ROT Global Initialization of the ROT

Step	Register/Bit Field/Programming Model	Value
Enable the ROT module.	ROT_CTRL[0] EN	0x0

8.4.7.4.1.2 ISS SIMCOP ROT Operational Modes Configuration

8.4.7.4.1.2.1 ISS SIMCOP ROT Rotation

The proper value for the trigger source bit (ROT_CFG[8] TRIG_SRC) is set depending on whether the operation is to be triggered by software, writing to MMR, or by the hardware sequencer. Table 8-1537 lists the procedure to set the value of the trigger source bit.

Table 8-1537. ISS SIMCOP ROT Trigger Source Bit Value

Step	Register/Bit Field/Programming Model	Value
Configure the degree of rotation.	ROT_CFG[2:0] OP	xxx
Configure the data format.	ROT_CFG[6:4] FMT	xxx
Specify the block width and height.	ROT_BLKSZ[11:0] BLKW ROT_BLKSZ[27:16] BLKH	xxx
Specify the input and output starting addresses.	ROT_SRC_START1[13:0] ADDR, ROT_DST_START1[13:0] ADDR	xxx
Specify the line offsets.	ROT_SRC_LOFST[15:0] LOFST, ROT_DST_LOFST[15:0] LOFST	xxx

Table 8-1537. ISS SIMCOP ROT Trigger Source Bit Value (continued)

Step	Register/Bit Field/Programming Model	Value
For UV data of YUV4:2:0, input and output second starting addresses.	ROT_SRC_START2[13:0] ADDR, ROT_DST_START2[13:0] ADDR	xxx

8.4.7.4.1.2.2 ISS SIMCOP ROT Data-Block Shifting

Table 8-1538 lists the bit field values for data-block shifting.

Table 8-1538. ISS SIMCOP ROT Data-Block Shifting

Step	Register/Bit Field/Programming Model	Value
Configure shifting.	ROT_CFG[2:0] OP	xxx
Set the data shifting block.	ROT_CFG[6:4] FMT	xxx
Specify the block width and height.	ROT_BLKSZ[11:0] BLKW, ROT_BLKSZ[27:16] BLKH	xxx
Specify the input and output starting addresses.	ROT_SRC_START1[13:0] ADDR, ROT_DST_START1[13:0] ADDR	xxx
Specify the line offsets.	ROT_SRC_LOFST[15:0] LOFST, ROT_DST_LOFST[15:0] LOFST	xxx

Once the input data and output buffer are available, the ROT_CTRL[0] EN bit is set to 1 to trigger the operation through software. Alternatively, DMA transfer(s) and the hardware sequencer are configured to trigger the ROT with the hardware start signal when appropriate.

Face Detect

This chapter describes the features and functions of the face detection interface (FDIF) module of the multimedia device.

Topic **Page**

9.1 Face Detect Overview

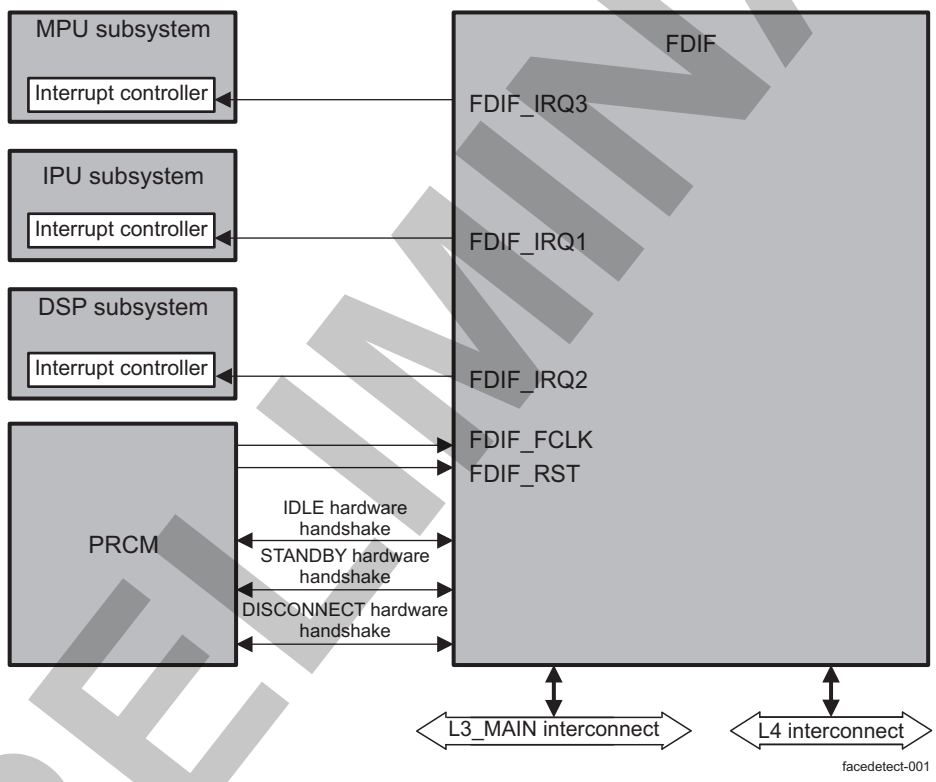
The FDIF module performs face detection within a picture stored in memory (QVGA luminance data resolution). This module is typically used for video encoding, face-based priority auto-focusing, or red-eye removal.

The face detect (FD) core is a stand-alone module: it embeds its own direct memory access (DMA) engine for accessing data in memory. The FD core is under microprocessor unit (MPU) control for its initialization and to start the processing operation.

The FD core supports single input resolution (QVGA) in a single format (8-bit Luma). The FD core requires that the input image is stored in synchronous dynamic random access memory (SDRAM). The core also requires working memory mapped in SDRAM. The input image data (320 × 240) requires 75KiB for the SDRAM and 51.25KiB for the working memory.

Figure 9-1 is an overview of the FDIF. Three interrupt lines go to the three central processing units (CPUs) to allow control of the FD core module by different processors, but only one interrupt at a time can be active. The three interrupt lines provide flexibility for controlling the module.

Figure 9-1. Face Detect Highlight



9.1.1 Main Features

The FDIF has the following features:

- Two interconnects interface:
  - 32-bit-wide level 4 (L4) interface for register configuration
  - 32-bit-wide level 3 (L3_MAIN) interface for command
- Supports the IDLE, STANDBY, and DISCONNECT protocols
- Asynchronous bridge (asynchronous master and slave interfaces)
- 60fps frame rate for FaceDetection processing
- Third-party IP features: For information about the input image features and detection capabilities, see Table 9-1.

Table 9-1. Third-Party IP Features

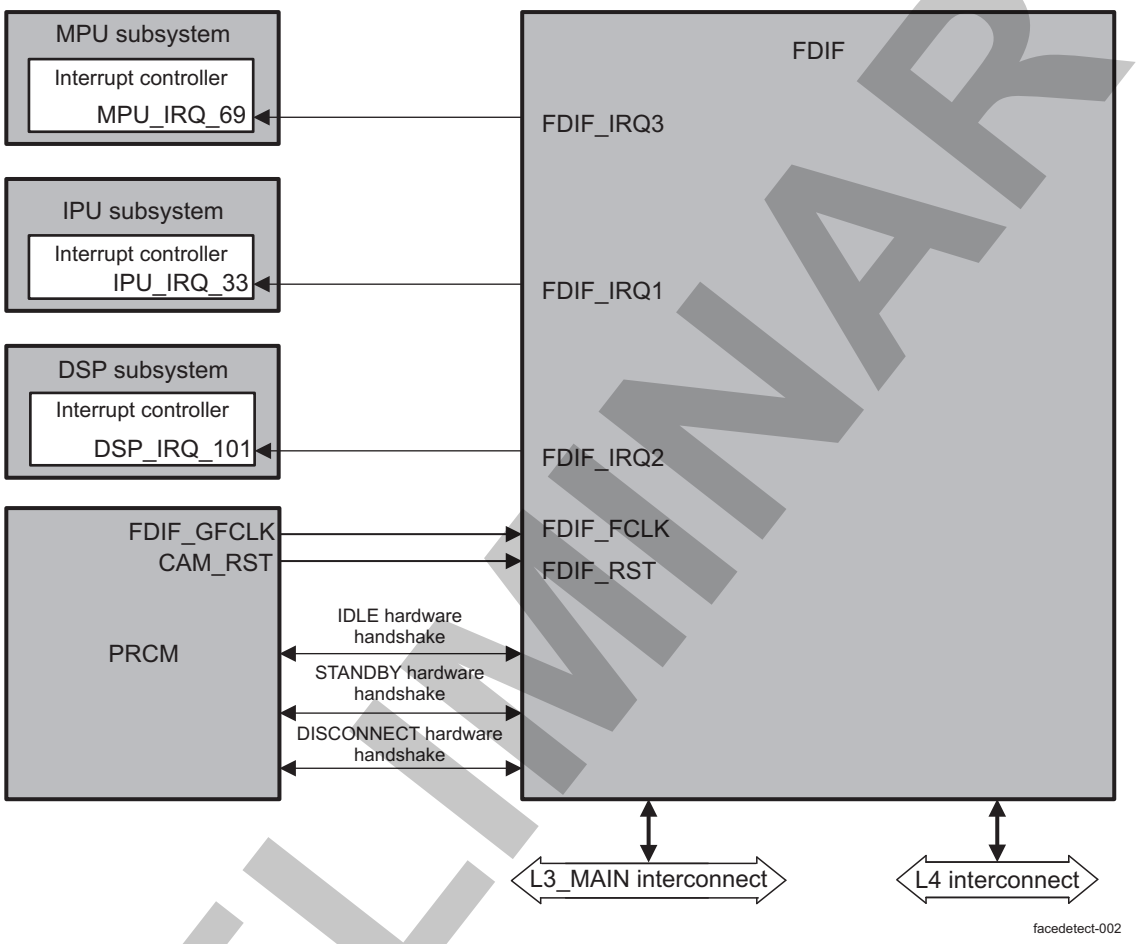
Items	Description
Input image size	QVGA input image size H x V = 320 x 240
Input image data format	8-bit gray scale data in little-endian format (color pictures must be converted before FD can be applied) 0x00 = black and 0xFF = white
Face inclination	± 45 degrees
Face direction	Up or down: ± 30 degrees Left or right: ± 60 degrees
Maximum detection count	35 faces
Detection direction	The face orientation must be selected from the following possibilities: 0 degrees: Faces are vertical. + 90 degrees: Faces are rotated right by 90 degrees. – 90 degrees: Faces are rotated left by 90 degrees.
Detection minimum face size	Four grades are available: 20 pixels 25 pixels 32 pixels 40 pixels
Detection area	Detection start position: X = 0 to 160 Y = 0 to 120 Detection area size: X = 160 to 320 Y = 120 to 240
Detection result	The following information is provided by the module for each face: Size Position Angle Confidence level

9.2 FDIF Integration

This section describes the integration of FDIF in the device, including information about clocks, resets, and hardware requests.

Figure 9-2 shows the integration of the module in the device.

Figure 9-2. FDIF Integration



NOTE: For more information about the IDLE, STANDBY, and DISCONNECT hardware handshakes, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-2 through Table 9-4 summarize the integration of the module in the device. For more information about the power domain or the clock and reset signals, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
Face detect	PD_CAM	No	L3_MAIN

Table 9-3. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

Table 9-3. Clocks and Resets (continued)

Face detect	FDIF_RST	CAM_RST	PRCM	For information about PRCM reset sources and distribution, see Section 3.5 *Reset Management Functional Description, in* Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-4. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
Face detect	FDIF_IRQ3	MPU_IRQ_69	MPU subsystem	FDIF interrupt to the MPU subsystem
Face detect	FDIF_IRQ1	IPU_IRQ_33	IPU subsystem	FDIF interrupt to the IPU subsystem
Face detect	FDIF_IRQ2	DSP_IRQ_101	DSP subsystem	FDIF interrupt to the digital signal processor (DSP) subsystem
No DMA Requests				

NOTE: For more information about interrupt sources, see Section 9.3.4, *Interrupts and Events*.

9.3 FDIF Functional Description

9.3.1 FDIF Block Description

The FDIF is a stand-alone module. It has a port connected to the L4 interconnect, which is used for configuration, and a port connected to the L3_MAIN interconnect, which is used to read and write data to the system memory.

NOTE: These ports are accessible only in 32 bits.

The FD core contains the following submodules:

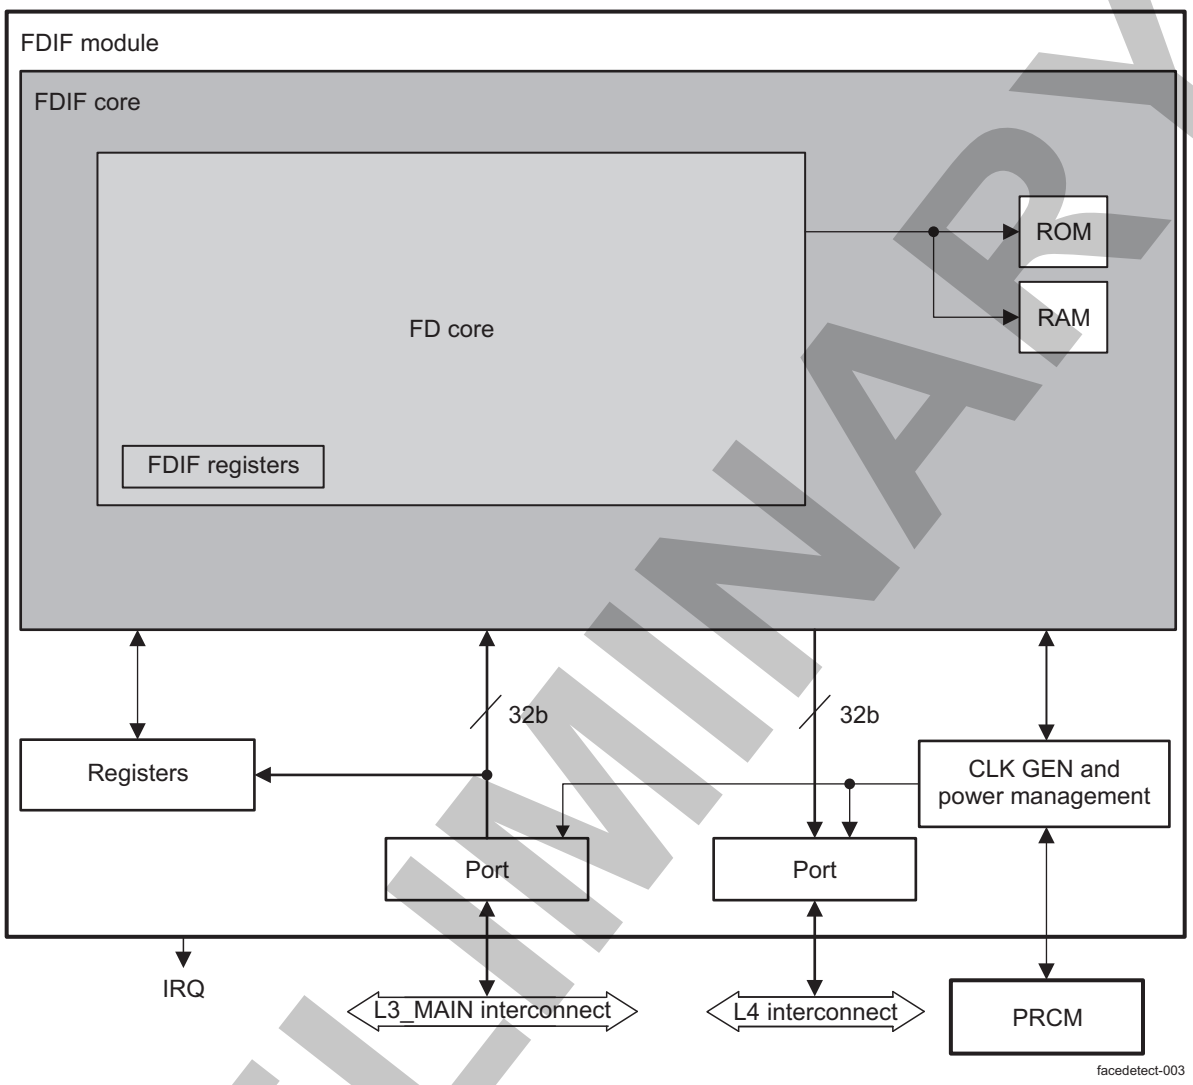
- FD IP core
- RAM and ROM memories

The FDIF module wraps the FD core for integration in the device. The following submodules are added:

- Clock generation
- Interrupt generation
- Power management
- L3_MAIN and L4 interface ports: Two ports required to decorrelate the FDIF clocks from other system clocks, one on the L3_MAIN port interface, and one on the L4 port interface.

Figure 9-3 shows the overall architecture of the FDIF.

Figure 9-3. FDIF Block Diagram



9.3.2 Software Reset

The module is reset by setting the FDIF_SYSCONFIG[0] SOFTRESET bit to 1. The bit is automatically reset by hardware. During reads, it always returns 0.

The FD core also provides a software reset setup by the FD_CTRL[0] SRST bit, but it is strongly recommended to use only the FDIF_SYSCONFIG[0] SOFTRESET bit.

9.3.3 System Power Management

There is one clock domain in FDIF: the L4 port domain and L3_MAIN port domain are synchronized with the module functional clock domain, FDIF_FCLK.

Table 9-5 lists the power-management features available for FDIF.

NOTE:

- For more information about source clock gating, see Section 3.1.1, *Power, Reset, and Clock Management*.
- For descriptions of idle mode and standby mode and the power, reset, and clock management (PRCM) power handshake, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 9-5. Local Power-Management Features

Feature	Registers	Description
Clock autogating	No software control for it.	It is always enabled.
Slave idle modes	FDIF_SYSCONFIG[3:2] IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	N/A	
Master standby modes	FDIF_SYSCONFIG[5:4] STANDBYMODE	Force-standby, no-standby, and smart-standby modes are available. For more information, see Section 9.3.3.2.1, *Protocol Transitions*.
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

9.3.3.1 Autogating

The FDIF performs clock autogating whenever possible. There is no software control for the FDIF; it is always enabled.

9.3.3.2 PRCM Hardware Handshake

The FDIF supports the IDLE protocol between the L4 port and the PRCM module and the STANDBY protocol between the L3_MAIN port and the PRCM module. The FDIF also supports the DISCONNECT protocol on the L4 and L3_MAIN ports.

The FDIF first initiates the STANDBY protocol with the PRCM module, which in turn generates the IDLE protocol with the FDIF. The functional clock is gated by the PRCM module only when the IDLE and STANDBY power-management protocols are complete.

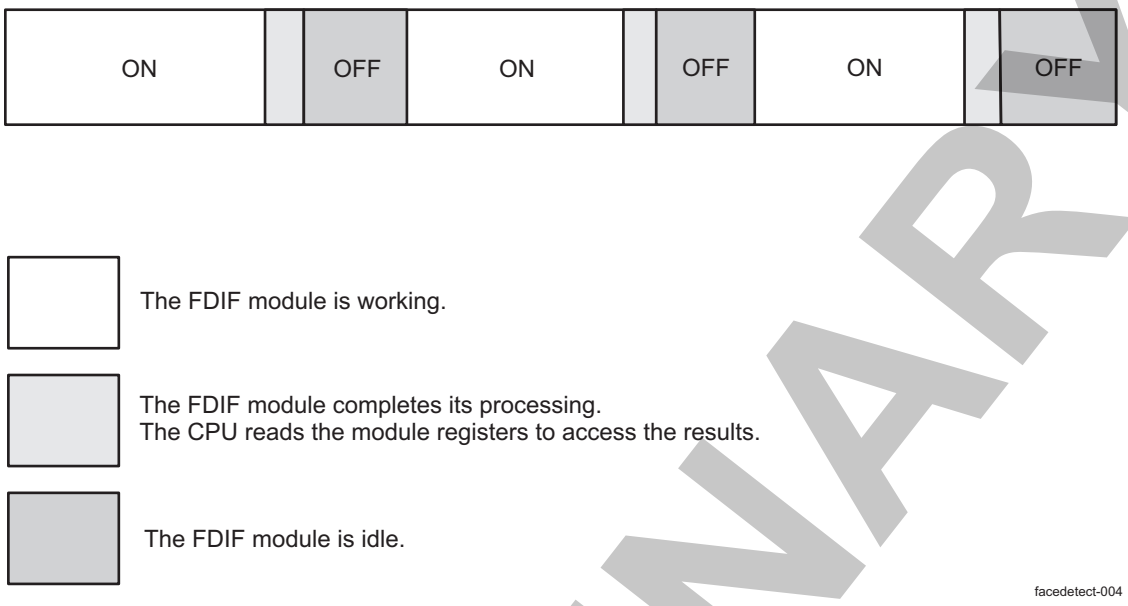
For more information about these protocols, see Section 3.1.1, *Power, Reset, and Clock Management*.

9.3.3.2.1 Protocol Transitions

The FDIF enters the IDLE state as soon as it is done processing and the MPU has read the results of the computation.

Figure 9-4 shows the principle. The 33-ms period corresponds to a 60 fps, which is usually the target for imaging applications. Time spent in the READ state (ON state) is always the same, and the time in OFF state depends on the time spent in ON state.

Figure 9-4. FDIF Power-Management Transitions



9.3.3.2.1.1 Normal Mode to Idle Mode

Software sets the FDIF_SYSCONFIG[5:4] STANDBYMODE bit field to 0x2 to program the power-management mode.

When its processing completes, the FD core generates the FINISH_IRQ event. At this time the FD_CTRL[1] RUN bit reflects that the FD core is idle.

Software running on the MPU reads the results of the FD algorithm. After software reads the results, it clears the FDIF_IRQSTATUS_RAW_j[8] FINISH_IRQ bit and sets the FDIF_CTRL[5] MSTANDBY bit to 1 to initiate the MStandby signal generation. For more information about the STANDBY and IDLE hardware handshakes, see Section 3.1.1, *Power, Reset, and Clock Management*.

The FDIF clock is gated only when the STANDBY and IDLE protocols are complete.

9.3.3.2.1.2 Idle Mode to Normal Mode

The PRCM module deasserts a signal to the FDIF under software control so that the module can switch back to normal mode. Then, the module functional clock is ensured and stable. Software disables the MStandby signal generation by setting the FDIF_CTRL[5] MSTANDBY bit to 0, and then polls for FDIF_CTRL[6] MSTANDBY_HDSHK = 1 to ensure that the power-management handshaking is complete. For more information about the standby and idle modes, see Section 3.1.1, *Power, Reset, and Clock Management*.

9.3.4 Interrupts and Events

The FDIF has three interrupt lines (FDIF_IRQ1, FDIF_IRQ2, and FDIF_IRQ3) to enable flexibility for controlling the module. Each event can be enabled to only a single interrupt line (that is, to only one interrupt controller [INTC]), because only one interrupt at a time can be active.

Table 9-6 lists the events the FDIF generates. The FDIF_IRQENABLE_SET_j register is used to enable an interrupt, and the FDIF_IRQENABLE_CLR_j register is used to disable an interrupt.

Table 9-6. Interrupts and Events Description

Event Name	Description
FDIF_IRQSTATUS_RAW_j / FDIF_IRQSTATUS_j[8] FINISH_IRQ	This event is generated by the FD IP core. It flags the completion of the processing by the IP.

Table 9-6. Interrupts and Events Description (continued)

Event Name	Description
FDIF_IRQSTATUS_RAW_j / FDIF_IRQSTATUS_j[0] OCP_ERR_IRQ	This event flags that the L3_MAIN port has received an error.

The FDIF_IRQSTATUS_RAW_j and FDIF_IRQSTATUS_j registers give the interrupt status. The difference between them is that the FDIF_IRQSTATUS_RAW_j register is set even if events are not enabled.

The FDIF_IRQSTATUS_j register can be used to clear events.

9.3.5 Typical Use

Typically, FD processing is applied to buffers provided by the ISP module, already in the correct format.

To enable FD processing, the 32-bit address of the input image in memory must be set up in the FDIF_PICADDR register, and the 32-bit address of the working memory must be set up in the FDIF_WKADDR register.

The detection condition settings can be set with the following registers:

- FD_DCOND
- FD_STARTX
- FD_STARTY
- FD_SIZEX
- FD_SIZEY

For more information, see Section 9.4, *FDIF Programming Guide*.

When the FD_CTRL[1] RUN bit is set to 1, the process starts. When the process completes (FD_CTRL[2] FINISH = 1), the results are available in the following registers:

- FD_DNUM
- FD_CENTERX_i
- FD_CENTERY_i
- FD_CONFSIZE_i
- FD_ANGLE_i

For more information, see Section 9.4, *FDIF Programming Guide*.

9.3.6 Performance Parameters

Table 9-7 lists the register settings that affect performance.

Table 9-7. Performance Parameters

Parameter	Comments
FD_DCOND[1:0] MIN	Sets the minimum face size. The permitted values are 20x20, 25x25, 32x32, and 40x40. A high value leads to higher performance.
FD_DCOND[3:2] DIR	Sets the detection direction setting. The permitted values are UP, RIGHT, and LEFT. The UP value should lead to better performance than RIGHT and LEFT.
FD_LHIT[3:0] LHIT	Sets the detection threshold. The permitted values are in the range from 0 to 9. A low value increases the FD probability detection, but it also increases false detections.

9.3.7 Error Reporting

Interconnect protocol errors on the FDIF modules slave port are reported usin eror response. Such response is returned when non supported byte enable patterns are used to address the FD core.

Accesses to reserved or unmapped locations in the FDIF memory address range will return 0's for reads, and writes will be ignored. When the master port makes an invalid request, error is returned to the port and FDIF triggers an interrupt(OCP_ERR_IRQ, see Section 9.3.4 Interrupts and Events).

For more information about the logged errors see Section 14.2.3.9 L3_MAIN Interconnect Error Handling and Section 14.3.3.4 L4 Error Detection and Reporting.

NOTE: In case of errors, it is software responsibility to take the appropriate actions.

9.3.8 L3_MAIN Interconnect Parameters

The FDIF is an initiator on the L3_MAIN interconnect. L3 accesses can be configured with the FDIF_CTRL[4:1] MAX_TAGS bit field and the FDIF_CTRL[0] WRNP bit. For more information about these parameters, see Section 14.2.1 *L3 Interconnect*.

9.4 FDIF Programming Guide

9.4.1 FDIF Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the FDIF.

9.4.1.1 Global Initialization

9.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules the first time the FDIF is used after a device reset. This initialization of the surrounding modules is based on the integration of the FDIF. Table 9-8 describes the global initialization of surrounding modules.

For more information, see Section 9.2, *FDIF Integration*.

Table 9-8. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	FDIF_FCLK functional clock must be enabled. See Section 3.6.22, *CD_CAM Clock Domain*, in Section 3.1.1, *Power, Reset, and Clock Management*.
MPU INTC (or IPU INTC or DSP INTC)	The MPU (or IPU or DSP) INTC must be configured to enable the interrupt request generation to the MPU (or IPU or DSP) subsystem when interrupt requests are generated by the FDIF. See the respective Functional Description in Section 17.1, *Interrupt Controller*, for the MPUs Section 17.4.1, Section 17.4.2, and the DSP interrupt request lines in Section 5.1, *DSP Subsystem*, for the DSP.
Interconnect (L3 and L4)	For more information, see Section 14.2.1, *L3 Interconnect*, and Section 14.3.1, *L4 Interconnect*.

9.4.1.1.2 FDIF Global Initialization

9.4.1.1.2.1 Main Sequence – FDIF Global Initialization

Table 9-9 lists the procedure to initialize the FDIF after a poweron or software reset.

Table 9-9. FDIF Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	FDIF_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is finished.	FDIF_SYSCONFIG[0] SOFTRESET	0x0
Set the maximum interconnect tags.	FDIF_CTRL[4:1] OCP_MAX_TAGS	0xA
Enable ERROR type interrupt.	FDIF_IRQENABLE_SET_j[0] OCP_ERR_IRQ	0x1

9.4.1.2 FD Operational Modes Configuration

9.4.1.2.1 FD Processing Modes

9.4.1.2.1.1 Main Sequence – FDIF Polling Method

Step	Register/Bit Field/Programming Model	Value
Set image parameters.	See Section 9.4.1.2.1.3, *Subsequence – Set Image Parameters*.	
Request the processing.	FD_CTRL[1] RUN	0x1
Wait until process is finished.	FD_CTRL[2] FINISH	0x1
Read the results.	See Section 9.4.1.2.1.4 *Subsequence - Read the Results*.	

9.4.1.2.1.2 Main Sequence – FDIF Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Set image parameters.	See Section 9.4.1.2.1.3, *Subsequence – Set Image Parameters*.	
Enable FINISH type interrupt.	FDIF_IRQENABLE_SET_j[8] FINISH_IRQ	0x1
Request the processing.	FD_CTRL[1] RUN	0x1

WHEN INTERRUPT OCCURS:

Step	Register/Bit Field/Programming Model	Value
IF: This is FD Process Complete Event?	FDIF_IRQSTATUS_j[8] FINISH_IRQ	0x1
Clear (Disable) FINISH type interrupt.	FDIF_IRQENABLE_CLR_j[8] FINISH IRQ	0x1
Read the results.	See Section 9.4.1.2.1.4, *Subsequence – Read the Results*.	
ELSE		
Clear (Disable) ERROR type interrupt.	FDIF_IRQENABLE_CLR_j[0] OCP_ERR_IRQ	0x1
Perform a software reset.	FDIF_SYSCONFIG[0] SOFTRESET	0x1
For possible errors and the explanations of them, see Section 14.2.1, *Interconnect*.		
ENDIF		

9.4.1.2.1.3 Subsequence – Set Image Parameters

Step	Register/Bit Field/Programming Model	Value
Set input image 32-bit address.	FDIF_PICADDR[31:5] ADDR	0x----
Set working memory 32-bit address.	FDIF_WKADDR[31:5] ADDR	0x----
Set the minimum face size.	FD_DCOND[1:0] MIN	0x-
Set the face direction.	FD_DCOND[3:2] DIR	0x-
Set the horizontal start position of the detection area.	FD_STARTX[7:0] STARTX	0x-
Set the vertical start position of the detection area.	FD_STARTY[6:0] STARTY	0x-
Set the horizontal start size of the detection area.	FD_SIZEX[8:0] SIZEX	0x–
Set the vertical start size of the detection area.	FD_SIZEY[7:0] SIZEY	0x-
Set the detection threshold.	FD_LHIT[3:0] LHIT	0x-

9.4.1.2.1.4 Subsequence – Read the Results

Step	Register/Bit Field/Programming Model	Value
For each face detected, read the following parameters by processing loop until DNUM = 0:		
Read X_i coordinate	FD_CENTERX_i[8:0] CENTERX	0x–
Read Y_i coordinate	FD_CENTERY_i[7:0] CENTERY	0x-
Read confidence level	FD_CONFSIZE_i[11:8] CONF	0x-
For each face read size_i	FD_CONFSIZE_i[7:0] SIZE	0x-
For each face read the angle	FD_ANGLE_i[8:0] ANGLE	0x-

RESERVED																										STANDBYMODE		IDLEMODE		RESERVED	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	R	0x0000000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events. 0x3: Reserved	RW	0x2
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Reserved	RW	0x2
1	RESERVED	Reserved	R	0
0	SOFTRESET	Software reset. Read 0x0: Reset done, no pending action Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing	RW	0

Table 9-28. FDIF_CTRL

Address Offset	0x0000 0064		
Physical Address	0x4A10 A064	**Instance**	FDIF
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																									MSTANDBY_HDSHK	MSTANDBY	OCP_MAX_TAGS				OCP_WRNP

Bits	Field Name	Description	Type	Reset
31:7	RESERVED	Reserved	R	0x0000000
6	MSTANDBY_HDSHK	MStandby / Wait power-management handshaking status bit The power-management framework of the FDIF module is based on the handshaking of the MSTANDBY and WAIT signals. When going from a idle to normal power-management transition, the software polls for FDIF_CTRL.MSTANDBY_HDSHK = 1 before starting the face detection processing. Read 0x0: Handshaking is not complete. Do not initiate traffic on L3. Read 0x1: Handshaking is complete. Can safely use the FDIF module.	R	0

Bits	Field Name	Description	Type	Reset
5	MSTANDBY	MStandby signal generation. This bit shall be set to initiate a power-management transition from NORMAL to IDLE or IDLE to NORMAL. 0x0: Write: Clear MStandby signal. One polls FDIF_CTRL.MSTANDBY_HDSHK = 1 after writing this bit to ensure that the power-management handshaking is completed. 0x1: Write: Asserts MStandby signal	RW	1
4:1	OCP_MAX_TAGS	Max OCP tags. This bit field sets the maximum number of interconnect tags that the module shall use. This number is programmable between 1 (MAX_TAGS = 0) and FDIF_TAGS (MAX_TAGS = FDIF_TAGS – 1). The value of MAX_TAGS is reflected in the FIDIF_HWINFO register setting. This register setting is expected to have impact on performance. It shall be set once at initialization. Higher value gives more bandwidth to the initiator. Lower value gives less bandwidth to the initiator. This value shall be set as low as possible such that other system initiators are not penalized.	RW	0xF
0	OCP_WRNP	L3 port nonposted write control. Dynamic use of this feature is not supported. This bit shall be set at initialization and not modified hereafter until the processing completes. When nonposted writes are used, tags are used for best performance (MAX_TAGS > 1). 0x0: All writes are nonposted. 0x1: All writes are posted.	RW	0

Display Subsystem

This chapter describes the display subsystem for the device.

Topic **Page**

10.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer on a liquid-crystal display (LCD) panel or TV set.

The display subsystem can display different pictures simultaneously by using three LCD outputs (LCD1, LCD2, and LCD3), in addition to the TV output.

All three LCD outputs can use one of the following interfaces:

- Display serial interface (DSI) (MIPI® DSI)
- Remote frame buffer interface (RFBI) (MIPI DBI 2.0)
- Parallel CMOS output interface (DPI) (MIPI DPI 2.0, BT-656, or BT-1120)

NOTE: Because of device pad multiplexing, some restrictions may apply for simultaneous use of the RFBI and DP

The TV output can be one of the following:

- DPI composite signal
- High-definition multimedia interface (HDMI)

The modules integrated in the display subsystem are:

- Display controller (DISPC):
  - One direct memory access (DMA) engine
  - Three LCD outputs and one TV output, each with a dedicated overlay manager
  - One graphics pipeline (GFX), three video pipelines, and one write-back pipeline
- RFBI:
  - 8-, 9-, 12-, and 16-bit parallel interface
  - Programmable pixel memory formats
  - Programmable output formats on one or multiple cycles per pixel
- Two DSI protocol engines (DSI1_A and DSI1_C):
  - Four data-lane complex input/output (I/O) in addition to the clock lane
  - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
  - Video mode and command mode support
  - Data interleaving support
- HDMI protocol engine:
  - HDMI 1.4 support at 1080p, 60 Hz (including 3D frame-packing support)
  - 36-bit RGB color
  - DES_HDCP 1.4 key protection
  - Deep color mode support (10- or 12-bit for 148.5-MHz pixel clock)

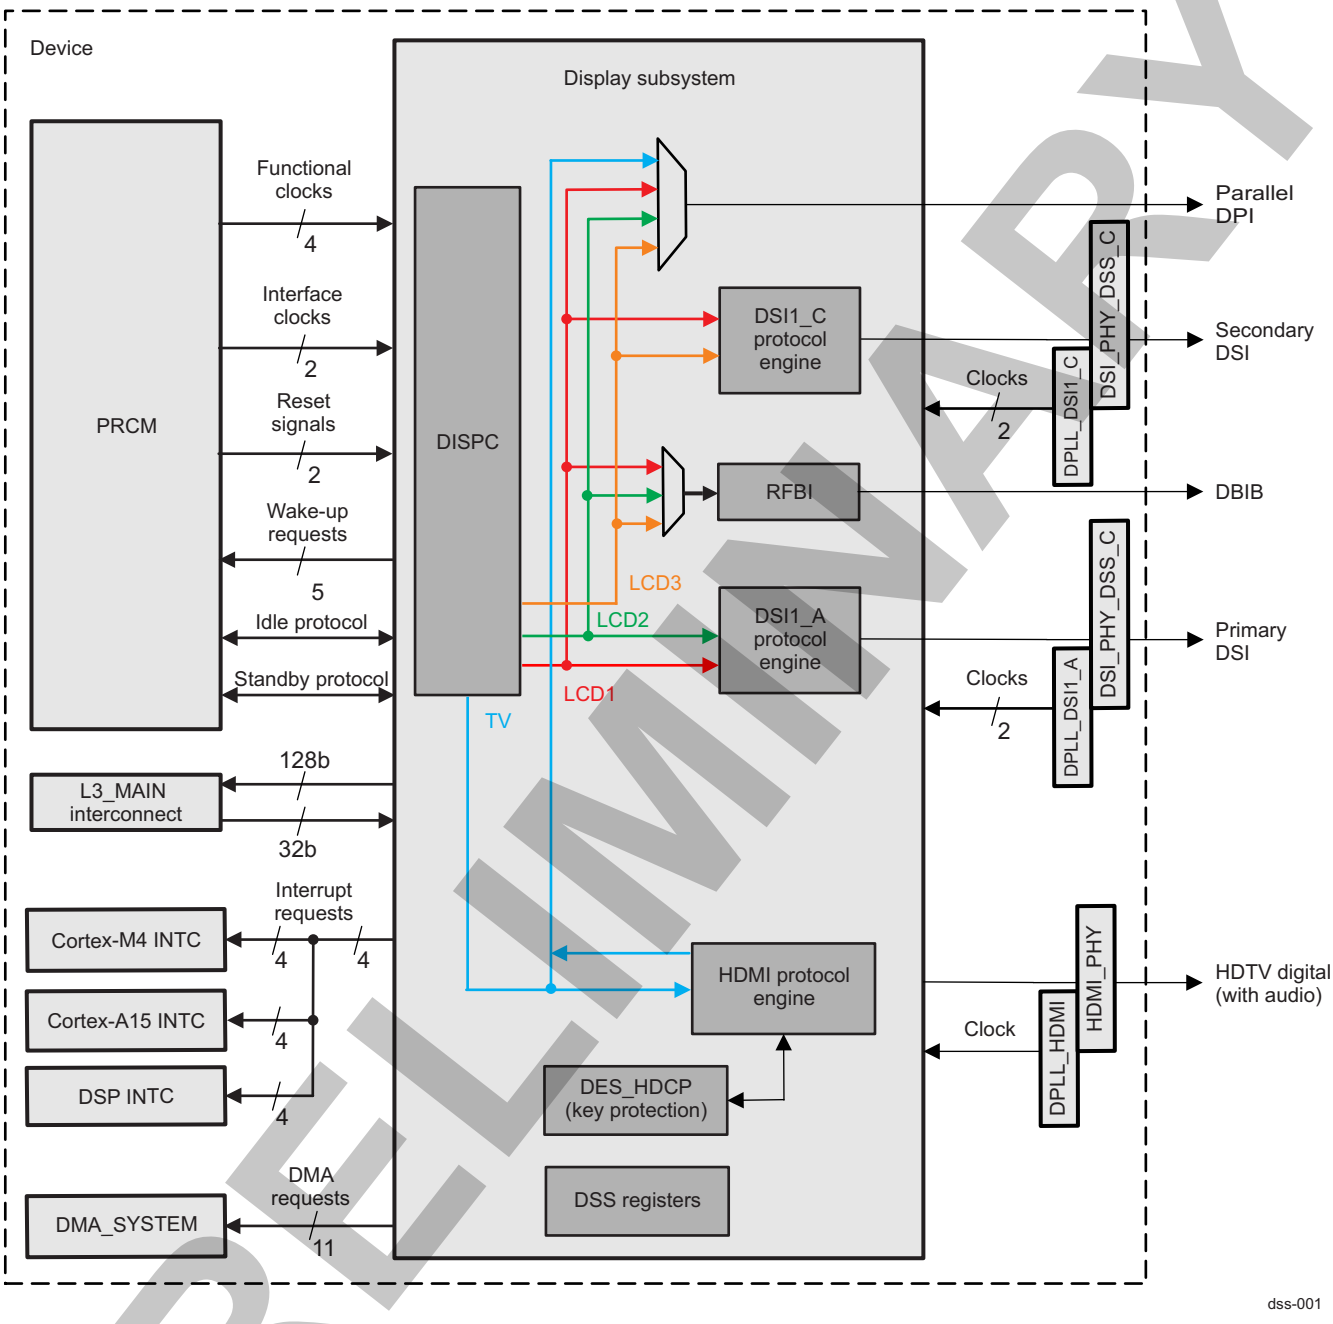
The necessary phase-locked loops (PLLs) with their control modules and the physical layers (PHYs) are outside the display subsystem. The PLLs and PHYs are paired as follows:

- DPLL_HDMI and HDMI_PHY
- DPLL_DSI1_A and DSI_PHY_DSS_A
- DPLL_DSI1_C and DSI_PHY_DSS_C

To ensure efficient bandwidth, the display subsystem integrates a connection between the level 3 (L3_MAIN) interconnect and the DISPC to exchange data with synchronous dynamic random access memory (SDRAM) and memory using the DISPC DMA engine. This connection is also used for configuration.

Figure 10-1 is a high-level diagram of the display subsystem.

Figure 10-1. Display Subsystem Overview



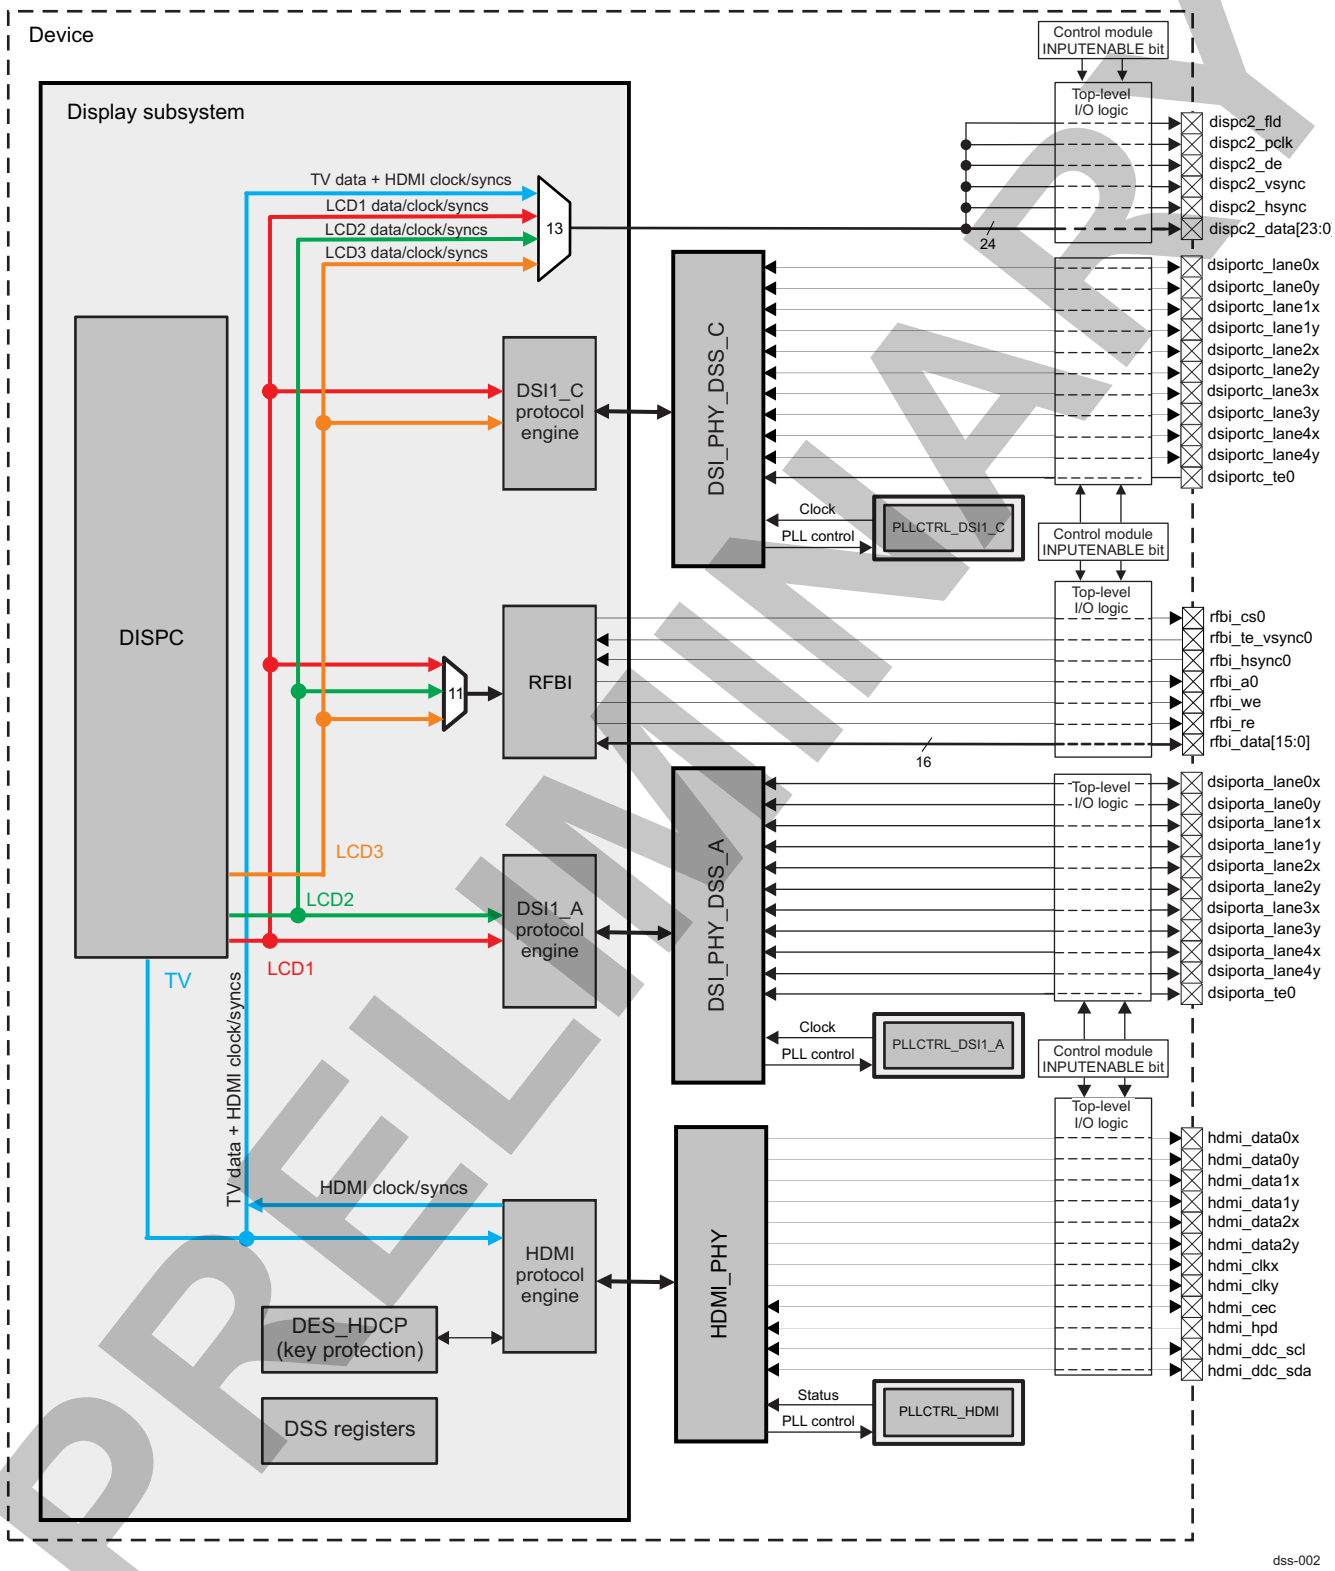
10.1.1 Display Subsystem Environment

This section describes the various outputs handled by the display subsystem:

- LCD support
- TV display support

Figure 10-2 is a diagram of the display subsystem environment.

Figure 10-2. Display Subsystem Environment



NOTE: The path from a module pin to device pad (or pads) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

10.1.1.1 Display Subsystem LCD Support

LCD panels must be connected to the display subsystem of the device using parallel and/or serial interfaces.

10.1.1.1.1 Display Subsystem LCD With Parallel Interfaces

Using parallel output mode, the modules of the display subsystem path are the DISPC and RFBI or DPI.

The DISPC is connected to the memory through the L3_MAIN interconnect and uses its own DMA (with embedded FIFO) to read data from the system memory.

The remote frame buffer (RFB) of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads and writes to and from the RFB. The RFBI receives the output data from the DISPC and generates the signals to control the LCD panel. Through the RFBI, the microprocessor unit (MPU) can send commands or parameter and display data to the LCD panel and directly set the DISPC registers to read or write the data to and from the memory in the LCD panel.

The RFBI can be connected to all LCD outputs of the DISPC, but only one output at a time can be used. The selection (multiplexer 11 in Figure 10-2) is done through the DSS_CTRL[14] RFBI_SWITCH and DSS_CTRL[20] RFBI_SWITCH2 bit. It is not allowed to change the configuration, when the DISPC or RFBI modules are active.

For more details, see DISPC Overview, *Display Controller*, and RFBI Overview, in *Remote Frame Buffer Interface*.

In synchronous parallel interface, the required data and control signals are provided directly to an external MIPI DPI-compatible parallel panel.

All three configuration options for the LCD outputs, LCS1 to LCD3, are available, selected through the DSS_CTRL[17:16] PARALLEL_SEL bit field (multiplexer 13 in Figure 10-2):

Table 10-1 lists the outgoing display subsystem signals on the device boundary pads.

Table 10-1. Display Subsystem LCD Parallel Interface Signals Mapping

Signal Names at Device Pads (See Figure 10-2.)	DSS_CTRL[17:16] PARALLEL_SEL = 1, 2, or 3 DISPC LCDx Channel Out (pixel data, clock, syncs) (where x = 1, 2, or 3)
dispc2_fid	DISPC_LCDx_FID
dispc2_pclk	DISPC_LCDx_PCLK
dispc2_de	DISPC_LCDx_DE
dispc2_vsync	DISPC_LCDx_VSYNC
dispc2_hsync	DISPC_LCDx_HSYNC
dispc2_data[23:0]	DISPC_LCDx_DATA[23:0]

For more details on LCD output pixel data formats for the parallel interface, see DISPC Environment, in *Display Controller*.

10.1.1.1.2 Display Subsystem LCD With Serial Interfaces

In serial interface, the DISPC and the two DSI modules with their associated PLLs are used in the data path. The DISPC is connected to the memory through the L3_MAIN interconnect and uses its own DMA to read the data from the system memory.

The DSI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on one to four differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

For more details, see DSI Overview, in *MIPI Display Serial Interface*.

10.1.1.2 Display Subsystem TV Display Support

When TV data flow is needed from the display subsystem, the DPI or HDMI can be used.

10.1.1.2.1 Display Subsystem TV With Parallel Interfaces

In synchronous parallel interface, the required data is provided from the TV pipeline, and control signals are provided by the HDMI. Then they are merged and provided to the DPI.

This configurations option is available and can be selected through the DSS_CTRL[17:16] PARALLEL_SEL bit field (multiplexer 13 in Figure 10-2):

Table 10-2 lists the outgoing display subsystem signals on the device boundary pads.

Table 10-2. Display Subsystem TV Parallel Interface Signals Mapping

Signal Names at Device Pads (See Figure 10-2.)	**DSS_CTRL[17:16] PARALLEL_SEL = 0 DISPC TV Channel Out (pixel data) HDMI (pixel clock, syncs)**
dispc2_fid	HDMI_M_FID
dispc2_pclk	DSS_HDMI_PCLK
dispc2_de	HDMI_M_DE
dispc2_vsync	HDMI_M_VS
dispc2_hsync	HDMI_M_HS
dispc2_data[23:0]	DISPC_TV_DATA[29:0]

For more details on TV output pixel data formats for the parallel interface, see DISPC Environment, in *Display Controller*.

10.1.1.2.2 Display Subsystem TV With Serial Interfaces

In serial interface, the HDMI is used. The DISPC, HDMI, and DES_HDCP modules and the associated PLL modules are used in the data path. The HDMI module converts the RGB video into standard high-definition digital video format. The module has a PLL, which can multiply the pixel clock by an appropriate factor. The data is transmitted on three differential data pairs and an additional clock pair.

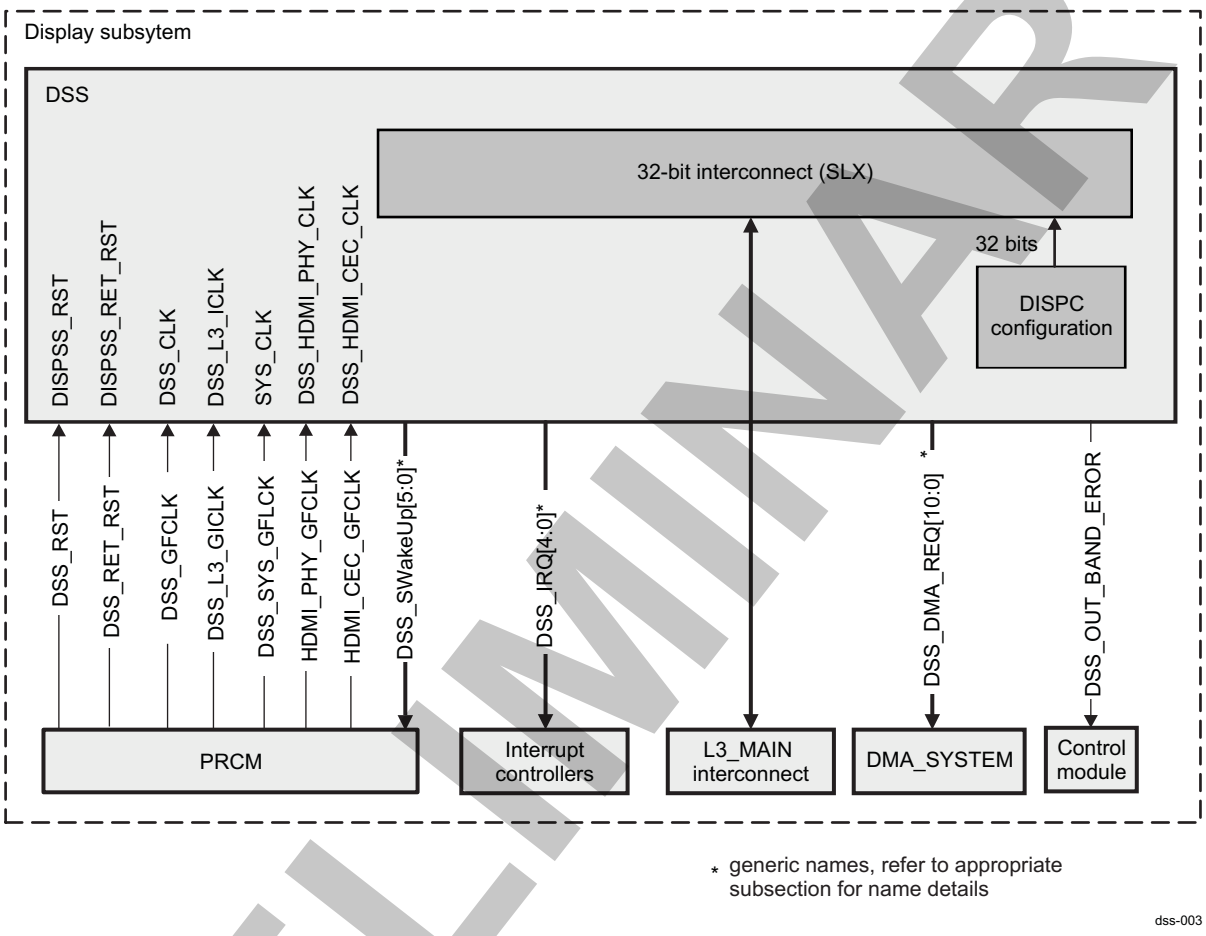
For more details, see HDMI Overview, in *High-Definition Multimedia Interface*.

10.1.2 Display Subsystem Integration

This section describes the integration of the display subsystem module in the device, including information about clocks, resets, and hardware requests.

Figure 10-3 shows the integration of the display subsystem in the device.

Figure 10-3. Display Subsystem Integration



10.1.2.1 Display Subsystem Clocks

The power, reset, and clock management (PRCM) module provides clock signals to the display subsystem.

Figure 10-4 shows the details of the display subsystem clock tree.

Figure 10-4. Display Subsystem Clock Tree

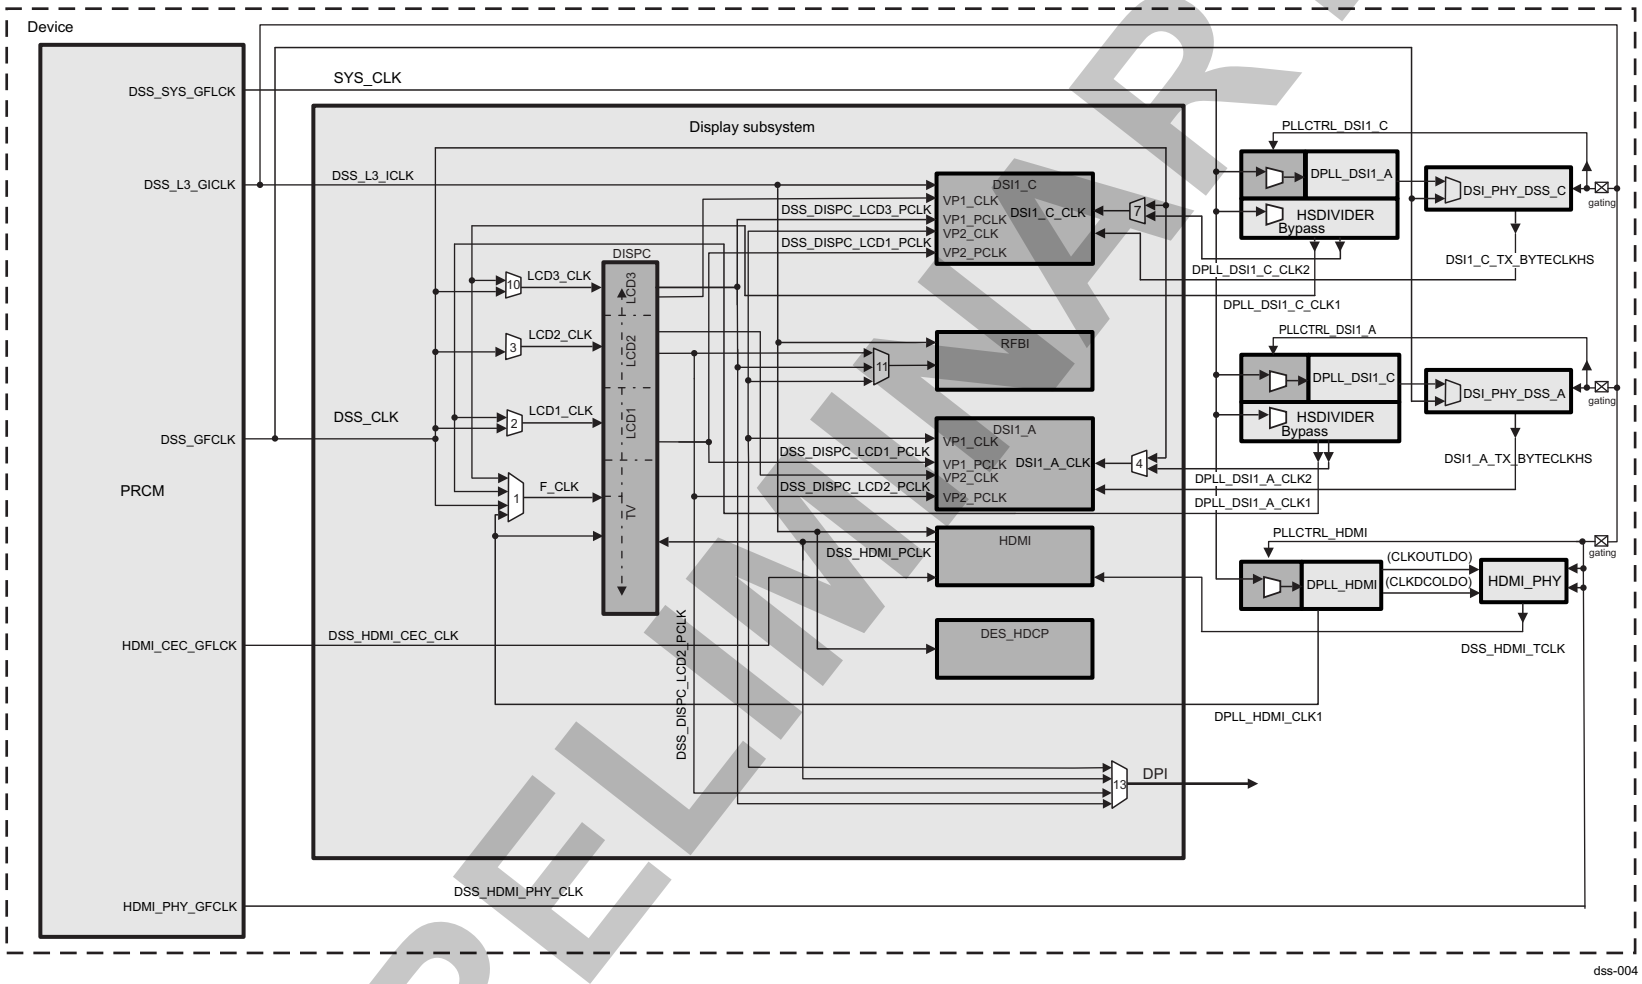


Table 10-3 lists the main DSS clocks and their sources.

Table 10-3. Display Subsystem Clocks

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DSS	DSS_SYS_GFCLK	SYS_CLK	PRCM module	System clock
	DSS_L3_GICLK	DSS_L3_ICLK	PRCM module	Interface clock
	DSS_GFCLK	DSS_CLK	PRCM module	Main display subsystem functional clock
	HDMI_CEC_GFCLK	DSS_HDMI_CEC_CLK	PRCM module	HDMI core CEC engine clock
	HDMI_PHY_GFCLK	DSS_HDMI_PHY_CLK	PRCM module	HDMI_PHY clock

- The clock source for the L3 interface clock is DSS_L3_ICLK. All clocks can be gated at the PRCM level. See , *Module-Level Clock Management*, in *Chapter 3, Power, Reset and Clock Management*.
- Table 10-4 lists the clock sources for the display subsystem modules.

Table 10-4. Display Subsystem Modules Clock Sources

Destination	Source Signal Name	Source	Multiplexer Number	DSS_CTRL Bit Field
DISPC functional clock (F_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external PER_PLL	1	[9:7] F_CLK_SWITCH
	DPLL_DSI1_A_CLK1	DPLL_DSI1_A		
	DPLL_DSI1_C_CLK1	DPLL_DSI1_C		
	DPLL_HDMI_CLK1	DPLL_HDMI		
DISPC LCD1 functional clock (LCD1_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external PER_PLL	2	[0] LCD1_CLK_SWITCH
	DPLL_DSI1_A_CLK1	DPLL_DSI1_A		
DISPC LCD2 functional clock (LCD2_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external DPLL_PER	3	[12] LCD2_CLK_SWITCH
DISPC LCD3 functional clock (LCD3_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external DPLL_PER	10	[19] LCD3_CLK_SWITCH
	DPLL_DSI1_C_CLK1	DPLL_DSI1_C		
DISPC TV functional clock (186 MHz at OPP_NOM)	DPLL_HDMI_CLK1	DPLL_HDMI	N/A	N/A
DISPC TV pixel clock (186 MHz at OPP_NOM)	DSS_HDMI_PCLK	HDMI	N/A	N/A
DISPC internal functional clock (DISPC_CLK after diveder of F_CLK) (209.25 MHz at OPP_NOM)	F_CLK	DSS	N/A	N/A
DSI1_A protocol engine functional clock (DSI1_A_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external DPLL_PER	4	[1] DSI1_A_CLK_SWITCH
	DPLL_DSI1_A_CLK2	DPLL_DSI1_A		
DSI1_A protocol engine interface clock (209.25 MHz at OPP_NOM)	DSS_L3_ICLK	PRCM external DPLL_CORE	N/A	N/A
DSI1_A protocol engine pixel clock (209.25 MHz at OPP_NOM)	DSS_DISPC_LCD1_PCLK	DISPC	N/A	N/A
DSI1_A protocol engine byte clock (157 MHz at OPP_NOM)	DSI1_A_TX_BYTECLKHS	DPLL_DSI1_A	N/A	N/A
DSI1_C protocol engine functional clock (DSI1_C_CLK) (209.25 MHz at OPP_NOM)	DSS_CLK	PRCM external DPLL_PER	7	[18] DSI1_C_CLK_SWITCH
	DPLL_DSI1_C_CLK2	DPLL_DSI1_C		
DSI1_C protocol engine interface clock (266 MHz at OPP_NOM)	DSS_L3_ICLK	PRCM external DPLL_CORE	N/A	N/A
DSI1_C protocol engine pixel clock (209.25 MHz at OPP_NOM)	DSS_DISPC_LCD3_PCLK	DISPC	N/A	N/A
DSI1_C protocol engine byte clock (157 MHz at OPP_NOM)	DSI1_C_TX_BYTECLKHS	DPLL_DSI1_C	N/A	N/A

Table 10-4. Display Subsystem Modules Clock Sources (continued)

Destination	Source Signal Name	Source	Multiplexer Number	DSS_CTRL Bit Field
RFBI interface clock (266 MHz at OPP_NOM)	DSS_L3_ICLK	PRCM external DPLL_CORE	N/A	N/A
RFBI functional/pixel clock (209.25 MHz at OPP_NOM)	DSS_DISPC_LCD1_PCLK	DISPC	11	[14] RFBI_SWITCH and [20] RFBI_SWITCH2
	DSS_DISPC_LCD2_PCLK	DISPC		
	DSS_DISPC_LCD2_PCLK	DISPC		
DPI functional/pixel clock (170 MHz at OPP_NOM)	DSS_DISPC_LCD1_PCLK	DISPC	13	[17:16] PARALLEL_SEL
	DSS_DISPC_LCD2_PCLK	DISPC		
	DSS_DISPC_LCD2_PCLK	DISPC		
	DSS_HDMI_PCLK	HDMI		
HDMI timing clock (DSS_HDMI_TCLK) (186 MHz at OPP_NOM)	N/A	HDMI_PHY	N/A	N/A
HDMI PCLK to DISPC (DSS_HDMI_PCLK) (186 MHz at OPP_NOM)	N/A	HDMI	N/A	N/A

NOTE: For more information about the DSI1_A and DSI1_C video port clocks (VPn_PCLK and VPn_CLK, where n = 1 or 2), see Section 10.3.4.2, *DSI Clock Configuration*.

NOTE: 209.25 MHz is provided by DPLL_DSI1_A/ DPLL_DSI1_C, while frequencies provided by PRCM DPLLs have other OPP frequency restrictions. For more details, refer to the respective DPLL setting in the *Device Data Manual*.

10.1.2.2 Display Subsystem Resets

The PRCM module provides two reset signals to the display subsystem.

Figure 10-5 shows the details of the reset tree for the display subsystem.

Figure 10-5. Display Subsystem Reset Scheme

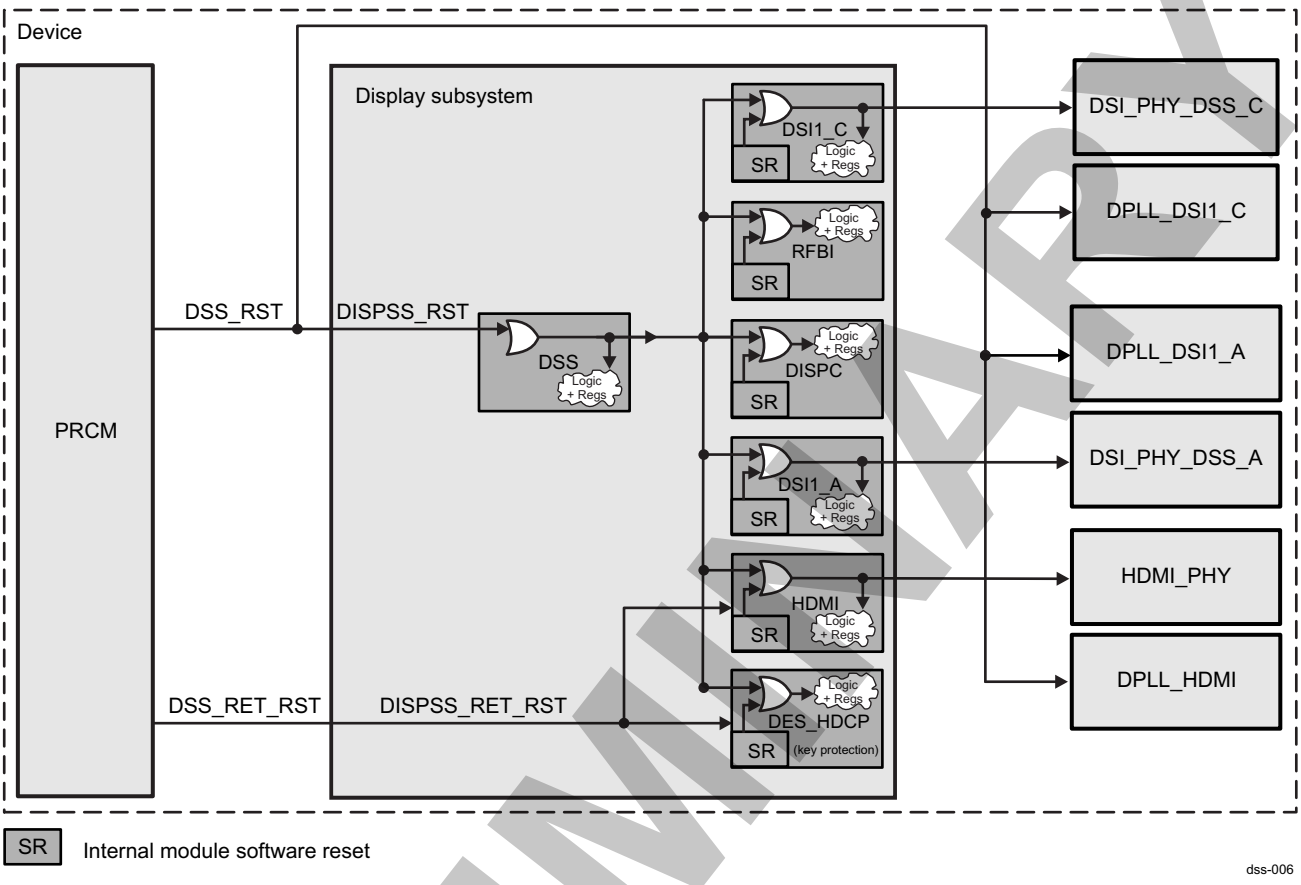

Table 10-5 lists the resets for the display subsystem.

Table 10-5. Display Subsystem Resets

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DSS	DISPSS_RET_RST	DSS_RET_RST	PRCM module	Retention reset
	DISPSS_RST	DSS_RST	PRCM module	Nonretention reset

The display subsystem receives its DISPSS_RST reset signal (the reset signal of the display subsystem power domain) from the PRCM module. The DISPSS_RET_RST is used only for the DES_HDCP key protection module and HDMI.

10.1.2.3 Display Subsystem Power Management

The display subsystem modules are in the display subsystem power domain.

Table 10-6 lists the power domains in the display subsystem.

Table 10-6. Display Subsystem Power Domains

Module Instance	Attributes
	Power Domain
Display subsystem	PD_DSS
DISPC	For more details, see Section 10.2.1, *DISPC Overview*.
MIPI DSI1_A	For more details, see Section 10.3.1, *DSI Overview*.
MIPI DSI1_C	For more details, see Section 10.3.1, *DSI Overview*.

Table 10-6. Display Subsystem Power Domains (continued)

Module Instance	Attributes
RFBI	For more details, see Section 10.5.1, *RFBI Overview*.
HDMI	For more details, see Section 10.4.1, *HDMI Overview*.

10.1.2.3.1 Display Subsystem Standby Mode

As part of the system-wide power-management scheme, the display subsystem supports the MStandby/MWait and SIdleReq/SIdleAck protocols:

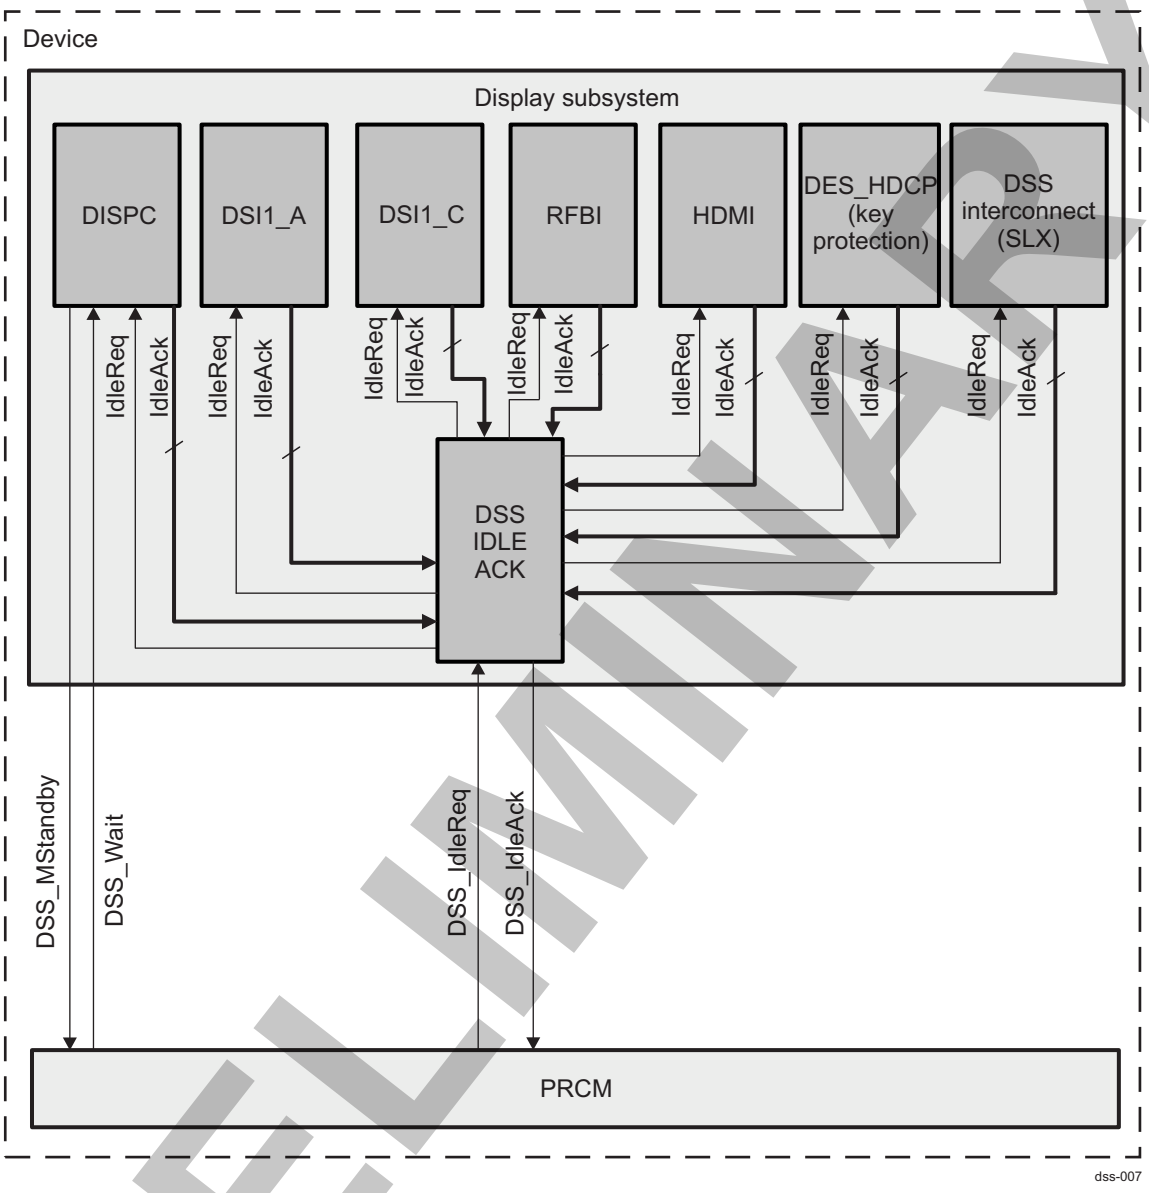
- MStandby/MWait
  - DISPC
- SIdleReq/SIdleAck
  - DISPC
  - DSI1_A
  - DSI1_C
  - RFBI
  - HDMI
  - DES_HDCP (key protection)
  - DSS interconnect

The PRCM module asserts the MWait and received MStandby directly from DISPC. When the display subsystem initiates a standby procedure, it also initiates a standby/wait handshake protocol with the PRCM module that lets the PRCM module cut the display subsystem clocks. For information about the conditions that allow the subsystem to exit standby mode, see DISPC Overview, in *Display Controller*.

The PRCM also asserts the SIdleReq. Then, it is split at the display subsystem level and sent to the appropriate modules. Consequently, all SIdleAck are merged into one and sent back to the PRCM module.

Figure 10-6 shows the generation of SIdleAck/MStandby in the display subsystem.

Figure 10-6. Display Subsystem SIdleAck/MStandby Generation

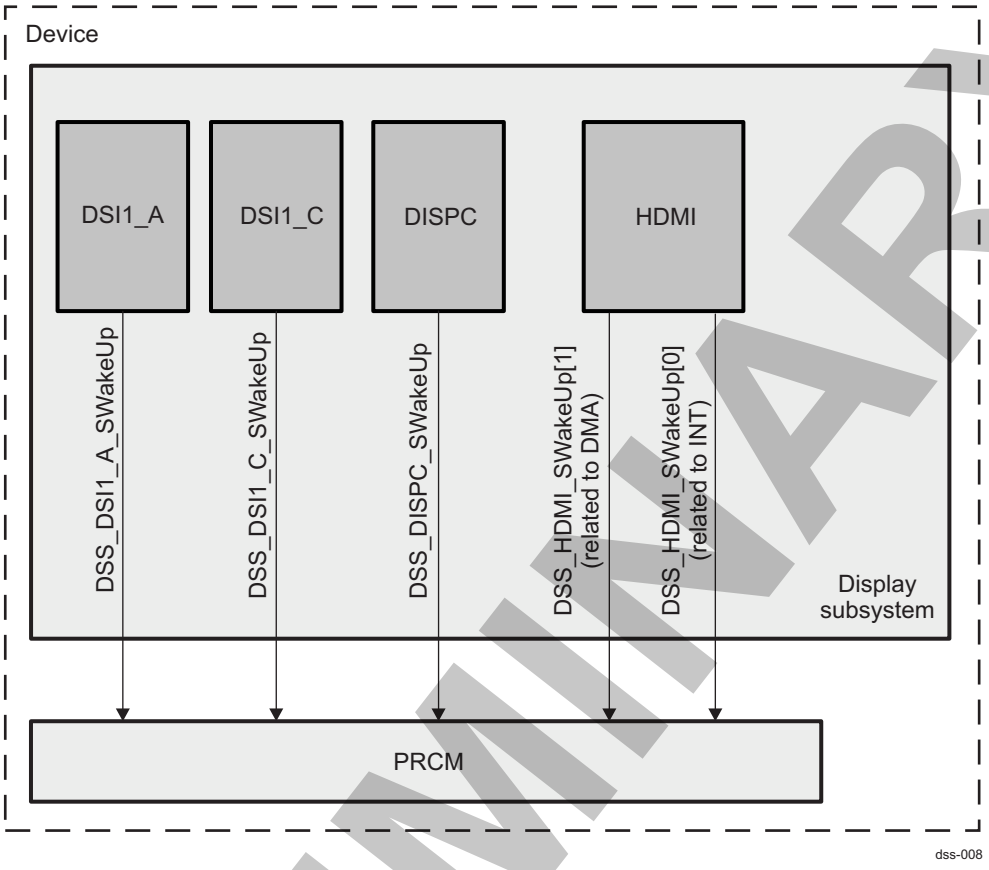


10.1.2.3.2 Display Subsystem Wake-Up Mode

The DISPC, DSI1_A, DSI1_C, and HDMI modules support the wake-up protocol. DSS_HDMI_SWakeUp is associated with DSS_HMDI_IRQ, which is generated by the HDMI module. For the events that generate an SWakeUp and the description and configuration of the registers, see the DISPC, DSI, and HDMI TRM chapters.

Figure 10-7 shows wake-up generation in the display subsystem.

Figure 10-7. Display Subsystem Wake-Up Generation



10.1.2.4 Display Subsystem Interrupt Requests

The display subsystem has four interrupt lines. The interrupt signals are connected to the MPUs and digital signal processor (DSP) interrupt controller (INTC) modules. The interrupts are generated from the DISPC, DSI1_A, DSI1_C, and HDMI.

Figure 10-8 shows interrupt generation in the display subsystem.

Figure 10-8. Display Subsystem Interrupt Generation

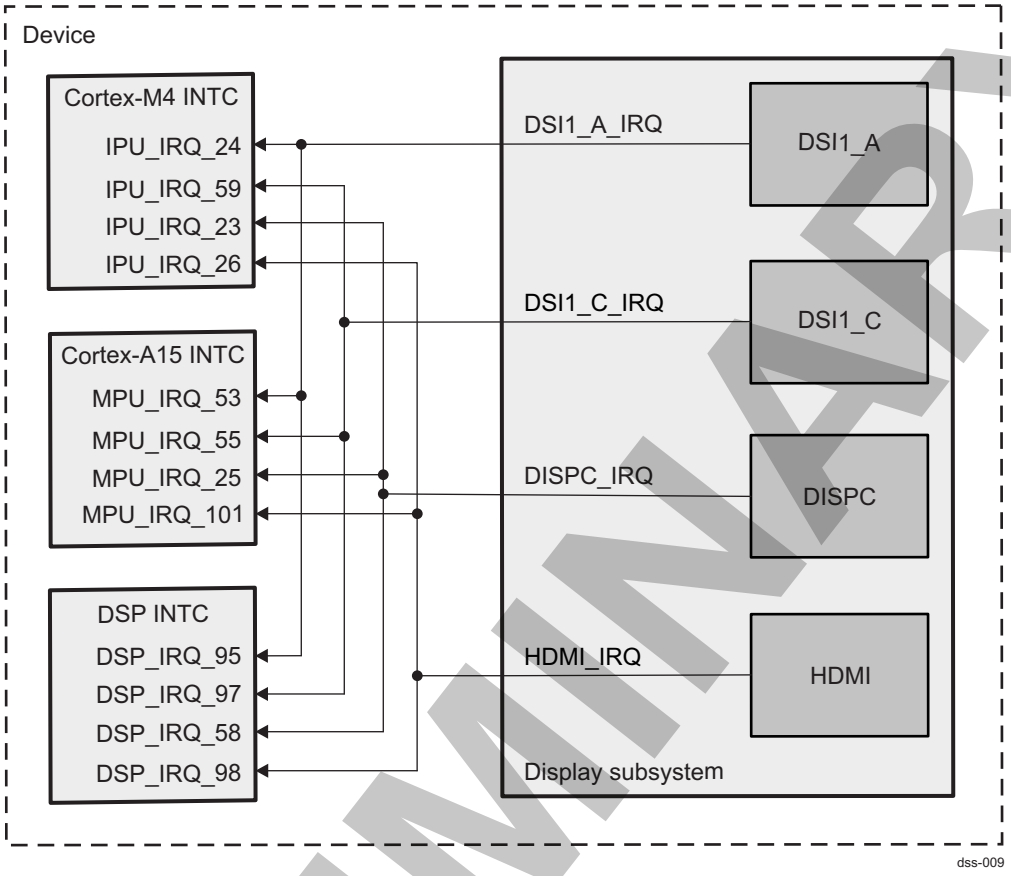


Table 10-7 lists the display subsystem interrupts.

Table 10-7. Display Subsystem Interrupts

		Interrupt Requests		
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
DSS				
DISPC	DSS_DISPC_IRQ	DSP_IRQ_58	DSP INTC	DISPC interrupt request
		MPU_IRQ_25	Cortex™-A15 INTC	DISPC interrupt request
		IPU_IRQ_23	Cortex™-M4 INTC	DISPC interrupt request
MIPI DSI1_A	DSI1_A_IRQ	DSP_IRQ_95	DSP INTC	Display DSI1_A interrupt request
		MPU_IRQ_53	Cortex-A15 INTC	Display DSI1_A interrupt request
		IPU_IRQ_24	Cortex-M4 INTC	Display DSI1_A interrupt request
MIPI DSI1_C	DSI1_C_IRQ	DSP_IRQ_97	DSP INTC	Display DSI1_C interrupt request
		MPU_IRQ_55	Cortex-A15 INTC	Display DSI1_C interrupt request
		IPU_IRQ_59	Cortex-M4 INTC	Display DSI1_C interrupt request
HDMI	HDMI_IRQ	DSP_IRQ_98	DSP INTC	Display HDMI interrupt request
		MPU_IRQ_101	Cortex-A15 INTC	Display HDMI interrupt request
		IPU_IRQ_26	Cortex-M4 INTC	Display HDMI interrupt request

10.1.2.5 Display Subsystem DMA Requests

Eleven DMA requests are connected to the DMA_SYSTEM.

The DMA_SYSTEM requests are:

- Four DMA request signals from each DSI protocol engine (data traffic: from SDRAM or IVA-HD SL2 to DSI protocol engine and from DSI protocol engine to SDRAM or IVA-HD SL2)
- One DMA request signal from RFBI module (data traffic: from SDRAM to RFBI)
- One DMA request signal from HDMI module (audio traffic: from SDRAM or IVA-HD SL2 to HDMI)
- One DMA request signal from DISPC module (used for synchronization of a logical channel in the DMA_SYSTEM for memory-to-memory transfers)

Figure 10-9 shows the details of DMA request generation in the display subsystem.

Figure 10-9. Display Subsystem DMA Request Generation

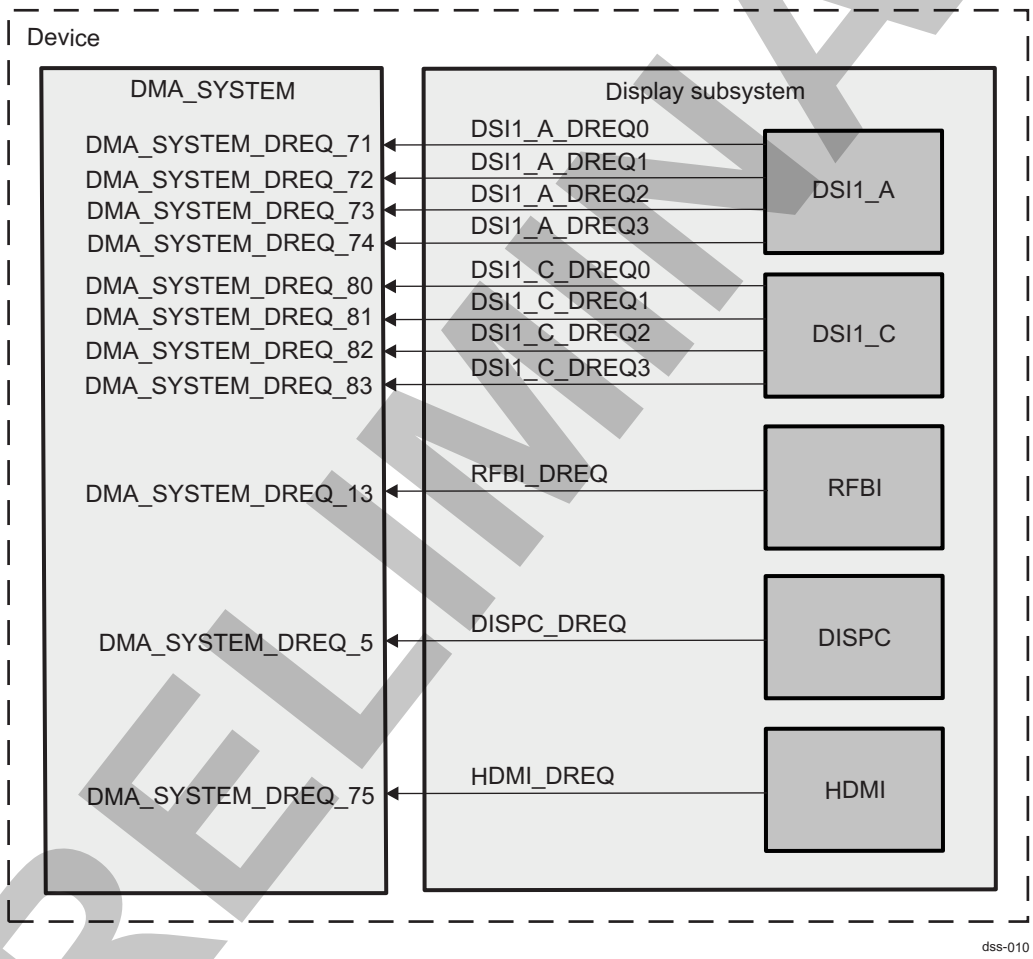

Table 10-8 lists the display subsystem DMA_SYSTEM requests.

Table 10-8. Display Subsystem DMA_SYSTEM Requests

DMA_SYSTEM Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
RFBI	RFBI_DREQ	DMA_SYSTEM_DREQ_13	DMA_SYSTEM	Display subsystem RFBI DMA request
DISPC	DISPC_DREQ	DMA_SYSTEM_DREQ_5	DMA_SYSTEM	The line trigger signal to synchronize a memory-to-memory logical channel in the DMA4 DMA_SYSTEM is generated by the DISPC IP.

Table 10-8. Display Subsystem DMA_SYSTEM Requests (continued)

20	RFBI_SWITCH2	Selects the video port 3 from DISPC or select RFBI_SWITCH bit-field If RFBI_SWITCH2 is not set, the video port selectecion is done through the bit-field RFBI_SWITCH 0x0: The video port is selected using only RFBI_SWITCH bit-field. 0x1: Video port 3 (also named third LCD output or LCD3) is selected. The bit-field RFBI_SWITCH is ignored.	RW	0x0
19	LCD3_CLK_SWITCH	DSS_CLK/DPLL_DSI1_C_CLK1 clock switch (multiplexer 10) Selects the clock source for the DISPC LCD3_CLK clock 0x0: DSS_CLK selected (from PRCM) 0x1: DPLL_DSI1_C_CLK1 selected	RW	0x0

Bits	Field Name	Description	Type	Reset
18	DSI1_C_CLK_SWITCH	DSS_CLK/DPLL14_DSI1_C_CLK2 clock switch (multiplexer 7) Selects the clock source for the DSI1_C functional clock DSI1_C_CLK 0x0: DSS_CLK selected (from PRCM) 0x1: DPLL_DSI1_C_CLK2 selected (from DPLL_DSI1_C)	RW	0x0
17:16	PARALLEL_SEL	Selection between LCD1, LCD2, LCD3 and TV channel out on the parallel output (multiplexer 13) 0x0: Select HDMI channel output. 0x1: Select LCD1 channel output. 0x3: Select LCD3 channel output. 0x2: Select LCD2 channel output.	RW	0x0
15	RESERVED	Reserved	R	0x0
14	RFBI_SWITCH	Selects the video port from DISPC between Video port 1 and Video port 2 (multiplexer 11). If RFBI_SWITCH2 is set, RFBI_SWITCH field is ignored. 0x0: Video port #1 (also named primary LCD output or LCD1) is selected (backward compatible mode) 0x1: Video port #2 (also named secondary LCD output or LCD2) is selected	RW	0x0
13	RESERVED	Reserved	R	0x0
12	LCD2_CLK_SWITCH	DSS_CLK clock switch (multiplexer 3) Selects the clock source for the DISPC LCD2_CLK clock 0x0: DSS_CLK selected (from PRCM) 0x1: Reserved	RW	0x0
11:10	RESERVED	Reserved	RW	0x0
9:7	F_CLK_SWITCH	Selects the clock source for the DISPC functional clock F_CLK 0x0: DSS_CLK selected (from PRCM) 0x1: DPLL_DSI1_A_CLK1 selected (from DPLL_DSI1_A) 0x3: DPLL_HDMI_CLK1 selected (from DPLL_HDMI) 0x4: DPLL_DSI1_C_CLK1 selected (from DPLL_DSI1_C) 0x2: Reserved	RW	0x0
6:2	RESERVED	Reserved	R	0x00
1	DSI1_A_CLK_SWITCH	DSS_CLK/DPLL_DSI1_A_CLK2 clock switch (multiplexer 4) Selects the clock source for the DSI1_A functional clock DSI1_A_CLK 0x0: DSS_CLK selected (from PRCM) 0x1: DPLL_DSI1_A_CLK2 selected (from DSI1_A PLL)	RW	0x0
0	LCD1_CLK_SWITCH	DSS_CLK/DPLL_DSI1_A_CLK1 clock switch (multiplexer 2) Selects the clock source for the DISPC LCD1_CLK clock 0x0: DSS_CLK selected (from PRCM) 0x1: DPLL_DSI1_A_CLK1 selected (from DSI1_A PLL)	RW	0x0

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved	R	0x00
25:24	LCD3_CLK_STATUS	LCD3_CLK clock selection status (multiplexer 10) indicates which clock is used by the glitch-free mux selecting the source of LCD3_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is ongoing. Read 0x2: DPLL_DSI1_C_CLK1 is used by DISPC as LCD3_CLK clock Read 0x1: DSS_CLK is used as LCD3_CLK Read 0x0: LCD3_CLK clock switch is on-going	R	0x1
23:22	DSI1_C_CLK_STATUS	DSI1_C_CLK clock selection status (multiplexer 4) indicates which clock is used by the glitch-free mux selecting the source of DSI1_C_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is ongoing. Read 0x2: DPLL_DSI1_C_CLK2 is used by DSI1_C as DSI1_C_CLK clock Read 0x1: DSS_CLK is used by DSI1_C as DSI1_C_CLK clock Read 0x0: DSI1_C_CLK clock switch is ongoing	R	0x1
21:20	RFBI_STATUS	Video port selection status (multiplexer 11) Indicates if video port 1 or video 2 from DISPC is used to provide data to the RFBI Read 0x2: Video port 3 (named also third LCD output or LCD3) used to provide data to RFBI Read 0x1: Video port 2 (named also secondary LCD output or LCD2) used to provide data to RFBI Read 0x0: Video port 1 (named also primary LCD output or LCD1) used to provide data to RFBI	R	0x0

Bits	Field Name	Description	Type	Reset
19:15	F_CLK_STATUS	F_CLK clock selection status (multiplexer 1) indicates which clock is used by the glitch-free mux selecting the source of F_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is ongoing. Read 0x4: Reserved Read 0x2: DPLL_DSI1_A_CLK1 is used by DISPC as F_CLK clock Read 0x0: DSS_CLK clock switch is on-going Read 0x1: DSS_CLK is used by DISPC as F_CLK clock Read 0x8: DPLL_HDMI_CLK1 is used by DISPC as F_CLK clock Read 0x10: DPLL_DSI1_C_CLK1 is used by DISPC as F_CLK clock	R	0x01
14:13	RESERVED	Reserved	R	0x0
12:11	LCD2_CLK_STATUS	LCD2_CLK clock selection status (multiplexer 3) indicates which clock is used by the glitch-free mux selecting the source of LCD2_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is ongoing. Read 0x2: Reserved Read 0x1: DSS_CLK is used as LCD2_CLK Read 0x0: LCD2_CLK clock switch is on-going	R	0x1
10:9	RESERVED	Reserved	R	0x1
8:7	DSI1_A_CLK_STATUS	DSI1_A_CLK clock selection status (multiplexer 4) indicates which clock is used by the glitch-free mux selecting the source of DSI1_A_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is ongoing. Read 0x2: DPLL_DSI1_A_CLK2 is used by DSI1_A as DSI1_A_CLK clock Read 0x1: DSS_CLK is used by DSI1_A as DSI1_A_CLK clock Read 0x0: DSI1_A_CLK clock switch is on-going	R	0x1
6:2	RESERVED	Reserved	R	0x0
1:0	LCD1_CLK_STATUS	LCD1_CLK clock selection status (multiplexer 2) indicates which clock is used by the glitch-free mux selecting the source of LCD1_CLK. It is required to have the current clock and the new selected clock being running in order to be able to switch. Both clocks are used at the same time while the switch is on going. Read 0x2: DPLL_DSI1_A_CLK1 is used by DISPC as LCD1_CLK clock Read 0x1: DSS_CLK is used as LCD1_CLK Read 0x0: LCD1_CLK clock switch is on-going	R	0x1

Table 10-18. Register Call Summary for Register DSS_STATUS

Display Subsystem Overview

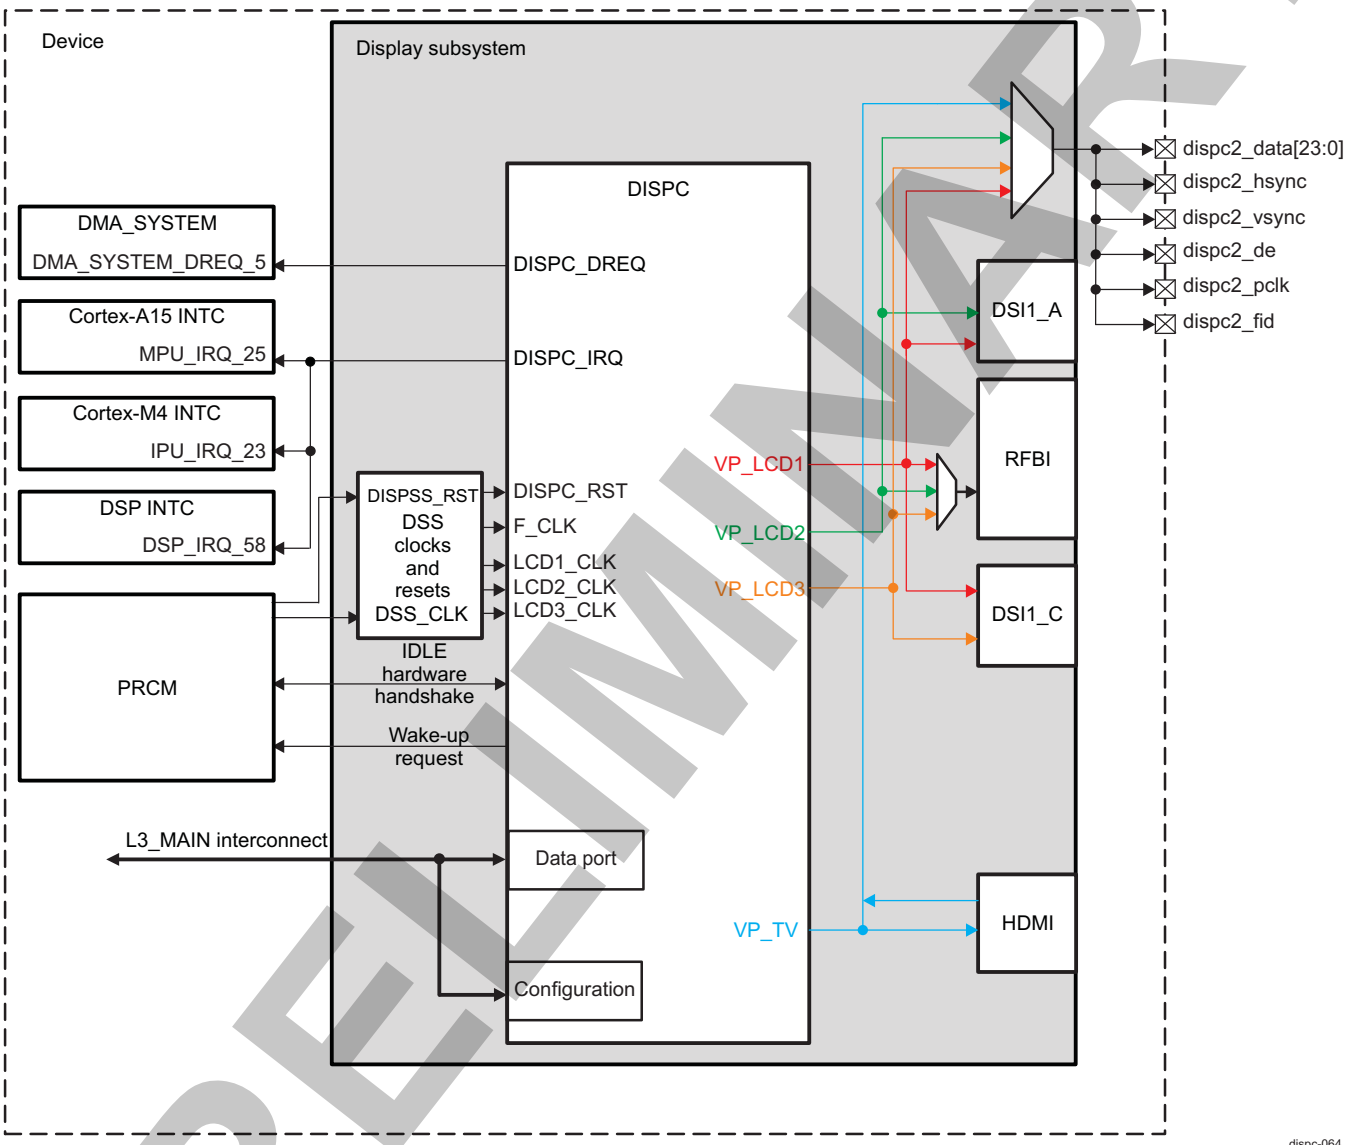
- Display Subsystem Registers Mapping Summary: [0]

10.2 Display Controller

10.2.1 DISPC Overview

Figure 10-10 shows a block diagram of the display controller (DISPC) within the display subsystem.

Figure 10-10. DISPC Overview



The DISPC includes the following main features:

- Five pipelines for processing:
  - One GFX:
    - Pixel formats: ARGB16-4444, xRGB12-4444, RGBA16-4444, RGBx12-4444, RGB16-565, ARGB16-1555, xRGB16-1555, ARGB32-8888, RGBA32-8888, xRGB32-8888, RGBx32-8888, xRGB24-8888, RGBx24-8888, BGRA32-8888, RGB24-888 (packed), and BITMAP (1 2, 4, or 8 bits per pixel) (where x means that the corresponding bits in the container are not used)
    - Premultiplied ARGB and RGBA formats
    - Selection of the color depth expansion from ARGB16-4444, RGBA16-4444, and ARGB16-1555 to ARGB32-8888, and from xRGB12-4444, RGBx12-4444, and xRGB16-1555 to xRGB32-8888 (replication of the most significant bits [MSBs] or adding 0s)

- Support for color look-up table (CLUT): 256 × 24-bit entries palette in RGB
- Support for antiflicker on RGB pixel formats using 3-tap filter

– Three video pipelines (VID1, VID2, and VID3):
  - Pixel formats: ARGB16-4444, xRGB12-4444, RGBx12-4444, RGBA12-3333, RGBA16-4444, RGB16-565, ARGB16-1555, xRGB16-1555, ARGB32-8888, RGBA32-8888, xRGB32-8888, RGBx32-8888, RGB24-888, BGRA32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21 (where x means that the corresponding bits in the container are not used)
  - Premultiplied ARGB and RGBA formats
  - Selection of the color depth expansion from ARGB16-4444, RGBA16-4444, and ARGB16-1555 to ARGB32-8888, and from xRGB12-4444, RGBx12-4444, and xRGB16-1555 to xRGB32-8888 (replication of the MSBs or adding 0s)
  - Programmable poly-phase filter:
    - Independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4)
    - Maximum input width of 1920 pixels
    - No limitation on the input height
    - Supported input formats are ARGB32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21
    - Alpha blending factor is rescaled like the R, G, and B color components.
  - Programmable color space conversion from YUV4:2:2 (YUV4:4:4, YUV4:2:0 after Chroma upsampling through the scaler) into ARGB32-8888. Images in YUV4:2:2 format with 90- or 270-degree rotation are preprocessed to YUV4:4:4 before the scaler, by duplicating the missing Chroma.
  - Programmable VC-1 range mapping

– One write-back (WB) pipeline: Allows the use of the hardware processing available inside the DISPC, such as color space conversion, rescaling, and compositing to perform memory-to-memory transfer with data processing or capturing a displayed frame
  - Programmable color space conversion RGB24 into YUV4:4:4 or to YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, or YUV4:2:0-NV21 using programmable poly-phase filter
  - Programmable color space conversion RGB24 into YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, or YUV4:2:0-NV21
  - Selection of the color depth reduction from RGB24 to RGB16
  - Programmable poly-phase filter:
    - Independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4)
    - Maximum input width of 1920 pixels
    - No limitation on the input height
    - Supported input formats are ARGB32-8888, YUV4:2:2-UYVY, YUV4:2:2-YUV2, YUV4:2:0-NV12, and YUV4:2:0-NV21
    - Alpha blending factor is rescaled like the R, G, and B color components.
  - Selection of the source of the data:
    - Overlay output:
      - Primary LCD output
      - Secondary LCD output
      - Third LCD output
      - TV output
    - Pipelines:
      - Graphic
      - Video 1

    - Video 2
    - Video 3
- Three LCD outputs: primary (LCD1), secondary (LCD2), and tertiary (LCD3):
  - Input pixel format: ARGB32-8888
  - Output pixel format: RGB24-888 and YUV4:2:2 (YUV4:2:2 only available when Bluetooth mode output is enabled)
  - Overlay of graphic and video for one to four pipelines
  - Source and destination transparency color key
  - Global and pixel alpha blending (up to 8-bit blending factor)
  - Z-order programmable (full flexibility)
  - Displays supported:
    - Active matrix color: 12-, 16-, 18-, and 24-bit panel interface support (replicated or dithered encoded pixel values)
  - Independent programmable timing generators for LCD1, LCD2, and LCD3 to support:

Using DSI1_A interface	WUXGA (1920x1200) @ 60 fps with 24 bpp (VESA timing)
Using RFBI	WVGA @ 30 fps
Using DSI1_C interface	WUXGA (1920x1200) @ 60 fps with 24 bpp (VESA timing)
Using CMOS interface	SXGA VESA timing @ 60 fps, 1080i/720p @ 60 fps CEA-861-D, UXGA @ 60 fps

  - Configurable LCD output mode: progressive or interlace mode
  - Remote frame buffer support through the RFBI module
  - Partial display through the RFBI
  - Multiple-cycle output format on 8-, 9-, 12-, and 16-bit interface time division multiplexing (TDM)
- One TV output:
  - Input pixel format: ARGB40-10.10.10.10
  - Output pixel format: ARGB40-10.10.10.10
  - Overlay of graphic and video for one to four pipelines
  - Source and destination transparency color key
  - Global and pixel alpha blending (up to 10-bit blending factor)
  - Z-order programmable (full flexibility)
  - Slave mode support (no master mode support) with synchronization signals provided by HDMI TX:
    - HSYNC (horizontal synchronization signal)
    - VSYNC (vertical synchronization signal)
    - RE (data request signal)
    - FID (field ID: even and odd field information)
  - RGB30-10.10.10 data bus output for connection to HDMI TX and extended to 36 by duplication of the MSBs
  - HD-1080p, HD-1080i, HD-720p, SD-480p, SD-576p, SD-576i, and SD-480i using HDMI
  - HDMI deep color mode support, 30-bit data output to HDMI encoder
  - Pixel duplication capability (from one pixel clock cycle up to eight cycles)
- Panel support with MIPI DPI protocol:
  - 12-, 16-, 18-, and 24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
- Common:
  - Rotation 0, 90, 180, and 270 degrees using DMM-TILER
  - Synchronized buffer update

  - Hardware cursor (using the graphics pipeline or one of the video pipelines)
  - Independent gamma curve support on LCDs outputs and TV output
  - Multiple-buffer support
  - Mirroring/flip-flop support (using DMM-TILER)
  - Programmable color phase rotation (CPR)
  - Alpha blending support:
    - Embedded pixel factor (ARGB and RGBA)
    - Global alpha
- DMA (internal to the DISPC):
  - Support for accessing tiled structure through the TILER inside the dynamic memory management (DMM)
  - Support for accessing nontiled structure through the TILER or directly
  - Support for rotation, flip-flop, and mirroring though the TILER inside the DMM
  - Support for memory fragmentation though the TILER inside the DMM
  - Integrated shared buffers between DMA engine and pipelines
  - Programmable buffer thresholds
  - Bandwidth limiter on write request (insertion on idle cycles between requests)
- Advanced:
  - Mode outputting data on display only from the DMA buffer (self-refresh using the DMA FIFO)
  - DMA buffer hand-check in stall mode
  - Arbitration between high and low priority (GFX, VID1, VID2, VID3, and WB pipelines)
- Power modes:
  - Low-power saving modes
  - Support on-the-fly dynamic voltage and frequency scaling (DVFS)
  - Merge capability of the DMA buffers to support greater OFF period on the L3_MAIN interconnect
    - All buffers associated to a single pipeline
    - Reallocation of the buffers of the nonactive pipelines to the active pipelines

10.2.2 DISPC Environment

The DISPC provides the required control signals to interface directly to an external parallel panel for the MIPI DPI protocol.

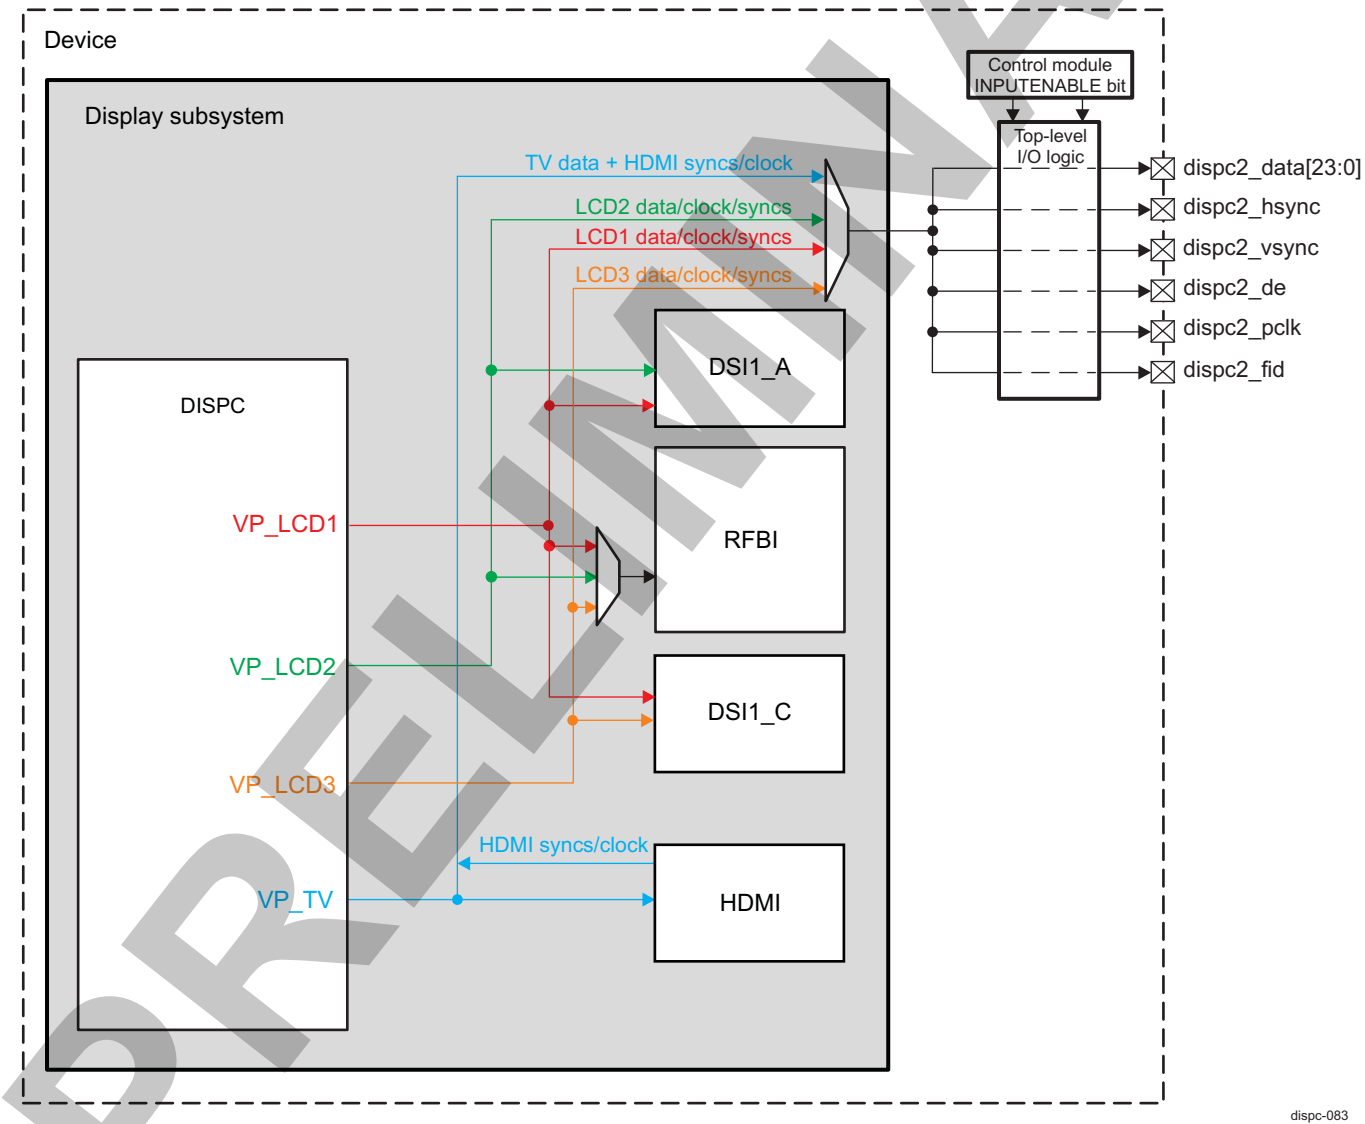
Figure 10-11 shows the LCD support parallel interface.

NOTE: Parallel interface is available through the LCD1, LCD2, LCD3, and TV outputs of the DISPC.

The LCD data and control signals are multiplexed with the TV output data, and control signals are provided by the HDMI module.

The selection can be done at the top level of the display subsystem. For further details and signal mapping, see Section 10.1.1, *Display Subsystem Environment*.

Figure 10-11. DISPC LCD Support Parallel Interface



NOTE: The path from a module pin to device pad (or pads) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 10-19 describes the interface signals to/from the LCD panel in bypass mode.

Table 10-19. DISPC Parallel Interface Signals

Signal Name	Type[1]	Description
dispc2_data[23:0]	O	Pixel data
dispc2_pclk	O	Pixel clock
dispc2_vsync	O	Vertical synchronization. The LCD frame clock (vsync) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed at the beginning and end of each frame.
dispc2_hsync	O	Horizontal synchronization. The LCD line clock (hsync) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states has elapsed at the beginning and end of each line.
dispc2_de	O	In active matrix technology, the DE signal acts as an output-enable signal to indicate when data must be latched using the pixel clock.
dispc2_fid	O	The FID signal indicates the field identifier for the LCD output field: • 0 means even. • 1 means odd.

(1) I = Input, O = Output, I/O = Input/Output

10.2.2.1 DISPC LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations.

Figure 10-12 through Figure 10-15 show the pixel data bus, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins.

In the Active matrix display type, one pixel per pixel clock is displayed.

Active matrix technology:

Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

Figure 10-12 through Figure 10-15 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

Figure 10-12. DISPC LCD Pixel Data Color12 Active Matrix

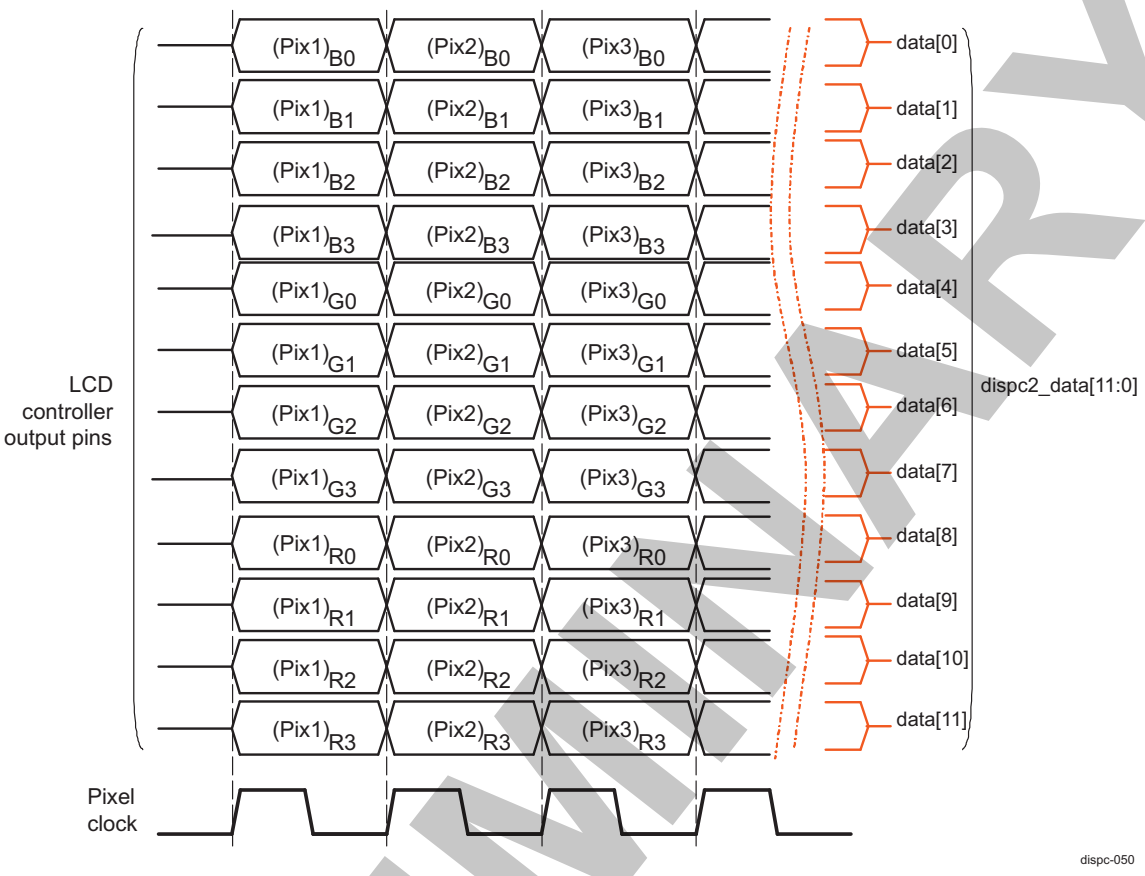


Figure 10-13. DISPC LCD Pixel Data Color16 Active Matrix

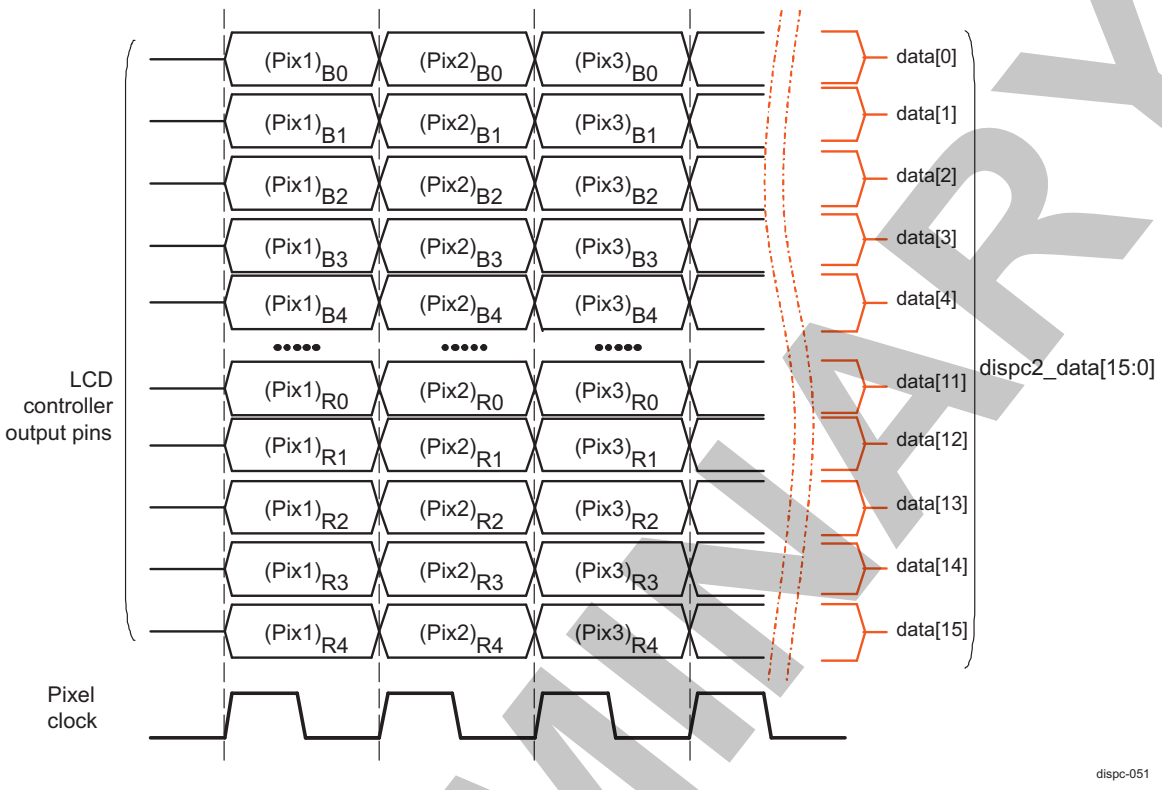

Figure 10-14. DISPC LCD Pixel Data Color18 Active Matrix

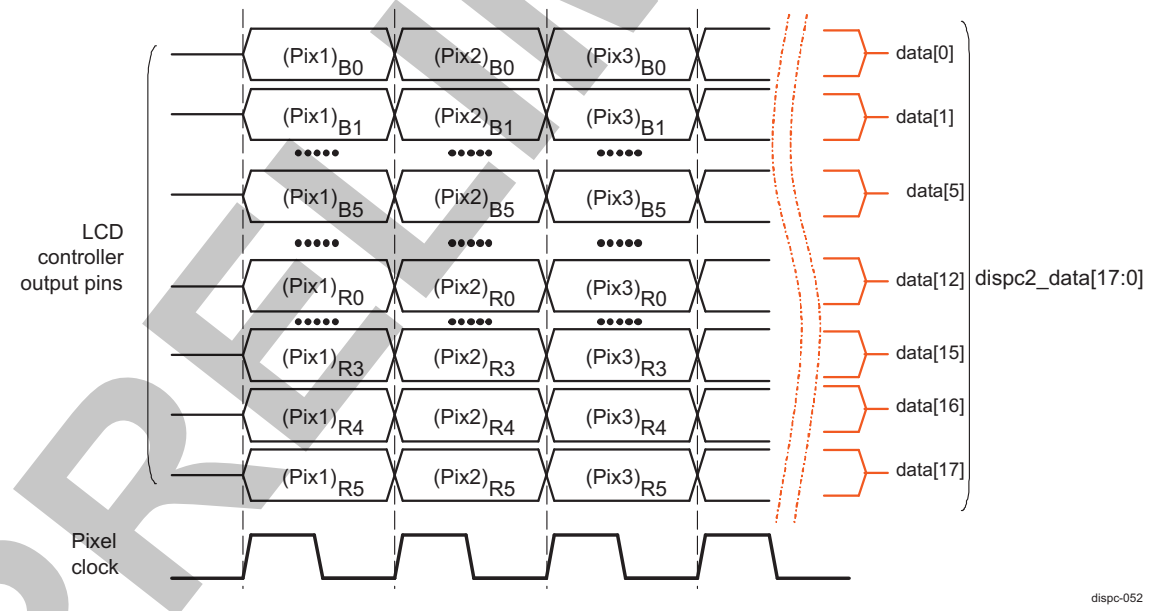

Figure 10-15. DISPC LCD Pixel Data Color24 Active Matrix

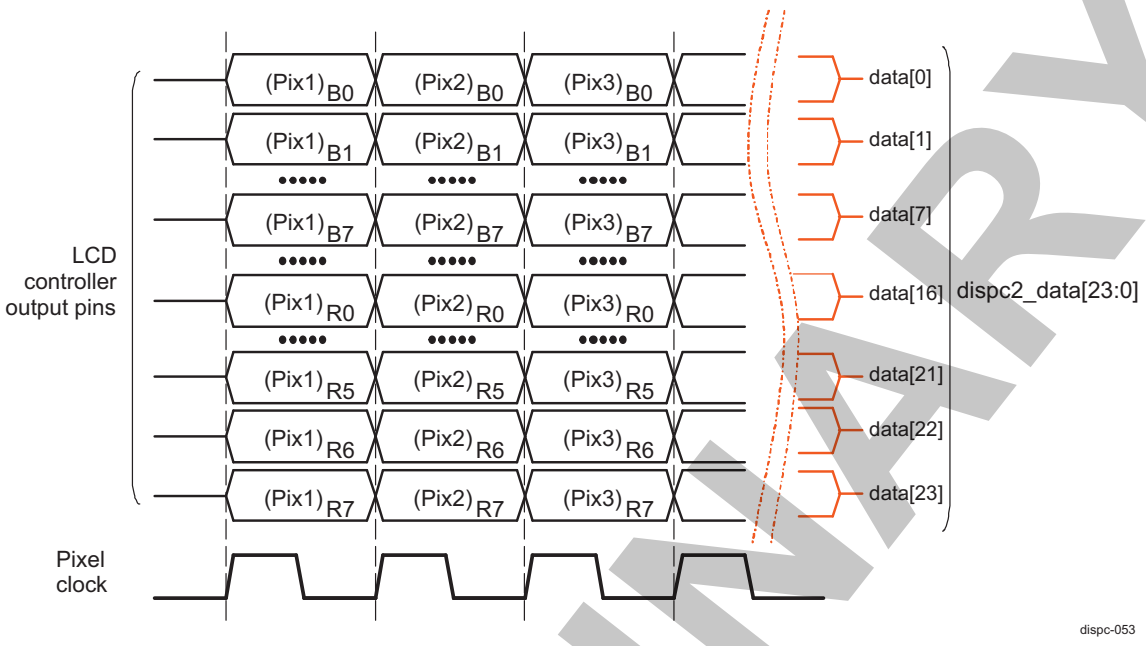

10.2.2.2 DISPC Transaction Timing Diagrams

Figure 10-16 through Figure 10-19 show timing diagrams of synchronization signals and pixel clocks for active matrix panels. The DISPC directly drives these signals, which are related to the programmable fields listed in Table 10-20.

Table 10-20. DISPC Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DISPC_SIZE_LCDo[11:0] PPL value + 1	Pixels per line
LPP	DISPC_SIZE_LCDo[27:16] LPP value + 1	Lines per panel
HBP	DISPC_TIMING_Ho[31:20] HBP value + 1	Horizontal back porch
HFP	DISPC_TIMING_Ho[19:8] HFP value + 1	Horizontal front porch
HSW	DISPC_TIMING_Ho[7:0] HSW value + 1	Horizontal synchronization pulse width
VBP	DISPC_TIMING_Vo[31:20] VBP value	Vertical back porch
VFP	DISPC_TIMING_Vo[19:8] VFP value	Vertical front porch
VSW	DISPC_TIMING_Vo[7:0] VSW value + 1	Vertical synchronization pulse width
ONOFF	DISPC_POL_FREQo[17] ONOFF	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DISPC_POL_FREQo[16] RF	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DISPC_POL_FREQo[15] IEO	Invert DISPC_ACBIAS
IPC	DISPC_POL_FREQo[14] IPC	Invert DISPC_PCLK
IHS	DISPC_POL_FREQo[13] IHS	Invert DISPC_HSYNC
IVS	DISPC_POL_FREQo[12] IVS	Invert DISPC_VSYNC

- Active matrix timing configuration 1:
  - DISPC_POL_FREQo[17] ONOFF = 0
  - DISPC_POL_FREQo[16] RF = 0

    The HSYNC and VSYNC signals are driven on the opposite edge of PCLK from the pixel data.
  - DISPC_POL_FREQo[15] IEO = 0

The DE signal is active high.

– DISPC_POL_FREQo[14] IPC = 0

The pixel data are driven on the rising edge of PCLK.

– DISPC_POL_FREQo[13] IHS = 0

The HSYNC signal is active high.

– DISPC_POL_FREQo[12] IVS = 0

The VSYNC signal is active high.

Figure 10-16. DISPC Active Matrix Timing Diagram of Configuration 1 (Start of Frame)

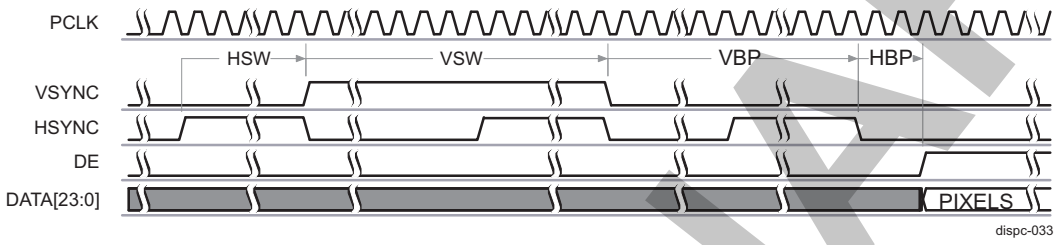

Figure 10-17. DISPC Active Matrix Timing Diagram of Configuration 1 (Between Lines)

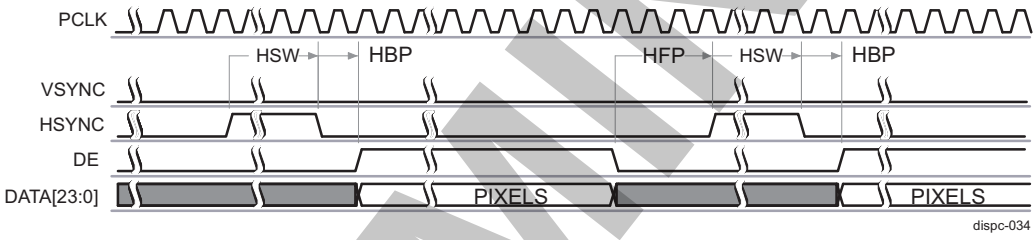

Figure 10-18. DISPC Active Matrix Timing Diagram of Configuration 1 (Between Frames)

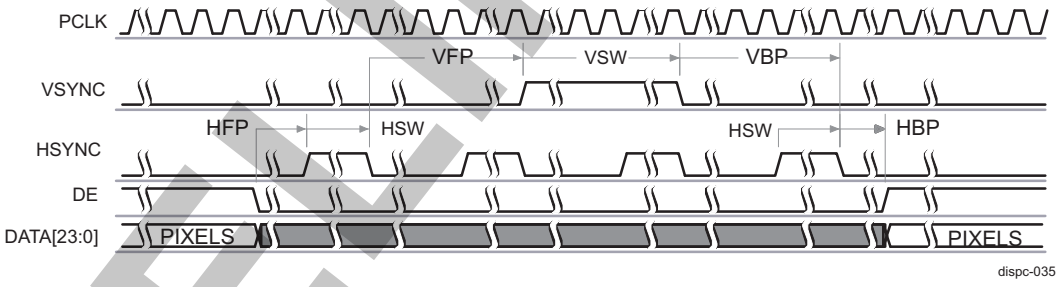

Figure 10-19. DISPC Active Matrix Timing Diagram of Configuration 1 (End of Frame)

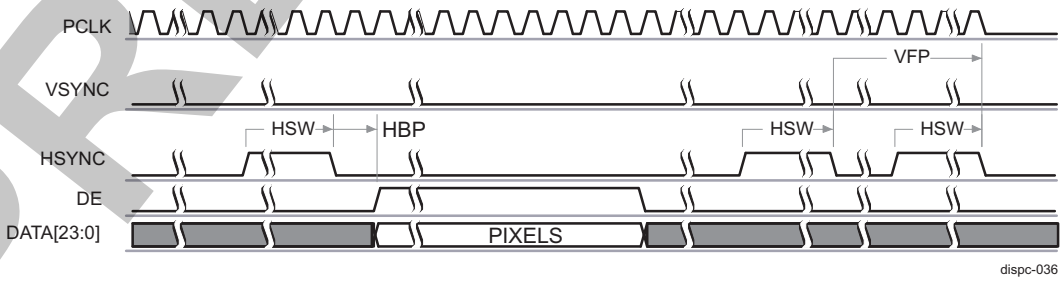

- Active matrix timing configuration 2:

– DISPC_POL_FREQo[17] ONOFF = 1

– DISPC_POL_FREQo[16] RF = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

– DISPC_POL_FREQo[15] IEO = 1
  The DE signal is active low.
– DISPC_POL_FREQo[14] IPC = 1
  The pixel data is driven on the falling edge of PCLK.
– DISPC_POL_FREQo[13] IHS = 1
  The HSYNC signal is active low.
– DISPC_POL_FREQo[12] IVS = 1
  The VSYNC signal is active low.

Figure 10-20. DISPC Active Matrix Timing Diagram of Configuration 2 (Start of Frame)

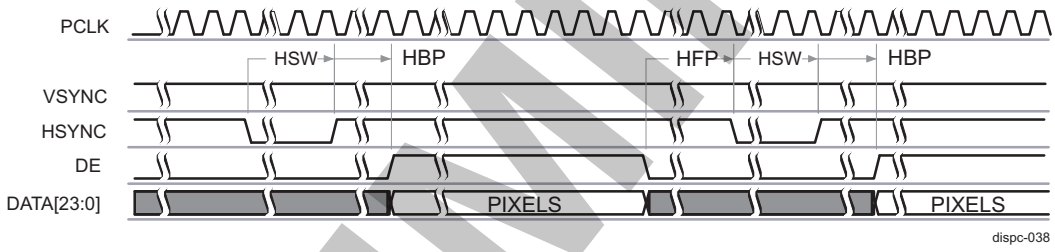

Figure 10-22. DISPC Active Matrix Timing Diagram of Configuration 2 (Between Frames)

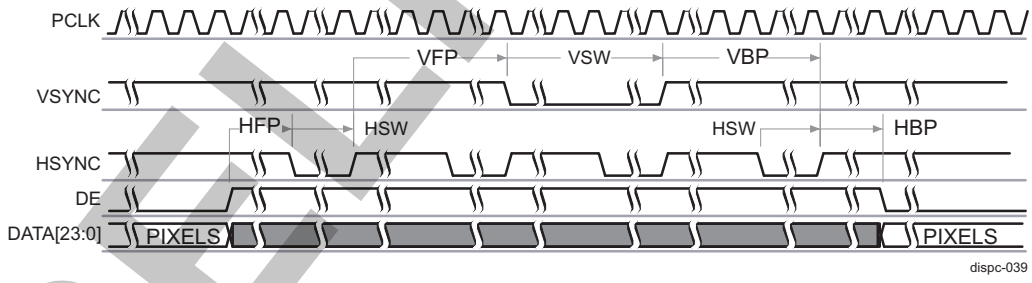

Figure 10-23. DISPC Active Matrix Timing Diagram of Configuration 2 (End of Frame)

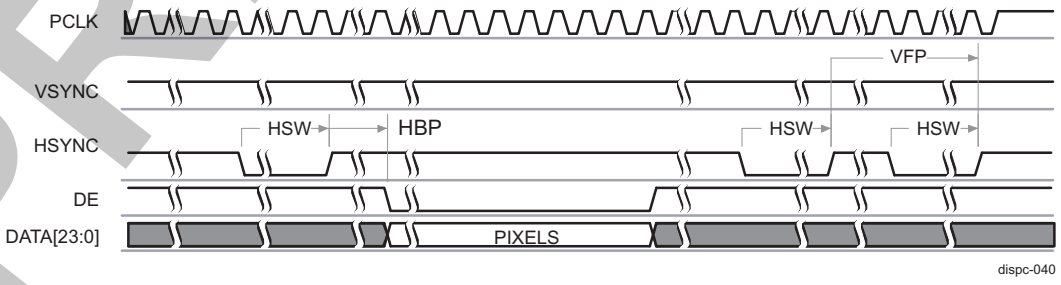

- Active matrix timing configuration 3:
  – DISPC_POL_FREQo[17] ONOFF bit = 1
  – DISPC_POL_FREQo[16] RF bit = 1

The HSYNC and VSYNC signals are driven on the rising edge of PCLK.

– DISPC_POL_FREQo[15] IEO = 0
  The DE signal is active high.
– DISPC_POL_FREQo[14] IPC = 0
  The pixel data are driven on the rising edge of PCLK.
– DISPC_POL_FREQo[13] IHS = 0
  The HSYNC signal is active high.
– DISPC_POL_FREQo[12] IVS = 0
  The VSYNC signal is active high.

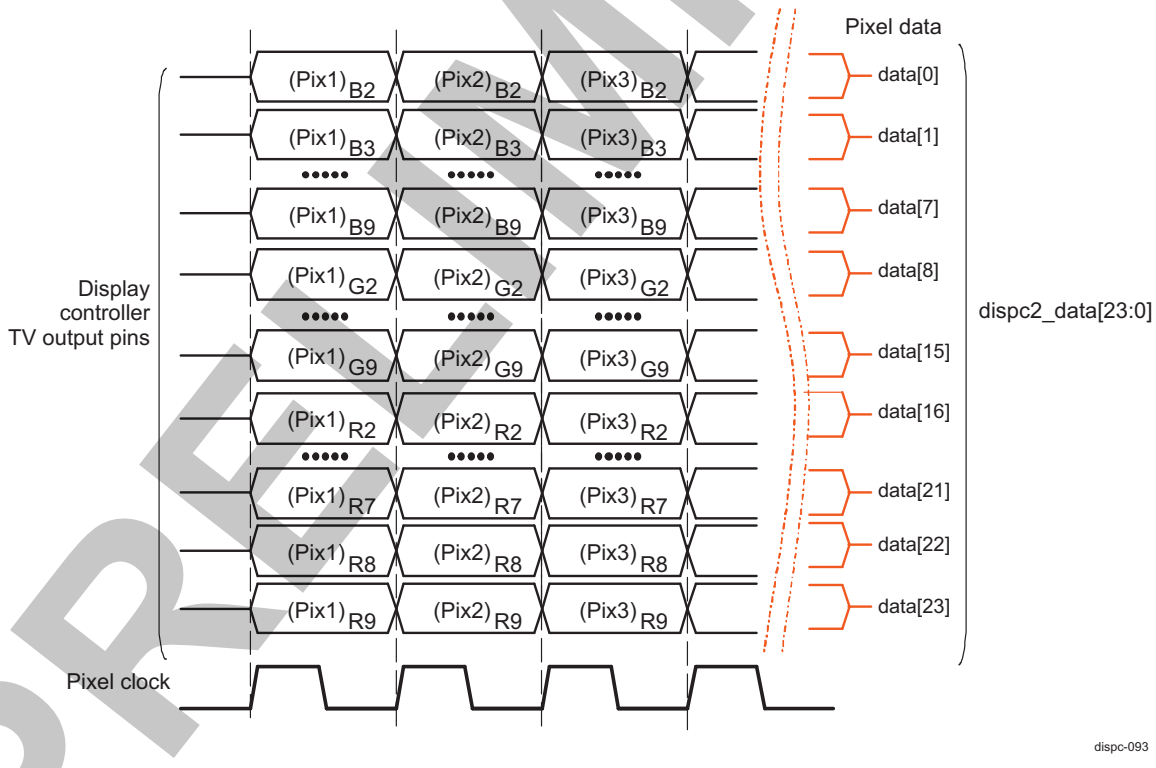
10.2.2.3 DISPC TV Output and Data Format for the Parallel Interface

This section describes the TV output pixel data bus for the parallel interface.

The TV pixel data interface is a 30-bit RGB interface. Only the MSB part of each color component is connected to the display subsystem boundary: R[9:2], G[9:2], B[9:2]. The output of the data is synchronized to the data request signal (HDMI_M_DE) from the HDMI encoder.

Figure 10-28 shows the format of the TV output pixel data.

Figure 10-28. DISPC TV Output Pixel Data



10.2.3 DISPC Integration

This section describes the DISPC integration in the device (see Figure 10-29). For complete details about clocks and resets, see Section 10.1, *Display Subsystem Overview*.

Figure 10-29. DISPC Integration

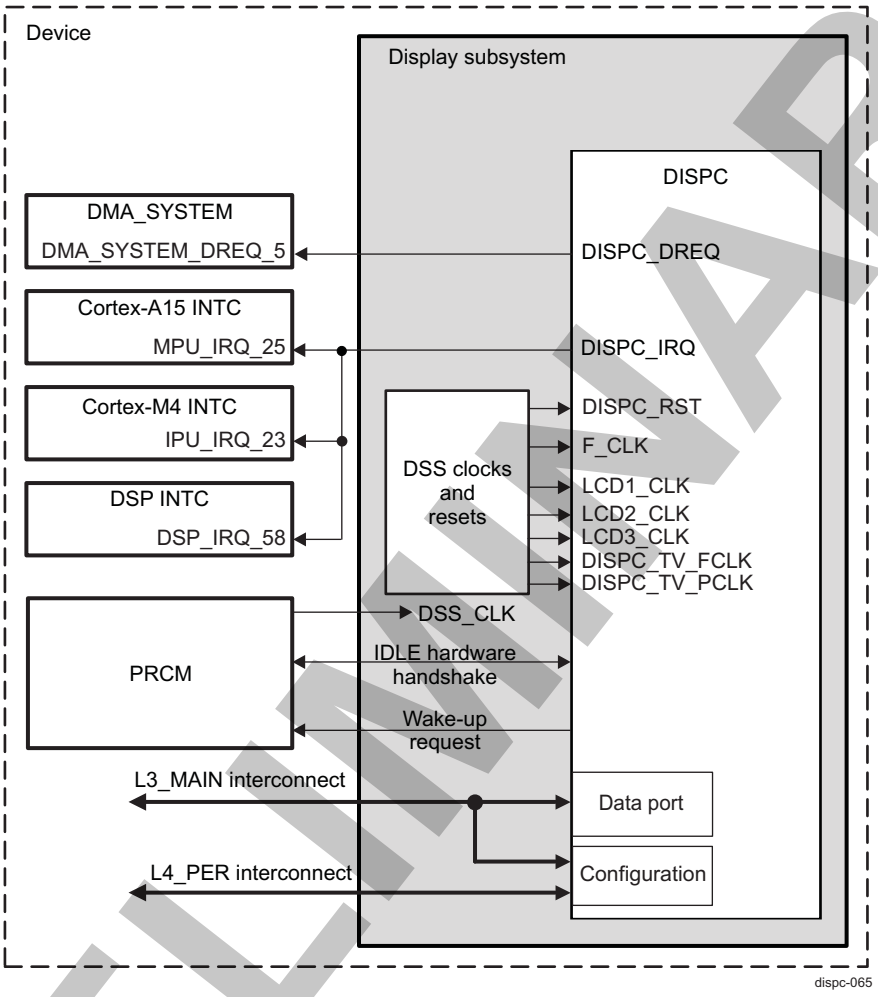


Table 10-21 and Table 10-22 list the integration attributes and clock and resets, respectively.

Table 10-23 summarizes the integration of the module in the device.

Table 10-21. DISPC Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
DISPC	PD_DSS	L3_MAIN for data transfer and configuration

Table 10-22. DISPC Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DISPC	F_CLK	DSS_CLK, DPLL_DSI1_A_CLK1, DPLL_DSI1_C_CLK1, DPLL_HDMI_CLK1	PRCM, PLLs	Functional clock for the DISPC logic. For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.
	LCD1_CLK	DSS_CLK, DPLL_DSI1_A_CLK1	PRCM, DPLL_DSI1_A	Clock used to generate the divided pixel clock for the primary LCD interface. For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.
	LCD2_CLK	DSS_CLK	PRCM	Clock used to generate the divided pixel clock for the secondary LCD interface. For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.
	LCD3_CLK	DSS_CLK, DPLL_DSI1_C_CLK1	PRCM, DPLL_DSI1_C	Clock used to generate the divided pixel clock for the third LCD interface. For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.
	DISPC_TV_FCLK	F_CLK, DPLL_HDMI_CLK1	DSS, DPLL_HDMI	TV functional clock (this is either the F_CLK or a clock driven from the DPLL_HDMI). For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.
	DISPC_TV_PCLK	DSS_HDMI_PCLK	HDMI	Pixel clock provided by the HDMI module. For the multiplexing description, see Section 10.1.2, *Display Subsystem Integration*.

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
DISPC	DISPC_RST	DSS_RST	PRCM	Hardware reset is coming from the PRCM module or through a software reset performed at the DSS level. For the tree reset description, see Section 10.1.2, *Display Subsystem Integration*. **NOTE:** The DSS_RST signal is provided to the entire display subystem. When inside the display subsystem boundaries, it is named DISPSS_RST, which on its end is provided to the DISPC and is named DISPC_RST.

Table 10-23. DISPC Hardware Requests

Interrupt Requests

DISPC	DISPC_IRQ	IPU_IRQ_23	Cortex-M4	Display controller interrupt. For information about Cortex-M4 interrupt control, see , *Dual Cortex-M4 IPU Subsystem Overview*.
	DISPC_IRQ	DSP_IRQ_58	DSP	Display controller interrupt. For information about DSP interrupt control, see , *DSP Subsystem Overview*.
	DISPC_IRQ	MPU_IRQ_25	Cortex-A15	Display controller interrupt. For information about Cortex-A15 interrupt control, see , *Dual Cortex-A15 MPU Subsystem Overview*.

DMA_SYSTEM Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**

Table 10-23. DISPC Hardware Requests (continued)

DISPC	DISPC_DREQ	DMA_SYSTEM_DREQ_5	DMA_SYSTEM	The line trigger signal informs the DMA_SYSTEM that a programmable number of lines is output to the LCD, and that the system memory can be updated. For more details, see Section 10.2.4.5, *DISPC DMA Requests*.

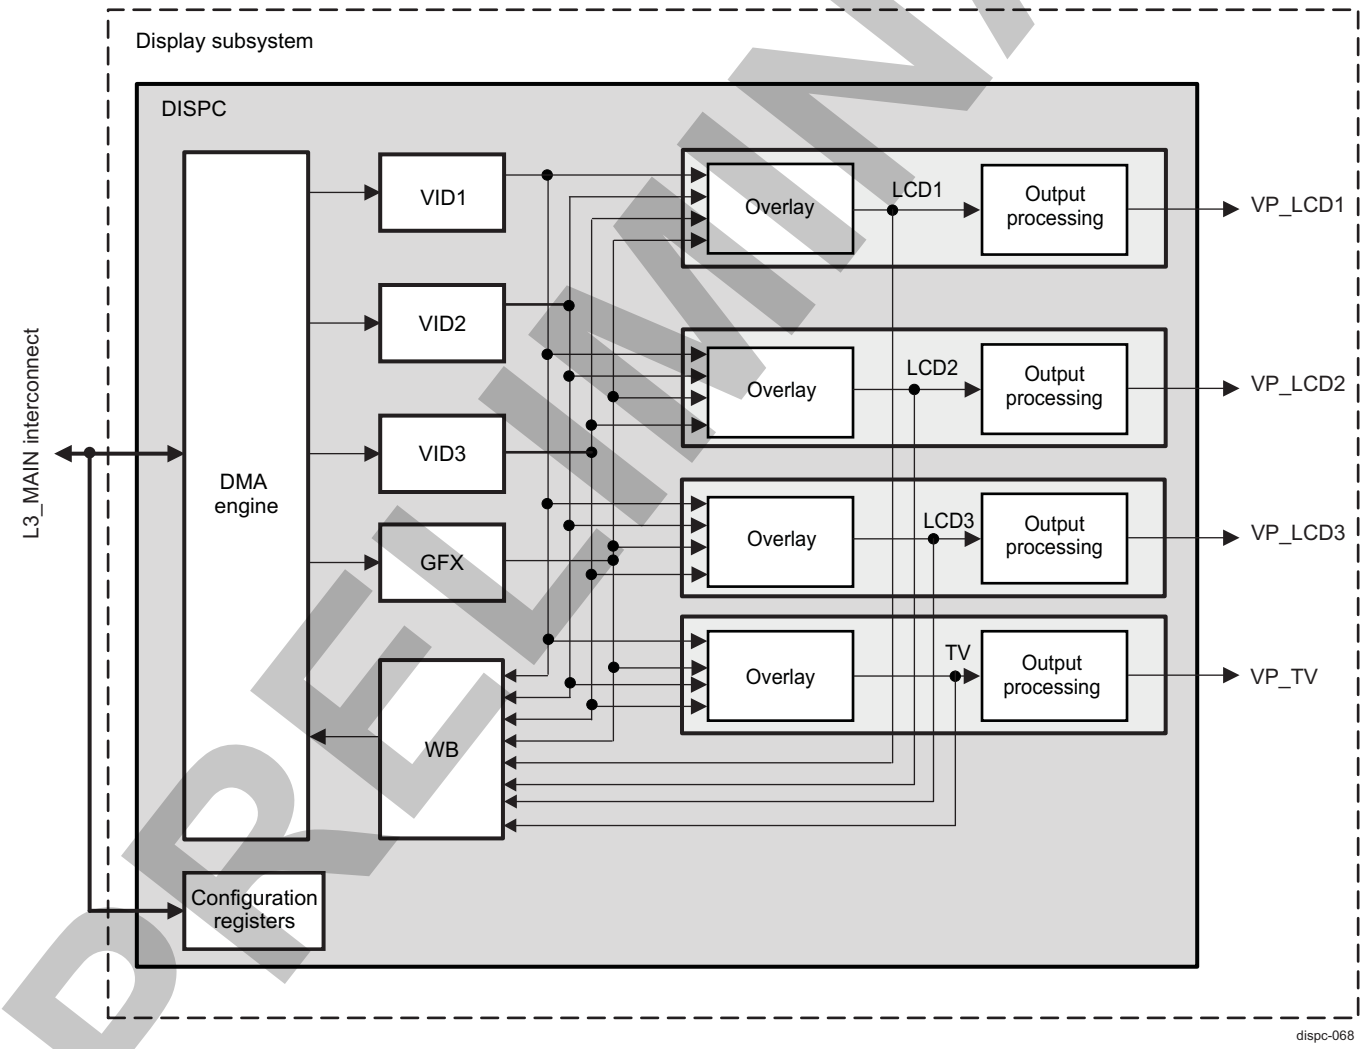
NOTE:

- For a description of interrupt sources, see Section 10.2.4.4, *DISPC Interrupt Requests*.
- For a description of DMA sources, see Section 10.2.4.5, *DISPC DMA Requests*.

10.2.4 DISPC Functional Description

The DISPC can read and display the encoded pixel data stored in memory (see Figure 10-30).

Figure 10-30. DISPC Architecture Overview



The DISPC can read and display the encoded pixel data stored in memory and write the output of one of the overlays or one of the pipelines into system memory.

Several processes can be configured to manage the graphics pipeline (palette, antiflicker) and video pipelines (VC-1, color space conversion, scaling, overlay, transparency, and so forth).

The data coming out of a pipeline is sent to one of the four outputs, depending on the user configuration. An overlay manager manages inputs of multiple pipelines. User timing configurations for LCD and TV are available.

The DISPC allows the capturing of one output of the pipeline or overlay manager to redirect it into the WB pipeline. It allows the use of the hardware processing available inside the DISPC, such as color space conversion, rescaling, and compositing, and so forth to perform memory-to-memory transfer with data processing.

10.2.4.1 DISPC Clock Configuration

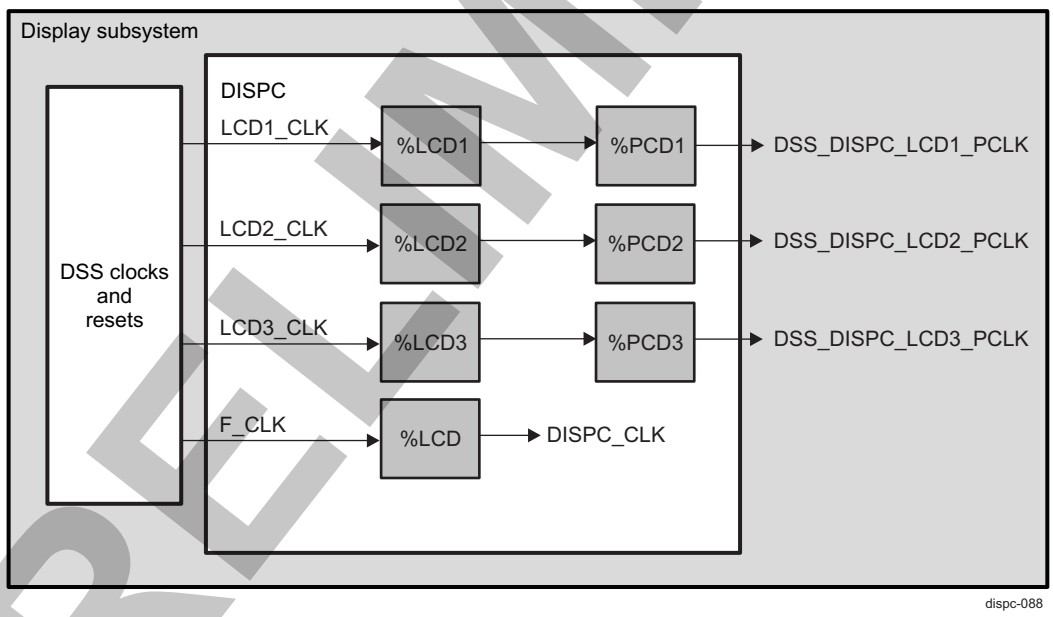
The PCLK frequency for each LCD output is derived from a dedicated input clock: LCD1_CLK, LCD2_CLK, or LCD3_CLK for the three LCD outputs, respectively. Each input clock is divided by the values of the DISPC_DIVISORo[23:16] LCD bit field and then the DISPC_DIVISORo[7:0] PCD bit field independently for each LCD pixel clock (see Figure 10-31). DSS_DISPC_LCD1_PCLK, DSS_DISPC_LCD2_PCLK, and DSS_DISPC_LCD3_PCLK are independent:

- DSS_DISPC_LCD1_PCLK = (LCD1_CLK/LCD1) / PCD1
- DSS_DISPC_LCD2_PCLK = (LCD2_CLK/LCD2) / PCD2
- DSS_DISPC_LCD3_PCLK = (LCD3_CLK/LCD3) / PCD3

The functional clock of the DISPC is derived from F_CLK by an independent divisor. The dividing value is set in the DISPC_DIVISORo[23:16] LCD bit field.

For backward compatibility, the divisor value LCD can be set to the value of LCD1. To enable this functionality, the DISPC_DIVISOR[0] ENABLE bit must be set to 1.

Figure 10-31. DISPC Clock Tree Overview



10.2.4.2 DISPC Software Reset

To perform a software reset on the DISPC, set the DISPC_SYSCONFIG[1] SOFTRESET bit to 0x1. The DISPC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 0x1. When the software reset completes, the DISPC_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing DISPC operations.

10.2.4.3 DISPC Power Management

The DISPC supports the MStandby/Wait, IdleReq/SidleAck, and wake-up protocols as defined in Chapter 3, *Power, Reset, and Clock Management*.

10.2.4.3.1 DISPC Idle Mode

The DISPC supports no-idle mode, force-idle mode, and smart-idle mode. The mode can be selected by programming the appropriate value in the DISPC_SYSCONFIG[4:3] SIDLEMODE bit field.

Condition of assertion of the SIdleAck signal:

- In no-idle mode: SIdleAck is never asserted.
- In force-idle mode: SIdleAck is asserted unconditionally with a 1-configuration port interface clock cycle delay with respect to an IdleReq assertion.

NOTE: The proper use of force-idle mode assumes that no interrupt needs to be generated.

- In smart-idle mode: SIdleAck is asserted when at least the following conditions are satisfied:
  - No interrupt is pending.
  - The DISPC no longer uses the interface clock for the slave port.

Once SIdleAck is asserted, the DISPC interface lock used by the slave port can be shut down at any time.

The conditions of deassertion of the SIdleAck signal are:

- In force-idle mode: SIdleAck is deasserted with a 1-configuration port interface clock cycle delay with respect to an IdleReq deassertion.
- In smart-idle mode: SIdleAck is deasserted with a 1-configuration port interface clock cycle delay with respect to an IdleReq deassertion.

Once SIdleAck is released, the DISPC is fully operational and a DMA request can be processed normally.

10.2.4.3.2 DISPC StandBy Mode

The DISPC supports no-standby mode, force-standby mode, and a single smart-standby mode. The mode is set in the DISPC_SYSCONFIG[13:12] MIDLEMODE bit field. The functional clock is always active if the module is enabled. The L3_MAIN clock can be shut down at any time independently of the status of MStandby.

The conditions of assertion of the MStandby signal are:

- In no-standby mode: MStandby is never asserted.
- In force-standby mode: MStandby is asserted when the module is disabled.
- In smart-standby: In the case of one of the following conditions:
  - The GFX pipeline is disabled or enabled and the data fetch is complete for the GFX window, or the GFX pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID1 pipeline is disabled or enabled and the data fetch is complete for the VID1 window, or the VID1 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID2 pipeline is disabled or enabled and the data fetch is complete for the VID2 window, or the VID2 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The VID3 pipeline is disabled or enabled and the data fetch is complete for the VID3 window, or the VID3 pipeline is enabled but the data fetch did not complete and data in the DMA buffer is greater than the high threshold value.
  - The WB pipeline is disabled or enabled and the data store to memory is complete for the WB picture, or the WB pipeline is enabled but the data storage did not complete and data in the DMA buffer is lower than the low threshold value.

The MStandby signal asserts whenever all five events have occurred or the DISPC is disabled. While MStandby is asserted, the DISPC does not generate any transaction on the L3_MAIN master port.

The conditions of deassertion of the MStandby signal are:

- In force-standby mode: MStandby is deasserted only when the DISPC is enabled.

- In smart-standby mode: In the case of one of the following conditions:
  - The GFX pipeline is enabled but the data fetch did not complete for the GFX window, and the data in the DMA buffer is less than the low threshold value.
  - The VID1 pipeline is enabled but the data fetch did not complete for the VID1 window, and the data in the DMA buffer is less than the low threshold value.
  - The VID2 pipeline is enabled but the data fetch did not complete for the VID2 window, and the data in the DMA buffer is less than the low threshold value.
  - The VID3 pipeline is enabled but the data fetch did not complete for the VID3 window, and the data in the DMA buffer is less than the low threshold value.
  - The WB pipeline is enabled but the data store did not complete for the WB picture, and the data in the DMA buffer more than the high threshold value.

Detection of the deassertion conditions assumes that the interface clocks are active.

10.2.4.3.3 DISPC Wakeup

The DISPC supports wake-up signaling. The mode can be selected by programming the appropriate value in the DISPC_SYSCONFIG[2] ENAWAKEUP bit. Because the SWakeUp signal is asynchronous, it does not require the interface clock.

The conditions of assertion of the SWakeUp signal are:

- The GFX pipeline is enabled but the data fetch did not complete for the GFX window, and the data in the DMA buffer is less than the low threshold value.
- The VID1 pipeline is enabled but the data fetch did not complete for the VID1 window, and the data in the DMA buffer is less than the low threshold value.
- The VID2 pipeline is enabled but the data fetch did not complete for the VID2 window, and the data in the DMA buffer is less than the low threshold value.
- The VID3 pipeline is enabled but the data fetch did not complete for the VID3 window, and the data in the DMA buffer is less than the low threshold value.
- The WB pipeline is enabled and the data in the DMA buffer is more than the high threshold value.
- The last pixel displayed into the LCD1 panel if it is not the last frame
- The last pixel displayed into the LCD2 panel if it is not the last frame
- The last pixel displayed into the LCD3 panel if it is not the last frame
- The last pixel displayed into the TV panel if it is not the last frame

The SWakeUp signal is asserted whenever any one of these nine events occurs and IdleAck is asserted.

When one of the active pipelines reaches the low threshold and must refill its DMA buffer for the current frame, all other pipelines refill their own DMA buffer even if their low threshold has not been reached. The DISPC_CONFIG1[17] BUFFERFILLING bit is used to increase the probability that the time increases, where there is no access to the L3_MAIN interconnect.

The condition of deassertion of the SWakeUp signal is:

- Immediately after deassertion of IdleReq

10.2.4.4 DISPC Interrupt Requests

The interrupt line, DISPC_DREQ, indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DISPC_IRQENABLE register.

To check when a particular interrupt event occurs and to reset a particular event, the DISPC_IRQSTATUS register must be accessed. This register regroups the status of internal events in the module that generate an interrupt (read 0: no interrupt occurred; read 1: interrupt occurred; write 1: status bit reset). For more information about checking and clearing interrupt events, see Section 10.1.3, *Display Subsystem Register Manual*.

Table 10-24 describes the interrupts generated for the DISPC.

Table 10-24. DISPC Interrupts

Interrupt Name	Description
FLIPIMMEDIATEDONE_IRQ	Flip immediate done: Occurs when the DMA engine has acknowledged the immediate BA change, and software can write the new BA0.
FRAMEDONE1_IRQ	Frame done for LCD1 output: Active frame related to the LCD1 is complete and LCD1 output of the DISPC is disabled.
FRAMEDONE2_IRQ	Framedone for LCD2 output: Active frame related to the LCD2 is complete and LCD2 output of the DISPC is disabled.
FRAMEDONE3_IRQ	Frame done for LCD3 output: Active frame related to the LCD3 is complete and LCD3 output of the DISPC is disabled.
FRAMEDONETV_IRQ	Frame done for TV output: Active frame related to the TV output is complete and TV output of the DISPC is disabled.
FRAMEDONEWB_IRQ	Frame done for WB output: Active frame related to the WB is complete. First, it is used when the WB channel is connected to one of the pipelines to determine when the memory-to-memory transfer through DISPC is completed. Second, it is used when the WB channel is connected to one of the overlay output in nonreal-time mode to determine when the memory-to-memory transfer with overlay processing is completed.
VSYNC1_IRQ	VSYNC for primary LCD output: VSYNC interrupt for the primary LCD has occurred at the end of the frame.
VSYNC2_IRQ	VSYNC for secondary LCD output: VSYNC interrupt for the secondary LCD has occurred at the end of the frame.
VSYNC3_IRQ	VSYNC for third LCD output: VSYNC interrupt for the third LCD has occurred at the end of the frame.
EVSYNC_EVEN_IRQ	VSYNC for even field: EVSYNC_EVEN interrupt has occurred at the end of the frame (EVSYNC received and the field polarity is even) (HDMI)
EVSYNC_ODD_IRQ	VSYNC for odd field: EVSYNC_ODD interrupt has occurred at the end of the frame (EVSYNC received and the field polarity is odd) (HDMI)
ACBIASCOUNTSTATUS1_IRQ	AC bias count status for LCD1 output: AC bias transition counter has decremented to 0.
ACBIASCOUNTSTATUS2_IRQ	AC bias count status for LCD2 output: AC bias transition counter has decremented to 0.
ACBIASCOUNTSTATUS3_IRQ	AC bias count status for LCD3 output: AC bias transition counter has decremented to 0.
PROGRAMMEDLINENUMBER_IRQ	Programmed line number: The primary LCD has reached the user programmed line number.
VID1ENDWINDOW_IRQ	End of the VID1 window: The DMA engine has fetched all the data from memory for the VID1 for the current frame.
VID2ENDWINDOW_IRQ	End of the VID2 window: The DMA engine has fetched all the data from memory for the VID2 for the current frame.
VID3ENDWINDOW_IRQ	End of the VID3 window: The DMA engine has fetched all the data from memory for the VID3 for the current frame.
GFXENDWINDOW_IRQ	End of the graphics window: The DMA engine has fetched all the data from memory for the graphics for the current frame.
VID1BUFFERUNDERFLOW_IRQ	VID1 DMA buffer underflow: The input VID1 DMA buffer goes underflow.
VID2BUFFERUNDERFLOW_IRQ	VID2 DMA buffer underflow: The input VID2 DMA buffer goes underflow.
VID3BUFFERUNDERFLOW_IRQ	VID3 DMA buffer underflow: The input VID3 DMA buffer goes underflow.
WBBUFFEROVERFLOW_IRQ	WB DMA buffer overflow: The output WB DMA buffer goes overflow. It cannot occur when WB channel is used in memory-to-memory transfer mode but only in capture mode. In capture mode the timings are defined by the timer associated with the output. In memory-to-memory mode, there is timing constraint.
GFXBUFFERUNDERFLOW_IRQ	GFX DMA buffer underflow: The input graphics DMA buffer goes underflow.

Table 10-24. DISPC Interrupts (continued)

Interrupt Name	Description
PALETTEGAMMALOADING_IRQ	Palette/gamma table loading: The palette/gamma table in the graphics pipeline has been loaded using the DISPC DMA engine.
WBUNCOMPLETEERROR_IRQ	The write-back buffer has been flushed before being fully drained. In WB capture mode, if the new frame starts before the WB DMA buffers are fully drained (onto external memory), then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). This interrupt is an indication of that, and will trigger every frame.
OCPERROR_IRQ	OCP error: L3_MAIN interconnect has sent SResp = ERR
SYNCLOST1_IRQ	Synchronization lost on LCD1 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOST2_IRQ	Synchronization lost on LCD2 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOST3_IRQ	Synchronization lost on LCD3 output: Occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTTV_IRQ	Synchronization lost on TV output: Occurs when porches are not wide enough to load the pipelines with data (TV output connected to the HDMI).
WAKEUP_IRQ	Wakeup: Occurs when the SWakeUp signal is asserted.

10.2.4.5 DISPC DMA Requests

The DMA_SYSTEM synchronization line, DISPC_DREQ, is connected to the DMA_SYSTEM (DMA_SYSTEM_DREQ_5). This DMA request is not a classical one, but rather a synchronization signal between the DISPC and DMA_SYSTEM. The DMA_SYSTEM is informed that a programmable number of lines are output to the LCD and that a system memory can be updated. This request is related to the interrupt event PROGRAMMEDLINENUMBER_IRQ described in Table 10-24. This allows the DMA_SYSTEM channel to be synchronized with the internal DMA controller in the display subsystem.

In other words, it allows synchronizing a memory-to-memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the DISPC. The DISPC_DREQ request is generated at a programmable line number defined in the DISPC_LINE_NUMBER[11:0] LINENUMBER bit field. This process allows an application to use a single frame buffer and to update it after a certain number of lines are read by the DISPC.

10.2.4.6 DISPC DMA Engine

The DMA engine:

- Supplies data (encoded pixel data, palette, and gamma curve) from memories to the GFX, VID1, VID2, and VID3 pipelines through the interconnect based on the configuration of the DISPC and pipeline setting.
- Stores encoded pixel data from GFX/VID pipelines or overlays to memories through the WB pipeline and interconnect based on the configuration of the DISPC and WB pipeline setting.

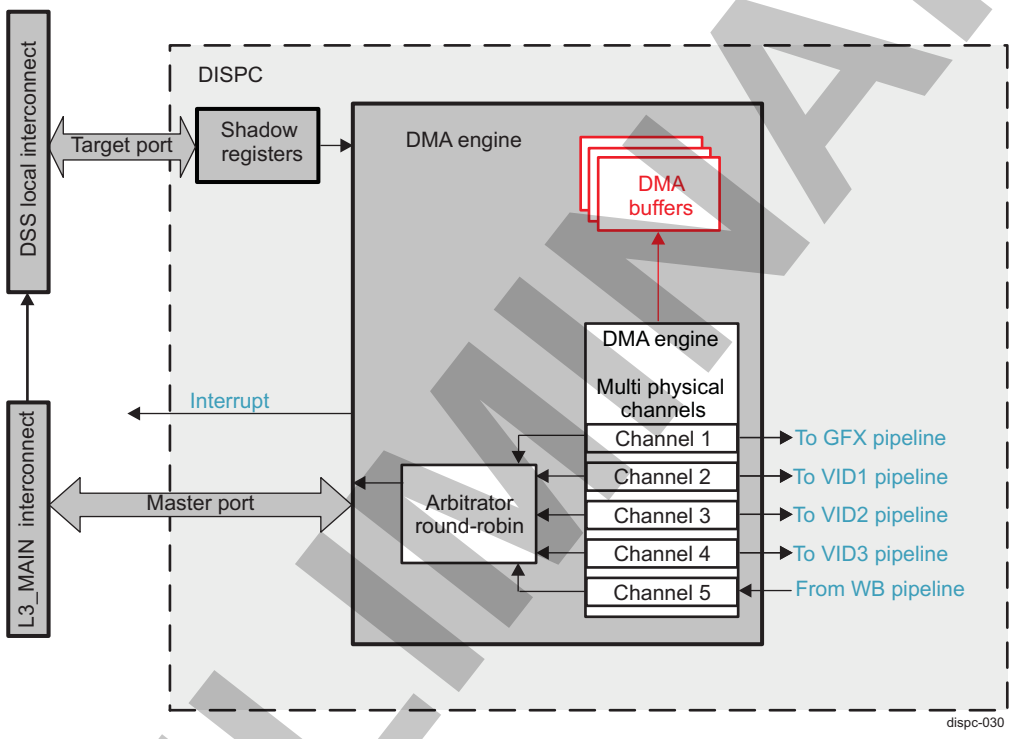
Each pipeline has a dedicated buffer and a channel with independent settings. Table 10-25 lists the default size and allocation of the DMA buffer. Each DMA buffer is divided into two spaces, top and bottom. Depending on the application, a DMA buffer space can be associated to a pipeline or merged with other spaces. The total number of spaces for each pipeline is from 0 (pipeline inactive) to the number of pipelines × 2 (in that case, all the DMA buffers are associated to a single pipeline). The sum of the number of spaces allocated for each pipeline must not be greater than the maximum number of available spaces. The correct number of spaces must be allocated to ensure no underflow. The spaces allocated to each pipeline must be greater than or equal to the minimum number of spaces required to support the throughput and system latency. The space assignations are done in the DISPC_GLOBAL_BUFFER register.

Table 10-25. DISPC DMA Buffer Size

Pipelines	DMA Buffer Size
GFX	2 lines × 640 × 128 bits
VID1	2 lines × 1024 × 128 bits
VID2	2 lines × 1024 × 128 bits
VID3	2 lines × 1024 × 128 bits
WB	2 lines × 1024 × 128 bits

Figure 10-32 is an overview of the DMA engine.

Figure 10-32. DISPC DMA Engine Overview



10.2.4.6.1 DISPC

For each line to be fetched/stored, the DMA engine:

- Calculates the pixel address
- Aligns the address
- Defines the burst structure:
  - Type of burst (1D- or 2D-burst structure)
  - Length of the burst

The DMA engine generates scan addresses to read and write data to and from system memory. The base address defines the start address of the first pixel, and then the address is incremented based on the number of pixels per line, offset between two consecutive lines and number of lines. The byte address of each pixel in the frame buffer in the system memory is determined by:

Pixel address = Base address + x × bpp + (y × ((width × bpp) + increment))

where:

- Base address corresponds to the base address (for YUV–NV12 or YUV4:2:0-NV21 format) defined by:
  - DISPC_GFX_BA_0[31:0] BA bit field
  - DISPC_GFX_BA_1[31:0] BA bit field

  - DISPC_VIDp_BA_0[31:0] BA bit field
  - DISPC_VIDp_BA_1[31:0] BA bit field
  - DISPC_VIDp_BA_UV_0[31:0] BA bit field
  - DISPC_VIDp_BA_UV_1[31:0] BA bit field
- bpp corresponds to the number of bits per pixel defined by the DISPC_GFX_ATTRIBUTES[4:1] FORMAT bit field or the DISPC_VIDp_ATTRIBUTES[4:1] FORMAT bit field.
- width corresponds to the number of pixels per line defined by the DISPC_GFX_SIZE[11:0] SIZEX + 1 bit field or DISPC_VIDp_SIZE[11:0] SIZEX + 1 bit field.
- increment corresponds to the number of bytes to skip between two contiguous lines defined by the DISPC_GFX_ROW_INC[31:0] ROWINC – 1 bit field or the DISPC_VIDp_ROW_INC[31:0] ROWINC – 1 bit field.
- x corresponds to the pixel position on the x-axis.
- y corresponds to the pixel position on the y-axis.

NOTE: For YUV format, the pixel values are defined in two buffers (Y and UV). The base address of the Y buffers is defined in the DISPC_VIDp_BA_j[31:0] BA bit field. The base address of the UV buffers is defined in the DISPC_VIDp_BA_UV_j[31:0] BA bit field.

Table 10-26 summarizes the register settings for a simple access of a picture in the system memory.

Table 10-26. DISPC Register Settings for Accessing Image in Internal Memory

Registers	Value
DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA, the physical base address of image in the memory
DISPC_VIDp_BA_UV_j/DISPC_WB_BA_UV_j	PBA, the physical base address of UV buffers image in the memory
DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 or other in pixel incremental value
DISPC_GFX_ROW_INC/DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	1 or other in row incremental value

An interconnect request (128 bits) corresponds to one or several pixels, depending on the bits per pixel. Therefore, the DMA engine determines the appropriate burst sequence to optimize the fetching/storing of each new line. The DMA engine must prevent a single burst from crossing two lines. The DMA engine supports bursts of 2 × 128 bits, 4 × 128 bits, and 8 × 128 bits. The default burst size at reset time is 8 × 128 bits. The maximum burst size can be configured for each pipeline by setting the DISPC_GFX_ATTRIBUTES[7:6] BURSTSIZE or DISPC_VIDp_ATTRIBUTES[15:14] BURSTSIZE bit field. Because the burst size must be aligned to the burst boundary, in case of misalignment, the DMA engine may issue one request and/or smaller burst requests. Two types of burst are present which can be configured from the DISPC_GFX_ATTRIBUTES[29] BURSTTYPE or DISPC_VIDp_ATTRIBUTES[29] BURSTTYPE bit. Also, a force function is present configured from the DISPC_GFX_ATTRIBUTES[16] FORCE1DTILEDMODE or DISPC_VIDp_ATTRIBUTES[20] FORCE1DTILEDMODE or DISPC_WB_ATTRIBUTES[20] FORCE1DTILEDMODE bit for the following burst types:

- 1-D burst is used if the fetch/storage is linear in memory through the TILER. There is no rotation of the frame buffer. The frame buffer is not tiled.
- 2-D burst is used if the frame buffer is tiled.

Even if the DISPC_VIDp_ROW_INC register does not equal 1, the user can select 2-D burst. 2-D burst is used when the DISPC is configured to read one field of a frame by accessing only the even and odd lines.

NOTE: The burst size is initialized once at configuration and can be changed when the DISPC is disabled.

10.2.4.6.2 DISPC Immediate Base Address Flip Mechanism

The Flip Immediate mechanism is used to change of the fly the content of the frame buffer which is currently being displayed. The mechanism allows multiple changes (flips) of the base address (BA) during a frame. The mechanism is available for all pipelines (VID1, VID2, VID3, and GFX). Changes to the BA can be applied during the same line, or during different lines.

The following considerations must be considered:

- Data fetching from a new immediate BA is aligned with the data fetch mechanism of the DISPC DMA engine itself, and not with HSYNC or any other DISPC timing signal. After new VSYNC frame pulse, new BA is taken by hardware, as soon as the first set of lines is sent to internal pipeline of the DMA engine.
  - If multiple new BAs are written during the same line (before DMA engine acknowledges the first BA change), then programming steps 1 and 2 must be applied for each new BA (see the programming sequence in this section). The DMA takes only the last BA provided within the current line scan.
  - If multiple new BAs are written during different lines within the current frame, then programming steps 1 and 2 must be applied for each new BA (see the programming sequence in this section). The DMA takes the new BA each time it is updated.
- Immediate BA change cannot be achieved synchronously for two or more pipelines.
- Immediate BA change is possible only for BA0; it is not possible for BA1. Interlaced mode using BA0 and BA1 is not supported.
- Immediate BA change is supported only in RGB color space.

The Flip Immediate mechanism programming sequence follows:

1. Software writes the new immediate BA to the DISPC_GFX_BA_j register (where j=0) for the GFX pipeline, or to the DISPC_VID1_BA_j / DISPC_VID2_BA_j / DISPC_VID3_BA_j register (where j=0) for the required VID pipeline.
2. Software sets to 0x1 the corresponding EN bit for the required pipeline in the DISPC_BA0_FLIPIMMEDIATE_EN register.
3. The DISPC DMA engine, after completing its current line (or set of lines) fetch, takes the new immediate BA.
4. Hardware resets the EN bit in DISPC_BA0_FLIPIMMEDIATE_EN register and asserts a flip immediate IRQ. The IRQ can be enabled through the DISPC_IRQENABLE[31] FLIPIMMEDIATEDONE_EN bit. The status of the event is available in the DISPC_IRQSTATUS[31] FLIPIMMEDIATEDONE_IRQ bit.

10.2.4.6.3 DISPC DMA Buffers

10.2.4.6.3.1 DISPC READ DMA Buffers (GFX and VID Pipelines)

When the vertical front porch (VFP) period starts after the last horizontal front porch (HFP) of the last line or the external VSYNC is received, the DMA buffers are flushed according to the selected output associated with the pipeline. The DMA engine restarts fetching data from the memory through the L3_MAIN interconnect. Enabling or disabling the DISPC flushes the DMA buffers (except the WB DMA buffers).

Programmable high and low thresholds, independent for each DMA buffer, are used by the DMA engine to start and stop requesting data to the L3_MAIN interconnect.

- When low threshold (set in the DISPC_GFX_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD or DISPC_VIDp_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field) is reached, the DMA engine starts a request on the L3_MAIN interconnect to fill the DMA buffer.
- When high threshold (set in the DISPC_GFX_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD or DISPC_VIDp_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, the DMA engine stops requesting encoded pixels.

To avoid underflow at the beginning of a frame and have sufficient encoded pixel data to start some processing, a preloading of the DMA buffer is configurable between a fixed value of bytes or the high threshold value. The preload ensures a minimum number of pixels present in the buffer. When the preload value is reached, the associated channel must start pulling pixels out of the DMA buffer. To enable the preload based on the value entered in the DISPC_GFX_PRELOAD[11:0] PRELOAD or DISPC_VIDp_PRELOAD[11:0] PRELOAD bit field, the DISPC_GFX_BUF_THRESHOLD[11] BUFPRELOAD bit, or the DISPC_VIDp_BUF_THRESHOLD[19] BUFPRELOAD bit must be set to 0x0.

NOTE: When self-refresh mode is selected, meaning the data in the DMA buffers are used for multiple frames, and at the end of each frame, the DMA buffers are not flushed.

10.2.4.6.3.2 DISPC WRITE DMA Buffer (WB Pipeline)

Two modes are supported by the WB channel, selectable through the DISPC_WB_ATTRIBUTES[19] WRITEBACKMODE bit:

- Capture mode, WRITEBACKMODE bit set to 0: One of the overlay outputs going to LCD or TV outputs is captured and at the same time the data are sent on the output. The WB timings are controlled by the LCD or TV timings.
- Memory-to-memory mode, WRITEBACKMODE bit set to 1: One of the overlay outputs or one of the pipelines is captured to perform a memory-to-memory transfer, with some processing by the DISPC (rescaling, overlaying, color space conversion, etc.).

In capture mode: The WB DMA buffers are flushed when the VFP period starts after the HFP following the last line, or when the external VSYNC is received, depending on which output (LCD/TV) the WB pipeline is capturing data, if the programmed value in DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to 0. If the programmed value in DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to N (1:255), the write buffers DMA are flushed N lines later. The DMA engine starts storing data to memory through the L3_MAIN-based interconnect as soon as enough data is available for the programmed burst size. When enabling/disabling the DISPC, the DMA buffers are flushed. The programmable thresholds low and high are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

NOTE: If the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field is set to 0, the WB is reinitialized at the end of the last line of a frame at the beginning of the VFP signal. To let the WB complete the data write to the external memory, the highest possible value compatible with the vertical blanking period must be set.

NOTE: In WB capture mode, if a new frame starts before the WB DMA buffers contents are fully written onto external memory, then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). The DISPC_IRQSTATUS[26] WBUNCOMPLETEERROR_IRQ interrupt bit indicates this situation and triggers every frame. The WBUNCOMPLETEERROR interrupt can be enabled through the DISPC_IRQENABLE[26] WBUNCOMPLETEERROR_EN register bit.

Software can avoid this by delaying the flush of WB DMA buffers through proper programming of the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field.

In memory-to-memory mode: The WB pipeline is not synchronized to any internal or external timing generator. The WB pipeline stores the output of one of the overlay outputs or one of the pipelines. When enabling or disabling the DISPC, the DMA buffers are flushed. The programmable thresholds low and high are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

Programmable high and low thresholds are used by the DMA engine to start and stop sending data to the L3_MAIN interconnect.

- When high threshold (set in the DISPC_WB_BUF_THRESHOLD[31:16] BUFHIGHTHRESHOLD bit field) is reached, the DMA engine starts sending data on the L3_MAIN interconnect to empty buffer.
- When low threshold (set in the DISPC_WB_BUF_THRESHOLD[15:0] BUFLOWTHRESHOLD bit field)

is reached, the DMA engine stops sending encoded pixels.

At the end of the frame, to completely drain the DMA buffer, some smaller bursts (even single requests) must be issued. To limit the number of interconnect requests from the DISPC, a number of IDLE cycles between requests can be inserted. IDLE cycles can be inserted only when WB is used in memory-to-memory mode. It is ignored when WB is in capture mode.

The number of IDLE cycles between requests can be activated and determined by:

- Setting the DISPC_WB_ATTRIBUTES[27] IDLESIZE bit to 0x0 (default value) and entering the number of idles between requests in the DISPC_WB_ATTRIBUTES[31:28] IDLENUMBER bit field. Idle numbers vary from 0 to 15.
- Setting the DISPC_WB_ATTRIBUTES[27] IDLESIZE bit to 0x1, which considers the size of the burst (the DISPC_WB_ATTRIBUTES[15:14] BURSTSIZE bit field) to determine the number of IDLE cycles.
  - If BURSTSIZE = 0x0, then the number of IDLE cycles equals IDLENUMBER (0 to 15).
  - If BURSTSIZE = 0x1, then the number of IDLE cycles equals IDLENUMBER × 4 (0 to 60).
  - If BURSTSIZE = 0x2, then the number of IDLE cycles equals IDLENUMBER × 8 (0 to 120).

10.2.4.6.4 DISPC MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of DISPC real-time traffic, when required, based on the fullness of the DISPC DMA read and write buffers.

The mechanism is implemented for all DMA buffers (GFX, VID1, VID2, VID3 and WB). Only high-priority pipelines can contribute to the MFLAG mechanism.

Programmable buffer thresholds (hysteresis) for each pipeline are used to indicate when the local MFLAG signal for each pipeline is generated. All local MFLAG signals are ORed to generate a single DSS MFLAG out band signal, which is provided to the L3 interconnect for granting OCP requests. The out band DSS MFLAG signal is asynchronous to any ongoing OCP transaction.

The threshold for each pipeline corresponds to the fullness of the associated DMA buffer, and is defined by two threshold parameters:

- HT_MFLAG: High threshold.
  - For read access from the GFX, VID1, VID2, and VID3 pipelines, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - For write access from the WB pipeline, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - This threshold can be programmed in the following bit fields:
    - For the GFX pipeline in the DISPC_GFX_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID1 pipeline in the DISPC_VID1_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID2 pipeline in the DISPC_VID2_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the VID3 pipeline in the DISPC_VID3_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
    - For the WB pipeline in the DISPC_WB_MFLAG_THRESHOLD[31:16] HT_MFLAG bit field
- LT_MFLAG: Low threshold.
  - For read access from the GFX, VID1, VID2, and VID3 pipelines, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted).
  - For write access from the WB pipeline, when the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted).
  - This threshold can be programmed in the following bit fields:
    - For the GFX pipeline in the DISPC_GFX_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID1 pipeline in the DISPC_VID1_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID2 pipeline in the DISPC_VID2_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the VID3 pipeline in the DISPC_WB_MFLAG_THRESHOLD[15:0] LT_MFLAG bit field
    - For the WB pipeline in the DISPC_WB_MFLAG_THRESHOLD [15:0] LT_MFLAG bit field

By default, the MFLAG mechanism is disabled (DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field = 0x0), and the DSS MFLAG out band signal is low (deasserted). The arbitration scheme for the DISPC pipelines is the same as described in Section 10.2.4.6.7, *DISPC Arbitration*. That is, round-robin either between high-priority pipelines, or between normal-priority pipelines (if all pipelines are of normal priority).

When the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field is set to 0x2, the MFLAG mechanism is enabled, and the DSS MFLAG out band signal is dynamically set to 0 or 1, depending on DMA buffers fullness and programmed threshold levels, as explained previously in this section. In this case, the arbitration scheme for DISPC pipelines is round-robin between those high-priority pipelines, which have asserted local MFLAG signals. If there are no high-priority pipelines with asserted local MFLAG signals, then the arbitration scheme is the same as described in Section 10.2.4.6.7, *DISPC Arbitration*.

The DISPC_GLOBAL_MFLAG_ATTRIBUTE[2] MFLAG_START bit defines additional rules for the MFLAG mechanism:

- If the MFLAG_START bit is set to 0x0 (default value), then in the beginning of the frame when the DMA buffer is empty, the local MFLAG signal of each pipeline is kept at 0 until PRELOAD is reached (for more information on preloading, see Section 10.2.4.6.3.1, *DISPC READ DMA Buffers (GFX and VID Pipelines)*. Then, based on the setting of the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field, the MFLAG signal is generated and internal logic is arbitrating between pipeline requests.
- If the MFLAG_START bit is set to 0x1, then even in the beginning of the frame when the DMA buffer is empty, the DISPC_GLOBAL_MFLAG_ATTRIBUTE[1:0] MFLAG_CTRL bit field defines the generation of the MFLAG signal for each pipeline.

10.2.4.6.5 DISPC Predecimation

The predecimation process consists of downscaling an image by fetching only the necessary pixels in the memory. Vertical and horizontal predecimation are possible:

- Vertical predecimation: The picture stored in memory can be predecimated vertically by skipping lines. Burst mode is used to fetch the data when skipping lines. Only the lines that will be used by the DISPC are fetched from memory; the other lines are skipped. The DMA engine sends requests only for the useful lines using 1-D or 2-D burst, depending on the setting. The base address indicates the first valid pixel to fetch from memory. The number of lines to skip is set in the DISPC_GFX_ROW_INC[31:0] ROWINC or DISPC_VIDp_ROW_INC[31:0] ROWINC bit field.

  NOTE: When 2-D burst mode is used, the access to data in memory is performed through the TILER module of DMM (for more details, see , *TILER Overview*, in Chapter 15, *Memory Subsystem*), and as a result a maximum of one line can be skipped.

- Horizontal predecimation: When fetching data from memory, it is possible to skip 1 of 2 pixel data containers, up to 1 of 16 pixel data containers, by setting the DISPC_GFX_PIXEL_INC[7:0] PIXELINC or DISPC_VIDp_PIXEL_INC[7:0] PIXELINC bit field to the number of pixel data containers to skip (n), multiplied by the size of a pixel data container (in bytes), + 1. See the following note for more details.

NOTE: The restriction to horizontal predecimation is that there is at least one useful pixel per 128-bit request. In that case, the DMA engine uses burst mode instead of singles to optimize the requests in terms of latency and SDRAM efficiency.

No decimation is supported when the input format is 1, 2, 4, or 8 BITMAP.

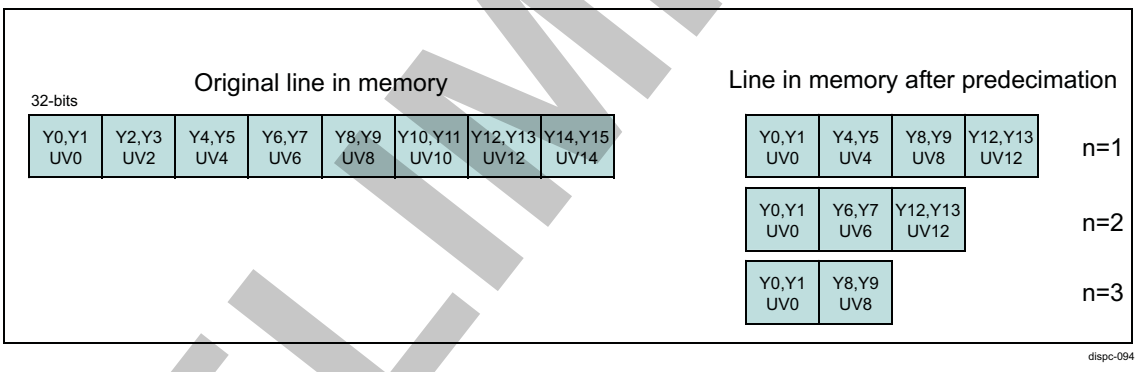
For RGB and YUV4:2:0 data formats, each pixel data container in memory holds 1 pixel. Thus, when configuring the PIXELINC bit field, the value of n equals the number of pixels to skip:

- For RGB format, one pixel data container = 32 bits = 1 pixel
- For YUV format:
  - One Y pixel data container = 8 bits = 1 pixel
  - One UV pixel data container = 16 bits = 1 pixel

For YUV4:2:2 format, each 32-bit pixel data container holds the Luma components for 2 pixels, and the Chrominance component of 1 pixel (see Figure 10-33). Therefore, for the valid values of the PIXELINC bit field in the case of the following YUV4:2:2 format, caution must be taken because n equals the number of pixel data containers to skip, not the number of pixels:

- For n = 1, PIXELINC = 5
- For n = 2, PIXELINC = 9
- For n = 3, PIXELINC = 13
- For n = 4, PIXELINC = 17, etc.

Figure 10-33. YUV4:2:2 Predecimation



10.2.4.6.6 DISPC Progressive-to-Interlaced Format Conversion

The DMA engine can be used to perform YUV4:2:0 NV12 and YUV4:2:0 NV21 progressive-to-interlaced data conversion with 0-degree orientation. This section provides generic approach details.

Two possible configurations are available, depending on the setting of the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit, which defines the stride of each pixel value buffer for the YUV format. The following must be considered for both configurations:

- The DISPC_VIDn_BA_j[31:29] BA and DISPC_VIDn_BA_UV_j[31:29] BA bit fields, and the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field must be set to 0x0 to indicate 0-degree orientation.
- The DISPC_VIDn_BA_j[31:29] BA and DISPC_VIDn_BA_UV_j[31:29] BA bit fields must be set to 0x3, and the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field must be set to 0x2 to indicate 180-degree orientation.

Configuration 1 – YUV4:2:0 progressive to interlaced conversion

The DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit is set to 0x1. The CbCr container is twice the size of the Y container. All Luma and Chroma lines for even and odd fields are fetched from memory. The scaler unit of the respective pipeline can be used to downscale by 2 (through filtering) the fetched data to create the interlaced output. For more information about the scaler configuration, see Section 10.2.4.10.4, *Scaler Unit*.

Configuration 2 – YUV4:2:0 progressive to YUV4:2:2 interlaced conversion

The DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit is set to 0x0. The CbCr container is the same size as the Y container. The DISPC_VIDn_ROW_INC register for the respective pipeline must be configured so that only the Y data is vertically predecimated by 2 (for more information, see Section 10.2.4.6.5, *Predecimation*). The CbCr data must not be predecimated. As a result, only the even Luma lines for the even field and the odd Luma lines for the odd field are fetched from memory. To create the interlaced output, all the Chroma lines are fetched from memory.

10.2.4.6.7 DISPC Arbitration

The requests (reads or writes) sent to the L3_MAIN interconnect are pipelined and arbitrated in a round-robin scheme. The default arbitration scheme must be modified by setting the priority attribute of each pipeline as defined in the following bits:

- DISPC_GFX_ATTRIBUTES[14] ARBITRATION
- DISPC_VIDp_ATTRIBUTES[14] ARBITRATION
- DISPC_WB_ATTRIBUTES[14] ARBITRATION

By default, all pipelines have the same priority (normal), which means all pipeline requests are treated in a round-robin order manner. If one or more pipelines require a higher number of requests going to the L3_MAIN interconnect, its priority can be moved up to high priority. In this case, the high-priority pipeline is granted access before any pipeline in normal priority. If more than one active pipeline is in high priority, the behavior is the same as all active pipelines in normal priority. Normal active pipelines are not treated until all high active pipelines are finished. The ARBITRATION bit cannot be modified during the entire frame.

This functionality balances the bandwidth of the pipeline depending on its constraint. It can be used to give higher priority to the pipelines with real-time constraints versus non-real-time pipelines. For example, pipelines associated with the LCD output in stall mode must have lower priority than pipelines associated with TV output.

10.2.4.6.8 DISPC DMA Power Modes

10.2.4.6.8.1 DISPC DMA Low-Power Mode

Each DMA buffer is divided into two spaces. Each space can be associated with the pipeline or merged with other DMA buffers. The total number of DMA buffers for each pipeline is from 0 (pipeline inactive) to the number of pipelines × 2 (in that case all the DMA buffers are associated with a single pipeline). The sum of the number of DMA buffers allocated for each pipeline must not be greater than the maximum available. The correct number of DMA buffers must be allocated to ensure no underflow. The number of DMA buffers allocated to each pipeline must be greater than or equal to the minimum required to support the throughput and the system latency.

NOTE: When the number of buffers is changed, the thresholds must be reprogrammed to reflect the new configuration of the DMA buffer.

10.2.4.6.8.2 DISPC DMA Ultralow-Power Mode

In low-power mode, the L3_MAIN interconnect is used to fill up the DMA buffers to store all the data required to display a full frame. The L3_MAIN interconnect is not used to fetch new pixels for the following frames. The data in the DMA buffer are reused to display on the screen.

The setting of the mode is independent for each pipeline. One pipeline may have all the frame pixels in its DMA buffer and the other pipelines may have to refill their respective DMA buffers along the display scan because the frame buffer is too big to be stored in the DMA buffer.

The DMA buffers can be merged to optimize the L3_MAIN interconnect off time. Merging the DMA buffers into a single buffer can be used at the same time to improve ultralow-power mode (see Section 10.2.4.6.8.1, *Low-Power Mode*).

During the time in which the frames are fetched in the internal DMA buffer, MStandby must be asserted if the DISPC_SYSCONFIG[13:12] MIDLEMODE bit field is set to 0x2 (smart-standby mode).

Two ultralow-power modes can be entered manually or automatically:

- Self-refresh mode: Starting self-refresh mode is done manually by setting the DISPC_GFX_ATTRIBUTES[15] SELFREFRESH or DISPC_VIDp_ATTRIBUTES[15] SELFREFRESH bit to 0x1 after capturing a frame in the DMA buffers. Self-refresh mode is stopped by setting the SELFREFRESH bit to 0x0.
- Automatic self-refresh mode: By setting the DISPC_GFX_ATTRIBUTES[17] SELFREFRESHAUTO or DISPC_VIDp_ATTRIBUTES[17] SELFREFRESHAUTO bit to 0x1, the transition from off to on self-refresh mode is done by hardware after capturing the first frame. The hardware reflects the status of the self-refresh mode by setting the SELFREFRESH bit to 0x1, which means that the data are read inside the DMA buffer without accessing the interconnect and system memory during the frame. Setting the SELFREFRESH bit to 0x0 updates the DMA buffer.

NOTE: The WB pipeline does not support ultralow-power mode.

10.2.4.7 DISPC Rotation and Mirroring

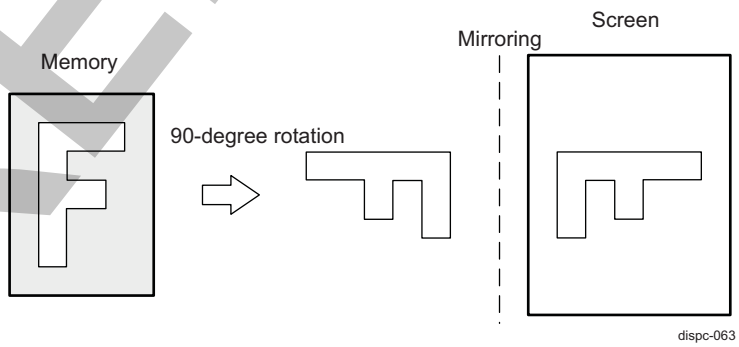
The DISPC provides flexible mechanisms for efficient implementation of rotation using the DISPC, its DMA engine, and the rotation engine of the TILER. The rotation is handled only through the TILER, which supplies the encoded pixels to the DISPC.

NOTE: No rotation or mirroring is supported when accessing internal SDRAM directly.

The TILER supports:

- Rotation: 0-, 90-, 180-, and 270-degree views
- Mirroring
- Any combination of rotation and mirroring (for example, Rot-90 + mirroring)

Figure 10-34. DISPC 90-Degree Rotation With Mirroring



When accessing YUV4:2:2 data, each 32-bit value loaded into the DMA buffer can represent either:

- Two consecutive pixels on the same line (for instance, 0- to 180-degree rotation)
- Two pixels adjacent vertically (for instance, 90- to 270-degree rotation)

The reading from the DMA buffer supports the extraction of the two pixels, regardless of the rotation. When the pixels are not consecutive on the same line (90- to 270-degree rotation), the chrominance sample of the first pixel of each 32-bit value is duplicated for the second pixel in the same 32-bit value.

The rotation flag DISPC_VIDn_ATTRIBUTES[13:12] ROTATION and DISPC_VIDn_ATTRIBUTES[4:1] FORMAT bit fields define the processing to extract the pixels from YUV4:2:2 32-bit values. Software must ensure that the settings of the ROTATION and FORMAT bit fields are coherent with the rotation and mirroring defined through the address format in the TILER-specific address map. For more information, see , *Dynamic Memory Manager*, in *Chapter 15, Memory Subsystem*.

NOTE: For YUV4:2:0 NV12, 2D tiled memory access cases, the DISPC_VIDn_ATTRIBUTES[13:12] ROTATION bit field should be set properly to match with the intended rotation of the use case.

Table 10-27 describes the register settings of the DISPC when accessing, rotating, and mirroring an image using the TILER. A physical base address (PBA) for each rotation is determined and set as the buffer address (BA). The row incremental is determined and set in ROW_INC. The value of the pixel increment, PIXEL_INC, is set to 0x1 (contiguous pixels).

Table 10-27. DISPC Register Settings for Rotation Using TILER

Rotation	Registers	Rotation With and Without Mirroring
0 degree	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA0
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW0
90 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA90
	DISPC_GFX_PIXEL_INC/ DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW90
180 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA180
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW180
270 degrees	DISPC_GFX_BA_j/DISPC_VIDp_BA_j/DISPC_WB_BA_j	PBA270
	DISPC_GFX_PIXEL_INC/DISPC_VIDp_PIXEL_INC/DISPC_WB_PIXEL_INC	1 to 16
	DISPC_GFX_ROW_INC/ DISPC_VIDp_ROW_INC/DISPC_WB_ROW_INC	ROW270

NOTE: For YUV format, in addition to the DISPC_VIDp_BA_j register used for the Y component, the DISPC_VIDp_BA_UV_j register must be set to define the base address of the UV frame buffer in memory.

The PBA rotation is determined by:

- PBA0 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA90 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA180 = PBA | (mode << 27) | (orientation << 29) | (1<<32)
- PBA270 = PBA | (mode << 27) | (orientation << 29) | (1<<32)

Where PBA is the physical base address of the image in the memory.

The ROW rotation is determined by:

- If 8 bits per pixel:
  - ROW0 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 8192: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 8192: Width of the video picture in memory (in bytes) + 1

- If 16 bits per pixel:
  - ROW0 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 8192: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 8192: Width of the video picture in memory (in bytes) + 1
- If 32 bits per pixel:
  - ROW0 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW90 = 16384: Width of the video picture in memory (in bytes) + 1
  - ROW180 = 32768: Width of the video picture in memory (in bytes) + 1
  - ROW270 = 16384: Width of the video picture in memory (in bytes) + 1

Table 10-28 and Table 10-29 list the DISPC rotation mode and rotation orientation definitions, respectively.

Table 10-28. DISPC Rotation Mode Definition

	8-Bit Tiled	16-Bit Tiled	32-Bit Tiled	Page Tiled
Mode	0	1	2	3

Table 10-29. DISPC Rotation Orientation Definition

Type of Orientation	Value
0-degree view	0x0
180-degree view with mirroring	0x1
0-degree view with mirroring	0x2
180-degree view	0x3
270-degree view with mirroring	0x4
270-degree view	0x5
90-degree view	0x6
90-degree view with mirroring	0x7

NOTE: For YUV4:2:0 progressive pixel format, because the value of the DISPC_VIDp_ROW_INC register is defined for the Y buffer, the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit must be set to 1 when rotating the picture by 0 and 180 degrees, and must be reset to 0 when rotating the picture by 90 and 270 degrees.

For YUV4:2:0 interlaced pixel format, because the value of the DISPC_VIDp_ROW_INC register is defined for the Y buffer, the DISPC_VIDp_ATTRIBUTES[22] DOUBLESTRIDE bit must be set to 1 when rotating the picture by 0 and 180 degrees. Rotations of 90 and 270 degrees are not supported with this pixel format.

10.2.4.8 DISPC Memory Format

The graphic and video pipelines support various types of memory formats. Table 10-30 lists all supported formats for each pipeline. Nibble mode is enabled by setting the DISPC_GFX_ATTRIBUTES[9] NIBBLEMODE bit to 0x1 and applies only to BITMAP format for the GFX pipeline.

Table 10-30. DISPC Memory Formats Supported

Formats	GFX	VID1	VID2	VID3	WB
BITMAP 1-bpp	x				
BITMAP 2-bpp	x				
BITMAP 4-bpp	x				
BITMAP 8-bpp	x				

Table 10-30. DISPC Memory Formats Supported (continued)

10.2.4.9 DISPC Graphics Pipeline

The graphics pipeline is connected to the GFX FIFO for the input port and to the four overlay managers for the output or WB pipeline. The pixel output is directed to an LCD, TV, or WB path by setting the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT bit and the DISPC_GFX_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 lists the bit field settings to orient a pipeline to an LCD, TV, or WB output. The default value directs the GFX pipeline to LCD1. The GFX pipeline can be enabled by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x1.

NOTE: It is not possible to change the direction of the GFX pipeline on the fly. If the graphics pipeline must be connected to an overlay manager different from the one to which it is currently connected, then the following steps must be performed:

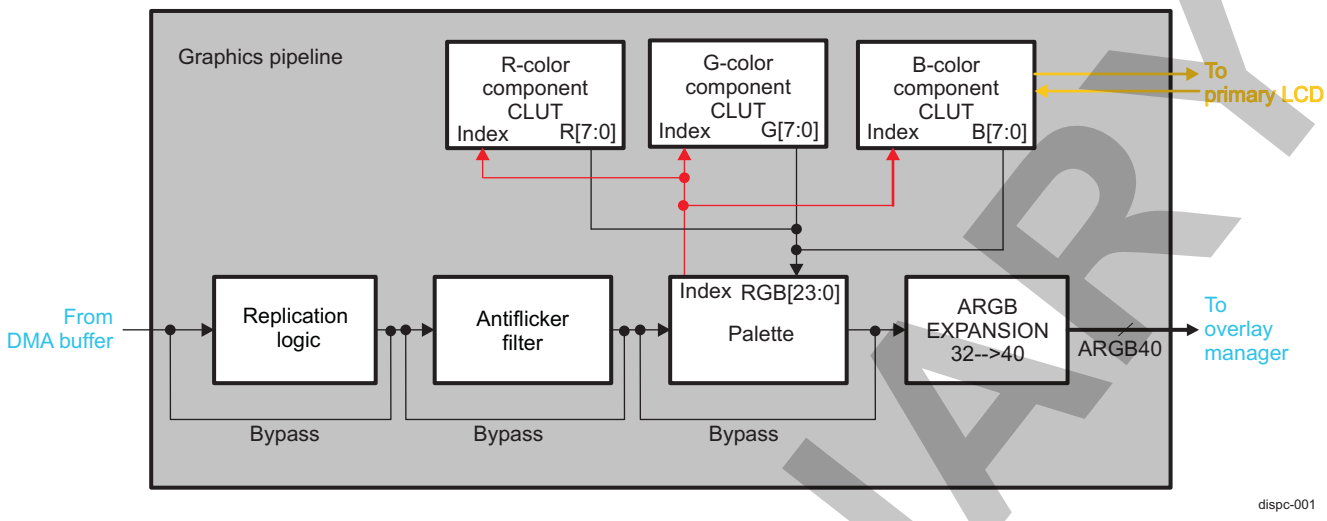
1. Disable the GFX pipeline by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x0.
2. Direct the GFX pipeline to the new overlay manager by modifying the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT and [31:30] CHANNELOUT2 bits.
3. Disable the DISPC output which corresponds with the overlay manager to which the GFX pipeline will be connected next. This is done by setting the in the following bits to 0x0 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output
4. Enable the GFX pipeline by setting the DISPC_GFX_ATTRIBUTES[0] ENABLE bit to 0x1.
5. Enable the DISPC output that corresponds with the overlay manager to which the GFX pipeline will be connected. This is done by setting the following bits to 0x1 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output

The pipeline consists of programmable replication logic, an antiflicker filter, and one 256-entry palette table. The replication logic is used to convert the RGB pixel formats into an ARGB40-based format. The antiflicker filter processes the graphics data in RGB format to remove some of the vertical flicker. The 256-entry palette is used to convert bitmap formats into RGB formats or for gamma corrections when RGB format is inputted.

Table 10-30 lists the input formats supported by the graphics pipeline.

Figure 10-35 shows the graphics pipeline.

Figure 10-35. DISPC Graphics Pipeline



10.2.4.9.1 DISPC Replication Logic

The replication logic increases the color depth of the graphics-encoded pixels (from true color RGB 12, and 16 to 40 bpp).

- When the replication logic is enabled by setting the DISPC_GFX_ATTRIBUTES[5] REPLICATIONENABLE bit to 0x1, the MSBs are copied to the missing LSB. Table 10-31 describes the remapping of the RGB pixels into ARGB 40-bit values.

Table 10-31. DISPC Replication Enabled: RGB Pixel Formats Remapping Into ARGB40-10.10.10.10

	A[9:0]	R[9:0]	G[9:0]	B[9:0]
Format	**MSB LSB**	**MSB LSB**	**MSB LSB**	**MSB LSB**
xRGB12-4444	1111111111	R[3:0]R[3:0]R[3:2]	G[3:0]G[3:0]G[3:2]	B[3:0]B[3:0]B[3:2]

10.2.4.9.2 DISPC Antiflicker Filter

The antiflicker filter processes the graphics data to remove some of the vertical flicker. It is based on a 3-tap FIR filter with fixed coefficients. For each pixel to be output from the graphics pipeline, the pixel above and below the current line must be read from the DMA graphics FIFO. Therefore, three lines of pixels must be stored in the DMA graphics FIFO.

The antiflickering equations for A, R, G, and B components are:

$A_{out}(x,y) = 0.25 \times A_{in}(x,y-1) + 0.5 \times A_{in}(x,y) + 0.25 \times A_{in}(x,y+1)$

$R_{out}(x,y) = 0.25 \times R_{in}(x,y-1) + 0.5 \times R_{in}(x,y) + 0.25 \times R_{in}(x,y+1)$

$G_{out}(x,y) = 0.25 \times G_{in}(x,y-1) + 0.5 \times G_{in}(x,y) + 0.25 \times G_{in}(x,y+1)$

$B_{out}(x,y) = 0.25 \times B_{in}(x,y-1) + 0.5 \times B_{in}(x,y) + 0.25 \times B_{in}(x,y+1)$

For the first line of processing, because there is no pixel above, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y) + 0.5 \times In(x,y) + 0.25 \times In(x,y+1)$

For the last line of processing, because there is no pixel below, the value (x,y) is duplicated.

$Out(x,y) = 0.25 \times In(x,y-1) + 0.5 \times In(x,y) + 0.25 \times In(x,y)$

NOTE: Antiflicker filtering is supported only in RGB formats and not in BITMAP formats.

Antiflickering is not supported for pictures with fewer than two lines. In this case, the user must disable the antiflickering processing.

By default, the antiflicker filtering is disabled. It can be enabled by setting the DISPC_GFX_ATTRIBUTES[24] ANTIFLICKER bit to 0x1.

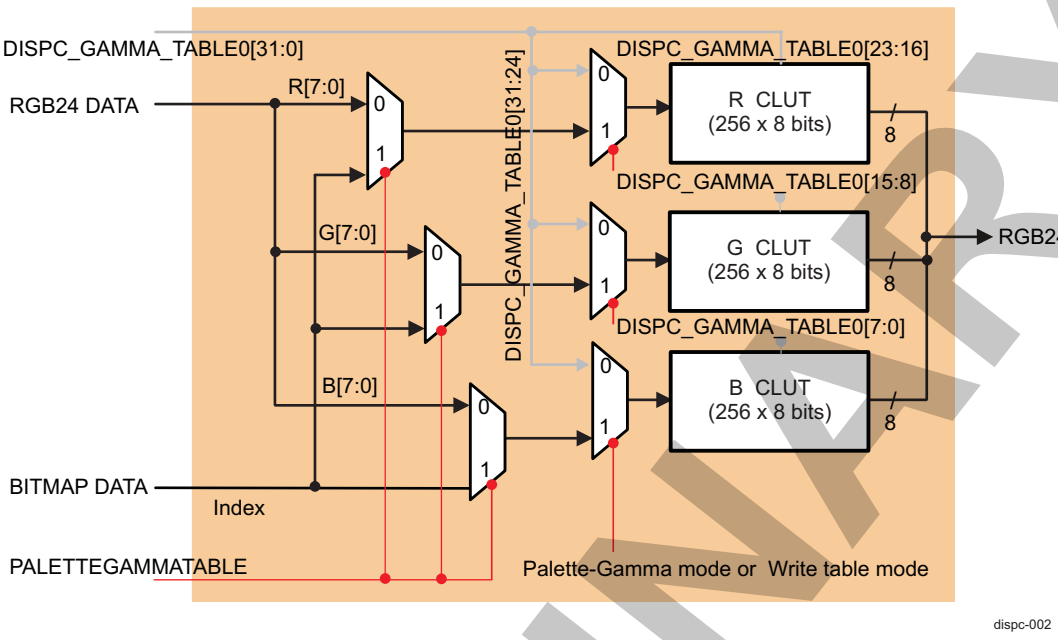
10.2.4.9.3 DISPC Color Look-Up Table (CLUT)

The graphics pipeline supports conversion of the BITMAP formats into RGB24 formats through a palette table. To enable palette mode, the DISPC_CONFIG1[3] PALETTEGAMMATABLE bit must be set to 0x0. Figure 10-36 shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit × 8-bit entries. For bitmap (CLUT) indexes, the same value (1, 2, 4, or 8 bpp) indexes the three memories. The table can be reloaded every frame, once, or never (at the beginning of the frame before fetching pixels for the graphics). The table is loaded dynamically at the beginning of the frame by the DISPC DMA engine. The base address of the table buffer is set in the DISPC_GFX_TABLE_BA[31:0] TABLEBA bit field. It is possible to load the table for every frame or only for a specific frame by setting the DISPC_CONFIG1[2:1] LOADMODE bit field.

The table can be loaded without fetching data for the graphics pipeline. The DMA buffer associated with the graphics pipeline is used to fetch the table from memory. Regardless of the mode (color or monochrome) for each entry into the table, one 32-bit value is fetched from memory.

Figure 10-36. DISPC Palette/Gamma Correction Architecture



The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-bpp pixel address 2 palette entries, 2-bpp pixel address 4 palette entries, 4-bpp pixel address 16 palette entries, and 8-bpp pixel address 256 palette entries. In color mode, the value within the palette consists of three 8-bit fields, one for each color component: red, green, and blue (see Figure 10-37). For a color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In monochrome mode, only one 8-bit value is present; 256 grayscales and 16,777,216 colors are obtained after passing through the palette (see Figure 10-38)

Figure 10-37. DISPC Data Memory Organization: Color Mode

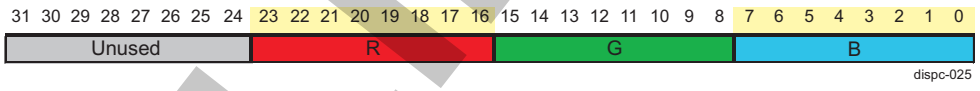


Figure 10-38. DISPC Data Memory Organization: Gray Mode

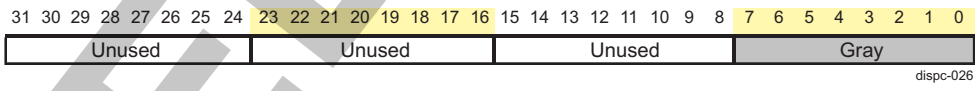
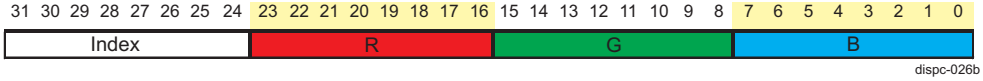


When a palette entry is selected by the encoded pixel value, the content of the entry and the index are sent to the LCD1 overlay manager.

In gamma curve mode, the selected encoded pixel values based on the color keys by the overlay manager from the video or grahics paths are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to the R, G, or B component. Figure 10-39 describes the format of one of the gamma curve values in the memory.

Figure 10-39. DISPC Data Memory Organization: Gamma Curve 24 BPP

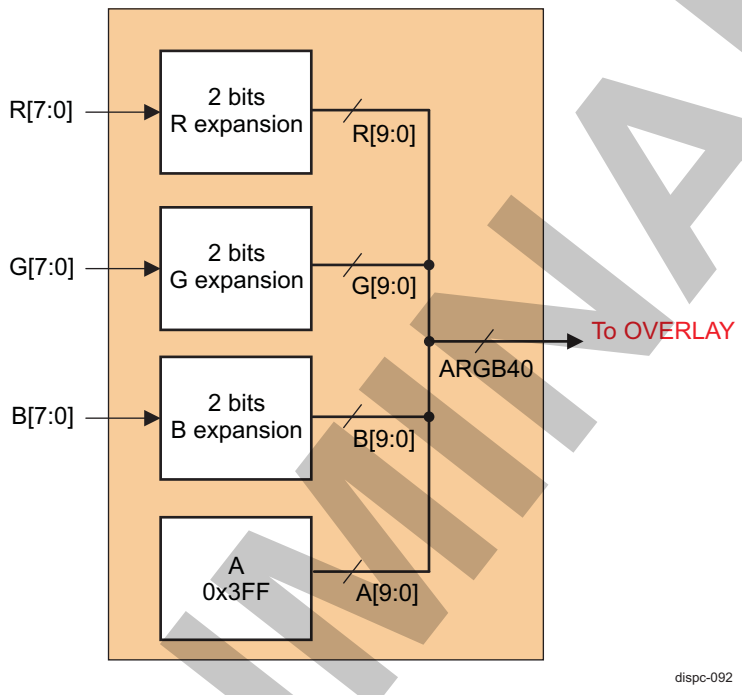


10.2.4.9.4 DISPC Expansion to ARGB40

When the GFX pipeline input data is in an RGB pixel format, the expansion to ARGB40 format is done as described in Section 10.2.4.10.1, *DISPC Replication Logic*.

When the GFX pipeline input data is in BITMAP format, the expansion module input receives the RGB24 pixel format output from the pallette module. The expansion module automatically replicates the 2 MSBs of each color component to create an ARGB40 pixel with the A component set to 0x3FF (see Figure 10-40).

Figure 10-40. DISPC Expansion to ARGB40



10.2.4.10 DISPC Video Pipelines

Three identical video pipelines are available, VID1, VID2, and VID3. Each video pipeline is connected to its video FIFO controller for the input port and to the four overlay managers, LCD1, LCD2, LCD3, and TV or WB pipeline. The pixel output is directed to the LCD, TV, or WB path by setting the DISPC_VIDp_ATTRIBUTES[16] CHANNELOUT bit and the DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 summarizes the bit field settings to orient a pipeline to LCD, TV, or WB output. The default value directs all video pipelines to LCD1.

NOTE: It is not possible to change the direction of the video pipelines on the fly. If a video pipeline needs to be connected to a different overlay manager than what it is currently connected, then the following steps need to be performed:

1. Disable the VIDp pipeline by setting the DISPC_VIDp_ATTRIBUTES[0] ENABLE bit to 0x0.
2. Direct the VIDp pipeline to the new overlay manager by modifying the [16] CHANNELOUT bit and the [31:30] CHANNELOUT2 bit in the DISPC_VIDp_ATTRIBUTES register.
3. Disable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x0 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1 output
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output
4. Enable the VIDp pipeline by writing 0x1 to the DISPC_VIDp_ATTRIBUTES [0] ENABLE bit.
5. Enable the DISPC output that corresponds with the overlay manager to which the VIDp pipeline will be connected next. This is done by setting the following bits to 0x1 for the listed outputs:
   - The DISPC_CONTROL1[0] LCDENABLE bit for LCD1
   - The DISPC_CONTROL2[0] LCDENABLE bit for LCD2 output
   - The DISPC_CONTROL3[0] LCDENABLE bit for LCD3 output
   - The DISPC_CONTROL1[1] TVENABLE bit for TV output

A video pipeline consists of a scaler unit, color space conversion (CSC) unit, VC-1 range mapping unit, and some programmable replication logic. The order of the video pipeline unit can be configured in two manners (see Figure 10-41 and Figure 10-42):

- Configuration 1 (YUVCHROMARESAMPLING = 0): VC-1 range mapping unit followed by a CSC unit and then a scaler unit. The configuration is used to support RGB, ARGB, and RGBA formats and YUV4:2:2 in backward mode for both data types. Each block can be independently bypassed.
- Configuration 2 (YUVCHROMARESAMPLING = 1): VC-1 range mapping unit followed by a scaler unit and then a CSC unit. The configuration is used to support RGB, ARGB, and RGBA formats and YUV4:2:2, YUV420-NV12, and YUV420-NV21 formats, taking advantage of the scaler to resample the chrominance using five taps horizontally and three or five taps vertically. Each block can be independently bypassed.

The DISPC_VIDn_ATTRIBUTES2[8] YUVCHROMARESAMPLING bit controls the order of the scaler unit in the video pipeline:

- When the YUVCHROMARESAMPLING bit is set to 0x0, the video pipeline is in configuration 1, and the scaler comes after the CSC unit. In case of YUV input data in 4:2:2 format, the chrominance resampling (4:2:2 to 4:4:4 format) is done by averaging the chrominance adjacent samples for only 0 degrees (zero rotation), because other rotation (90/180/270 degrees) is not supported in this mode. For more information about the supported chrominance resampling methods, see Section 10.2.4.10.3.1, *Chrominance Resampling*.
- When the YUVCHROMARESAMPLING bit is set to 0x1, the video pipeline is in configuration 2, and the scaler comes before the CSC unit.
  - In case of YUV4:2:2 input data with 90-/270-degree rotation, the data is preprocessed by duplicating the missing chrominance samples.
  - In case of YUV4:2:2 input data with 0-/180-degree rotation, the Chroma upsampling is performed in the scaler unit.

Table 10-30 lists the input formats supported by the video pipelines.

The video pipeline is enabled by setting the DISPC_VIDp_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 10-41. DISPC Configuration 1: Video Pipeline

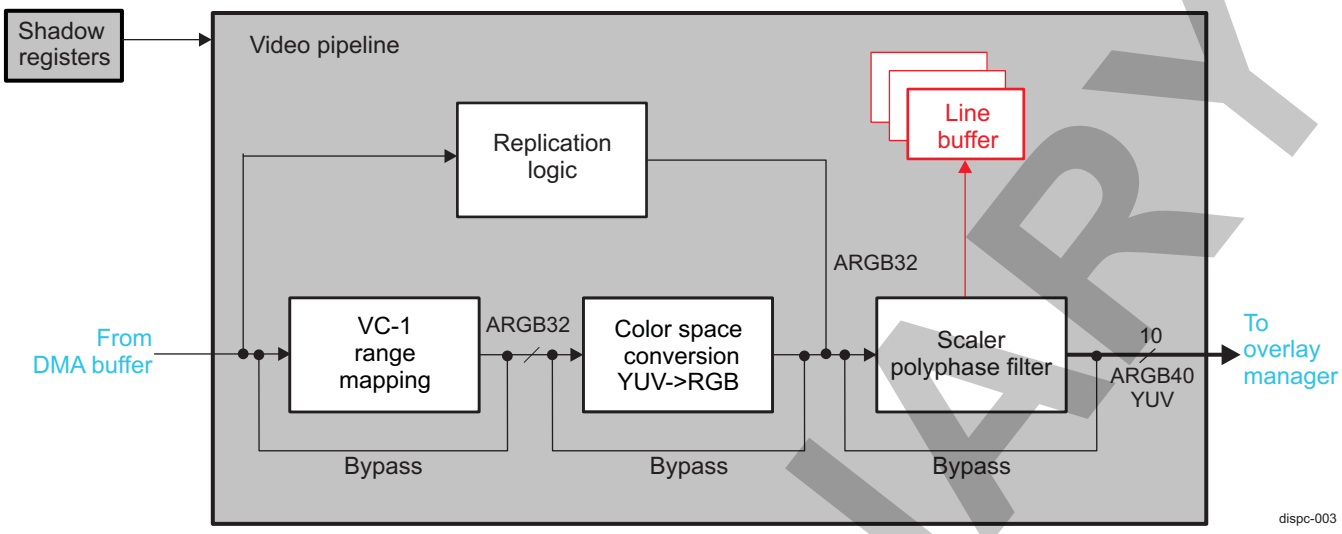


Figure 10-42. DISPC Configuration 2: Video Pipeline

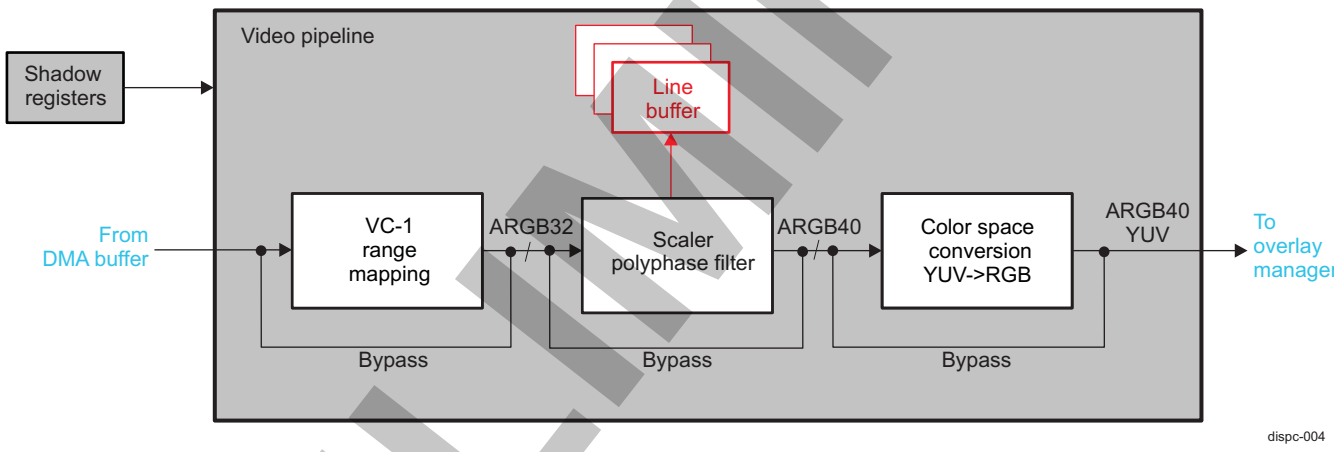

10.2.4.10.1 DISPC Replication Logic

The replication logic increases the color depth of the video-encoded pixels (from true color RGB 12, and 16 to 32 bpp) available only in configuration 1.

The expansion from 8- to 10-bit color component is done by the following units:

- The CSC unit, when the scaler is after the CSC module and when the vertical scaler is disabled
- The vertical scaler, when the scaler is after the CSC unit and enabled
- The replication bit module, when the CSC unit and scaler are disabled
- When the replication logic is enabled by setting the DISPC_VIDp_ATTRIBUTES[10] REPLICATIONENABLE bit to 0x1, the MSBs are copied to the missing LSBs. Table 10-33 describes the remapping of the RGB pixels into ARGB 32-bit values.

Table 10-33. DISPC Replication Enabled: RGB Pixel Formats Remapping Into ARGB32-8888

RGBA16-4444	A[3:0]A[3:0]	R[3:0]0000	G[3:0]0000	B[3:0]0000

10.2.4.10.2 DISPC VC-1 Range Mapping Unit

The VC-1 range mapping unit is used when the video frame picture is decoded using a VC-1 codec by the video accelerator. It remaps the Y, Cb, and Cr components. The unit is used primarily for YUV4:2:0-NV12 and YUV4:2:0-NV21 pixel formats but also can be applied to YUV4:2:2 pixel formats (YUV2 and UYVY).

The VC-1 range mapping unit is enabled by setting the DISPC_VIDp_ATTRIBUTES2[0] VC1ENABLE bit to 0x1. The DISPC_VIDp_ATTRIBUTES2[3:1] VC1_RANGE_Y and DISPC_VIDp_ATTRIBUTES2[6:4] VC1_RANGE_CBCR bit fields are two 3-bit values programmed by the user and are independent for each video pipeline. The module is governed by the equations:

$Y_{out} = CLIP(((Y_{int} – 128) \times (VC1\_RANGE\_Y + 9) + 4) / 8) + 128)$

$C_b = CLIP(((C_b – 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$

$C_r = CLIP(((C_r – 128) \times (VC1\_RANGE\_CBCR + 9) + 4) / 8) + 128)$

NOTE: The input and output pixel values are unsigned (Y, Cr, and Cb).

The function CLIP () clips to 0 or 255 when minimum or maximum, respectively, are reached; otherwise, the resulting output remains identical.

10.2.4.10.3 DISPC CSC Unit YUV to RGB

The CSC unit converts the video-encoded pixel values from YUV4:4:4 format into RGB24 or RGB30 format. The output format depends on the video pipeline configuration selected:

- Configuration 1: RGB24 output format, with 8-bit value per component: red, green, and blue
- Configuration 2: RGB30 output format, with 10-bit value per component: red, green, and blue

In case of YUV4:2:0 or YUV4:2:2 formats, a chrominance resampling to YUV4:4:4 is required before converting the YUV into RGB values (see Section 10.2.4.10.3.1, *Chrominance Resampling*). YUV4:2:2 or YUV4:2:0 to YUV4:4:4 chrominance resampling is a preprocessing to the color space conversion.

Figure 10-43 through Figure 10-46 show the 3 × 3 11-bit coefficients used to convert from YUV4:4:4 into RGB24. The coefficients are set according to the standard used to encode the pixel data in YUV color space. Table 10-35 summarizes the coefficients with their respective bit fields.

Table 10-35. DISPC Color Space Conversion YUV to RGB Bit Field Setting

Coefficients	Bit Field Registers
R_Y	DISPC_VIDp_CONV_COEF0[10:0] RY
R_{Cr}	DISPC_VIDp_CONV_COEF0[26:16] RCR
R_{Cb}	DISPC_VIDp_CONV_COEF1[10:0] RCB
G_Y	DISPC_VIDp_CONV_COEF1[26:16] GY
G_{Cr}	DISPC_VIDp_CONV_COEF2[10:0] GCR
G_{Cb}	DISPC_VIDp_CONV_COEF2[26:16] GCB
B_Y	DISPC_VIDp_CONV_COEF3[10:0] BY
B_{Cr}	DISPC_VIDp_CONV_COEF3[26:16] BCR
B_{Cb}	DISPC_VIDp_CONV_COEF4[10:0] BCB

- For configuration 1 with an RGB24 output:

  If the active range for the luminance samples (Y) is [235:16] and [240:16] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [255:0].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

Figure 10-43. DISPC YCbCr to RGB Registers (FULLRANGE = 0), 8-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 16 \\ Cr_{IN} - 128 \\ Cb_{IN} - 128 \end{bmatrix}$$

dispc-005

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [255:0], the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x1. The values of R, G, and B output components are clipped to the range [255:0].

Figure 10-44. DISPC YCbCr to RGB Registers (FULLRANGE = 1), 8-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 128 \\ Cb_{IN} - 128 \end{bmatrix}$$

dispc-006

- For configuration 2 with an RGB30 output:

  If the active range for the luminance samples (Y) is [940:64] and [960:64] for the chrominance samples (Cb and Cr), the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x0. The values of R, G, and B output components are clipped to the range [1023:0].

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

Figure 10-45. DISPC YCbCr to RGB Registers (FULLRANGE = 0), 10-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} - 64 \\ Cr_{IN} - 512 \\ Cb_{IN} - 512 \end{bmatrix}$$

dispc-074

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [1023:0], the range selection is done by setting the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit to 0x1. The values of R, G, and B output components are clipped to the range [1023:0].

Figure 10-46. DISPC YCbCr to RGB Registers (FULLRANGE = 1), 10-Bit Outputs

$$\begin{bmatrix} R_{OUT} \\ G_{OUT} \\ B_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} R_Y & R_{cr} & R_{cb} \\ G_Y & G_{cr} & G_{cb} \\ B_Y & B_{cr} & B_{cb} \end{bmatrix} * \begin{bmatrix} Y_{IN} \\ Cr_{IN} - 512 \\ Cb_{IN} - 512 \end{bmatrix}$$

dispc-075

10.2.4.10.3.1 DISPC Chrominance Resampling

Two methods are supported to resample chrominance:

- Averaging of the chrominance is done by software, followed by hardware conversion when the video pipeline is in configuration 1.
- Filtering of the chrominance using the scaler unit (chrominance resampling and rescaling can be combined to support native rescaling of YUV format) when the video pipeline is in configuration 2.

To convert the YUV4:2:2 encoded pixel values into YUV4:4:4 format, the averaging of the chrominance technique can be used as shown in Figure 10-47. The missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (,) or are repeated from the second pixel in the same 32-bit container (see Figure 10-48). For the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values. Figure 10-49 shows the flow of the pixel.

Figure 10-47. DISPC Averaging of the Chrominance Formula

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

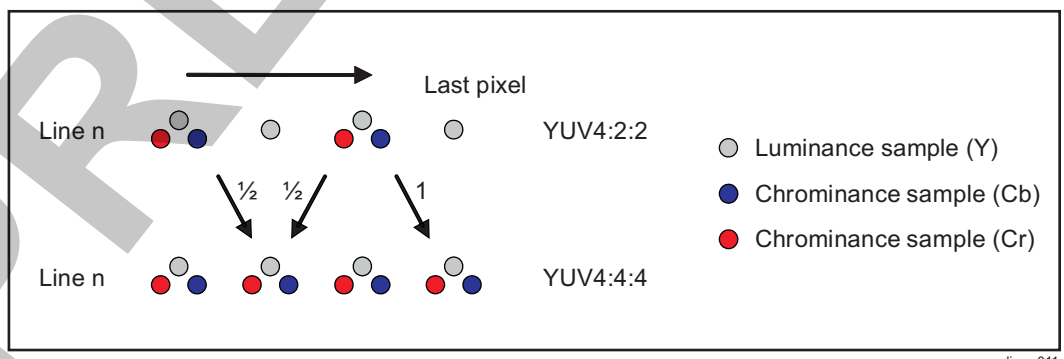
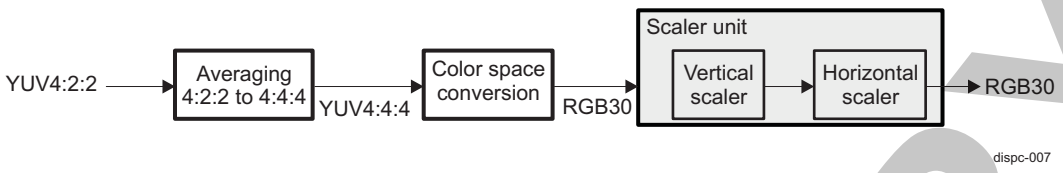
Figure 10-48. DISPC Averaging of the Chrominance Representation



dispc-011

Figure 10-49. DISPC YUV4:2:2 to RGB30 Using Averaging of the Chrominance



The scaler unit can be used to resample the chrominance of YUV4:2:0 and YUV4:2:2, as shown in Figure 10-50 and Figure 10-51, respectively. The settings of the scaler unit to perform chrominance resampling are described in Section 10.2.4.10.4, *DISPC Scaler Unit*.

Figure 10-50. DISPC YUV4:2:0 to RGB30 Using Scaler Unit for Resampling Chrominance

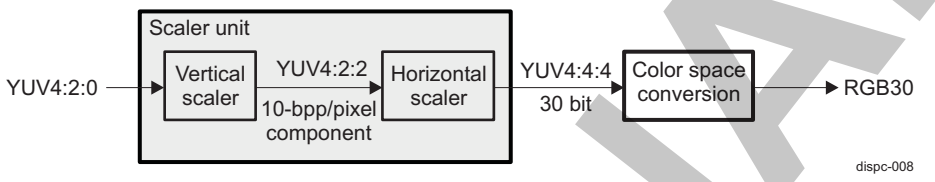


Figure 10-51. DISPC YUV4:2:2 to RGB30 Using Scaler Unit for Resampling Chrominance

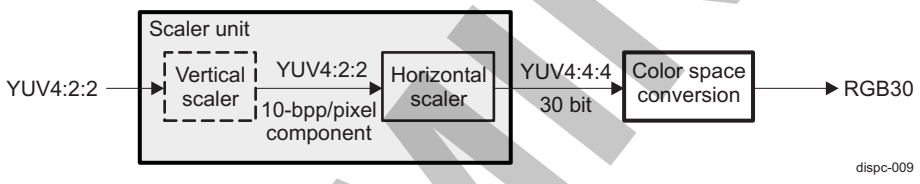


NOTE: If rotation must be supported, YUV4:2:2 and YUV4:2:0 (0-/180-degree rotation) chrominance resampling is done as shown in Figure 10-51 and Figure 10-50, respectively.
For YUV4:2:2 (90-/270-degree rotation) data are preprocessed to present YUV4:4:4 on the scaler input (duplication of the missing chroma), as shown in Figure 10-49.

10.2.4.10.4 DISPC Scaler Unit

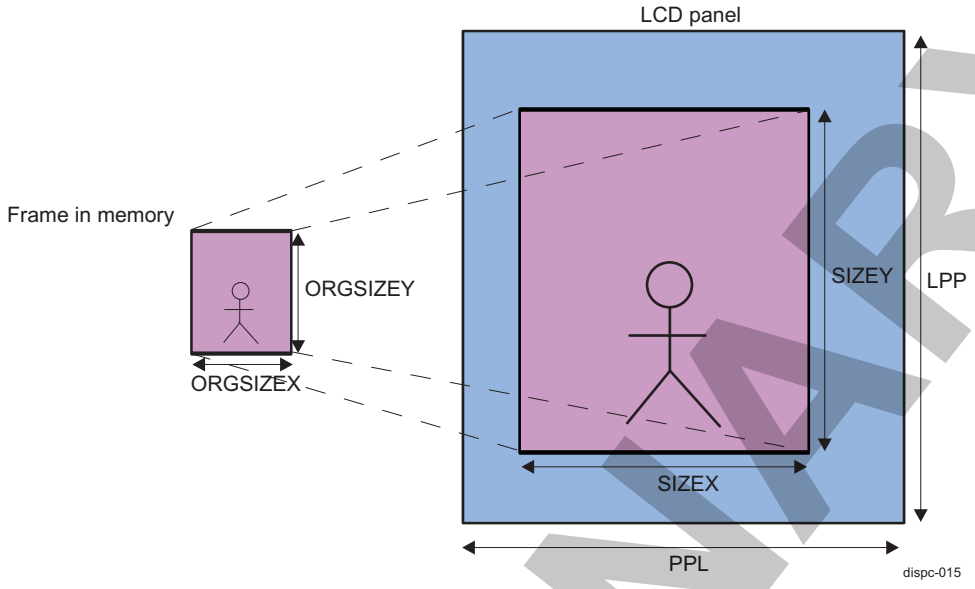
All video formats are supported, including formats with alpha blending. Alpha blending is scaled with the same parameters as RGB color components. For the YUV formats, Y and Cb/Cr are processed independently. The filter is based on a finite impulse response (FIR) filter. The filtering can be used for different processing:

- Upsampling of the picture
- Downsampling of the picture
- Antiflicker reduction
- De-interlacing using bob algorithm
- Chrominance resampling in case of YUV data formats

NOTE: The user must ensure that the resizing frame displays in the LCD/screen boundaries.

Figure 10-52 shows an example of video upsampling.

Figure 10-52. DISPC Video Upsampling



The upsampling and downsampling filter is a polyphase filter with five taps and eight phases for the horizontal filter, and a programmable number of taps (three or five) and eight phases for vertical filter. The input buffer has five input memory lines. The following limitations must be considered:

- The upsampling ratio is up to x8.
- The downsampling ratio using 3-tap configuration is down to x0.5 for RGB format.
- The downsampling ratio using 5-tap configuration is down to x0.25 for RGB format.
- If the input format is changed from YUV4:2:2 to YUV4:2:0 (WB pipeline), the downsampling ratio is further reduced:
  - Using 5-tap configuration, the ratio is down to x0.5 for RGB format.
  - Using 3-tap configuration, no downscaling is available.

For vertical upsampling and downsampling in a 3-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*A_{in}(n+i)\right)>>5$$

$$R_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*R_{in}(n+i)\right)>>5$$

$$G_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*G_{in}(n+i)\right)>>5$$

$$B_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi)*B_{in}(n+i)\right)>>5$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vi}(\Phi_y)*Y_{in}(n+i)\right)>>5$$

$$Cr_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cb_{in}(n+i)\right)>>5$$

$$Cb_{out}(n)=\left(\sum_{i=-1}^{i=1} C_{vci}(\Phi_c)*Cr_{in}(n+i)\right)>>5$$

dispc-013

(7)

For vertical upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*A_{in}(n+i)\right)>>5$$

$$R_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*R_{in}(n+i)\right)>>5$$

$$G_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*G_{in}(n+i)\right)>>5$$

$$B_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi)*B_{in}(n+i)\right)>>5$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vi}(\Phi_y)*Y_{in}(n+i)\right)>>5$$

$$Cb_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cb_{in}(n+i)\right)>>5$$

$$Cr_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{vci}(\Phi_c)*Cr_{in}(n+i)\right)>>5$$

dispc-012

(8)

For horizontal upsampling and downsampling in a 5-tap configuration, the equations are:

For RGB formats

$$A_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*A_{in}(n+i)\right)>>7$$

$$R_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*R_{in}(n+i)\right)>>7$$

$$G_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*G_{in}(n+i)\right)>>7$$

$$B_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi)*B_{in}(n+i)\right)>>7$$

For YUV formats

$$Y_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hi}(\Phi_y)*Y_{in}(n+i)\right)>>7$$

$$Cb_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cb_{in}(n+i)\right)>>7$$

$$Cr_{out}(n)=\left(\sum_{i=-2}^{i=2} C_{hci}(\Phi_c)*Cr_{in}(n+i)\right)>>7$$

dispc-014

(9)

NOTE: The pixel (n + 1) is the previous pixel with respect to pixel (n). The line (n + 1) is the previous line with respect to line (n).

The coefficients Ci() depend on the phase between input and output pixels.

NOTE: The coefficients are different for Y and Cr, Cb filtering because the calculations are independent due to the chrominance resampling for YUV4:2:2 and YUV4:2:0.

First, the vertical filter is applied to the encoded input pixel data, and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. The vertical input of the filter consists of five lines of 2048 × 32 bits for both 3-tap and 5-tap configurations (see Table 10-36).

Table 10-36. DISPC Line Buffer Width for Scaler Unit

Vertical Taps	Maximum Input Width (Pixels)
3, 5	2048 × 32 bits

At the beginning of frame scaling processing, the first line is duplicated to fill the first two lines in 3-tap configuration and the first three lines in 5-tap configuration.

At the end of frame scaling processing, the last line is duplicated if the scaling logic requires loading more lines and the last line has been reached.

The programmable coefficients of the polyphase filters are signed 8-bit values (except for the central coefficient, which is unsigned). The video scalers have an 8-bit input and a 10-bit output. The vertical scaling changes the 8-bit input into a 10-bit clipped output and the horizontal scaling takes the 10-bit input.

Figure 10-53 and Figure 10-54 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 10-55 and Figure 10-56 show the scaler macro-architecture for component Cr and Cb.

The scaling output can be clipped to an output range of [1023:0] or [960:64] by configuring the DISPC_VIDp_ATTRIBUTES[11] FULLRANGE bit.

NOTE: The scaling and CSC clipping is set by the same bit, DISPC_VIDp_ATTRIBUTES[11] FULLRANGE.

	Chc(2)		FIRHC0	DISPC_VIDp_FIR_COEF_H2_i

The VID scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_VIDp_ATTRIBUTES[6:5] RESIZEENABLE bit field.

A set of configurations must be valid before enabling the video upsampling and downsampling block.

The following fields define the configuration of the video upsampling downsampling block for VIDp:

- Vertical upsampling and downsampling increments the value of the DISPC_VIDp_FIR[28:16] FIRVINC bit field. The unsigned integer value range is [4096:1]. Software calculates the value using the following equation:

$$FIRVINC = 1024 \times \left(\frac{MEMSIZEY}{SIZEY} \right)$$

dispc-066 (10)

NOTE:

- If the value of the DISPC_VIDp_FIR[28:16] FIRVINC bit field is greater than 4096, it is clipped to 4096.
- If the ISPC_VIDp_SIZE[27:16] SIZEY bit field equals 0x1, SIZEY is replaced by 0x2 in the previous equation.
- The values of the DISPC_VIDp_PICTURE_SIZE[27:16] MEMSIZEY and DISPC_VIDp_SIZE[27:16] SIZEY bit fields must be programmed with the value desired minus 1.

- Horizontal upsampling and downsampling increments the value of the DISPC_VIDp_FIR[12:0] FIRHINC bit field. The unsigned integer value range is [4096:1]. Software calculates the value using the following equation:

$$FIRHINC = 1024 \times \left(\frac{MEMSIZEX}{SIZEX} \right)$$

dispc-067 (11)

NOTE:

- If the value of the DISPC_VIDp_FIR[12:0] FIRHINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_VIDp_SIZE[11:0] SIZEX bit field equals 1, SIZEX is replaced by 2 in the previous equation.
- The values of the DISPC_VIDp_PICTURE_SIZE[10:0] MEMSIZEX and DISPC_VIDp_SIZE[11:0] SIZEX bit fields must be programmed with the value desired minus 1.

- Vertical up/downsampling accumulator value DISPC_VIDp_ACCU_j[26:16] VERTICALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_VIDp_ACCU_0 is used for progressive output and for interlace output; the DISPC_VIDp_ACCU_0 and DISPC_VIDp_ACCU_1 registers are used. Similarly, DISPC_VIDp_ACCU2_0 and DISPC_VIDp_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical upsampling and downsampling line buffer configuration DISPC_VIDp_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal upsampling and downsampling accumulator value DISPC_VIDp_ACCU_j[10:0] HORIZONTALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_VIDp_ACCU_0 is used for progressive output and for interlace output; the DISPC_VIDp_ACCU_0 and DISPC_VIDp_ACCU_1 registers are used. Similarly, DISPC_VIDp_ACCU2_0 and DISPC_VIDp_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.

Table 10-39 lists the DISPC vertical and horizonatal accumulator values and phases.

Table 10-39. DISPC Vertical and Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128 or –896	1
256 or –768	2
384 or –640	3
512 or –512	4
640 or –384	5
768 or –256	6
896 or –128	7

- Vertical upsampling and downsampling coefficients:
  - The 3-tap vertical upsampling and downsampling coefficients are defined in the DISPC_VIDp_FIR_COEF_HV_i registers. There are 8 registers for the 8 phases with 3 coefficients for each, or a total of 24 programmable coefficients for the vertical upsampling and downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).
  - The 5-tap vertical upsampling and downsampling coefficients: Two extra-tap vertical upsampling and downsampling coefficients are defined in the DISPC_VIDp_FIR_COEF_V_i registers. There are 8 registers for the 8 phases with 2 coefficients for each of them, so a total of 16 programmable coefficients for the vertical upsampling downsampling block are used in addition to the 3-tap registers previously defined.

  Four YUV vertical upsampling and downsampling coefficients are set in DISPC_VIDp_FIR_COEF_HV2_i and DISPC_VIDp_FIR_COEF_V2_i registers. Table 10-37 and Table 10-38 summarize all coefficients and their respective registers.
- Horizontal upsampling and downsampling coefficients:

– The DISPC_VIDp_FIR_COEF_H_i and DISPC_VIDp_FIR_COEF_HV_i registers define the 5-tap horizontal up/downsampling coefficients. Each DISPC_VIDp_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DISPC_VIDp_FIR_COEF_HV_i register contains one 8-bit signed coefficient. A total of 40 programmable coefficients for the horizontal upsampling and downsampling block are used.

Four YUV horizontal upsampling and downsampling coefficients are set in the DISPC_VIDp_FIR_COEF_HV2_i and DISPC_VIDp_FIR_COEF_H2_i registers. Table 10-37 and Table 10-38 summarize all coefficients and their respective registers.

Section 10.2.4.10.4.3, *DISPC Filter Coefficients*, provides reference tables with example values for filter coefficients.

10.2.4.10.4.1 DISPC Scaling Algorithms

Figure 10-57 and Figure 10-58 show details of the vertical and horizontal upsampling and downsampling finite state-machines (FSMs), respectively.

Figure 10-57. DISPC Vertical Upsampling and Downsampling Algorithm

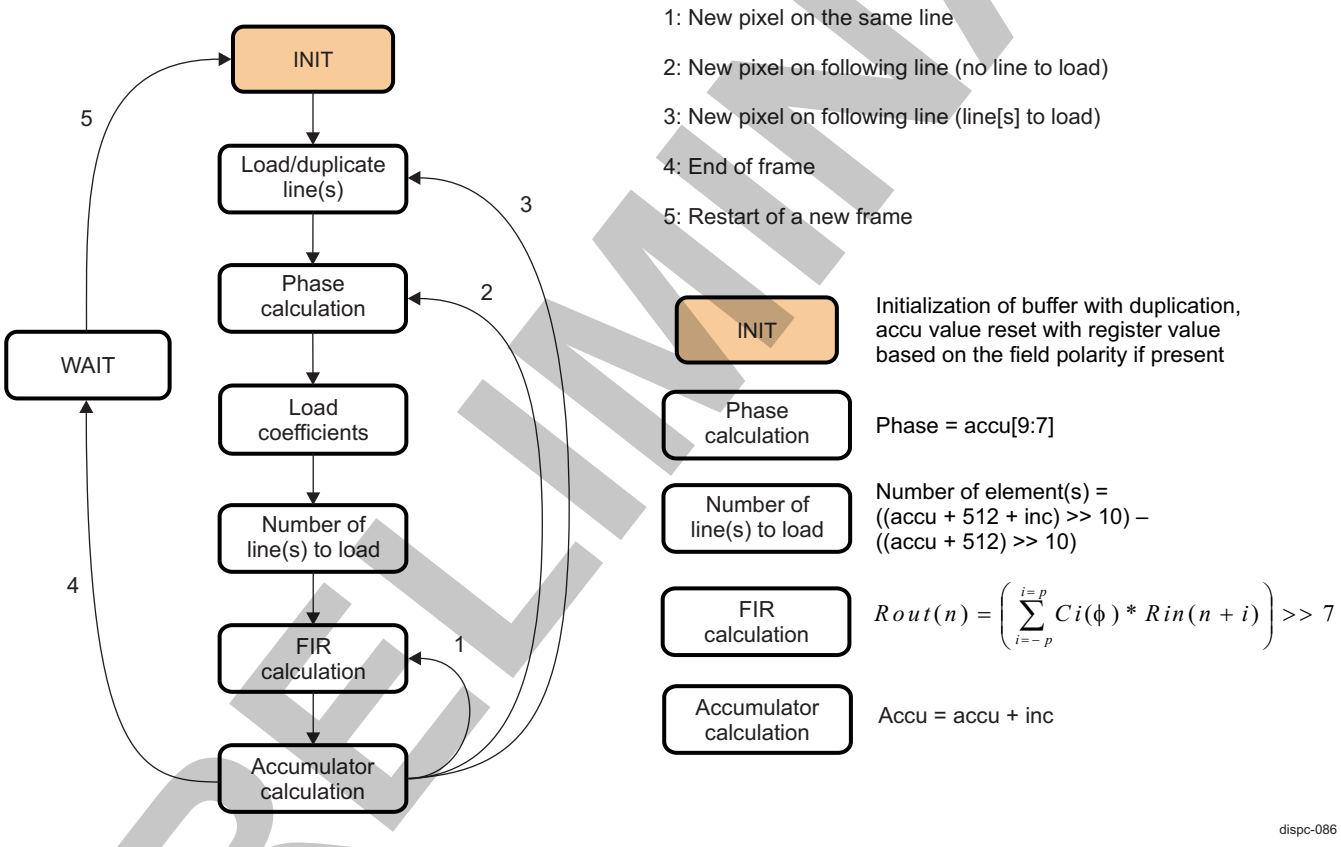

Figure 10-58 shows the horizontal up/downsampling FSM.

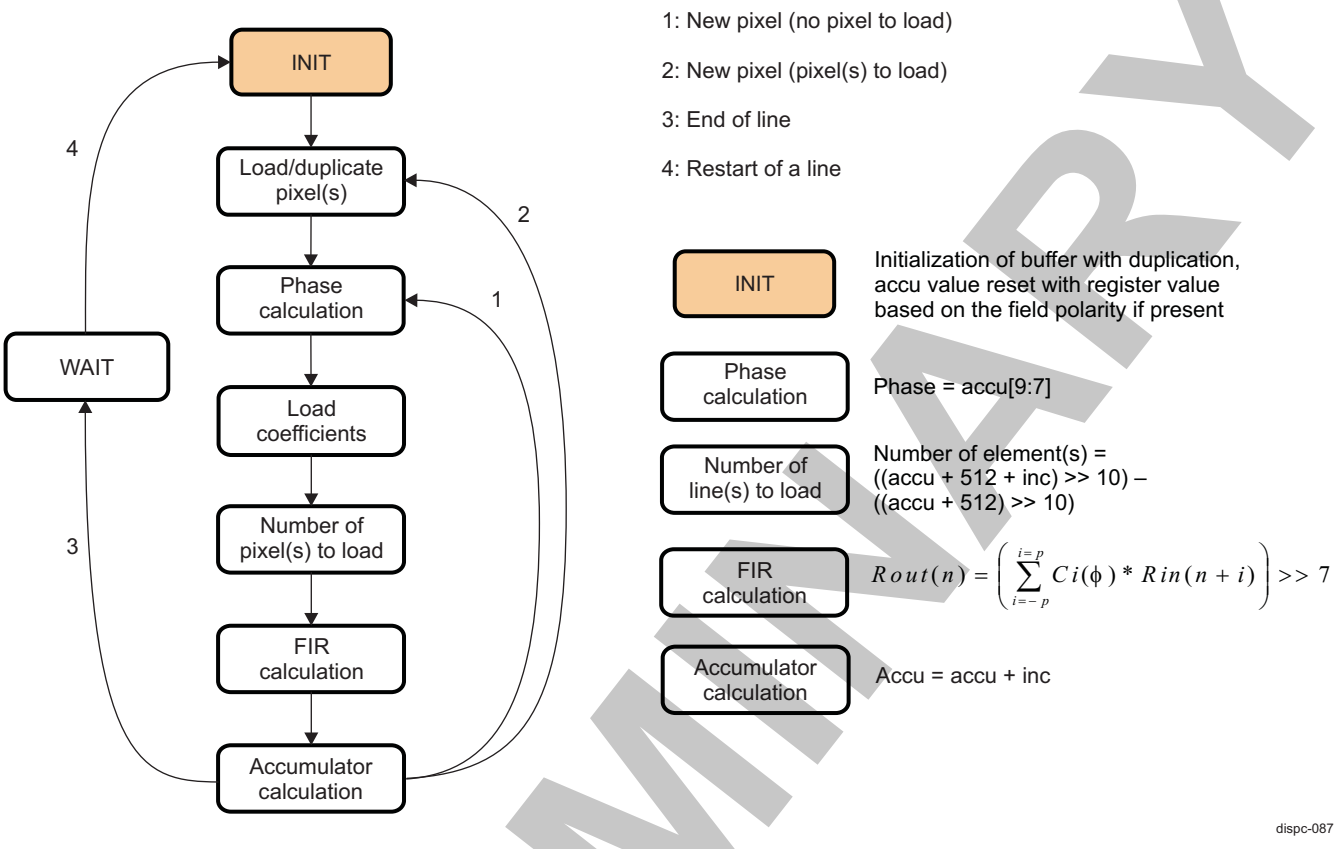
Figure 10-58. DISPC Horizontal Up/Downsampling Algorithm



10.2.4.10.4.2 DISPC Scaling limitations

Table 10-40 lists the minimum ratio between the pixel clock frequency (DSS_DISPC_LCDn_PCLK) and the functional clock (F_CLK) in the input pixel format when using the scaler unit. DSS_DISPC_LCDn_PCLK and F_CLK are asynchronous. For each LCD output, a dedicated LCD clock is programmable with the LCD and PCD divisor values in DISPC_DIVISORo[23:16][7:0].

NOTE: The F_CLK is derived from DSS_FCLK through the LCD divisor.

NOTE: The downscaling ratio is not an integer, it is the ratio F_CLK / DSS_DISPC_LCDn_PCLK, meaning if the ratio is 2.7, then the downscaling ratio is 2.7 and not 2.

Table 10-40. DISPC Pixel Clock Frequency Limitations (Any Pixel Format) – Active Matrix Display

F_CLK/DSS_DISPC_LCDn_PCLK Minimum Ratio	Horizontal Resampling				
	Off	Up	1:1–1:2	1:2–1:3	1:3–1:4
	2 or 1(1)	2 or 1(1))	2	3	4

(1) The minimum ratio can be 1 if the data are output on the rising edge of the PCLK (DISPC_POL_FREQo.IPC = 0); otherwise, the minimum ratio must be 2.

10.2.4.10.4.3 DISPC Filter Coefficients

NOTE: This section provides reference tables with filter-coefficient example values obtained using the Lanczos window function.

All scaler coefficients and their corresponding registers are summarized in Table 10-37 and Table 10-38.

Table 10-41 gives the 40 coefficients for the 8 phases of 5-tap configuration for different values of the downsampling factor M.

Table 10-42 gives the 24 coefficients for the 8 phases of 3-tap configuration for different values of the downsampling factor M.

The selection of coefficients from Table 10-41 and Table 10-42 is based on the target scaling ratio:

- Dividing the scaling ratio by 8 gives the ideal FIR filter cut-off frequency (Fc) and matching decimation factor (M). For example, a scaling ratio of ½ gives an ideal cut-off frequency of 1/16 (in other words, the decimation factor M = 16).
- If a sharper image result is required, then the coefficients corresponding to lower M value than calculated should be selected. For example, a scaling ratio of 1/3 gives M = 24. For sharper image result, the coefficients for M = 22 should be selected. This is the preferred method when using the DISPC scaler unit.
- If a smoother image result is required, then the coefficients corresponding to higher M value than calculated should be selected. In the same example as above, a scaling ratio of 1/3 gives M = 24. For smoother image result, the coefficients for M = 26 should be selected.
- The coefficients for M = 8 could be used for any up-scaling ratio, but are preferred for up-scaling ratios up to 2.
- For up-scaling ratio > 2, in order to avoid possible blockiness and outlines around the image when using filter coefficients for M = 8, the following could be considered:
  - For calculated M = 3, the coefficient values for M = 11 should be used.
  - For calculated M = 2, the coefficient values for M = 16 should be used.
  - For calculated M = 0 to 1, the coefficient values for M = 19 should be used.

Table 10-41. Filter Coefficients (Five Taps)

10.2.4.11 DISPC Write-Back Pipeline

The write-back pipeline is used to store in the system memory the capture of the overlay output or the output of one of the pipelines. The WB pipeline consists of a CSC unit, a scaler unit, and an RGB truncation logic. Because the overlay works on ARGB32-8888 format and the video accelerator works on YUV format, the color space conversion from RGB to YUV is used to directly output to memory the format that can be encoded with no extra processing.

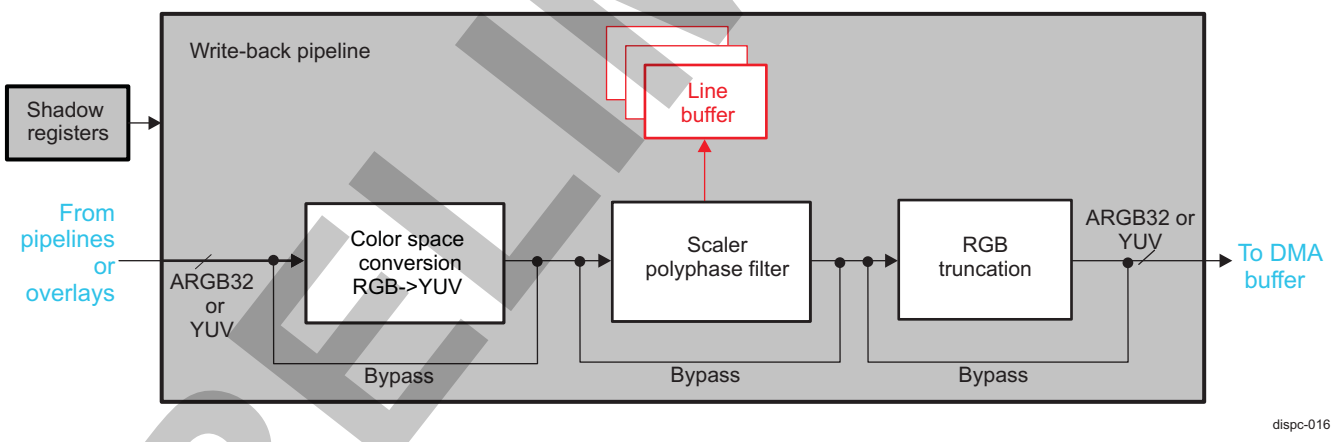
The write-back pipeline is connected to all the pipeline outputs (GFX, VD1, VID2, and VID3 pipelines) and to the output of the three overlay managers (LCD1, LCD2, LCD3, and TV). The input is selected by setting the DISPC_WB_ATTRIBUTES[18:16] CHANNELIN bit field, and the capture frame rate is set in the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field.

Because the output format of the TV overlay manager is ARGB40, the graphics pipeline output is ARGB40, the video pipeline outputs are YUV4:2:2, YUV4:2:0, or ARGB40, and the WB input is ARGB32, the WB input does not consider the 2 LSBs of each ARGB component.

The WB pipeline is enabled by setting the DISPC_WB_ATTRIBUTES[0] ENABLE bit to 0x1.

Figure 10-59 shows the graphics pipeline.

Figure 10-59. DISPC Write-Back Pipeline



10.2.4.11.1 DISPC CSC Unit RGB to YUV

The RGB-to-YUV CSC unit converts the encoded pixel values from RGB24 into YUV4:4:4 format. For YUV4:2:0 or YUV4:2:2 formats, a chrominance sub-sampling is required after converting the RGB into YUV values. Because of the subsampling, the following limitations must be considered:

- When converting RGB into YUV4:2:0 NV12 format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.5
- When converting RGB into YUV4:2:2 format:
  - Maximum horizontal downscale = x0.5
  - Maximum vertical downscale = x0.25

Figure 10-60 and Figure 10-61 show the 3 × 3 11-bit coefficients used to convert from RGB24 into YUV4:4:4. The user sets the coefficients according to the standard used to encode the pixel data in YUV color space. Table 10-43 lists the coefficients with their respective bit fields.

Table 10-43. DISPC CSC RGB to YUV Bit Field Setting

Coefficients	Bit Fields
Y_R	DISPC_WB_CONV_COEF0[10:0] YR
Y_G	DISPC_WB_CONV_COEF0[26:16] YG
Y_B	DISPC_WB_CONV_COEF1[10:0] YB
Cr_R	DISPC_WB_CONV_COEF1[26:16] CRR
Cr_G	DISPC_WB_CONV_COEF2[10:0] CRG
Cr_B	DISPC_WB_CONV_COEF2[26:16] CRB
Cb_R	DISPC_WB_CONV_COEF3[10:0] CBR
Cb_G	DISPC_WB_CONV_COEF3[26:16] CBG
Cb_B	DISPC_WB_CONV_COEF4[10:0] CBB

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit to 0x0.

Figure 10-60. DISPC RGB to YCbCr (FULLRANGE = 0)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 16 \\ 128 \\ 128 \end{bmatrix}$$

dispc-017

If the active range for the luminance samples (Y) and or the chrominance samples (Cb and Cr)is [0:255], the values of Y, Cb, and Cr output components are clipped to the range [0:255]. The range selection is done by setting the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit to 0x1.

Figure 10-61. DISPC RGB to YCbCr (FULLRANGE = 1)

$$\begin{bmatrix} Y_{OUT} \\ Cb_{OUT} \\ Cr_{OUT} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} Y_R & Y_G & Y_B \\ Cb_R & Cb_G & Cb_B \\ Cr_R & Cr_G & Cr_B \end{bmatrix} * \begin{bmatrix} R_{IN} \\ G_{IN} \\ B_{IN} \end{bmatrix} + \begin{bmatrix} 0 \\ 128 \\ 128 \end{bmatrix}$$

dispc-018

10.2.4.11.2 DISPC Scaler Unit

The functional aspect of the WB pipeline scaler unit is identical to the video pipeline scaler unit (see Section 10.2.4.10.4, *DISPC Scaler Unit*), except in the output width when scaling ARGB components. The resulting output format is ARGB32 instead of ARGB40.In addition, the scaling limitations described in Section 10.2.4.10.4.2 are relevant only to the video pipelines scaler units. In WB memory-to-memory mode there are no limitations on the F_CLK/DSS_DISPC_LCDn_PCLK ratio for horizontal resampling.

The programmable coefficients of the polyphase filters are signed 8-bit values (except for the central coefficient, which is unsigned). The WB scaler component has an 8-bit input and an 8-bit output.

Figure 10-62 and Figure 10-63 show the scaler macro-architecture for the component A, R, G, B, and Y. Figure 10-64 and Figure 10-65 show the scaler macro-architecture for component Cr and Cb.

The scaling output can be clipped to an output range of [0:255] or [16:240] by configuring the DISPC_WB_ATTRIBUTES[11] FULLRANGE bit.

Figure 10-62. DISPC Macro-Architecture of the Vertical Scaling for A, R, G, B, and Y Components

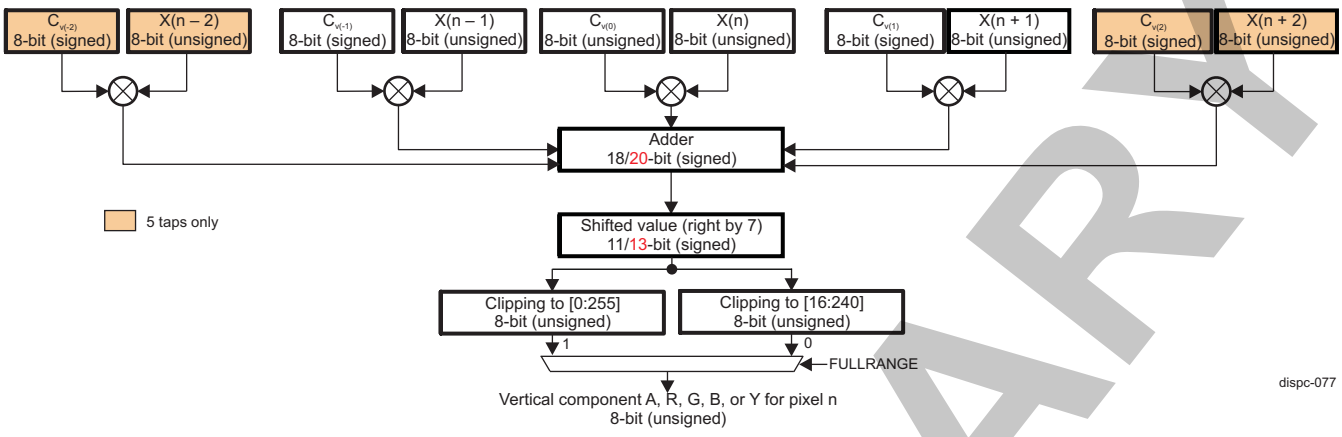


Figure 10-63. DISPC Macro-Architecture of the Horizontal Scaling for A, R, G, B, and Y Components

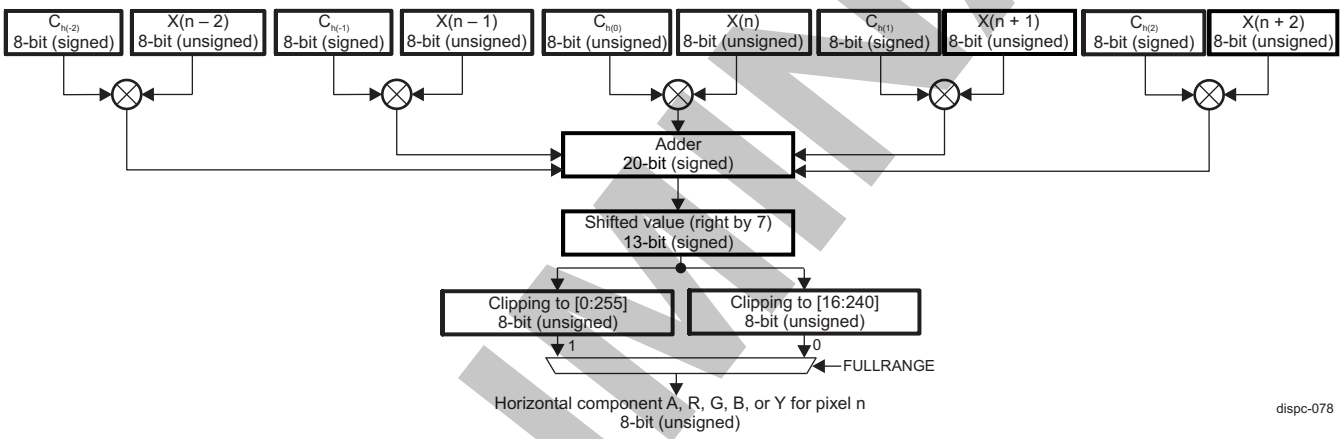

Figure 10-64. DISPC Macro-Architecture of the Vertical Scaling for Cr and Cb Components

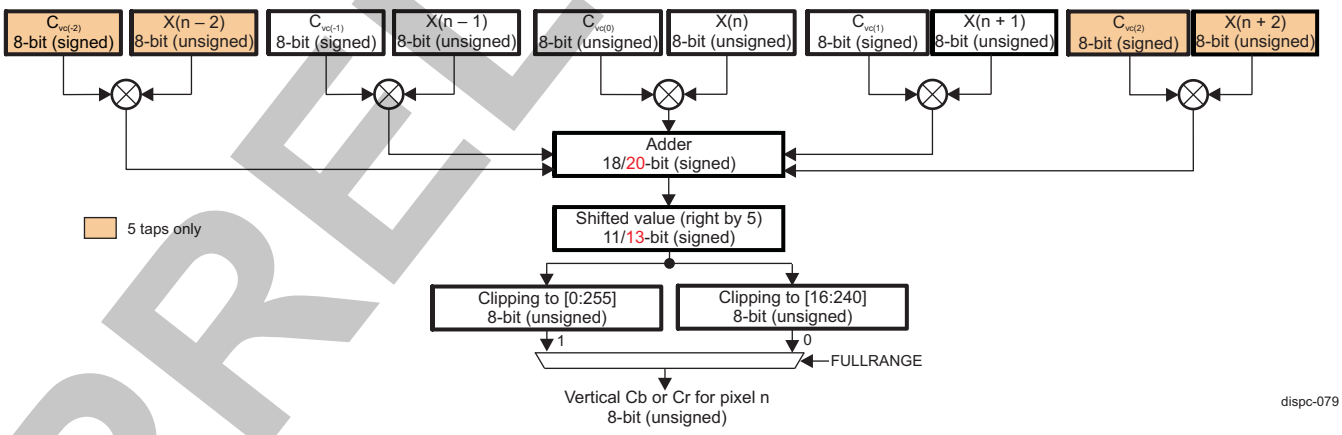

Figure 10-65. DISPC Macro-Architecture of the Horizontal Scaling for Cr and Cb Components

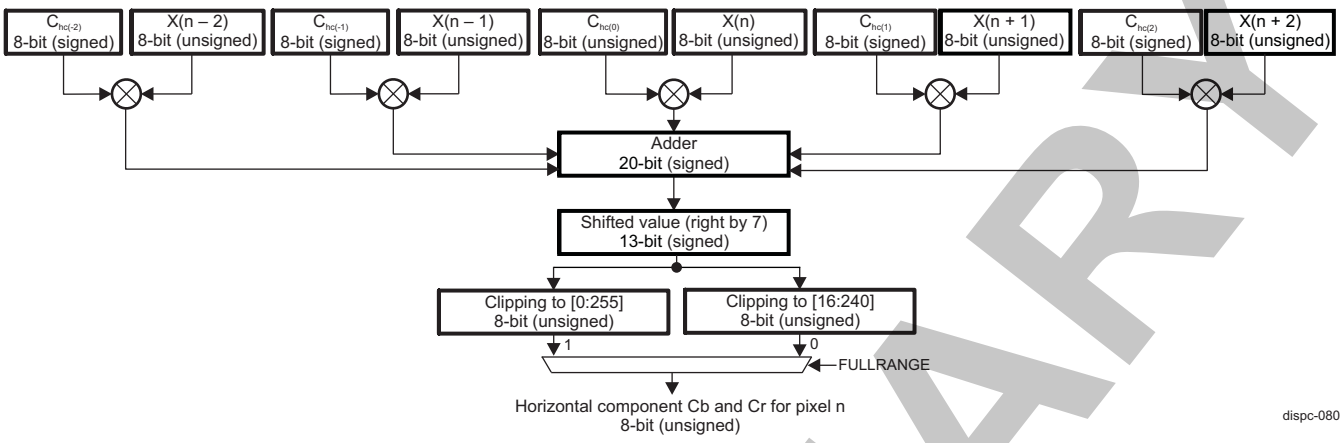

Table 10-44 and Table 10-45 list all the bit fields in the function to set each coefficient.

Table 10-44. DISPC Register Bit Field Associated With Coefficient for ARGB and Y Configuration in WB Scaler

Taps	Coefficient	3 Taps	5 Taps	Registers

	Cvc(2)		FIRVC00	DISPC_WB_FIR_COEF_V2_i
Horizontal	Chc(–2)		FIRHC4	DISPC_WB_FIR_COEF_HV2_i
	Chc(–1)		FIRHC3	DISPC_WB_FIR_COEF_H2_i
	Chc(0)	N/A	FIRHC2	DISPC_WB_FIR_COEF_H2_i
	Chc(1)		FIRHC1	DISPC_WB_FIR_COEF_H2_i
	Chc(2)		FIRHC0	DISPC_WB_FIR_COEF_H2_i

The WB scaler unit vertical or/and horizontal sampling is defined by setting/resetting the DISPC_WB_ATTRIBUTES[6:5] RESIZEENABLE bit field.

A set of configuration must be valid before enabling the video up/downsampling block.

The following fields define the configuration of the video up/downsampling block for WB:

- Vertical up/downsampling increments the value of the DISPC_WB_FIR[28:16] FIRVINC bit field. The unsigned integer value range is [1:4096]. Software calculates the value using the following equation:

$$FIRVINC = 1024 \times \left(\frac{MEMSIZEY}{SIZEY} \right)$$

dispc-066 (12)

NOTE:

- If the value of the DISPC_WB_FIR[28:16] FIRVINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_WB_SIZE[27:16] SIZEY bit field equals 0x1, SIZEY is replaced by 0x2 in the previous equation.
- The values of the DISPC_WB_PICTURE_SIZE[27:16] MEMSIZEY and DISPC_WB_SIZE[27:16] SIZEY bit fields must be programmed with the value desired minus 1.

- Horizontal up/downsampling increments the value of the DISPC_WB_FIR[12:0] FIRHINC bit field: The unsigned integer value range is [1:4096]. Software calculates the value using the following equation:

$$FIRHINC = 1024 \times \left(\frac{MEMSIZEX}{SIZEX} \right)$$

dispc-067 (13)

NOTE:

- If the value of the DISPC_WB_FIR[12:0] FIRHINC bit field is greater than 4096, it is clipped to 4096.
- If the DISPC_WB_SIZE[10:0] SIZEX bit field equals 1, the DISPC_WB_SIZE[10:0] SIZEX bit field is replaced by 2 in the previous equation.
- The value of the DISPC_WB_PICTURE_SIZE[10:0] MEMSIZEX and DISPC_WB_SIZE[10:0] SIZEX bit fields must be programmed with the value desired minus 1.

- Vertical up/downsampling accumulator value DISPC_WB_ACCU_j[26:16] VERTICALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the vertical filtering starts. The register DISPC_WB_ACCU_0 is used for progressive output and for interlace output the DISPC_WB_ACCU_0 and DISPC_WB_ACCU_1 registers are used. Similarly, DISPC_WB_ACCU2_0 and DISPC_WB_ACCU2_1 are used in progressive or interlace output to set the accumulator value of the Cb and Cr components when scaling YUV format.
- Vertical up/downsampling line buffer configuration DISPC_WB_ATTRIBUTES[21] VERTICALTAPS bit: The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used.
- Horizontal up/downsampling accumulator value DISPC_WB_ACCU_j[10:0] HORIZONTALACCU bit field: The signed integer value range is [–1024:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The register DISPC_WB_ACCU_0 is used for progressive output and for interlace output the DISPC_WB_ACCU_0 and DISPC_WB_ACCU_1 registers are used. Similarly, DISPC_WB_ACCU2_0 and DISPC_WB_ACCU2_1 are used in progressive or interlace output to set the accumulator value of Cb and Cr components when scaling YUV format.

Table 10-46 lists the DISPC vertical and horizontal accumulator values and phases.

Table 10-46. DISPC Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128 or –896	1
256 or –768	2
384 or –640	3
512 or –512	4
640 or –384	5
768 or –256	6
896 or –128	7

- Vertical up/downsampling coefficients:
  - The 3-tap vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_HV_i registers. There are 8 registers for the 8 phases with 3 coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).
  - The 5-tap vertical up/downsampling coefficients: Two extra-tap vertical up/downsampling coefficients are defined in the DISPC_WB_FIR_COEF_V_i registers. There are 8 registers for the 8 phases with 2 coefficients for each of them, so a total of 16 programmable coefficients for the vertical up/downsampling block are used in addition to the 3-tap registers previously defined.

  Four YUV vertical up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_HV2_i and DISPC_WB_FIR_COEF_V2_i registers. Table 10-44 and Table 10-45 summarize all coefficients and their respective registers.
- Horizontal up/downsampling coefficients:
  - The DISPC_WB_FIR_COEF_H_i and DISPC_WB_FIR_COEF_HV_i registers define the 5-tap horizontal up/downsampling coefficients. Each DISPC_WB_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each

DISPC_WB_FIR_COEF_HV_i register contains one 8-bit signed coefficient. A total of 40 programmable coefficients for the horizontal up/downsampling block are used.

Four YUV horizontal up/downsampling coefficients are set in the DISPC_WB_FIR_COEF_HV2_i and DISPC_WB_FIR_COEF_H2_i registers. Table 10-44 and Table 10-45 summarize all coefficients and their respective registers.

NOTE: The values and selection criteria for programmable filter coefficients of the WB scaler unit is the same as for VID pipelines (see Section 10.2.4.10.4.3, *DISPC Filter Coefficients*).

10.2.4.11.3 DISPC RGB Truncation Logic

Truncation logic is used to convert a pixel from ARGB 32-bit format into a lower color depth: 12- or 16-bit format based. Setting the DISPC_WB_ATTRIBUTES[10] TRUNCATIONENABLE bit to 0x1 enables the truncation to the pixel format defined by the DISPC_WB_ATTRIBUTES[4:1] FORMAT bit field. The truncation is done by removing the necessary LSB of each component to match the output format. Table 10-47 describes the truncation done on each component of the pixel.

Table 10-47. DISPC Truncation Logic

	A[7:0]	R[7:0]	G[7:0]	B[7:0]
Output Formats	**MSB LSB**	**MSB LSB**	**MSB LSB**	**MSB LSB**
xRGB12-4444	Ignored	R[7:4]	G[7:4]	B[7:4]
RGBx12-4444	Ignored	R[7:4]	G[7:4]	B[7:4]
RGB16-565	Ignored	R[7:3]	G[7:2]	B[7:3]
xRGB16-1555	Ignored	R[7:3]	G[7:3]	B[7:3]
ARGB16-4444	A[7:4]	R[7:4]	G[7:4]	B[7:4]
RGBA16-4444	A[7:4]	R[7:4]	G[7:4]	B[7:4]
ARGB16-1555	A[7]	R[7:3]	G[7:3]	B[7:3]

NOTE: If there is no alpha field in the pixel format description, 0s or 1s must fill the container. 0s must be used for transparent and 1s for opaque. For example, in xRGB12 pixel format, the upper 4 bits are set to 0s because the RGB value is only 12 bits inside a 16-bit container.

10.2.4.12 DISPC LCD Outputs

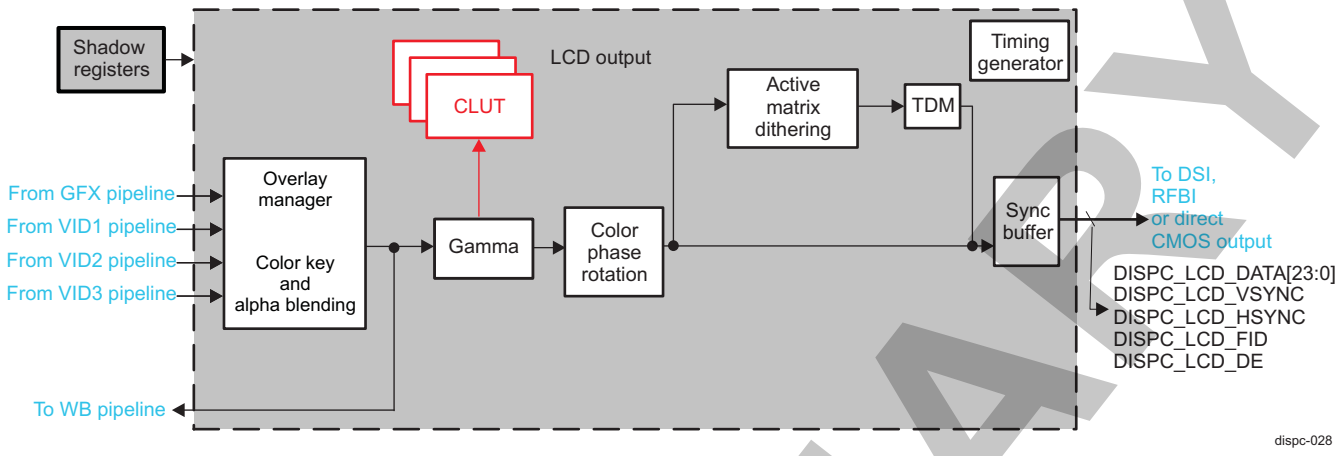
The LCD1, LCD2, LCD3 output paths consist of several processing blocks (see Figure 10-66):

- Overlay manager
- Gamma correction unit
- Color phase rotation (CPR) (also used for RGB-to-YUV conversion)
- Active matrix dithering with TDM
- Synchronization buffer
- Timing generator

The display subsystem supports active matrix technologie (monochrome and color modes):

- Active matrix displays: the configuration of colors depends on the color depth:
  - 24 bpp supports 16,777,216 colors.
  - 18 bpp supports 262,144 colors.
  - 16 bpp supports 65,536 colors.
  - 12 bpp supports 4096 colors.

Figure 10-66. DISPC LCD Output Architecture



10.2.4.12.1 DISPC Overlay Manager

The overlay mechanism consists of displaying more than one layer (GFX, VID1 to VID3 layers) using:

- A priority rule based on a Z-order: Application can set the ordering layer of the frames.
- Transparency color keys: Destination and source transparency color keys can be set.
- Alpha blending values: Using the A component of a pixel or a blending set by the user for a layer, a level of transparency can be determined.

Each pipeline (GFX, VID1, VID2, and VID3) is assigned to a single overlay and, as a consequence, to a single display controller output, LCD1, LCD2, LCD3, TV, or WB pipeline. An overlay manager can be connected to all four pipelines outputs simultaneously. The pipeline output is directed using the DISPC_GFX_ATTRIBUTES[8] CHANNELOUT bit and the DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2 bit field. Table 10-48 summarizes the bit field settings to direct a pipeline to an LCD/TV or WB output. The default value directs all pipelines to LCD1.

Table 10-48. DISPC Pipeline Connection to LCD, TV, or WB Output

	DISPC_GFX_ATTRIBUTES/DISPC_VIDp_ATTRIBUTES	
Overlay Manager/Output	**CHANNELOUT Bit**	**CHANNELOUT2 Bit Field**
LCD1	0x0	0x0
LCD2	0x0	0x1
LCD3	0x0	0x2
WB	0x0	0x3
TV	0x1	0x0 (See the following note.)

NOTE: When CHANNELOUT = 0x1, the settings CHANNELOUT2 = 0x0, 0x1, 0x2, and 0x3 are reserved.

The output of each LCD overlay manager is connected to CPR block through the palette unit in the case of gamma correction.

NOTE:

- When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.
- For LCD1 output, the same CLUT is used for BITMAP support by the graphics pipeline and for gamma correction. In case of BITMAP format for graphics, gamma correction is not available on the primary LCD output.

10.2.4.12.1.1 DISPC Priority Rule

The overlay manager is configured using the Z-order parameter. The Z-order value defined for each pipeline indicates the visibility order to the window on the screen. If the Z-order value of window A is lower than the Z-order to layer B, layer A is displayed below layer B. The transparency color keys and the alpha blending factors are then used to blend the layers together (see Section 10.2.4.12.1.2, *DISPC ALPHA Blender*, and Section 10.2.4.12.1.3, *DISPC Transparency Color Keys*). The Z-order is enabled by setting the DISPC_GFX_ATTRIBUTES[25] ZORDERENABLE bit or the DISPC_VIDp_ATTRIBUTES[25] ZORDERENABLE bit to 0x1 and by defining the Z-order in the DISPC_GFX_ATTRIBUTES[27:26] and DISPC_VIDp_ATTRIBUTES[27:26] ZORDER bit fields. Table 10-49 summarizes the register settings to enable and set the Z-order of a pipeline. Table 10-49 shows the default Z-order values when LCDALPHABLENDERENABLE and ZORDERENABLE are disabled.

Table 10-49. DISPC Z-Order Register Settings and Default Configuration

Pipeline	LCDALPHA BLENDERENABLE[1]	ZORDERENABLE	ZORDER	Resulting Z-Order Number
GFX	0	0	Don't care	0
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	3
VID1	0	0	Don't care	1
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	0
VID2	0	0	Don't care	2
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	1
VID3	0	0	Don't care	3
	0	1	ZORDER	ZORDER
	1	Don't care	Don't care	2

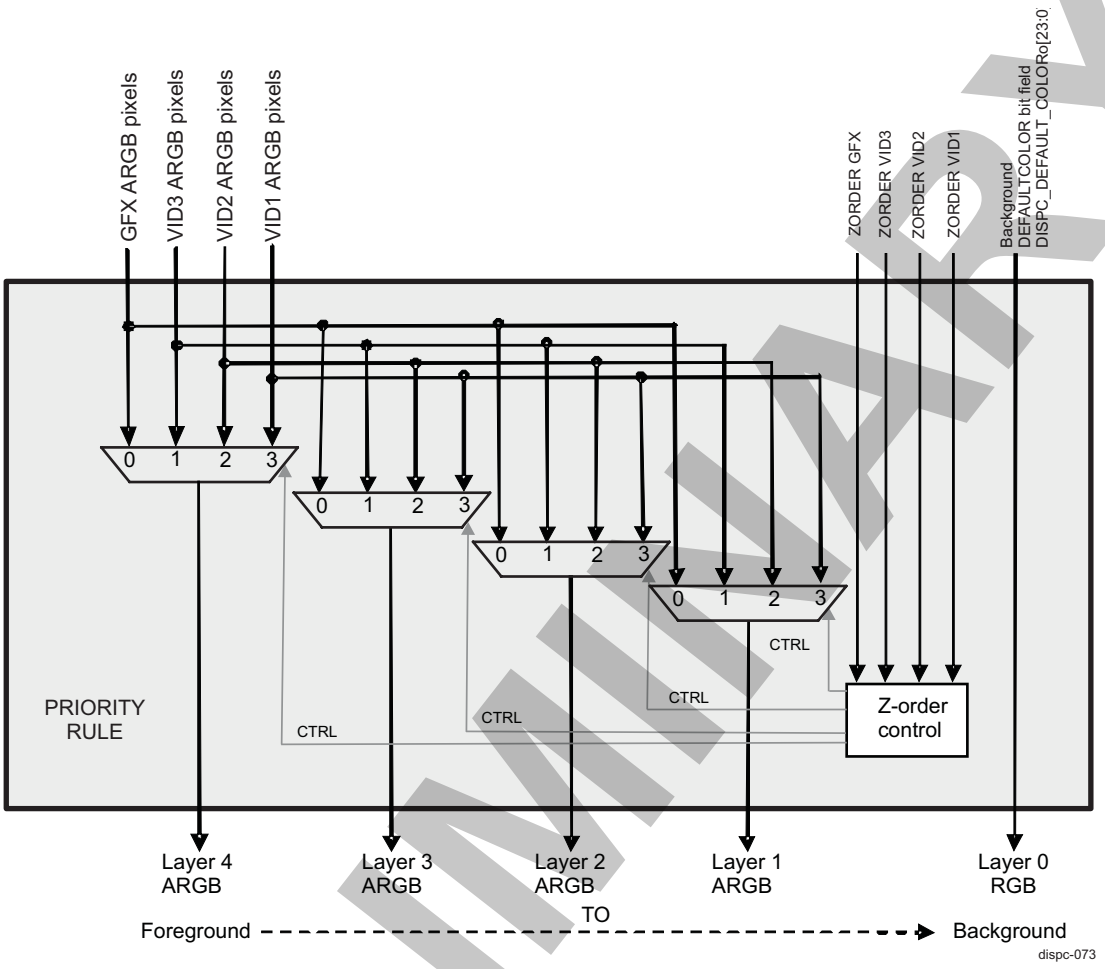
(1) Applies only to LCD1

Figure 10-67 shows the architecture of the priority rule.

NOTE:

- If ZORDERENABLE = 1, each Z-order must be different for each active pipeline. It is not possible to use the same value for more than one pipeline.
- Two modes are maintained for backward compatibility with legacy devices:
  - LCDALPHABLENDERENABLE = 0 and ZORDERENABLE = 0 equivalent to the normal mode overlay settings
  - LCDALPHABLENDERENABLE = 1 equivalent to the alpha mode overlay settings
- When OMAP3430 backward compatibility mode is to be used, the following must be considered:
  - If Z-order is disabled for the VID1 and VID2 pipelines, the pipeline data is output on the LCD1/LCD2/TV overlay.
  - If Z-order is disabled for the VID3 pipeline, the pipeline data is output only on the LCD2 overlay.

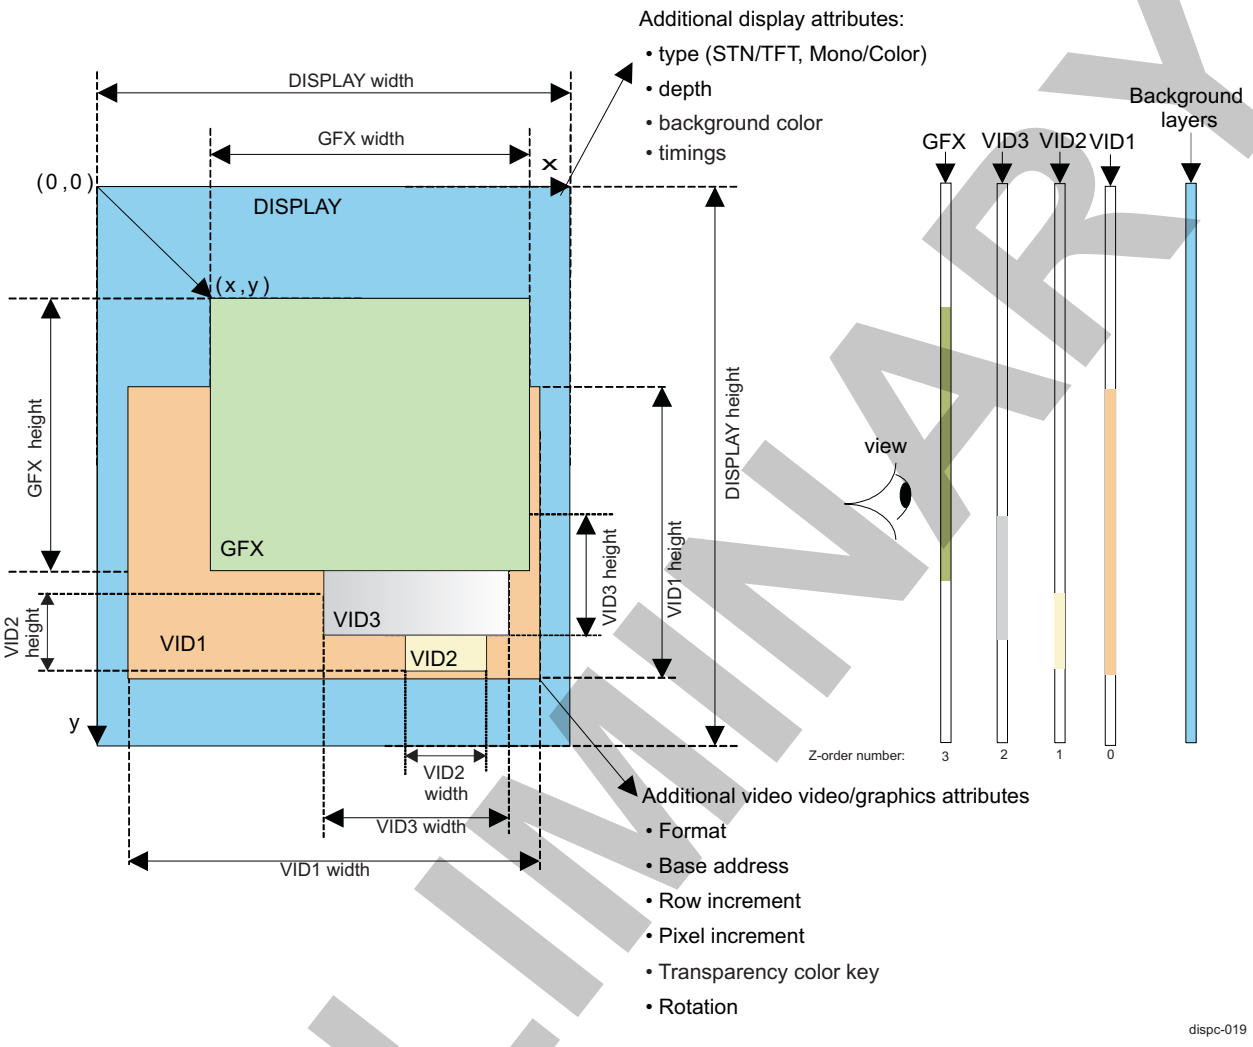
Figure 10-67. DISPC Priority Rule Architecture



The height and width of each enabled layer (pipeline) must be defined in the SIZEX and SIZEY bit fields DISPC_GFX_SIZE[27:16][11:0]/ DISPC_VIDp_SIZE[27:16][11:0], and its x and y positions defined in the POSX and POSY bit fields DISPC_GFX_POSITION[26:16][10:0]/DISPC_VIDp_POSITION[26:16][10:0]. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears. The solid background color is set in the DISPC_DEFAULT_COLORo[23:0] DEFAULTCOLOR bit field. Figure 10-68 is an example of priority rule.

The Z-order reordering block must always map the pipelines to the blender logic in the same order—from background to foreground.

Figure 10-68. DISPC Example of Priority Rule: From Lower to Higher VID1, VID2, VID3, GFX

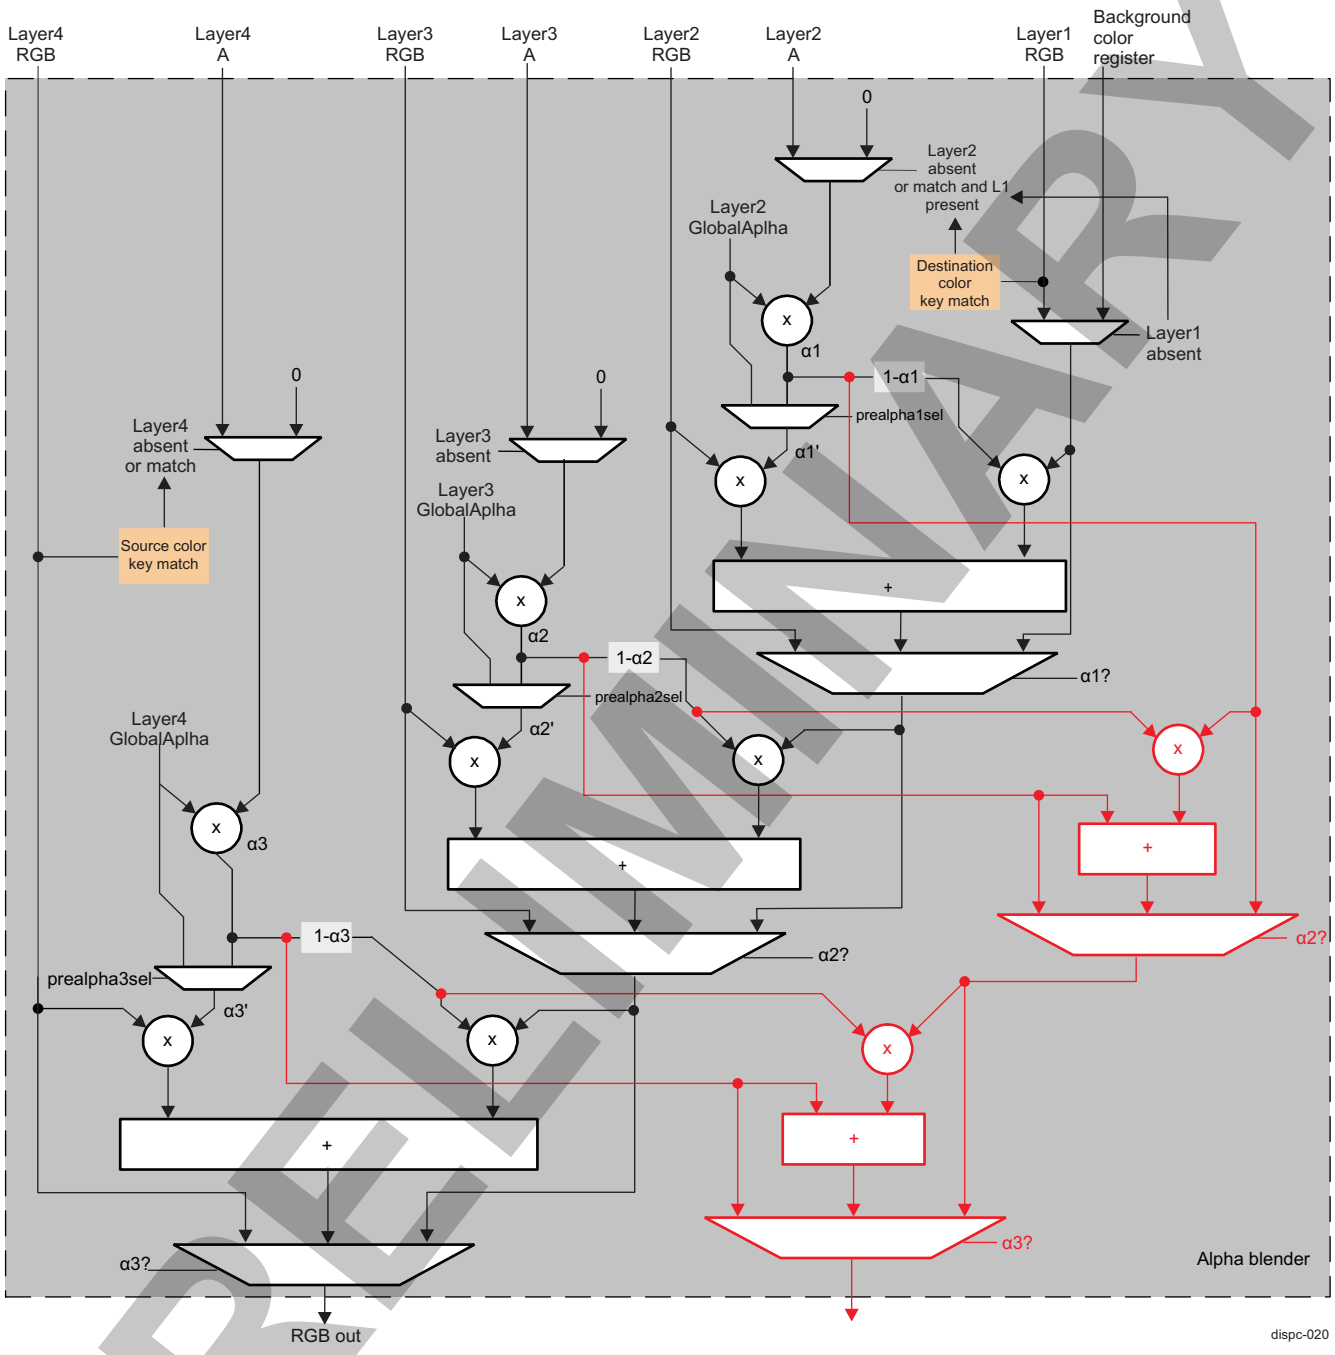


The DISPC is capable of outputting simultaniously two graphic/video windows in frame packing mode. Framepacking mode is enabled from DISPC_GFX_ATTRIBUTES[10] FRAMEPACKINGMODE / DISPC_VIDp_ATTRIBUTES[8] FRAMEPACKINGMODE. The position of the second graphic/video windows is defined in DISPC_GFX_POSITION2 / DISPC_VIDp_POSITION2 registers. The size is again defined in SIZEX and SIZEY bit fields of DISPC_GFX_SIZE[27:16][11:0]/ DISPC_VIDp_SIZE[27:16][11:0] registers.

10.2.4.12.1.2 DISPC Alpha Blender

Figure 10-69 shows the alpha blending processing in detail.

Figure 10-69. DISPC Alpha Blending Architecture With Premultiplied Alpha Support



CAUTION

The Z order of the Source Transparency Layer must have the value 3 (0x3: Z-order 3: layer above all the other layers).

NOTE: 1-alpha operator corresponds to the basic 1s-complement operation.

The alpha blending value is defined by:

- The component value A when using an ARGB or RGBA pixel format.

  - For ARGB-1555, the alpha blending is defined using a 1-bit value. It is converted into an 8-bit value by duplicating the 1-bit value (see Table 10-50).
  - For ARGB-4444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value (see Table 10-50).
  - If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF and if alpha is equal to 0xFF, there is no multiplication.
  - For BITMAP or YUV formats, there is no alpha blending factor associated with each pixel value. Only the global alpha blending factor associated with the window displaying the BITMAP or YUV format is used.
- The global alpha blending value set in the individual bit fields of the DISPC_GLOBAL_ALPHA register for LCD:
  - VID3GLOBALALPHA
  - VID2GLOBALALPHA
  - VID1GLOBALALPHA
  - GFXGLOBALALPHA
- A total alpha blending value can be used when a combination of the pixel alpha blending value A and a global alpha blending is present. The resulting alpha value is determined as: Alpha = (Pixel Alpha × Global Alpha) / 256.

Table 10-50 lists the percentage of alpha blending in the function of the alpha blending value on 8 bits.

Table 10-50. DISPC Alpha Blending – ARGB

Alpha Blending 1-Bit Value	Alpha Blending 4-Bit Value	Alpha Blending 8-Bit Value (Converted Value or Resulting Alpha)	Percent Blending
0x0	0x0	0x00	100 (transparent)
N/A	0x1	0x11	93.33
N/A	0x2	0x22	86.6
N/A	...	...	...
N/A	0xE	0xEE	6.6
0x1	0xF	0xFF	0 (opaque)

Premultiplied Alpha

The image ARGB may have its RGB component already premultiplied with the alpha (ARGB) where:

- R = A*R
- G = A*G
- B = A*B

In that case, the processing is as follows:

- Color component of premultiplied layers are multiplied with the Global Alpha, if Global Alpha is not equal to 0.
- Color component of the composed underlying layers are multiplied with (1-A) × Global Alpha.

The additional premultiplied alpha option is associated with the pipelines GFX, VID1, VID2, and VID3. The option is accessible through the [28] PREMULTIPLYALPHA bit for the respective pipeline register:

- DISPC_GFX_ATTRIBUTES
- DISPC_VID1_ATTRIBUTES
- DISPC_VID2_ATTRIBUTES
- DISPC_VID3_ATTRIBUTES

The following settings are available:

- PREMULTIPLYALPHA bit = 0: Source is not premultiplied with alpha. Full blending is done in the DISPC.

- PREMULTIPLYALPHA bit = 1: Source is premultiplied with alpha. Partial blending is done.

NOTE: The *prealphasel* controls in Figure 10-69, correspond to the PREMULTIPLYALPHA of the pipelines mapped on the respective layers.

The logic marked in red in Figure 10-69 corresponds to the alpha value, computed when the write-back channel copies back to memory the premultiplied color component: A (destination) = A (source) + (1-A (source) × A (destination))

When the DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is cleared, or when the overlay channel is not selected for WB, the computation of the A(destination) is disabled. The default value for DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is 0x0. When the WB is configured to copy back one of the output channels (output of overlay), the following configurations are available:

- The ALPHAENABLE bit is set to 0x1: The WB pipe copies back to memory the premultiplied alpha calculated through the overlay.
- The ALPHAENABLE bit is set to 0x0: The alpha value is not written back.

NOTE: The DISPC_WB_ATTRIBUTES[7] ALPHAENABLE bit is effective only when one of the output channels is written back, otherwise it is ignored.

10.2.4.12.1.3 DISPC Transparency Color Keys

The two transparency color keys are the source transparency color key and the destination transparency color key. The transparency color key can be used only with BITMAP formats (1-, 2-, 4-, and 8-bpp) and RGB formats (ARGB, RGB, RGBA, xRGB, and RGBx). in this case the A information is ignored for the comparison between the pixel value and the color key value. It is possible to use YUV formats with some care because the comparison is between the input pixel value of the overlay manager from pipeline (GFX or one of the VID pipelines depending on the Z-order) and the color key value. The YUV data is converted to RGB format. If the original format is YUV, the user must consider the color space conversion processing to define the RGB color key value used for the comparison.

The transparency color key is enabled by setting the following bits to 0x1:

- DISPC_CONFIG1[10] TCKLCDENABLE (for LCD1)
- DISPC_CONFIG2[10] TCKLCDENABLE (for LCD2)
- DISPC_CONFIG3[10] TCKLCDENABLE (for LCD3)
- DISPC_CONFIG1[12] TCKTVENABLE (for TV)

The transparency color key is determined in the following bit fields.

- DISPC_TRANS_COLOR0[23:0] TRANSCOLORKEY (for LCD1)
- DISPC_TRANS_COLOR2[23:0] TRANSCOLORKEY (for LCD2)
- DISPC_TRANS_COLOR3[23:0] TRANSCOLORKEY (for LCD3)
- DISPC_TRANS_COLOR1[23:0] TRANSCOLORKEY (for TV)

NOTE:

- The video source transparency color key and graphics destination transparency color key cannot be active at the same time.
- For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

- Video source transparency color key

  The value of the video source transparency color key defines the encoded pixel data considered as a transparent pixel. The encoded pixel values with the source color key value are not visible, and the encoded pixel values of the under layers or solid background color are visible (the pixel alpha blending value of layer 4 is forced to 0x00, fully transparent).

  The scaler can be enabled as a preprocessor in the VID pipeline, but it is necessary to consider the

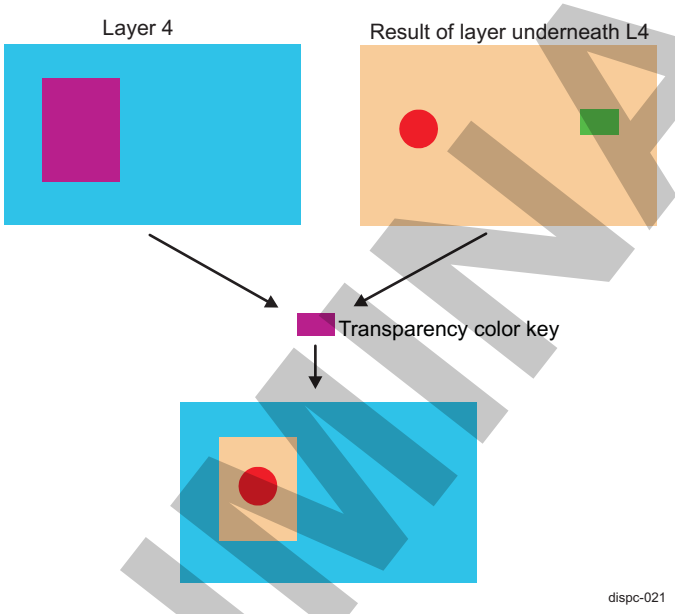
pixel scaling preprocessing in order to define the color key value to be used after the rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

The source transparency color key mode is selected by setting the following bits to 0x1:

– DISPC_CONFIG1[11] TCKLCDSELECTION (for LCD1)
– DISPC_CONFIG2[11] TCKLCDSELECTION (for LCD2)
– DISPC_CONFIG3[11] TCKLCDSELECTION (for LCD3)
– DISPC_CONFIG1[13] TCKTVENABLE (for TV)

Figure 10-70 shows an example of source color key. The pixels with the transparency color key are not displayed; instead, pixels of the resulting layer underneath are shown.

Figure 10-70. DISPC Source Transparency Color Key Example



- Graphics destination transparency color key value

  The graphics destination transparency color key value defines the encoded pixels in layer 1, which are not displayed. Other layer 1 pixels (nonequal to destination transparency color key) are displayed over layer 2. The encoded pixel values with the destination color key value are pixels not visible on the screen because pixels at the same position in layer 2 are visible; otherwise, encoded pixels are visible above layer 2 . The destination transparency color key applies only if layer 1 overlaps layer 2 (see the Z-order section for details on layer position depending on the Z-order parameter in Section 10.2.4.12.1.1, *Priority Rule*); otherwise, the destination transparency color key is ignored.

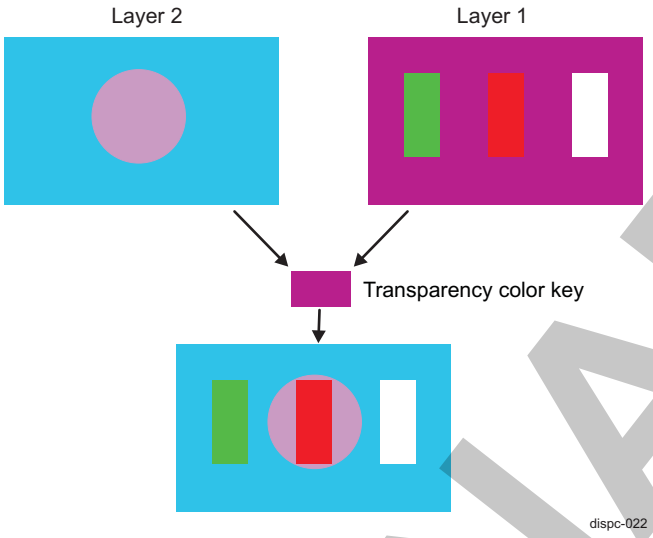
  The scaler can be enabled as a preprocessor in the VID pipeline. It is necessary, however, to consider the pixel scaling preprocessing in order to define the color key value to be used after rescaling for the comparison between the input pixel value to the overlay manager and the color key value.

  The destination transparency color key mode is selected by setting the following bits to 0x0:

  – DISPC_CONFIG1[11] TCKLCDSELECTION (for LCD1)
  – DISPC_CONFIG2[11] TCKLCDSELECTION (for LCD2)
  – DISPC_CONFIG3[11] TCKLCDSELECTION (for LCD3)
  – DISPC_CONFIG1[13] TCKTVSELECTION (for TV)

  Figure 10-71 shows an example of the destination color key. The pixels, equal to the transparency color key, are not displayed and are replaced by layer 2 pixels. All other layer 1 pixels, different from the transparency color key, are displayed over layer 2.

Figure 10-71. DISPC Destination Transparency Color Key Example



10.2.4.12.1.4 DISPC Overlay Optimization

The overlay optimization consists in fetching only the required pixels (that is, pixels that contribute to the final picture to be displayed [LCD1, LCD2, LCD3, or TV]). The decision to fetch the pixel from memory is based on the information available in the registers and on the following rules:

- The layer is enabled.
- The global alpha blending factor for the layer is different than 0x00.
- The current layer is behind an nonopaque layer (global alpha blending factor is different than 0xFF for the layer in the preceding).

The result of the overlay optimization is a reduction of the bandwidth by fetching only the mandatory pixels. The overlay mechanism is independent for each overlay: LCD1, LCD2, LCD3, and TV. Because each layer (GFX, VID1, VID2, and VID3) can be associated to only one overlay at a time, it is possible to optimize the fetch of the pixels for each layer based on the overlay information. The overlay optimization must be run on the DMA engine time window and not on the display time window. The pixels are fetched by the DMA engine before the display processing.

The overlay optimization is enabled by setting the following bits to 0x1:

- DISPC_CONTROL1[12] OVERLAYOPTIMIZATION (for LCD1)
- DISPC_CONTROL2[12] OVERLAYOPTIMIZATION (for LCD2)
- DISPC_CONTROL3[12] OVERLAYOPTIMIZATION (for LCD3)
- DISPC_CONTROL2[13] TVOVERLAYOPTIMIZATION (for TV)

NOTE:

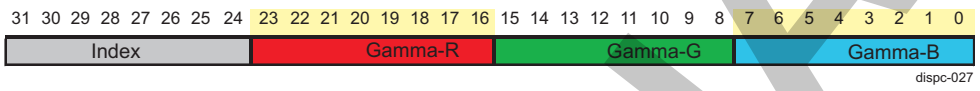
- The overlay optimization is not functional when a layer is using BITMAP1, BITMAP2, BITMAP3, or BITMAP4 pixel formats.
- The pixel alpha blending factor in case of ARGB and RGBA formats cannot be used to take advantage of the pixel fully transparent (alpha blending factor equals 0x00).
- By default, the overlay optimization is disabled (OVERLAYOPTIMIZATION bits = 0x0 for all DISPC outputs), and all the data for all the enabled pipelines are fetched from memory regardless of the overlay or alpha blending configuration.

10.2.4.12.2 DISPC Gamma Correction Unit

In gamma curve mode, the selected encoded pixel values based on the color keys by the overlay manager from the video or graphics paths are sent to the gamma curve table. Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to R, G, or B component. The table is loaded by software. It is possible to load only part of the table. For each access to the table, the 24-bit value is associated with index in the table by concatenating the 24-bit value (LSB of 32-bit access) and the 8-bit index value (MSB of the 32-bit access). Figure 10-72 describes the format of one of the gamma curve values in the memory.

NOTE: If the CLUT is used in the GFX pipeline for palette, the gamma correction unit is not available on the primary LCD.

Figure 10-72. DISPC Data Memory Organization for Gamma Mode in LCD Output



10.2.4.12.3 DISPC Color Phase Rotation Unit

The CPR unit can be used to correct the LCD output colorimetry in case of nonpure white backlight.

The CPR is enabled by setting the DISPC_CONFIGo[15] CPR bit to 0x1. The coefficients are programmed in the following registers:

- Red 10-bit signed coefficients in DISPC_CPRo_COEF_R
- Green 10-bit signed coefficients in DISPC_CPRo_COEF_G
- Blue 10-bit signed coefficients in DISPC_CPRo_COEF_B

The CPR can be selected for active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The CPR can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The CPR is processed by the equation shown in Figure 10-73. Table 10-51 lists all coefficients with their respective bit field registers for settings.

Figure 10-73. DISPC CPR Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} Rr & Rg & Rb \\ Gr & Gg & Gb \\ Br & Bg & Bb \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

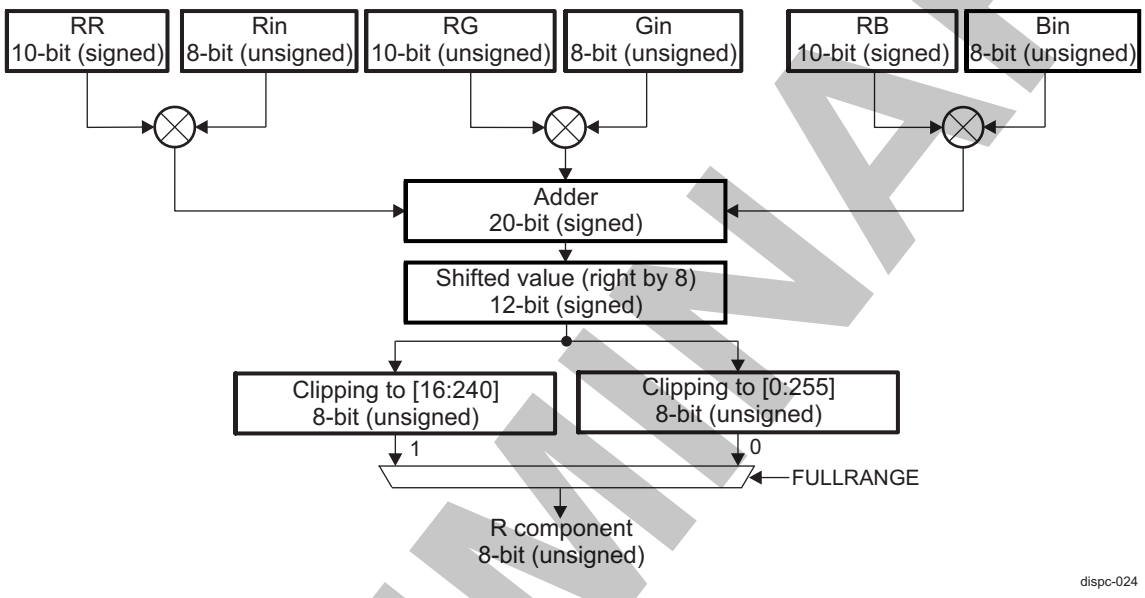
	BB	Bb	Crb

Figure 10-74 shows the CPR macro-architecture.

Figure 10-74. DISPC CPR Macro-Architecture



10.2.4.12.4 DISPC Active Matrix

Depending on the color depth, the active matrix output:

- 24 bpp supports 16,777,216 colors.
- 18 bpp supports 262,144 colors.
- 16 bpp supports 65,536 colors.
- 12 bpp supports 4096 colors.

When in active matrix path configuration, after setting the DISPC_CONTROLo[3] STNTFT bit to 0x1, two submodules must be configured:

- Spatial/temporal dithering
- Multiple cycle output format (TDM)

10.2.4.12.4.1 DISPC Spatial/Temporal Dithering

When the active matrix path is used, the spatial/temporal dithering logic can be selected to enhance the quality of the active matrix outputs. The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The dithering logic is integrated after the CPR and before the TDM. The spatial/temporal dithering algorithm is based on the (x,y) pixel position and frame rate control. The dithering logic can process the pixels over one frame, two frames, or four frames. The number of frames is selected by setting the DISPC_CONTROLo[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field. In the case of a single frame, only spatial processing is applied, and in multiple frames, spatial and temporal processing are applied to the pixels. The spatial/temporal dithering logic is enabled by setting the DISPC_CONTROLo[7] STDITHERENABLE bit to 0x1.

NOTE:

- If the interface data bus is smaller than the pixel format size and spatial/temporal dithering is not enabled, the MSBs of the pixel color components are output on the interface data bus.
- If the interface data bus is larger than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

10.2.4.12.4.2 DISPC Multiple Cycle Output Format (TDM)

The pixels, after the active matrix display processing, are formatted on one or multiple cycles (a maximum of three cycles). The number of bits for each cycle is set in the DISPC_DATAo_CYCLE1 register for the first cycle, the DISPC_DATAo_CYCLE2 register for the second cycle, and the DISPC_DATAo_CYCLE3 register for the third cycle. The interface data bus width can be 8, 9, 12, or 16 bits. The configuration of the data bus is done in the DIPSC_CONTROLo[9:8] TFTDATALINES bit field.

When the TDM is disabled, the DISPC outputs the pixels using the conventional formats: active matrix display monochrome/color.

Figure 10-75 through Figure 10-78 show various examples of TDM settings in the function of pixel data formats and the interface data bus width.

10.2.4.12.5 DISPC Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid it, a synchronization mechanism is used between the DISPC and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. The PROGRAMMEDLINENUMBER_IRQ interrupt (DISPC_IRQSTATUS and DISPC_IRQENABLE) is a level signal and stays active during the programmed line of the display.

10.2.4.12.6 DISPC Timing Generator and Panel Settings

The size of and panel is defined by:

- Number of lines, DISPC_SIZE_LCDo[27:16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_SIZE_LCDo[11:0]PPL bit field, with a value from 1 to 4096

Standard HSYNC/VSYNC timing generation are programmable for each LCD outputs independently:

- Horizontal front porch is set in the DISPC_TIMING_Ho[19:8] HFP bit field.
- Horizontal back porch is set in the DISPC_TIMING_Ho[31:20] HBP bit field.
- Horizontal synchronization pulse width is set in the DISPC_TIMING_Ho[7:0] HSW bit field.
- Vertical front porch is set in the DISPC_TIMING_Vo[19:8] VFP bit field.
- Vertical back porch is set in the DISPC_TIMING_Vo[31:20] VBP bit field.
- Vertical synchronization pulse width is set in the DISPC_TIMING_Vo[7:0] VSW bit field.

Horizontal/vertical synchronization and ACBIAS signals polarity are programmable by setting the DISPC_POL_FREQo[12] IVS, DISPC_POL_FREQo[13] IHS, and DISPC_POL_FREQo[15] IEO bits. These signals can be gated by setting the DISPC_CONFIGo[7] VSYNCGATED and DISPC_CONFIGo[6] HSYNCGATED bits.

The latch of data can be driven on the rising or falling edge of the pixel clock by setting the DISPC_POL_FREQo[14] IPC bit. The drive of the SYNC and VSYNC signals in the function of the pixel clock is done by setting the DISPC_POL_FREQo[16] RF bit.

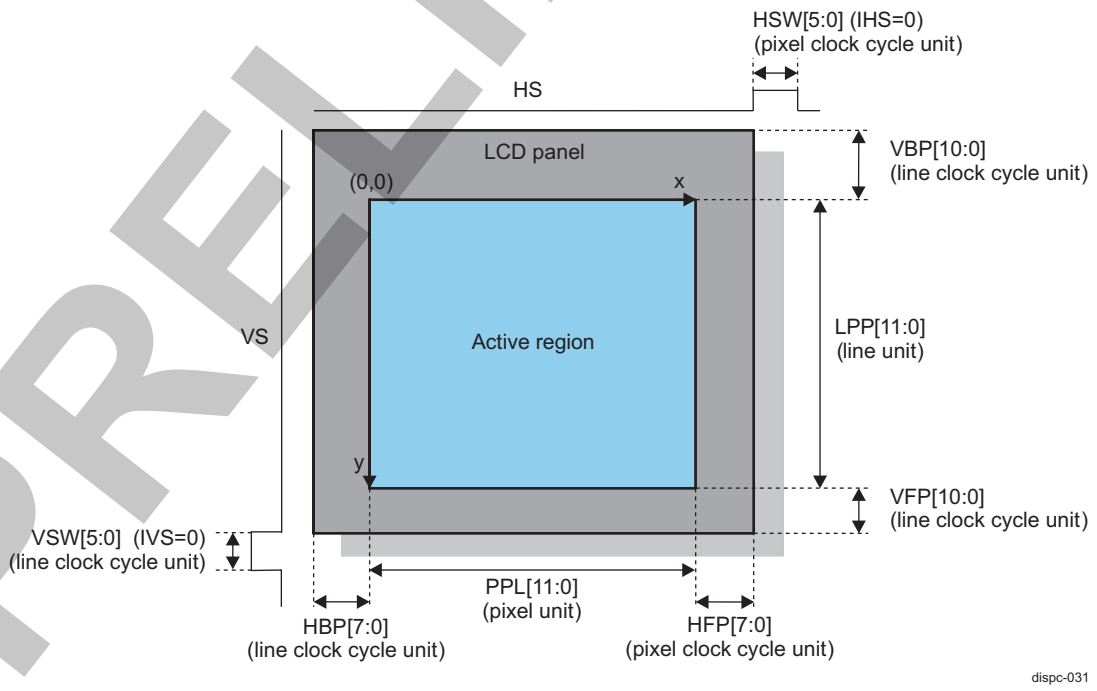
Table 10-52 describes the programming rules for LCD timing.

Table 10-52. DISPC Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) × PCD	>8	>10	>20

Figure 10-79 shows the timing values description in the case of an active matrix display.

Figure 10-79. DISPC Timing Values (Active Matrix Display)



The 8-bit pixel clock divider (the DISPC_DIVISORo[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/2 to LC/256, where LC is the logic clock from the divided functional clock of the DISPC by the DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

Pixel Clock = (FunctionalClock/LCD[7:0])/PCD[7:0]

The pixel clock can be gated by setting the DISPC_CONFIGo[5] PIXELCLOCKGATED bit to 0x1.

The LCD output can be configured in progressive output or interlace output. The selection is done by writing into the DISPC_CONFIGo[22] OUTPUTMODEENABLE bit. The reset value is 0x0, which means progressive mode. When progressive mode is selected, the FID signal associated to the LCD output is driven low (INACTIVE state). The selection can be changed only if the corresponding LCD output is disabled. The configuration is independent for each LCD output.

When in interlaced mode, the DISPC_CONFIGo[23] FIDFIRST bit indicates which field is output first:

- 0x0: Even field first (FID = 0)
- 0x1: Odd field first (FID = 1)

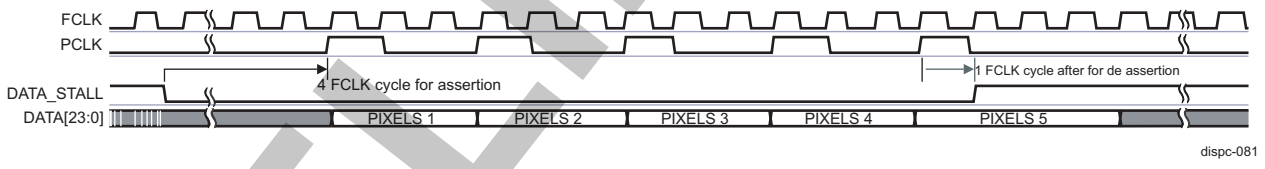
10.2.4.12.7 DISPC Stall Mode

Stall mode is used to indicate when the DISPC must stop sending data on the corresponding LCD output interface to avoid an overflow on the interface level. Stall mode is available when the RFBI and DSI interfaces are used. The Interface asserts the stall signal to stop data output by the DISPC. It is deasserted by the interface to indicate when new data must be output by the DISPC. Figure 10-80 shows the RFBI data stall mode activated.

Stall mode is selected by setting the DISPC_CONTROLo[11] STALLMODE bit.

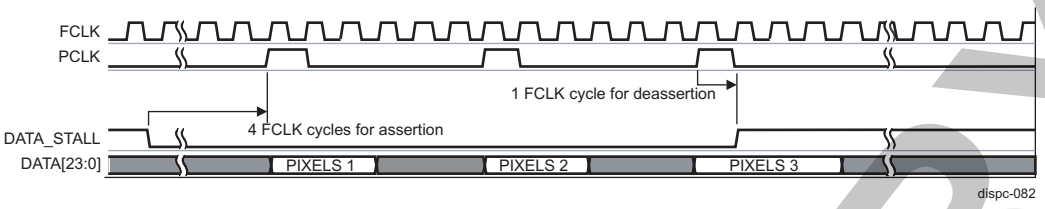
NOTE: The DISPC_CONTROLo[5] GOLCD bit must not be set, but the DISPC configuration (DMA engine, pipelines associated with the LCD output) must be set before enabling the LCD output by setting the DISPC_CONTROLo[1] LCDENABLE bit.

Figure 10-80. DISPC RFBI Data Stall Signal Diagram



To avoid an underflow of the DMA buffer, the DMA buffer handshake must be enabled by setting the DISPC_CONFIGo[16] BUFFERHANDCHECK bit. The fullness of the buffers associated to the pipelines used for the LCD output is checked before providing data to the pipeline when the STALL signal is inactive. It prevents emptying the DMA buffer when the RFBI or DSI module requests data and there is not enough data in the DMA buffer of the DISPC. This feature must be enabled only when stall mode is used (the STALLMODE bit set to 0x1). When the DMA buffer handshake is activated, the pixel transfer to the RFBI or DSI module, outside a STALL period, can be stopped and restarted when there are enough data in the DMA buffer. The DMA buffer handshake ensures that the underflow does not occur for the pipelines associated with the LCD output when RFBI/DSI interfaces are used. The rate of the data transfer to the RFBI or DSI is, then, fully dependent on the state of the DMA buffer. Figure 10-81 shows the RFBI data stall with FIFO handcheck mode activated.

Figure 10-81. DISPC RFBI Data Stall Signal Diagram With Handcheck



Stall mode is independently used when the RFBI or DSI protocol engines are connected to the LCD outputs and receive the pixels to reformat the data.

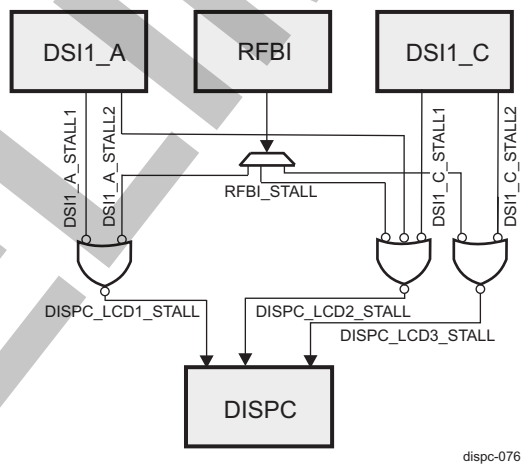
The STALL signals from the RFBI and DSI interfaces are merged into a single signal in the display subsystem. Only one signal for each LCD output is connected to the DISPC. Figure 10-82 shows the STALL signal implementation.

Two STALL signals are generated by the RFBI. The RFBI module asserts the STALL signal when no more data must be output by the DISPC. STALL is deasserted to indicate when new data must be output by the DISPC.

Two STALL signals are generated by the DSI1_A protocol engine. It is used by the DSI1_A protocol engine when data are provided from the DISPC to the DSI1_A protocol engine using the two video ports in command mode only. If one of the two video ports is in video mode, the STALL signal associated with the video port from the DSI1_A protocol engine is not used (it must be in INACTIVE state from the DSI1 protocol engine).

Two STALL signals are generated by the DSI1_C protocol engine. It is used by the DSI1_C protocol engine when data are provided from the DISPC to the DSI1_C protocol engine using the two video ports in command mode only. If one of the two video ports is in video mode, the STALL signal associated with the video port from the DSI1_C protocol engine is not used (it must be in INACTIVE state from the DSI1_C protocol engine).

Figure 10-82. DISPC STALL Signal

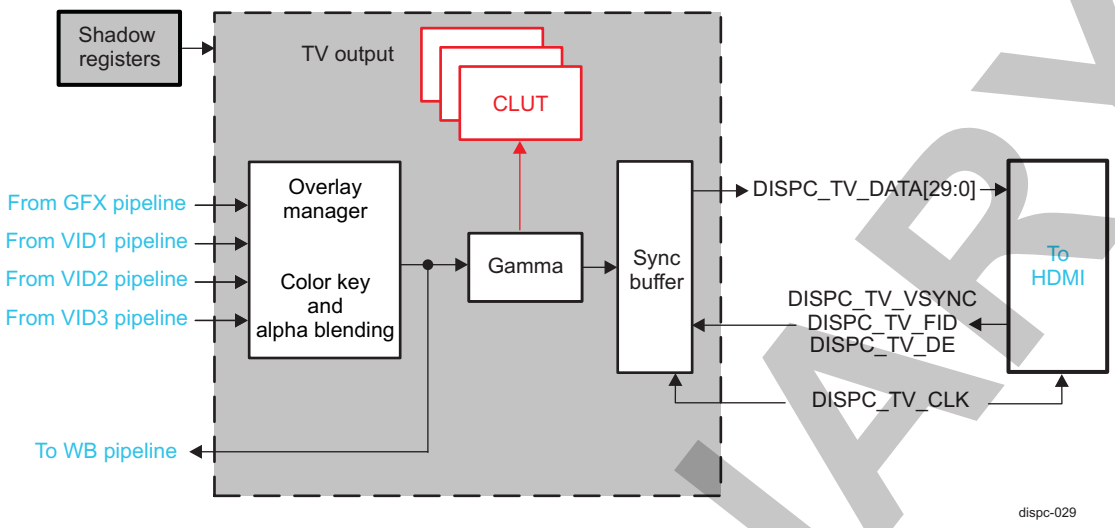


10.2.4.13 DISPC TV Output

The TV output paths consist of several processing blocks (see Figure 10-83):

- Overlay manager
- Gamma correction unit
- Synchronization buffer

Figure 10-83. DISPC TV Output Architecture



The TV output is connected to the HDMI. In analog output or HDMI, the DISPC TV output receives an external clock, DISPC_TV_CLK, and based on the VSYNC generated by the HDMI, hold time, vertical offset, and horizontal offset, outputs the pixels synchronously. The size of the field/frame to output defines the number of pixels to output on each line and the number of lines for each field/frame.

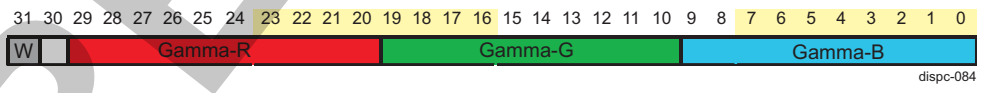
10.2.4.13.1 DISPC Overlay Manager

The overlay mechanism is identical in LCD1, LCD2, and LCD3 (see Section 10.2.4.12.1, *Overlay Manager*).

10.2.4.13.2 DISPC Gamma Correction Unit

The gamma correction unit works as described in Section 10.2.4.12.2, *Gamma Correction Unit*. The only difference is in the input pixel format RGB30. Each component of encoded pixel value is used as a pointer to index 1 out of 1024 30-bit gamma curve entries in the table. Each 10-bit component is replaced with the 10-bit table value corresponding to R, G, or B component. The table is loaded by software, through the DISPC_GAMMA_TABLE2 register. It is possible to load only part of the table. For each write access to the table, the 30-bit gamma value is associated with bit [31] INDEX to indicate that a new table is defined. Setting bit [31] INDEX to 0x1 for the first time, resets the internal index counter. All the following accesses are considered to be for incremented index addressing in the table (bit [31] INDEX is set to 0 for each subsequent access). Figure 10-84 shows the format of one of the gamma curve values in the memory.

Figure 10-84. DISPC Data Memory Organization for Gamma Mode in TV Output



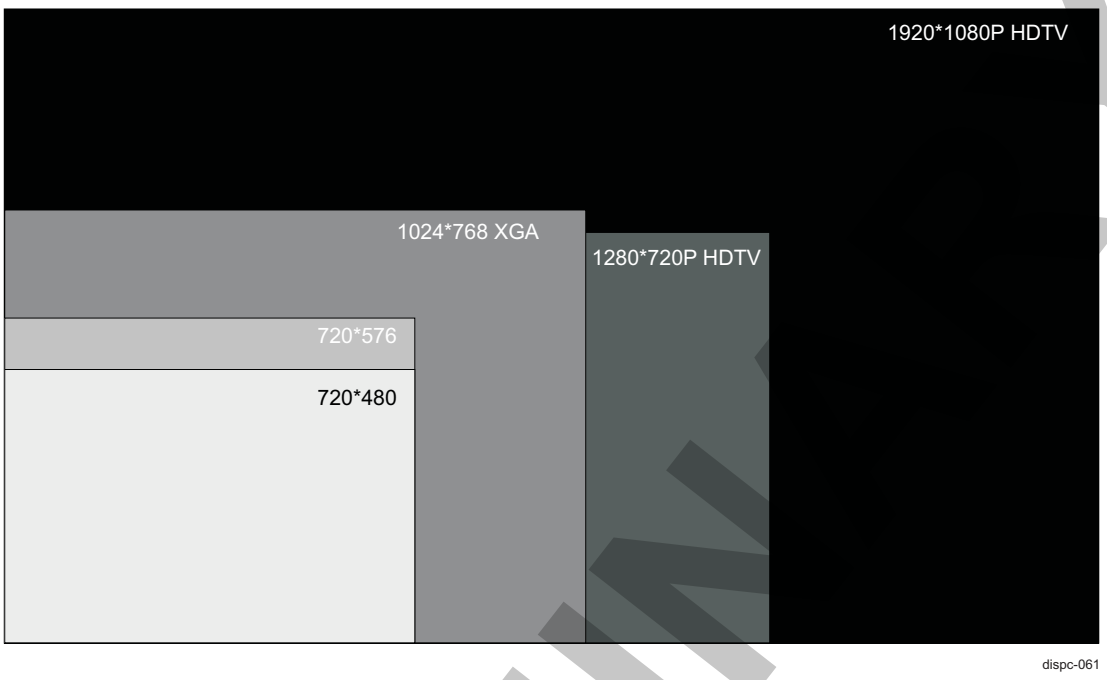
10.2.4.13.3 DISPC Synchronized Buffer Update

The synchronized buffer update is identical in LCD1, LCD2, and LCD3 (see Section 10.2.4.12.5, *Synchronized Buffer Update*).

10.2.4.13.4 DISPC Timing and TV Format Settings

Figure 10-85 shows the TV formats supported.

Figure 10-85. DISPC Example Timing TV Formats



The size of a TV output format is defined by:

- Number of lines, DISPC_SIZE_TV[27:16] LPP bit field, with a value from 1 to 4096
- Number of pixels per line, DISPC_SIZE_TV[11:0] PPL bit field, with a value from 1 to 4096
- Delta size between odd/even field, DISPC_SIZE_TV[15:14] DELTA_LPP bit field. This bit field controls only the output channel and not the size of the data field fetched from the frame buffer in memory.

The hold time of the pixels on the data bus is determined in clock cycles by the DISPC_CONTROL1[19:17] HT bit field. The default value at reset time is 0x0 (one cycle).

- When connected to the HDMI encoder, Table 10-53 indicates the DISPC_SIZE_TV (PPL and LPP) value for each HD standard.

Table 10-53. DISPC PPL and LLP Value for HD Standard

Standards		Active Pixels/Line	Active Lines	Digital Clock	DISPC_SIZE_TV
HDTV	720p	1280	720	74.25/74.125 MHz (60/59.99..frames/s)	0x02CF 04FF
	1080i	1920	540	74.25/74.125 MHz (60/59.99..frames/s)	0x021B 07FF
	1080p	1920	1080	148.5/148.25 MHz (60/59.99..frames/s)	0x0437 07FF
	720p 3D (frame packing)	1280	1470	148.5/148.35/148.5 MHz (60/59.94/50 frames/s)	0x05BD 04FF
	1080p 3D (frame packing)	1920	2205	148.5/148.35 MHz (24/23.98 frames/s)	0x089C 07FF
	1080p 3D (side-by-side half)	1920	1080	148.5 MHz (60 frames/s)	0x0437 07FF

NOTE: When configuring the DISPC for outputting any supported 3D frame-packing format, the following generic details must be considered:

- As defined by the *HDMI v1.4 Specification*, Section 8.2.3.2, 3D frame-packing is a video format structure composed of two stereoscopic pictures: left and right.
- The stereoscopic pictures can be processed through the three video pipelines (VID1, VID2, or VID3). For more information about the configuration of video pipelines, see Section 10.2.4.10, *Video Pipelines*.
- The 3D frame is generated by setting the TV overlay manager to combine the outputs of the selected video pipelines that hold the pictures. One video pipeline (VID1 or VID3) must carry the top field of the 3D frame (left stereoscopic picture), and the other video (VID2) pipeline must always carry the bottom field of the frame (right stereoscopic picture). The top and bottom fields are separated by an active space area. For more information, see the *HDMI v1.4 Specification*, Section 8.2.3.2.
- The pipeline carrying each field (top and bottom) of the 3D frame must have its height and width parameters defined in the [27:16] SIZEY and [11:0] SIZEX bit fields of the DISPC_VIDp_SIZE register, and its Y and X positions defined in the [26:16] POSY and [10:0] POSX bit fields of the DISPC_VIDp_POSITION register. The active space area of the 3D frame can be encoded by setting the solid background color for the TV output (the DISPC_DEFAULT_COLOR1[23:0] DEFAULTCOLOR bit field). For more information about the overlay mechanism, see Section 10.2.4.13.1, *DISPC Overlay Manager*.

10.2.4.14 DISPC Extended 3D Support

The DISPC supports several formats to support 3D displays. The following three sections provide further details.

10.2.4.14.1 DISPC Extended 3D Support - Line Alternative Format

Line alternative format is defined by the HDMI Specification 1.4a. In general the the functionality is:

- Lines from the left and the right frames are interleaved alternatively on the screen to produce a 3D image.
- Required also to support interleaving column-wise to support all possible screen orientations.

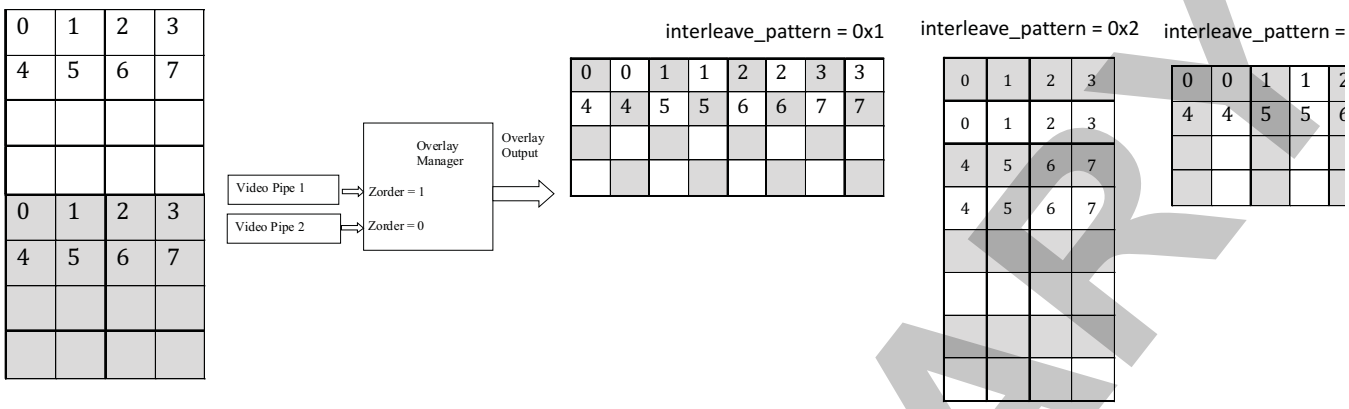
The functionality is done in the overlay manager:

- The layers are grouped into two categories based on the z-order: Odd z-order may blend together and will interleave with even z-order pipes, which may blend together.
- Two types of interleaves are possible, line-based interleaving and pixel-based interleaving to support landscape and portrait screen orientations.

The configuration is done from the DISPC_CONFIG1[29:28] TVINTERLEAVE for the TV output, DISPC_CONFIG1[27:26] PLCDINTERLEAVE for the primary LCD, DISPC_CONFIG2[27:26] SLCDINTERLEAVE for the secondary LCD, and DISPC_CONFIG3[27:26] TLCDINTERLEAVE for the third LCD. The following values apply for the these bitfields:

- 0x0: If zero then no interleaving happens in the overlay manager.
- 0x1: Checkerboard pattern:
  - All even pixels on even lines have a contribution from even z-order pipes.
  - All odd pixels on even lines have a contribution from odd z-order pipes.
  - All even pixels on odd lines have a contribution from odd z-order pipes.
  - All odd pixels on odd lines have a contribution from even z-order pipes.
- 0x2: All even lines (all pixels) have a contribution from even z-order pipes. All odd lines (all pixels) have a contribution from the odd z-order pipes.
- 0x3: All even pixels (for all lines) have a contribution from even z-order pipes. All odd pixels (for all lines) have a contribution from the odd z-order pipes.

Figure 10-86. DISPC Illustration of 3D Interleaving

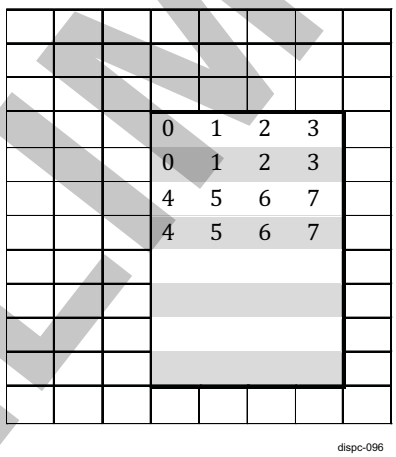


Moreover, from the above figure if interleave_pattern is programmed as 0x2, in this case the entire screen composited by the overlay manager (ppl x lpp) gets sub-divided into odd and even lines. It is possible for a 3D window created using the two pipes to have a non-zero position (i.e. posx and posy not equal to zero).

In such cases depending on the oddness or evenness of the posy setting, the first line in the window maybe from video pipe 1 or video pipe 2.

For instance if the posx =3, posy =3 (set in DISPC_GFX_POSITION, DISPC_VID1_POSITION, DISPC_VID2_POSITION, DISPC_VID3_POSITION registers), then the final composited screen with ppl =8, lpp =12 may look like below:

Figure 10-87. DISPC Illustration of a Non-zero Position of 3D Window



NOTE: In this case the first line comes from the odd-zorder pipe i.e. Video Pipe 1.

The following limitations apply to the 3D Line alternative format:

- Software must ensure that the left/right frames are of same size.
- Software must ensure that in case of line interleaving the sizey is not greater than lpp/2.
- Software must ensure that in case of pixel interleaving the sizex is not greater than ppl/2.
- Software must program PosX and PosY for both left and right frame to be the same.
- Color-keying is not available for 3D formats.
- Since each overlay manager can support 4k x 4k frames, max resolution of each left/right frame will be restricted to 2k x 2k.

10.2.4.14.2 DISPC Extended 3D Support - Frame Packing Format Format

In this mode the pipe fetches two windows (of SizeX X SizeY) during a complete panel frame (ppl X lpp). The mode is enabled from DISPC_GFX_ATTRIBUTES[10] FRAMEPACKINGMODE and DISPC_VID1_ATTRIBUTES[8], DISPC_VID2_ATTRIBUTES[8], DISPC_VID3_ATTRIBUTES[8] FRAMEPACKINGMODE

The position for the first window is set in DISPC_GFX_POSITION, DISPC_VID1_POSITION, DISPC_VID2_POSITION, DISPC_VID3_POSITION, while the position for the second window is set in DISPC_GFX_POSITION2, DISPC_VID1_POSITION2, DISPC_VID2_POSITION2, DISPC_VID3_POSITION2

When it is detected that a pipe has finished sending the programmed number of lines to the overlay or write-back pipe, a reset is generated for the pipe as well as the DMA channel associated with the pipe. At the same instant, the base address configuration for the DMA channel is changed from the BA0 to the BA1.

Due to the reset the pipe and DMA starts fetching the data from BA1. At the end of the processing of BA1 data, the DMA channel and the pipe become idle and clock gated.

The overlay manager composes the final frame to be sent to the panel and uses the posx, posy coordinates for the first window and posx2, posy2 for the second window.

The following limitations apply to the 3D Frame Packing format:

- Only frame packing for progressive mode is supported. Frame packing of interlaced formats is not supported.
- End-of-window interrupts will be generated twice per outgoing-frame.
- Flip Immediate will not work as expected.
- It is software responsibility to calculate and program the posx2, posy2 as per the active space required by the panel.

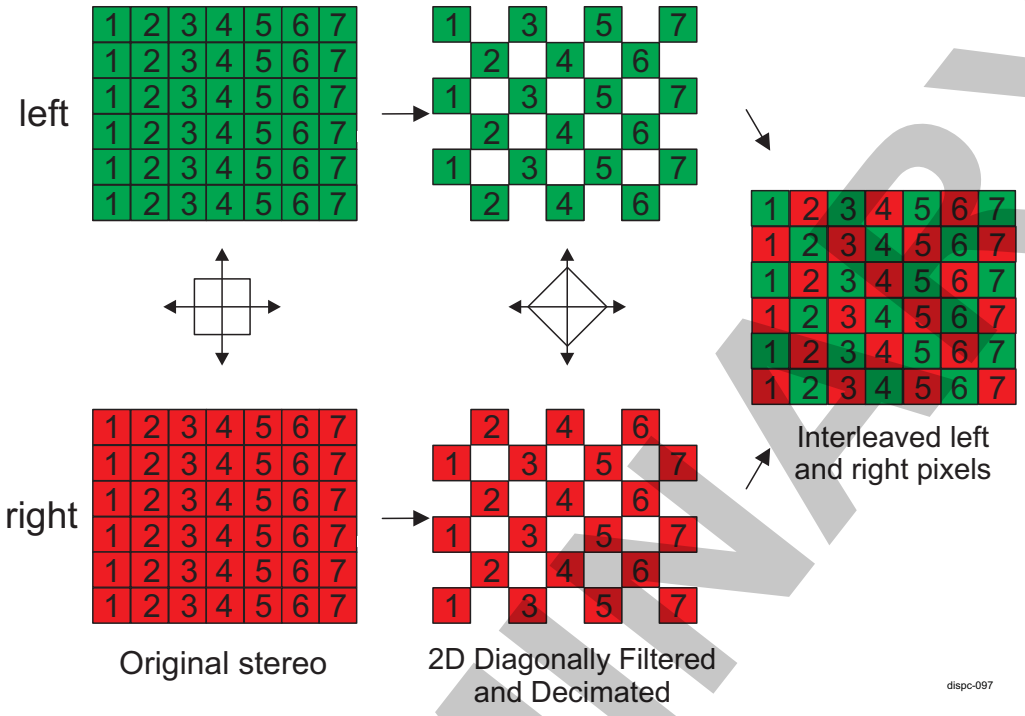
10.2.4.14.3 DISPC Extended 3D Support - DLP 3D Format

The DLP 3D format sub-samples the left and right frames across the diagonal before interleaving the frames in a checker-board fashion.

The sub-sampling required on the left and the right frame is complementary. This sampling pattern is also defined in the HDMI 3D Specification 1.4a as two Quincunx matrices. The format is configured from DISPC_GFX_ATTRIBUTES[20:18] SUBSAMPLINGPATTERN, DISPC_VID1_ATTRIBUTES2[11:9], DISPC_VID2_ATTRIBUTES2[11:9], DISPC_VID3_ATTRIBUTES2[11:9] SUBSAMPLINGPATTERN with the following possible configuration:

- 0x0: All pixels from the pipes are used. No sub-sampling.
- 0x1: Quincunx Matrix Odd-position sub-sampling is used.
- 0x2: Quincunx Matrix Even-position sub-sampling is used.
- 0x3 to 0x7: Reserved

Figure 10-88. DISPC Illustration of DLP 3D Format



The following limitations apply to the DLP 3D Format :

- Even z-order pipes can have only sub-sampling = 0x1. Odd z-order pipes can only have sub-sampling = 0x2.

10.2.4.15 DISPC Shadow Registers

Some DISPC registers are termed *shadow registers*. A shadow register change has no direct effect on the configuration of the DISPC. The registers are shadow registers let software change the values of the registers at any time. When all the registers for a given configuration are into the registers, software must set 1 bit only to validate the configuration. When hardware reaches the end of the current frame and sees that the bit field has been set by software, the new configuration is now the configuration used by the hardware.

NOTE: As a general rule, all shadow registers are updated with the value of their shadows when:

- The interface is enabled.
- The GO bit field of the pipeline, with which the register is associated, is set and the output sync is active.

The bits enabling the hardware to use the new configuration are:

- DISPC_CONTROL1[5] GOLCD bit for all the registers associated to the LCD1 output, and for all registers of WB and DMA, if the LCD1 channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.
- DISPC_CONTROL1[6] GOTV bit for all the registers associated to the TV output, and for all registers of WB and DMA, if the TV channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the external EVSYNC.
- DISPC_CONTROL2[5] GOLCD bit for all the registers associated to the LCD2 output, and for all registers of WB and DMA, if the LCD2 channel is captured. The update of the registers of the WB and

DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.

- DISPC_CONTROL3[5] GOLCD bit for all the registers associated to the LCD3 output, and for all registers of WB and DMA, if the LCD3 channel is captured. The update of the registers of the WB and DMA is further delayed by the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNTER bit field or done when the next frame is captured (the DISPC_WB_ATTRIBUTES[26:24] CAPTUREMODE bit field must be different from 0). The update of the registers occurs at the VFP start period.
- DISPC_WB_ATTRIBUTES[0] ENABLE bit for all the registers associated to the WB, if the transfer memory-to-memory is not associated with a channel out.
- The DISPC_CONTROL2[6] GOWB bit and the [5] GOLCD and [6] GOTV bits in the DISPC_CONTROL1/DISPC_CONTROL2 registers, combined with the synchronization event of the channel output selected for write back. This applies to all registers associated with the selected channel out and further delayed by the setting in the DISPC_WB_ATTRIBUTES2[7:0] WBDELAYCOUNT bit field, for all registers of the write back and DMA. The GOWB bit is required to be set only in WB capture mode; it is not required when WB memory-to-memory mode is used.

NOTE: Before setting the GOLCD, GOTV, or GOWB bits, the user must ensure that the bits are cleared. The hardware resets the bits when the update completes.

Table 10-54 lists the shadow registers. Registers that do not have a mark in any column are not shadowed.

10.2.5 DISPC Programming Guide

10.2.5.1 DISPC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

10.2.5.1.1 DISPC Global Initialization

10.2.5.1.1.1 DISPC Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DISPC module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DISPC. For more information, see Section 10.2.3, *DISPC Integration*, and , *DISPC Environment*.

Table 10-55. DISPC Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See , *PAD Functional Multiplexing and Configuration*, in *Chapter 18, Control Module*.
MPU INTC or DSP INTC	MPU and/or DSP interrupt controller configuration must be done to enable the interrupts from the DISPC. See , *Interrupt Controllers Overview*, in Chapter 17, *Interrupt Controllers*.
Interconnect	For more information about interconnect configuration, see , L3 Interconnect, in Chapter 14, *Interconnects*.

10.2.5.1.2 DISPC Operational Modes Configuration

Table 10-56 lists the steps to configure the operational modes in the DISPC.

Table 10-56. DISPC Configuration

Step	Register/Bit Field/Programming Model
For a GFX pipeline configuration	
Configure the GFX DMA channel.	See Table 10-57.
Configure the GFX pipeline.	See Table 10-60.
Configure the LCD or TV output.	For LCD output, see Table 10-78.
	For TV output, see Table 10-85.
For a Video pipeline configuration	
Configure the video DMA channel.	See Table 10-58.
Configure the video pipeline.	See Table 10-65.
Configure the LCD or TV output.	For LCD output, see Table 10-78.
	For TV output, see Table 10-85.
For a WB pipeline configuration	
Configure the WB DMA channel.	See Table 10-59.
Configure the WB pipeline.	For video pipelines, see Table 10-73.

10.2.5.1.2.1 DISPC DMA Configuration

10.2.5.1.2.1.1 DISPC Main Sequence – DISPC DMA Channel Configuration

This procedure describes the parameters of the GFX, video, and WB DMA channel parameters (see Table 10-57 through Table 10-59, respectively).

Table 10-57. DISPC Configure the GFX DMA Channel

Step	Register/Bit Field/Programming Model	Value
Set the base address for RGB pixel format or BITMAP component format according to memory access type, rotation, mirroring (see Section 10.2.4.6, *DISPC DMA Engine*).	DISPC_GFX_BA_j[31:0] BA	0x—
Set the rotation flag.	DISPC_GFX_ATTRIBUTES[13:12] ROTATION	0x–
Set the number of bytes to increment at the end of the row.	DISPC_GFX_ROW_INC[31:0] ROWINC	0x–
Set the number of bytes to increment between two pixels.	DISPC_GFX_PIXEL_INC[7:0] PIXELINC	0x–
Determine the FIFO preload mode.	DISPC_GFX_ATTRIBUTES[11] BUFPRELOAD	0x–
Set the preload value.	DISPC_GFX_PRELOAD[11:0] PRELOAD	0x–
Determine the burst type.	DISPC_GFX_ATTRIBUTES[29] BURSTTYPE	0x–
Set the burst size.	DISPC_GFX_ATTRIBUTES[7:6] BURSTSIZE	0x–
Set the high level of DMA FIFO threshold.	DISPC_GFX_BUF_THRESHOLD[31:16] BUFHIGHTRESHOLD	0x–
Set the low level of DMA FIFO threshold.	DISPC_GFX_BUF_THRESHOLD[15:0] BUFLOWTRESHOLD	0x–
Enable self-refresh.	DISPC_GFX_ATTRIBUTES[24] SELFREFRESH	0x–
Select priority over the other pipeline.	DISPC_GFX_ATTRIBUTES[23] ARBITRATION	0x–

Table 10-58. DISPC Configure the Video DMA Channel

Step	Register/Bit Field/Programming Model	Value
Set the base address for RGB pixel format or Y component format according to memory access type, rotation, mirroring (seeSection 10.2.4.6, *DISPC DMA Engine*).	DISPC_VIDp_BA_j[31:0] BA	0x—
Set the base address for Cb and Cr components according to memory access type, rotation, mirroring (seeSection 10.2.4.6, *DISPC DMA Engine*)[(1)].	DISPC_VIDp_BA_UV_j[31:0] BA	0x—
Set the rotation flag.	DISPC_VIDp_ATTRIBUTES[13:12] ROTATION	0x–
Set the number of bytes to increment at the end of the row.	DISPC_VIDp_ROW_INC[31:0] ROWINC	0x–
Set the number of bytes to increment between two pixels.	DISPC_VIDp_PIXEL_INC[7:0] PIXELINC	0x–
Set the X original image size.	DISPC_VIDp_PICTURE_SIZE[10:0] MEMSIZEX	0x–
Set the Y original image size.	DISPC_VIDp_PICTURE_SIZE[27:16] MEMSIZEY	0x–
Determine the FIFO preload mode.	DISPC_VIDp_ATTRIBUTES[19] BUFPRELOAD	0x–
Set the preload value.	DISPC_VIDp_PRELOAD[11:0] PRELOAD	0x–
Determine the burst type.	DISPC_VIDp_ATTRIBUTES[29] BURSTTYPE	0x–
Set the burst size.	DISPC_VIDp_ATTRIBUTES[15:14] BURSTSIZE	0x–
Set the high level of DMA FIFO threshold.	DISPC_VIDp_BUF_THRESHOLD[31:16] BUFHIGHTRESHOLD	0x–
Set the low level of DMA FIFO threshold.	DISPC_VIDp_BUF_THRESHOLD[15:0] BUFLOWTRESHOLD	0x–
Enable self-refresh.	DISPC_VIDp_ATTRIBUTES[24] SELFREFRESH	0x–
Select priority over the other pipeline.	DISPC_VIDp_ATTRIBUTES[23] ARBITRATION	0x–

(1) Applicable only for YUV pixel format

Table 10-59. DISPC Configure the WB DMA Channel

Step	Register/Bit Field/Programming Model	Value
Set the base address for RGB pixel format or Y component format according to memory access type, rotation, mirroring (see Section 10.2.4.6, *DISPC DMA Engine*).	DISPC_WB_BA_j[31:0] BA	0x—
Set the base address for Cb and Cr components according to memory access type, rotation, mirroring (see Section 10.2.4.6, *DISPC DMA Engine*) (1).	DISPC_WB_BA_UV_j[31:0] BA	0x—
Set the stride of CbCr component (2).	DISPC_WB_ATTRIBUTES[22] DOUBLESTRIDE	0x–
Set the rotation flag.	DISPC_WB_ATTRIBUTES[13:12] ROTATION	0x–
Set the number of bytes to increment at the end of the row.	DISPC_WB_ROW_INC[31:0] ROWINC	0x–
Set the number of bytes to increment between two pixels.	DISPC_WB_PIXEL_INC[7:0] PIXELINC	0x–
Set the X final image size in system memory.	DISPC_WB_PICTURE_SIZE[10:0] ORGSIZEX	0x–
Set the Y final image size in system memory.	DISPC_WB_PICTURE_SIZE[27:16] ORGSIZEY	0x–
Set the burst size.	DISPC_WB_ATTRIBUTES[15:14] BURSTSIZE	0x–
Set the high level of DMA FIFO threshold.	DISPC_WB_BUF_THRESHOLD[31:16] BUFHIGHTRESHOLD	0x–
Set the low level of DMA FIFO threshold.	DISPC_WB_BUF_THRESHOLD[15:0] BUFLOWTRESHOLD	0x–
Select priority over the other pipeline.	DISPC_WB_ATTRIBUTES[23] ARBITRATION	0x–

(1) Applicable only for YUV pixel format
(2) Applicable only for YUV pixel format

10.2.5.1.2.2 DISPC GFX Pipeline Configuration

10.2.5.1.2.2.1 DISPC Main Sequence – Configure the GFX Pipeline

This procedure details the steps for a GFX pipeline configuration (see Table 10-60).

Table 10-60. DISPC Configure the GFX Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the GFX window.	See Table 10-61.	
Configure the GFX pipeline processing.	See Table 10-62.	
Configure the GFX pipeline layer output.	See Table 10-64.	
Validate the GFX configuration according to outputs associated to the pipeline.	DISPC_CONTROL1[5] GOLCD	
	DISPC_CONTROL2[5] GOLCD	
	DISPC_CONTROL2[6] GOWB	
	DISPC_CONTROL1[6] GOTV	
Enable the GFX pipeline.	DISPC_GFX_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.2.2 DISPC Subsequence – Configure the GFX Window

This subsequence describes the parameters of the image to be displayed on the LCD panel (see Table 10-61).

Table 10-61. DISPC Configure the GFX Window

Step	Register/Bit Field/Programming Model	Value
Select the format of image.	DISPC_GFX_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be displayed onto LCD panel.	DISPC_GFX_SIZE[11:0] SIZEX	0x–
Set the Y size of image to be displayed onto LCD panel.	DISPC_GFX_SIZE[27:16] SIZEY	0x–
Set the X position of image in respect to LCD panel.	DISPC_GFX_POSITION[10:0] POSX	0x–
Set the Y position of image in respect to LCD panel.	DISPC_GFX_POSITION[26:16] POSY	0x–

10.2.5.1.2.2.3 DISPC Subsequence – Configure the GFX Pipeline Processing

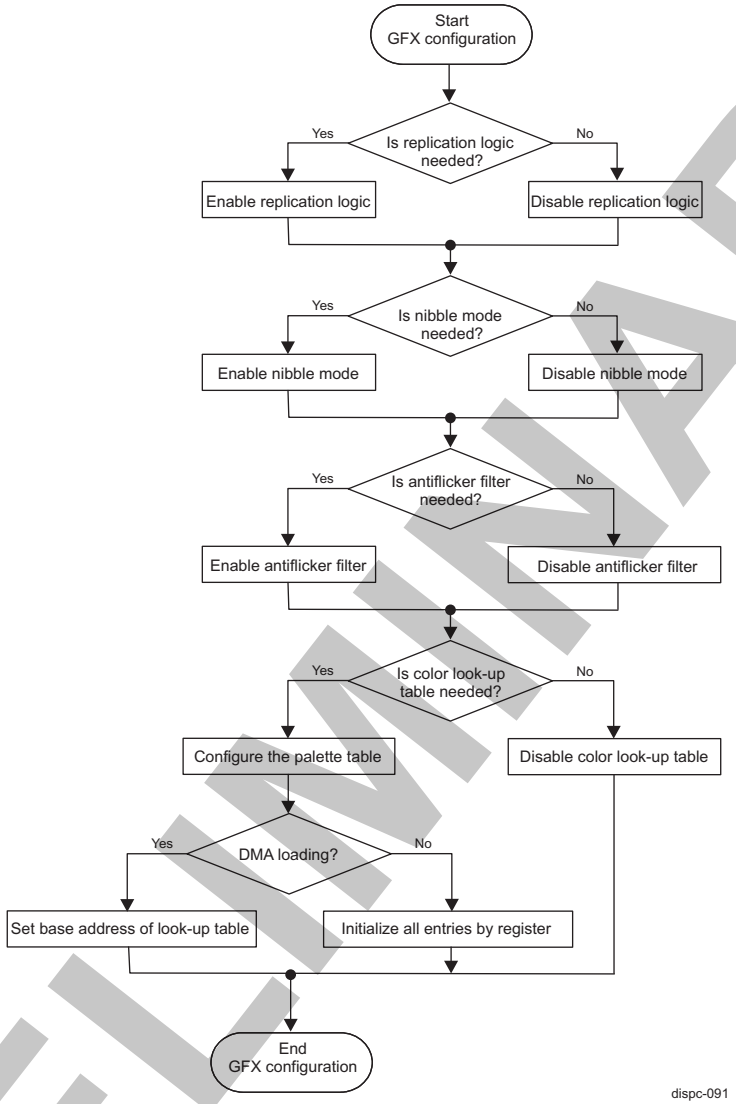
This subsequence describes the steps to configure the GFX pipeline processing in the DISPC (seeTable 10-62).

Table 10-62. DISPC Configure the GFX Pipeline Processing

Step	Register/Bit Field/Programming Model	Value
Enable replication logic.	DISPC_GFX_ATTRIBUTES[5] REPLICATIONENABLE	0x1
Enable nibble mode.	DISPC_GFX_ATTRIBUTES[9] NIBBLEMODE	0x1
Enable antiflicker filter.	DISPC_GFX_ATTRIBUTES[24] ANTIFLICKER	0x1
Configure the palette table.	See Table 10-63.	0x–

Figure 10-89 shows the configuration of the DISPC video pipeline processing.

Figure 10-89. DISPC Video Pipeline Processing Configuration



10.2.5.1.2.2.4 DISPC Subsequence – Configure the Palette Table

This subsequence describes the settings to configure the CLUT as a palette for the GFX pipeline (see Table 10-63).

NOTE:

- Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used for displaying the picture on the screen is not present for this mode.
- If the GFX pipeline is in BITMAP pixel format, gamma corrections are not available for LCD1.

Table 10-63. DISPC Configure the Palette Table

Step	Register/Bit Field/Programming Model	Value
Set look-up table as palette table.	DISPC_CONFIG1[3] PALETTEGAMMATABLE	0x0
Select the load mode of the palette look-up table.	DISPC_CONFIG1[2:1] LOADMODE	0x–
DMA loading		
Set base address of look-up table.	DISPC_GFX_TABLE_BA[31:0] TABLEBA	0x–
Initialize all entries by register		
Initialize all entries for the palette table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE0[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.5 DISPC Subsequence – Configure the GFX Pipeline Layer Output

This subsequence describes the video layer settings available at the pipeline level necessary when using the overlay manager (see Table 10-64).

Table 10-64. DISPC Configure the GFX Pipeline Layer Output

Step	Register/Bit Field/Programming Model	Value
Set the LCD/TV output.	DISPC_GFX_ATTRIBUTES[8] CHANNELOUT	0x–
If DISPC_GFX_ATTRIBUTES[8] = 0, set the LCD output.	DISPC_GFX_ATTRIBUTES[31:30] CHANNELOUT2	0x–
Set the Z-order priority of the layer for overlay manager.	DISPC_GFX_ATTRIBUTES[27:26] ZORDER	0x–
Enable the video pipeline Z-order.	DISPC_GFX_ATTRIBUTES[25] ZORDERENABLE	0x–
Set the Global Alpha value for the alpha blender unit.	DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA	0x–

10.2.5.1.2.3 DISPC Video Pipeline Configuration

10.2.5.1.2.3.1 DISPC Main Sequence – Configure the Video Pipeline

This sequence describes the steps to configure the video pipeline (see Table 10-65).

Table 10-65. DISPC Configure the Video Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the video window.	See Table 10-66.	
Configure the video pipeline processing.	See Table 10-67.	
Configure the video pipeline layer output.	See Table 10-72.	
Validate the video configuration according to outputs associated to the pipeline.	DISPC_CONTROL1[5] GOLCD	
	DISPC_CONTROL2[5] GOLCD	
	DISPC_CONTROL2[6] GOWB	
	DISPC_CONTROL1[6] GOTV	
Enable video pipeline.	DISPC_VIDp_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.3.2 DISPC Subsequence – Configure the Video Window

This subsequence describes the parameters of the image to be displayed on the LCD panel (see Table 10-66).

Table 10-66. DISPC Configure the Video Window

Step	Register/Bit Field/Programming Model	Value
Select the format of image.	DISPC_VIDp_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be displayed onto LCD panel.	DISPC_VIDp_SIZE[11:0] SIZEX	0x–
Set the Y size of image to be displayed onto LCD panel.	DISPC_VIDp_SIZE[27:16] SIZEY	0x–
Set the X position of image in respect to LCD panel.	DISPC_VIDp_POSITION[10:0] POSX	0x–
Set the Y position of image in respect to LCD panel.	DISPC_VIDp_POSITION[26:16] POSY	0x–

10.2.5.1.2.3.3 DISPC Subsequence – Configure the Video Pipeline Processing

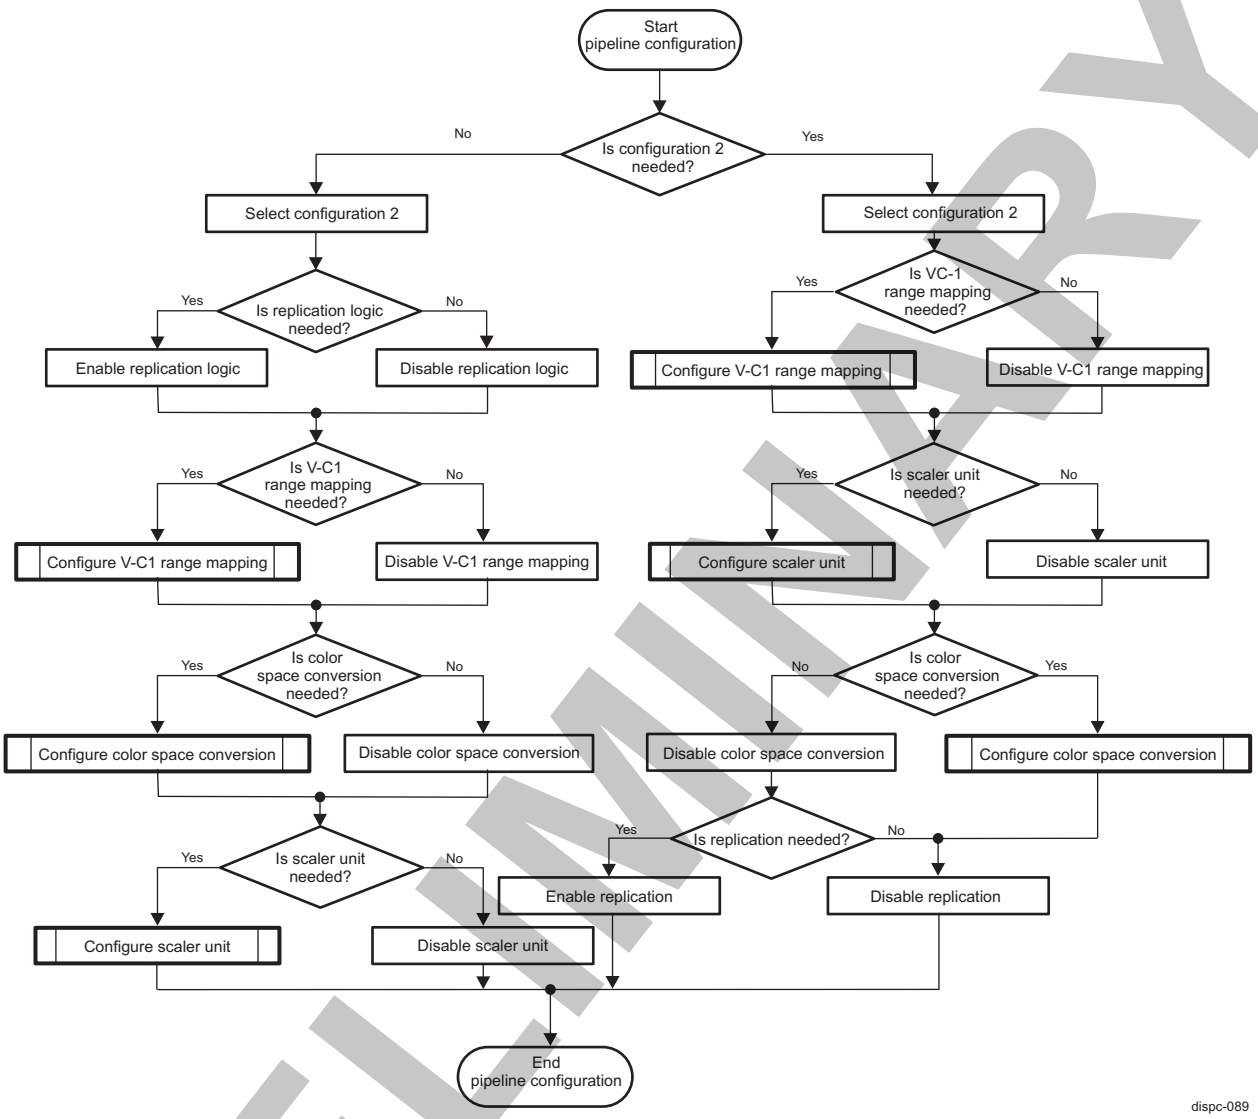
This subsequence describes the steps to configure video pipeline processing (see Table 10-67 and Figure 10-90).

Table 10-67. DISPC Configure the Video Pipeline Processing

Step	Register/Bit Field/Programming Model	Value
Select the video pipeline configuration 1 or 2.	DISPC_VIDp_ATTRIBUTES2[8] YUVCHROMARESAMPLING	0x–
Enable/disable replication logic(1).	DISPC_VIDp_ATTRIBUTES[10] REPLICATIONENABLE	0x1
Configure the VC-1 range mapping(1).	See Section 10.2.5.1.2.3.4.	
Configure the video color space conversion(1).	See Section 10.2.5.1.2.3.5.	
Configure the video scaler unit(1).	See Section 10.2.5.1.2.3.6.	

(1) This module configuration can be optional depending on:
- The video mode configuration selected. See Figure 10-90.
- The video format and application needs

Figure 10-90. DISPC Video Pipeline Processing Configuration



10.2.5.1.2.3.4 DISPC Subsequence – Configure the VC-1 Range Mapping

This subsequence describes the steps to configure the VC-1 range mapping (see Table 10-68).

Table 10-68. DISPC Configure the VC-1 Range Mapping

Step	Register/Bit Field/Programming Model	Value
Set the Y component VC-1 range mapping.	DISPC_VIDp_ATTRIBUTES2[3:1] VC1_RANGE_Y	0x–
Set the Cb and Cr component VC-1 range mapping.	DISPC_VIDp_ATTRIBUTES2[6:4] VC1_RANGE_CBCR	0x–
Enable VC-1 range mapping.	DISPC_VIDp_ATTRIBUTES2[0] VC1ENABLE	0x1

10.2.5.1.2.3.5 DISPC Subsequence – Configure the Video Color Space Conversion

This subsequence describes the steps to configure the video color space conversion (see Table 10-69).

Table 10-69. DISPC Configure the Video Color Space Conversion

Step	Register/Bit Field/Programming Model	Value
Select the range of the color space conversion.	DISPC_VIDp_ATTRIBUTES[11] FULLRANGE	0x–
Set the RCr and RY coefficients.	DISPC_VIDp_CONV_COEF0[26:16][10:0] RCR, RY	0x–
Set the GY and RCb coefficients.	DISPC_VIDp_CONV_COEF1[26:16][10:0] GY, RCB	0x–
Set the GCb and GCr coefficients.	DISPC_VIDp_CONV_COEF2[26:16][10:0] GCB, GCR	0x–
Set the BCr and BY coefficients.	DISPC_VIDp_CONV_COEF3[26:16][10:0] BCR, BY	0x–
Set the BCb coefficient.	DISPC_VIDp_CONV_COEF4[10:0] BCB	0x–
Enable color space conversion.	DISPC_VIDp_ATTRIBUTES[9] COLORCONVENABLE	0x1

10.2.5.1.2.3.6 DISPC Subsequence – Configure the Video Scaler Unit

This subsequence configures the video scaler unit. Table 10-70 is applicable for RGB pixel format. Table 10-70 and Table 10-71 are applicable for YUV pixel format.

Table 10-70. DISPC Configure the Video Scaler Unit for RGB Pixel Formats or Y Component

Step	Register/Bit Field/Programming Model	Value
Configure horizontal scaling		
Set the horizontal resizing ratio.	DISPC_VIDp_FIR[12:0] FIRHINC	0x–
Set the horizontal FIR coefficients.	DISPC_VIDp_FIR_COEF_H_i[31:24][23:16][15:8] [7:0] FIRHC3, FIRHC2, FIRHC1, FIRHC0	0x–
	DISPC_VIDp_FIR_COEF_HV_i[7:0] FIRHC4	0x–
Set the horizontal accumulators value.	DISPC_VIDp_ACCU_j[10:0] HORIZONTALACCU	0x–
Configure vertical scaling		
Select number of vertical taps.	DISPC_VIDp_ATTRIBUTES[21] VERTICALTAPS	0x–
Set the vertical resizing ratio.	DISPC_VIDp_FIR[28:16] FIRVINC	0x–
Set the vertical FIR coefficients for RGB pixel format or Y component.	DISPC_VIDp_FIR_COEF_HV_i[31:24][23:16][15:8] FIRVC2, FIRVC1, FIRVC0	0x–
	Only for 5-taps vertical: DISPC_VIDp_FIR_COEF_V_i[15:8][7:0] FIRVC22, FIRVC00	0x–
Set the vertical accumulators value for RGB pixel format or Y component.	DISPC_VIDp_ACCU_j[26:16] VERTICALACCU	0x–
Enable horizontal and vertical scaler unit.	DISPC_VIDp_ATTRIBUTES[6:5] RESIZEENABLE	0x–

Table 10-71. DISPC Configure the Video Scaler Unit for Cb and Cr Components

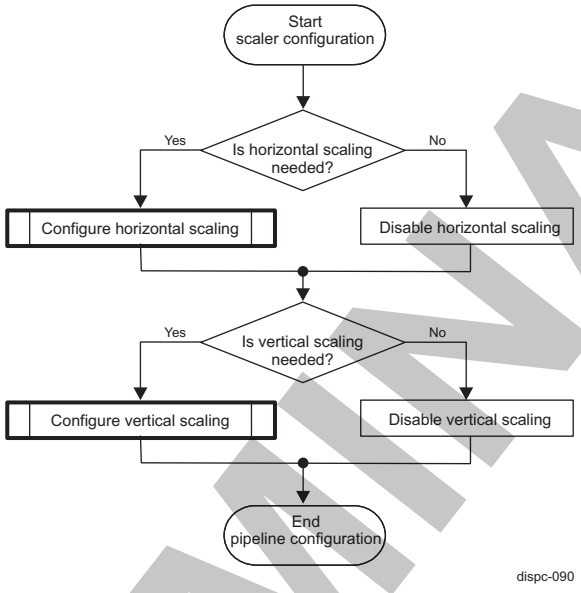
Step	Register/Bit Field/Programming Model	Value
Configure horizontal scaling		
Set the horizontal resizing ratio for Cb and Cr components.	DISPC_VIDp_FIR2[12:0] FIRHINC	0x–
Set the horizontal FIR coefficients for Cb and Cr components.	DISPC_VIDp_FIR_COEF_H2_i[31:24][23:16][15:8] [7:0] FIRHC3, FIRHC2, FIRHC1, FIRHC0	0x–
	DISPC_VIDp_FIR_COEF_HV2_i[7:0] FIRHC4	0x–
Set the horizontal accumulators value for Cb and Cr components.	DISPC_VIDp_ACCU2_j[10:0] HORIZONTALACCU	0x–
Configure vertical scaling		
Set the vertical resizing ratio for Cb and Cr components.	DISPC_VIDp_FIR2[28:16] FIRVINC	0x–
Set the vertical FIR coefficients for Cb and Cr components.	DISPC_VIDp_FIR_COEF_HV2_i[31:24][23:16][15:8] FIRVC2, FIRVC1, FIRVC0	0x–
	Only for 5-taps vertical: DISPC_VIDp_FIR_COEF_V2_i[15:8][7:0] FIRVC22, FIRVC00	0x–

Table 10-71. DISPC Configure the Video Scaler Unit for Cb and Cr Components (continued)

Step	Register/Bit Field/Programming Model	Value
Set the vertical accumulators value for Cb and Cr components.	DISPC_VIDp_ACCU2_j[26:16] VERTICALACCU	0x–

Figure 10-91 shows the programming flow of the DISPC scaler unit.

Figure 10-91. DISPC Scaler Unit Programming Flow



10.2.5.1.2.3.7 DISPC Subsequence – Configure the Video Pipeline Layer Output

This subsequence describes the video layer settings available at the pipeline level necessary when using the overlay manager (see Table 10-72).

Table 10-72. DISPC Configure the Video Pipeline Layer Output

Step	Register/Bit Field/Programming Model	Value
Set the LCD/TV output.	DISPC_VIDp_ATTRIBUTES[16] CHANNELOUT	0x–
If DISPC_VIDp_ATTRIBUTES[16] = 0, set the LCD output.	DISPC_VIDp_ATTRIBUTES[31:30] CHANNELOUT2	0x–
Set the Z-order priority of the layer for overlay manager.	DISPC_VIDp_ATTRIBUTES[27:26] ZORDER	0x–
Enable the video pipeline Z-order.	DISPC_VIDp_ATTRIBUTES[25] ZORDERENABLE	0x–
Set the Global Alpha value for the alpha blender unit.	DISPC_GLOBAL_ALPHA[31:24][23:16][15:8] VID3GLOBALALPHA, VID2GLOBALALPHA, VID1GLOBALALPHA	0x–

10.2.5.1.2.4 DISPC WB Pipeline Configuration

10.2.5.1.2.4.1 DISPC Main Sequence – Configure the WB Pipeline

This procedure describes the steps to configure the WB pipeline (see Table 10-73).

Table 10-73. DISPC Configure the WB Pipeline

Step	Register/Bit Field/Programming Model	Value
Configure the capture window.	See Table 10-74.	
Configure the WB scaler unit.	See Table 10-75.	
Enable truncation logic to match pixel size defined in the format of image DISPC_WB_ATTRIBUTES[4:1] FORMAT.	DISPC_WB_ATTRIBUTES[10] TRUNCATIONENABLE	0x–
If DISPC_WB_ATTRIBUTES[10] !=, configure the WB color space conversion unit.	See Table 10-77.	
Validate the configuration according to the registers modification.	DISPC_CONTROL2[6] GOWB	
Enable WB pipeline.	DISPC_WB_ATTRIBUTES[0] ENABLE	0x1

10.2.5.1.2.4.2 DISPC Subsequence – Configure the Capture Window

This subsequence describes the parameters of the image to be captured in the system memory (see Table 10-74).

Table 10-74. DISPC Configure the Capture Window

Step	Register/Bit Field/Programming Model	Value
Set the input source.	DISPC_WB_ATTRIBUTES[18:16] CHANNELIN	0x–
Select the format of image.	DISPC_WB_ATTRIBUTES[4:1] FORMAT	0x–
Set the X size of image to be captured.	DISPC_WB_SIZE[10:0] SIZEX	0x–
Set the Y size of image to be captured.	DISPC_WB_SIZE[10:0] SIZEY	0x–

10.2.5.1.2.4.3 DISPC Subsequence – Configure the WB Scaler Unit

This subsequence configures the scaler unit. Table 10-75 is applicable for RGB pixel format. Table 10-75 and Table 10-76 are applicable for YUV pixel format.

Table 10-75. DISPC Configure the WB Scaler Unit for RGB Pixel Formats or Y Component

Step	Register/Bit Field/Programming Model	Value
Configure horizontal scaling		
Set the horizontal resizing ratio.	DISPC_WB_FIR[12:0] FIRHINC	0x–
Set the horizontal FIR coefficients.	DISPC_WB_FIR_COEF_H_i[31:24][23:16][15:8][7:0] FIRHC3, FIRHC2, FIRHC1, FIRHC0	0x–
	DISPC_WB_FIR_COEF_HV_i[7:0] FIRHC4	0x–
Set the horizontal accumulators value.	DISPC_WB_ACCU_j[10:0] HORIZONTALACCU	0x–
Configure vertical scaling		
Select number of vertical taps.	DISPC_WB_ATTRIBUTES[21] VERTICALTAPS	0x–
Set the vertical resizing ratio.	DISPC_WB_FIR[28:16] FIRVINC	0x–
Set the vertical FIR coefficients for RGB pixel format or Y component.	DISPC_WB_FIR_COEF_HV_i[31:24][23:16][15:8] FIRVC2, FIRVC1, FIRVC0	0x–
	Only for 5-taps vertical: DISPC_WB_FIR_COEF_V_i[15:8][7:0] FIRVC22, FIRVC00	0x–
Set the vertical accumulators value for RGB pixel format or Y component.	DISPC_WB_ACCU_j[26:16] VERTICALACCU	0x–
Enable horizontal and vertical scaler unit.	DISPC_WB_ATTRIBUTES[6:5] RESIZEENABLE	0x–

Table 10-76. DISPC Configure the WB Scaler Unit for Cb and Cr Components

Step	Register/Bit Field/Programming Model	Value
Configure horizontal scaling		
Set the horizontal resizing ratio for Cb and Cr components.	DISPC_WB_FIR2[12:0] FIRHINC	0x–
Set the horizontal FIR coefficients for Cb and Cr components.	DISPC_WB_FIR_COEF_H2_i[31:24][23:16][15:8][7:0] FIRHC3, FIRHC2, FIRHC1, FIRHC0	0x–
	DISPC_WB_FIR_COEF_HV2_i[7:0] FIRHC4	0x–
Set the horizontal accumulators value for Cb and Cr components.	DISPC_WB_ACCU2_j[10:0] HORIZONTALACCU	0x–
Configure vertical scaling		
Set the vertical resizing ratio for Cb and Cr components.	DISPC_WB_FIR2[28:16] FIRVINC	0x–
Set the vertical FIR coefficients for Cb and Cr components.	DISPC_WB_FIR_COEF_HV2_i[31:24][23:16][15:8] FIRVC2, FIRVC1, FIRVC0	0x–
	Only for 5-taps vertical: DISPC_WB_FIR_COEF_V2_i[15:8][7:0] FIRVC22, FIRVC00	0x–
Set the vertical accumulators value for Cb and Cr components.	DISPC_WB_ACCU2_j[26:16] VERTICALACCU	0x–

10.2.5.1.2.4.4 DISPC Subsequence – Configure the WB Color Space Conversion Unit

This subsequence describes the steps to configure the WB color space conversion unit (see Table 10-77).

Table 10-77. DISPC Configure the WB Color Space Conversion Unit

Step	Register/Bit Field/Programming Model	Value
Select the range of the color space conversion.	DISPC_WB_ATTRIBUTES[11] FULLRANGE	0x–
Set the RCr and RY coefficients.	DISPC_WB_CONV_COEF0[26:16][10:0] YG, YR	0x–
Set the GY and RCb coefficients	DISPC_WB_CONV_COEF1[26:16][10:0] CRR, YB	0x–
Set the GCb and GCr coefficients.	DISPC_WB_CONV_COEF2[26:16][10:0] CRB, CRG	0x–
Set the BCr and BY coefficients.	DISPC_WB_CONV_COEF3[26:16][10:0] CBG, CBR	0x–
Set the BCb coefficient.	DISPC_WB_CONV_COEF4[10:0] CBB	0x–
Enable color space conversion.	DISPC_WB_ATTRIBUTES[9] COLORCONVENABLE	0x1

10.2.5.1.2.5 DISPC LCD Output Configuration

10.2.5.1.2.5.1 DISPC Main Sequence – Configure the LCD Output

This procedure details the LCD output configuration (see Table 10-78).

Table 10-78. DISPC Configure the LCD Output

Step	Register/Bit Field/Programming Model
Configure the LCD overlay manager.	See Table 10-79.
Configure the gamma table for gamma correction.	See Section 10.2.5.1.2.5.3.
Configure the CPR.	See Table 10-83.
Configure the LCD panel timings and parameters.	See Table 10-84.
Validate the LCD output configuration according.	DISPC_CONTROL1[5] GOLCD
	DISPC_CONTROL2[5] GOLCD
Enable LCD output.	DISPC_CONTROL1[0] LCDENABLE
	DISPC_CONTROL2[0] LCDENABLE

10.2.5.1.2.5.2 DISPC Subsequence – Configure the Overlay Manager

This subsequence describes the overlay manager settings and transparency color key configuration (see Table 10-79).

Table 10-79. DISPC Configure the LCD Overlay Manager

Step	Register/Bit Field/Programming Model	Value
Set the LCD panel background color.	DISPC_DEFAULT_COLORo[23:0] DEFAULTCOLOR	0x–
Enable/disable overlay optimization.	DISPC_CONTROLo[12] OVERLAYOPTIMIZATION	0x–
Enable the alpha blender(1).	DISPC_CONFIG1[18] LCDALPHABLENDERENABLE	0x1
Configure the transparency color key		
Set source or destination transparency color key mode.	DISPC_CONFIGo[11] TCKLCDSELECTION	0x–
Set the transparency color value.	DISPC_TRANS_COLORo[23:0] TRANSCOLORKEY	0x–
Enable transparency color key mode.	DISPC_CONFIGo[10] TCKLCDENABLE	0x–

(1) Backward compatibility with OMAP34xx available only for LCD1

10.2.5.1.2.5.3 DISPC Subsequence – Configure the Gamma Table for Gamma Correction

This subsequence describes the settings for configuring the gamma correction for LCD1, LCD2, and LCD3 (see Table 10-80 through Table 10-82, respectively).

NOTE:

- Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used to display the picture on the screen is not present for this mode.
- If the GFX pipeline is in BITMAP pixel format, gamma corrections are not available for LCD1.

Table 10-80. DISPC Configure the Gamma Table for LCD1

Step	Register/Bit Field/Programming Model	Value
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE0[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–
Set look up table as gamma table.	DISPC_CONFIG1[3] PALETTEGAMMATABLE	0x1
Select the load mode of the gamma look-up table.	DISPC_CONFIG1[2:1] LOADMODE	0x–

Table 10-81. DISPC Configure the Gamma Table for LCD2

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD2 and TV.	DISPC_CONFIG2[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE2[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

Table 10-82. DISPC Configure the Gamma Table for LCD3

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD3 and TV.	DISPC_CONFIG3[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values associated to this index.	DISPC_GAMMA_TABLE3[31:24][23:16][15:8][7:0], INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.5.4 DISPC Subsequence – Configure the Color Phase Rotation

Table 10-83 describes the settings for the CPR unit (see Table 10-83).

Table 10-83. DISPC Configure the Color Phase Rotation

Step	Register/Bit Field/Programming Model	Value
Set the Red coefficients.	DISPC_CPRo_COEF_R [31:22][20:11][9:0] RR, RG, RB	0x–
Set the Green coefficients	DISPC_CPRo_COEF_G [31:22][20:11][9:0] GR, GG, GB	0x–
Set the Blue coefficients.	DISPC_CPRo_COEF_B [31:22][20:11][9:0] BR, BG, BB	0x–
Disable the CPR unit in RGB to YUV conversion.	DISPC_CONFIGo[24] COLORCONVENABLE	0x0
Enable the CPR unit.	DISPC_CONFIGo[15] CPR	0x1

10.2.5.1.2.5.5 DISPC Subsequence – Configure the LCD Panel Timings and Parameters

This subsequence describes the setting for horizontal and vertical synchronization and signal polarity (see Table 10-84).

Table 10-84. DISPC Configure the LCD Panel Timings and Parameters

Step	Register/Bit Field/Programming Model	Value
Configure spatial/temporal dithering		
Select spatial/temporal number of frames.	DISPC_CONTROLo[31:30] SPATIALTEMPORALDITHERINGFRAMES	0x–
Enable spatial/temporal dithering.	DISPC_CONTROLo[7] STDITHERENABLE	0x–
Configure AC-bias		
Configure the VSYNC, HSYNC and AC bias polarity.	DISPC_POL_FREQo	0x–
Configure the gating of AC bias polarity.	DISPC_CONFIGo[8] ACBIASGATED	0x–
Configure the AC bias polarity.	DISPC_POL_FREQo[15] IEO	0x–
Set the AC bias frequency.	DISPC_POL_FREQo[7:0] ACB	0x–
Set the number of AC bias transitions per interrupt.	DISPC_POL_FREQo[11:8] ACBI	0x–
Configure the pixel clock		
Set the DISPC logic clock divisor.	DISPC_DIVISORo[23:16] LCD	0x–
Set the pixel clock divisor.	DISPC_DIVISORo[7:0] PCD	0x–
Configure the gating of pixel clock.	DISPC_CONFIGo[5] PIXELCLOCKGATED	0x–
Configure the data		
Set the pixel clock edge to drive data output.	DISPC_POL_FREQo[14] IPC	0x–
Configure the gating of data output.	DISPC_CONFIGo[4] PIXELDATAGATED	0x–
Set the data output mode.	DISPC_CONFIGo[22] OUTPUTMODEENABLE	0x–
Configure the panel parameters		
Set the vertical TV size.	DISPC_SIZE_LCDo[27:16] LPP	0x–
Set the horizontal TV size.	DISPC_SIZE_LCDo[11:0] PPL	0x–
Set the panel type.	DISPC_CONTROLo[3] STNTFT	0x–
Configure the refresh rate and horizontal and vertical parameters		
Set the vertical synchronization timing.	DISPC_TIMING_Vo[31:20][19:8][7:0], VBP, VFP, VSW	0x–
Configure the VSYNC polarity.	DISPC_POL_FREQo[12] IVS	0x–
Configure the gating of VSYNC.	DISPC_CONFIGo[7] VSYNCGATED	0x–
Set the horizontal synchronization timing.	DISPC_TIMING_Ho[31:20][19:8][7:0], HBP, HFP, HSW	0x–
Configure the HSYNC polarity.	DISPC_POL_FREQo[13] IHS	0x–
Configure the gating of HSYNC.	DISPC_CONFIGo[6] HSYNCGATED	0x–
Set the opposition of HSYNC and VSYNC driving.	DISPC_POL_FREQo[17] ONOFF	0x–

Table 10-84. DISPC Configure the LCD Panel Timings and Parameters (continued)

Step	Register/Bit Field/Programming Model	Value
If DISPC_POL_FREQo[17] = 1, set the pixel clock edge to drive HSYNC and VSYNC.	DISPC_POL_FREQo[16] RF	0x–
Set the alignment of HSYNC and VSYNC.	DISPC_POL_FREQo[18] ALIGN	0x–

10.2.5.1.2.6 DISPC TV Output Configuration

10.2.5.1.2.6.1 DISPC Main Sequence – Configure the TV Output

This procedure describes the TV output configuration (see Table 10-85).

Table 10-85. DISPC Configure the TV Output

Step	Register/Bit Field/Programming Model
Configure the TV overlay manager.	See Table 10-86.
Configure the gamma table for gamma correction.	See Table 10-87.
Configure the TV panel timings and parameters.	See Table 10-88.
Validate the TV output configuration accordingly.	DISPC_CONTROL1[6] GOTV
Enable the TV output.	DISPC_CONTROL1[1] TVENABLE

10.2.5.1.2.6.1.1 DISPC Subsequence – Configure the TV Overlay Manager

This subsequence describes the overlay manager settings and transparency color key configuration (see Table 10-86).

Table 10-86. DISPC Configure the TV Overlay Manager

Step	Register/Bit Field/Programming Model	Value
Set the TV panel background color.	DISPC_DEFAULT_COLOR1[23:0] DEFAULTCOLOR	0x–
Enable/disable overlay optimization.	DISPC_CONTROL2[13] TVOVERLAYOPTIMIZATION	0x–
Enable the alpha blender(1).	DISPC_CONFIG1[19] TVALPHABLENDERENABLE	0x1
Configure the transparency color key		
Set source or destination transparency color key mode.	DISPC_CONFIG1[13] TCKTVSELECTION	0x–
Set the transparency color value.	DISPC_TRANS_COLOR1[23:0] TRANSCOLORKEY	0x–
Enable transparency color key mode.	DISPC_CONFIG1[10] TCKTVENABLE	0x–

(1) Backward compatibility with OMAP34xx

10.2.5.1.2.6.1.2 DISPC Subsequence – Configure the Gamma Table for Gamma Correction

This subsequence describes the steps to configure the gamma table for gamma correction (see Table 10-87).

NOTE: Software must ensure there is no visible effect when modifying the table because it is not under hardware control. The synchronization done using the DMA engine inside the DISPC to load the table when it is not used for displaying the picture on the screen is not present for this mode.

Table 10-87. DISPC Configure the Gamma Table for TV Output

Step	Register/Bit Field/Programming Model	Value
Enable Gamma table for LCD2 and TV.	DISPC_CONFIG1[9] GAMATABLEENABLE	0x1
Initialize all entries for the gamma table by setting the table index and the RGB values. For more information, see Section 10.2.4.13.2, *Gamma Correction Unit*.	DISPC_GAMMA_TABLE2[31][29:20][19:10][9:0] INDEX, VALUE_R, VALUE_G, VALUE_B	0x–

10.2.5.1.2.6.1.3 DISPC Subsequence – Configure the TV Panel Timings and Parameters

This subsequence describes the settings for horizontal and vertical synchronization and signal polarity (see Table 10-88).

Table 10-88. DISPC Configure the TV Panel Timings and Parameters

Step	Register/Bit Field/Programming Model	Value
Set the hold time for TV data outputs.	DISPC_CONFIG1[19:17]	0x–
Set the vertical TV size.	DISPC_SIZE_TV[27:16] LPP	See Table 10-53 for HD standards.
Set the horizontal TV size.	DISPC_SIZE_TV[11:0] PPL	

10.2.6 DISPC Use Cases and Tips

10.2.6.1 DISPC Hardware Cursor

The video layer or graphics layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in one of the following formats if the source transparency color key is used:

- xRGB12-4444
- ARGB16-4444
- RGBx12-4444
- RGBA16-4444
- ARGB16-1555
- RGB16-565
- RGB24-888
- xRGB24-88888
- RGBA32-8888
- BGRA32-8888
- ARGB32-8888

Otherwise, any pixel format can be used for the cursor image, considering the limitation in terms of pixels supported by the pipeline used to display the cursor image. To display a nonrectangle cursor, the transparency color key or alpha blending (pixel alpha blending) can be used (see Section 10.2.4.12.1.3, *DISPC Transparency Color Keys*). Global alpha blending can be used in addition to the transparency source color key to create a fading effect when the cursor (with a nonrectangle shape) appears and disappears on the screen. The image of the cursor can be stored entirely inside the DMA buffer to use the self-refresh mode (see Section 10.2.4.6.8.2, *DISPC DMA Ultralow-Power Mode*). In that case, the image is loaded once and then displayed without accessing the system memory for loading the image for each frame. This saves bandwidth on interconnect and memory.

10.2.7 DISPC Register Manual

10.2.7.1 DISPC Instance Summary

Hardware Register	Description
DISPC_VID1_CONV_COEF1	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF1	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF1	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-110. DISPC_VIDp_CONV_COEF2 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF2	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF2	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF2	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-111. DISPC_VIDp_CONV_COEF3 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF3	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF3	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF3	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-112. DISPC_VIDp_CONV_COEF4 Logical Register Mapping

Hardware Register	Description
DISPC_VID1_CONV_COEF4	Configuration of the Color Space Conversion coefficients for the video pipeline 1
DISPC_VID2_CONV_COEF4	Configuration of the Color Space Conversion coefficient for the video pipeline 2
DISPC_VID3_CONV_COEF4	Configuration of the Color Space Conversion coefficient for the video pipeline 3

Table 10-113. DISPC_CONTROLo Logical Register Mapping

Hardware Register	Description
DISPC_CONTROL1	Configuration control of the LCD1 and TV.
DISPC_CONTROL2	Configuration control of the LCD2.
DISPC_CONTROL3	Configuration control of the LCD3.

Table 10-114. DISPC_CONFIGo Logical Register Mapping

Hardware Register	Description
DISPC_CONFIG1	Configuration of the LCD1 and TV.
DISPC_CONFIG2	Configuration of the LCD2.
DISPC_CONFIG3	Configuration of the LCD3.

Table 10-115. DISPC_DEFAULT_COLORo Logical Register Mapping

Hardware Register	Description
DISPC_DEFAULT_COLOR0	Configuration of the background color for LCD1.
DISPC_DEFAULT_COLOR1	Configuration of the background color for TV.
DISPC_DEFAULT_COLOR2	Configuration of the background color for LCD2.
DISPC_DEFAULT_COLOR3	Configuration of the background color for LCD3.

Table 10-116. DISPC_TRANS_COLORo Logical Register Mapping

Hardware Register	Description
DISPC_TRANS_COLOR0	Configuration of the transparency color key for LCD1.
DISPC_TRANS_COLOR1	Configuration of the transparency color key for TV.
DISPC_TRANS_COLOR2	Configuration of the transparency color key for LCD2.
DISPC_DEFAULT_COLOR3	Configuration of the background color for LCD3.

Table 10-117. DISPC_GAMMA_TABLEo Logical Register Mapping

Hardware Register	Description
DISPC_GAMMA_TABLE0	Configuration of the palette table for GFX or the gamma table for LCD1.
DISPC_GAMMA_TABLE1	Configuration of the gamma table for LCD2.
DISPC_GAMMA_TABLE2	Configuration of the gamma table for TV output.
DISPC_GAMMA_TABLE3	Configuration of the gamma table for LCD3.

Table 10-118. DISPC_TIMING_Ho Logical Register Mapping

Hardware Register	Description
DISPC_TIMING_H1	Configuration of the horizontal timing for LCD1.
DISPC_TIMING_H2	Configuration of the horizontal timing for LCD2.
DISPC_TIMING_H3	Configuration of the horizontal timing for LCD3.

Table 10-119. DISPC_TIMING_Vo Logical Register Mapping

Hardware Register	Description
DISPC_TIMING_V1	Configuration of the vertical timing for LCD1.
DISPC_TIMING_V2	Configuration of the vertical timing for LCD2.
DISPC_TIMING_V3	Configuration of the vertical timing for LCD3.

Table 10-120. DISPC_POL_FREQo Logical Register Mapping

Hardware Register	Description
DISPC_POL_FREQ1	Configuration of the output signals for LCD1.
DISPC_POL_FREQ2	Configuration of the output signals for LCD2.
DISPC_POL_FREQ3	Configuration of the output signals for LCD3.

Table 10-121. DISPC_DIVISORo Logical Register Mapping

Hardware Register	Description
DISPC_DIVISOR1	Configuration of the divisors for LCD1.
DISPC_DIVISOR2	Configuration of the divisors for LCD2.
DISPC_DIVISOR3	Configuration of the divisors for LCD3.

Table 10-122. DISPC_SIZE_LCDo Logical Register Mapping

Hardware Register	Description
DISPC_SIZE_LCD1	Configuration of the divisors for LCD1.
DISPC_SIZE_LCD2	Configuration of the divisors for LCD2.
DISPC_SIZE_LCD3	Configuration of the divisors for LCD3.

Table 10-123. DISPC_SIZE Logical Register Mapping

Hardware Register	Description
DISPC_SIZE_LCD1	Configuration of the LCD size on LCD1.
DISPC_SIZE_LCD2	Configuration of the LCD size on LCD2.
DISPC_SIZE_LCD3	Configuration of the LCD size on LCD3.

Table 10-124. DISPC_DATAo_CYCLE1 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE1	Configuration of the output data format for first cycle on LCD1.
DISPC_DATA2_CYCLE1	Configuration of the output data format for first cycle on LCD2.
DISPC_DATA3_CYCLE1	Configuration of the output data format for first cycle on LCD3.

Table 10-125. DISPC_DATAo_CYCLE2 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE2	Configuration of the output data format for second cycle on LCD1.
DISPC_DATA2_CYCLE2	Configuration of the output data format for second cycle on LCD2.
DISPC_DATA3_CYCLE2	Configuration of the output data format forsecond cycle on LCD3.

Table 10-126. DISPC_DATAo_CYCLE3 Logical Register Mapping

Hardware Register	Description
DISPC_DATA1_CYCLE3	Configuration of the output data format for third cycle on LCD1.
DISPC_DATA2_CYCLE3	Configuration of the output data format for third cycle on LCD2.
DISPC_DATA3_CYCLE3	Configuration of the output data format for third cycle on LCD3.

Table 10-127. DISPC_CPRo_COEF_R Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD1.
DISPC_CPR2_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD2.
DISPC_CPR3_COEF_R	Configuration of the CPR matrix coefficients for the red component on LCD3

Table 10-128. DISPC_CPRo_COEF_G Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD1.
DISPC_CPR2_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD2.
DISPC_CPR3_COEF_G	Configuration of the CPR matrix coefficients for the green component on LCD3.

Table 10-129. DISPC_CPRo_COEF_B Logical Register Mapping

Hardware Register	Description
DISPC_CPR1_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD1.
DISPC_CPR2_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD2.
DISPC_CPR3_COEF_B	Configuration of the CPR matrix coefficients for the blue component on LCD3.

10.2.7.3 DISPC Registers

10.2.7.3.1 DISPC Register Summary

Table 10-130. DISPC Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	L3_MAIN Physical Address
DISPC_REVISION	R	32	0x0000 0000	0x5800 1000

10.2.7.3.2 DISPC Register Description

Table 10-131. DISPC_REVISION

Address Offset	0x0000 0000		
Physical Address	0x5800 1000	**Instance**	DISPC
Description	IP Revision		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP revision	R	See(1).

(1) TI internal data

Table 10-132. Register Call Summary for Register DISPC_REVISION

Display Controller

- DISPC Shadow Registers: [0]
- DISPC Register Summary: [1]

Table 10-133. DISPC_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5800 1010	**Instance**	DISPC
Description	This register allows to control various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		MIDLEMODE		RESERVED		CLOCKACTIVITY		RESERVED		WARMRESET		SIDLEMODE		ENWAKEUP		SOFTRESET		AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00000
13:12	MIDLEMODE	Master interface power management, standby/wait control 0x0: Force-standby. MStandby is only asserted when the module is disabled. MStandby is only asserted when the module is disabled. 0x1: No-Standby: MStandby is never asserted. 0x2: Smart-Standby. MStandby is asserted based on the internal activity of the module. 0x3: Reserved	RW	0x0
11:10	RESERVED	Write 0s for future compatibility. Reads returns 0	R	0x0

Bits	Field Name	Description	Type	Reset
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: OCP and functional clocks can be switched off. 0x1: Functional clocks can be switched off and OCP clocks are maintained during wake up period. 0x2: OCP clocks can be switched off and Functional clocks are maintained during wake up period. 0x3: OCP and functional clocks are maintained during wake-up period.	RW	0x0
7:6	RESERVED	Write 0s for future compatibility. Reads returns 0	R	0x0
5	WARMRESET	Warm reset. Set this bit to 1 triggers a module warm reset. The bit is automatically reset by the hardware. During reads, it always returns 0. The warm reset keep the configuration registers unchanged. 0x0: Normal mode 0x1: The warm reset is set.	RW	0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module. 0x3: Reserved	RW	0x0
2	ENWAKEUP	WakeUp feature control 0x0: Wakeup is disabled. 0x1: Wakeup is enabled.	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic interface L3_MAIN gating strategy is applied, based on the OCP interface activity. Automatic functional clock gating is also applied to the functional clock based on the module activity (for instance DISPC_<pipe>_ATTRIBUTES.ENABLE).	RW	1

Table 10-137. DISPC_IRQSTATUS

Address Offset	0x0000 0018		
Physical Address	0x5800 1018	**Instance**	DISPC
Description	This register regroups all the status of the module internal events that generate an interrupt. Write 1 to a given bit resets this bit		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLIPIMMEDIATEDONE_IRQ	FRAMEDONE3_IRQ	ACBIASCOUNTSTATUS3_IRQ	VSYNC3_IRQ	SYNCLOST3_IRQ	WBINCOMPLETEERROR_IRQ	WBBUFFEROVERFLOW_IRQ	FRAMEDONETV_IRQ	FRAMEDONEWB_IRQ	FRAMEDONE2_IRQ	ACBIASCOUNTSTATUS2_IRQ	VID3BUFFERUNDERFLOW_IRQ	VID3ENDWINDOW_IRQ	VSYNC2_IRQ	SYNCLOST2_IRQ	WAKEUP_IRQ	SYNCLOSTTV_IRQ	SYNCLOST1_IRQ	VID2ENDWINDOW_IRQ	VID2BUFFERUNDERFLOW_IRQ	VID1ENDWINDOW_IRQ	VID1BUFFERUNDERFLOW_IRQ	OCPERROR_IRQ	PALETTEGAMMALOADING_IRQ	GFXENDWINDOW_IRQ	GFXBUFFERUNDERFLOW_IRQ	PROGRAMMEDLINENUMBER_IRQ	ACBIASCOUNTSTATUS1_IRQ	EVSYNC_ODD_IRQ	EVSYNC_EVEN_IRQ	VSYNC1_IRQ	FRAMEDONE1_IRQ

Bits	Field Name	Description	Type	Reset
31	FLIPIMMEDIATEDONE_IRQ	Flip Immediate Done. The DMA engine has acknowledged the immediate BA change, and software can write the new BA0. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
30	FRAMEDONE3_IRQ	Frame done for the third LCD. The third LCD output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
29	ACBIASCOUNT STATUS3_IRQ	AC bias count status for the third LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
28	VSYNC3_IRQ	Vertical synchronization for the third LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
27	SYNCLOST3_IRQ	Synchronization lost on the third LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the third LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
26	WBUNCOMPLETE ERROR_IRQ	Write-back DMA buffer is flushed before it is completely drained. In WB capture mode, if the new frame starts before the WB DMA buffers are fully drained (onto external memory), then the contents of the WB DMA buffers are lost (implying last few pixels/lines are corrupted in the captured frame in memory). This interrupt is an indication of that case and will trigger every frame 0x0: READS: Event is false. WRITES: Status bit unchanged 0x1: READS: Event is true (Pending) WRITES: Status bit is reset	RW W1toClr	0
25	WBBUFFER OVERFLOW_IRQ	Write-back DMA buffer overflow. The DMA buffer is full. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
24	FRAME DONETV_IRQ	Frame done for the TV. The TV output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
23	FRAME DONEWB_IRQ	Frame done for the write-back channel. The write-back channel has output the frame. All the data of the frame have been sent to the memory. There is no pending data inside the DMA engine for the write-back channel to be transferred to memory. It is available only when the write-back pipeline transfers back to memory the output of one of the pipelines. In case of overlay capture, the interrupt is not generated and the user shall use the FrameDone for the corresponding captured output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
22	FRAME DONE2_IRQ	Frame done for the secondary LCD. The secondary LCD output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
21	ACBIASCOUNT STATUS2_IRQ	AC bias count status for the secondary LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
20	VID3BUFFER UNDERFLOW_IRQ	Video 3 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
19	VID3END WINDOW_IRQ	The end of the video 3 window has been reached. It is detected by the overlay manager when the full video 3 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
18	VSYNC2_IRQ	Vertical synchronization for the secondary LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
17	SYNC LOST2_IRQ	Synchronization lost on the secondary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the secondary LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
16	WAKEUP_IRQ	Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
15	SYNCLOST TV_IRQ	Synchronization lost on the TV output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the TV output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
14	SYNC LOST1_IRQ	Synchronizationl ost on the primary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the primary LCD output. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
13	VID2END WINDOW_IRQ	The end of the video 2 Window has been reached. It is detected by the overlay manager when the full video 2 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
12	VID2BUFFER UNDERFLOW_IRQ	Video 2 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
11	VID1END WINDOW_IRQ	The end of the video 1 Window has been reached. It is detected by the overlay manager when the full video 1 has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
10	VID1BUFFER UNDERFLOW_IRQ	Video 1 DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
9	OCPERROR_IRQ	OCP error. L3_MAIN Interconnect has sent SResp=ERR. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
8	PALETTEGAMMA LOADING_IRQ	Palette Gamma loading status. The palette used as Color Look Up Table (CLUT) for the graphics BITMAP formats (1-, 2-, 4-, or 4-bpp) or as gamma table for the overlay output for the primary LCD output has been loaded successfully. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
7	GFXEND WINDOW_IRQ	The end of the graphics wndow has been reached. It is detected by the overlay manager when the full graphics has been displayed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
6	GFXBUFFER UNDERFLOW_IRQ	Graphics DMA buffer underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
5	PROGRAMMED LINENUMBER_IRQ	Programmed line number. It indicates that the scan of the primary LCD has reached the programmed user line number. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
4	ACBIASCOUNT STATUS1_IRQ	AC bias count status for the primary LCD 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
3	EVSYNC_ ODD_IRQ	VSYNC for odd field from the TV encoder (HDMI) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
2	EVSYNC_ EVEN_IRQ	VSYNC for even field from the TV encoder (HDMI) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
1	VSYNC1_IRQ	Vertical synchronization for the primary LCD. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0
0	FRAME DONE1_IRQ	Frame done for the primary LCD. The primary LCD output has been disabled by user. All the data have been sent. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
31	FLIPIMMEDIATEDONE_EN	Flip Immediate Done. The DMA engine has acknowledged the immediate BA change, and software can write the new BA0. 0x0: FrameDone for the primary LCD output is masked 0x1: FrameDone for the primary LCD output generates an interrupt when it occurs	RW	0
30	FRAME DONE3_EN	Frame done for the third LCD. The third LCD output has been disabled by user. All the data have been sent. 0x0: Frame Done for the secondary LCD is masked. 0x1: Frame Done for the secondary LCD generates an interrupt when it occurs.	RW	0
29	ACBIASCOUNT STATUS3_EN	AC Bias count status for the third LCD 0x0: ACBiasCountStatus for the secondary LCD output is masked 0x1: ACBiasCountStatus for the secondary LCD output generates an interrupt when it occurs	RW	0
28	VSYNC3_EN	Vertical synchronization for the third LCD 0x0: VSYNC for the secondary LCD output is masked. 0x1: VSYNC for the secondary LCD output generates an interrupt when it occurs.	RW	0
27	SYNC LOST3_EN	Synchronization lost on the third LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the third LCD output. 0x0: Synchronization Lost on the secondary LCD output is masked. 0x1: Synchronization Lost on the secondary LCD output generates an interrupt when it occurs.	RW	0
26	WBUNCOMPLETE ERROR_EN	The write back buffer has been flushed before been fully drained. Enable. 0x0: Interrupt is masked. 0x1: Interrupt is enabled.	RW	0

Bits	Field Name	Description	Type	Reset
25	WBBUFFER OVERFLOW_EN	Write-back DMA buffer overflow. The DMA buffer is full. 0x0: WBBufferOverflow is masked. 0x1: WBBufferOverflow generates an interrupt when it occurs.	RW	0
24	FRAME DONETV_EN	Frame done for the TV. The TV output has been disabled by user. All the data have been sent. 0x0: Frame Done for the TV output is masked. 0x1: Frame Done for the TV output generates an interrupt when it occurs.	RW	0
23	FRAME DONEWB_EN	Frame done for the write-back channel. The write-back channel has output the frame. All the data have been sent for the frame have been sent to the memory. There is no pending data inside the DMA engine for the write-back channel to be transferred to memory. 0x0: Frame done for the write-back is masked. 0x1: Frame done for the write-back generates an interrupt when it occurs.	RW	0
22	FRAME DONE2_EN	Frame done for the secondary LCD. The secondary LCD output has been disabled by user. All the data have been sent. 0x0: Frame done for the secondary LCD is masked. 0x1: Frame done for the secondary LCD generates an interrupt when it occurs.	RW	0
21	ACBIASCOUNT STATUS2_EN	AC Bias count status for the secondary LCD 0x0: ACBiasCountStatus for the secondary LCD output is masked. 0x1: ACBiasCountStatus for the secondary LCD output generates an interrupt when it occurs.	RW	0
20	VID3BUFFER UNDERFLOW_EN	Video 3 DMA Buffer Underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid3BufferUnderflow is masked. 0x1: Vid3BufferUnderflow generates an interrupt when it occurs.	RW	0
19	VID3END WINDOW_EN	The end of the video 3 window has been reached. It is detected by the overlay manager when the full video 3 has been displayed. 0x0: Vid3EndWindow is masked. 0x1: Vid3EndWindow generates an interrupt when it occurs.	RW	0
18	VSYNC2_EN	Vertical synchronization for the secondary LCD 0x0: VSYNC for the secondary LCD output is masked. 0x1: VSYNC for the secondary LCD output generates an interrupt when it occurs.	RW	0
17	SYNC LOST2_EN	Synchronization lost on the secondary LCD output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the secondary LCD output. 0x0: Synchronization Lost on the secondary LCD output is masked. 0x1: Synchronization Lost on the secondary LCD output generates an interrupt when it occurs.	RW	0
16	WAKEUP_EN	Wake up mask 0x0: WakeUp is masked. 0x1: WakeUp generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
15	SYNC LOSTTV_EN	Synchronization lost on the TV output. The required data are not output at the correct time due to too short blanking periods or stall of at least one pipelines associated with the TV output. 0x0: Synchronization Lost on the TV output is masked. 0x1: Synchronization Lost on the TV output generates an interrupt when it occurs.	RW	0
14	SYNC LOST1_EN	Synchronization lost for the primary LCD 0x0: SyncLost for the primary LCD output is masked. 0x1: SyncLost for the primary LCD output generates an interrupt when it occurs.	RW	0
13	VID2END WINDOW_EN	The end of the video 2 Window has been reached. It is detected by the overlay manager when the full video 2 has been displayed. 0x0: Vid2EndWindow is masked. 0x1: Vid2EndWindow generates an interrupt when it occurs.	RW	0
12	VID2BUFFER UNDERFLOW_EN	Video 2 DMA buffer underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid2BufferUnderflow is masked. 0x1: Vid2BufferUnderflow generates an interrupt when it occurs.	RW	0
11	ENDVID1 WINDOW_EN	The end of the video 1 window has been reached. It is detected by the overlay manager when the full video 1 has been displayed. 0x0: EndVid1Window is masked. 0x1: EndVid1Window generates an interrupt when it occurs.	RW	0
10	VID1BUFFER UNDERFLOW_EN	Video 1 DMA buffer underflow. The DMA buffer is not necessary empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: Vid1bufferunderflow is masked. 0x1: Vid1bufferunderflow generates an interrupt when it occurs.	RW	0
9	OCPERROR_EN	OCP Error. L3_MAIN Interconnect has sent SResp=ERR. 0x0: OCPError is masked. 0x1: OCPError generates an interrupt when it occurs.	RW	0
8	PALETTE GAMMA_EN	Palette gamma loading mask. The palette used as Color Look Up Table (CLUT) for the graphics BITMAP formats (1-, 2-, 4-, or 4-bpp) or as gamma table for the overlay output for the primary LCD output has been loaded successfully. 0x0: PaletteGamma is masked. 0x1: PaletteGamma generates an interrupt when it occurs.	RW	0
7	GFXEND WINDOW_EN	The end of the graphics Window has been reached. It is detected by the overlay manager when the full graphics has been displayed. 0x0: GfxEndWindow is masked. 0x1: GfxEndWindow generates an interrupt when it occurs.	RW	0
6	GFXBUFFER UNDERFLOW_EN	Graphics DMA Buffer Underflow. The DMA buffer is not necessarily empty but required data are not present in the DMA buffer (due to out of order responses) 0x0: GfxBufferUnderflow is masked. 0x1: GfxBufferUnderflow generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
5	PROGRAMMED LINENUMBER_EN	Programmed Line Number. It indicates that the scan of the primary LCD has reached the programmed user line number. 0x0: ProgrammedLineNumber is masked. 0x1: ProgrammedLineNumber generates an interrupt when it occurs.	RW	0
4	ACBIASCOUNT STATUS1_EN	AC Bias count status for the primary LCD 0x0: ACBiascountstatus for the primary LCD output is masked. 0x1: ACBiascountstatus for the primary LCD output generates an interrupt when it occurs.	RW	0
3	EVSYNC_ODD_EN	VSYNC for odd field from the TV encoder (HDMI) 0x0: EVSYNC_ODD for the TV output is masked. 0x1: EVSYNC_ODD for the TV output generates an interrupt when it occurs.	RW	0
2	EVSYNC_EVEN_EN	VSYNC for even field from the TV encoder (HDMI) 0x0: EVSYNC_EVEN for the TV output is masked. 0x1: EVSYNC_EVEN for the TV output generates an interrupt when it occurs.	RW	0
1	VSYNC1_EN	Vertical synchronization for the primary LCD. 0x0: VSYNC for the primary LCD output is masked. 0x1: VSYNC for the primary LCD output generates an interrupt when it occurs.	RW	0
0	FRAMEDONE_EN	Frame done for the primary LCD. The primary LCD output has been disabled by user. All the data have been sent. 0x0: Frame Done for the primary LCD output is masked. 0x1: FrameDone for the primary LCD output generates an interrupt when it occurs.	RW	0

Table 10-140. Register Call Summary for Register DISPC_IRQENABLE

Display Controller

- DISPC Interrupt Requests: [0]

Bits	Field Name	Description	Type	Reset
31:30	SPATIALTEMPORAL DITHERINGFRAMES	Spatial/temporal dithering number of frames for the primary LCD output wr: VFP start period of primary LCD 0x0: Spatial only 0x1: Spatial and temporal over 2 frames 0x2: Spatial and temporal over 4 frames 0x3: Reserved	RW	0x0
29	LCDENABLEPOL	Write 0s for future compatibility. Reads return 0.	R	0
28	LCDENABLESIGNAL	Write 0s for future compatibility. Reads return 0.	R	0
27	PCKFREEENABLE	Write 0s for future compatibility. Reads return 0.	R	0
26:25	TDMUNUSEDBITS	State of unused bits (TDM mode only) for the primary LCD output. wr: VFP start period of primary LCD 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved	RW	0x0
24:23	TDMCYCLEFORMAT	Cycle format (TDM mode only) for the primary LCD output WR: VFP start period of primary LCD 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels	RW	0x0
22:21	TDMPARALLELMODE	Output interface width (TDM mode only) for the primary LCD output WR: VFP start period of primary LCD 0x0: 8-bit parallel output interface selected 0x1: 9-bit parallel output interface selected 0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected	RW	0x0
20	TDMENABLE	Enable the multiple cycle format (TDM mode only used for TFT mode with the RFBI enable bit off) for the primary LCD output. WR: VFP start period of primary LCD 0x0: TDM disabled 0x1: TDM enabled	RW	0

Bits	Field Name	Description	Type	Reset
19:17	HT	Hold time for TV output WR: EVSYNC Encoded value (from 1 to 8) to specify the number of external digital clock periods to hold the data (programmed value = value minus 1)	RW	0x0
16	GPOUT1	General purpose output signal l WR: immediate 0x0: The GPout1 is reset. 0x1: The GPout1 is set.	RW	0
15	GPOUT0	General Purpose Output Signal WR:immediate 0x0: The GPout0 is reset. 0x1: The GPout0 is set.	RW	0
14	GPIN1	General purpose input signal WR: immediately Read 0x0: The GPin1 has been reset. Read 0x1: The GPin1 has been set.	R	0
13	GPIN0	General purpose input signal WR: immediately Read 0x0: The GPin0 has been reset. Read 0x1: The GPin0 has been set.	R	0
12	OVERLAYOPTIMIZATION	Overlay optimization for the primary LCD output WR: VFP start period of the primary LCD 0x0: All the data for all the enabled pipelines are fetched from memory regardless of the overlay/alpha blending configuration. 0x1: The data not used by the overlay manager because of overlap between layers with no alpha blending between them must not be fetched from memory in order to optimize the bandwidth.	RW	0
11	STALLMODE	STALL Mode for the primary LCD output WR: VFP start period of primary LCD 0x0: Normal mode selected 0x1: STALL mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output in order to generate a new frame. The stall mode is used in RFBI and DSI command modes.	RW	0
10	RESERVED	Reserved	R	0
9:8	TFTDATALINES	Number of lines of the primary LCD interface WR: VFP start period of primary LCD 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0
7	STDITHERENABLE	Spatial temporal dithering enable for the primary LCD output WR: VFP start period of primary LCD 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0

Bits	Field Name	Description	Type	Reset
6	GOTV	GO command for the TV output. It is used to synchronized the pipelines (graphics and/or video ones) associated with the TV output. WR: immediate 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the TV output using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished to program the shadow registers of the pipeline(s) associated with the TV output and the hardware can update the internal registers at the external VSYNC.	RW	0
5	GOLCD	GO command for the primary LCD output. It is used to synchronized the pipelines (graphics and/or video ones) associated with the primary LCD output. WR: immediate 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished to program the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period	RW	0
4	M8B	Mono 8-bit mode of the primary LCD wr: VFP start period of primary LCD output 0x0: Reserved 0x1: Reserved	RW	0
3	STNTFT	LCD Display type of the primary LCD WR: VFP start period of primary LCD output 0x0: STN display operation enabled. STN dither logic is enabled. 0x1: Active or TFT display operation enabled. STN Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/color selection for the primary LCD WR: VFP start period of primary LCD output 0x0: Color operation enabled (STN mode only) 0x1: Monochrome operation enabled (STN mode only)	RW	0
1	TVENABLE	Enable the TV output wr: immediate effect only occurs at the end of the current frame. 0x0: TV output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: TV output enabled	RW	0
0	LCDENABLE	Enable the primary LCD outputs wr: immediate Effect only occurs at the end of the current frame 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

Table 10-143. DISPC_CONFIG1

Address Offset	0x0000 0044		
Physical Address	0x5800 1044	**Instance**	DISPC
Description	The control register configures the Display Controller module for the primary LCD output and TV output. Shadow register, updated on VFP start period of primary LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31 30	29 28	27 26	25	24	23	22	21 20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0
29:28	TVINTERLEAVE	TV Interleave Pattern	RW	0x0
27:26	PLCDINTERLEAVE	pLCD Interleave Pattern	RW	0x0
25	FULLRANGE	Color Space Conversion full range setting. wr: VFP start of primary LCD 0x0: Limited range selected. 0x1: Full range selected.	RW	0
24	COLORCONV ENABLE	Enable the color space conversion. It shall be reset when CPR bit field is set to 0x1. wr: VFP start of primary LCD 0x0: Disable Color Space Conversion RGB to YUV 0x1: Enable Color Space Conversion RGB to YUV	RW	0
23	FIDFIRST	Selects the first field to output in case of interlace mode. In case of progressive mode, the value is not used. wr: VFP start of primary LCD 0x0: First field is even. 0x1: Odd field is first.	RW	0

Bits	Field Name	Description	Type	Reset
22	OUTPUTMODE ENABLE	Selects between progressive and interlace mode for the primary LCD output. wr: VFP start of primary LCD 0x0: Progressive mode selected. 0x1: Interlace mode selected.	RW	0
21:20	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0
19	TVALPHABLENDER ENABLE	Selects the alpha blender overlay manager for the TV output instead of the color key alpha blender (LCD output). The bit field is deprecated. It is present for software backward compatibility only. When it is enabled, the Z-order defined in each ATTRIBUTES registers for only the pipelines associated pipeline connected to the TV output are invalid and replaced by the following: graphics z-order = 3, video3 z-order = 2, video2 z-order =1 and video1 z-order=0 If it disabled, the z-order and z-order enable bit fields defined in each ATTRIBUTES register are used. wr: EVSYNC start of primary LCD 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDER ENABLE	Selects the alpha blender overlay manager for the primary LCD output instead of the color key alpha blender (LCD output). The bit field is deprecated. It is present for software backward compatibility only. When it is enabled, the Z-order defined in each ATTRIBUTES registers for only the pipelines associated with the primary LCD output are invalid and replaced by the following: graphics z-order = 3, video3 z-order = 2, video2 z-order =1 and video1 z-order=0 If it disabled, the z-order and z-order enable bit fields defined in each ATTRIBUTES register are used. wr: VFP start of primary LCD 0x0: Alpha blender is disabled. The color key alpha blending is used. 0x1: The alpha blender is enabled.	RW	0
17	BUFFERFILLING	Controls if the DMA buffers are refilled only when the LOW threshold is reached or if all DMA buffers are refilled when at least one of them reaches the LOW threshold. wr: immediate 0x0: Each DMA buffer is refilled when it reaches LOW threshold. 0x1: All DMA buffers are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active DMA buffers shall be considered and when reaching the end of the frame the DMA buffer goes to empty condition so no need to fill it again).	RW	0
16	BUFFERHAND CHECK	Controls the handcheck between DMA buffer and STALL signal in order to prevent from underflow. The bit shall be set to 0 when the module is not in STALL mode. (primary LCD output) wr: VFP start of primary LCD 0x0: Only the STALL signal (generated by RFBI, DSI1_A or DSI1_C depending on which IP uses the LCD output) is used regardless of the DMA buffer fullness information in order to provide data to the RFBI,DSI1_A or DS1_C module. 0x1: The STALL signal (generated by RFBI, DSI1_A or DSI1_C depending on which IP uses the LCD output) is used in combination with the DMA buffer fullness information in order to provide data to the RFBI, DSI1_A or DSI1_C module only when it does not generated buffer underflow.	RW	0

Bits	Field Name	Description	Type	Reset
15	CPR	Color phase rotation control (primary LCD output). It shall be reset when ColorConvEnable bit field is set to 1 wr: VFP start period of primary LCD output 0x0: Color Phase Rotation Disabled 0x1: Color Phase Rotation Enabled	RW	0
14	BUFFERMERGE	Buffer merge control wr: EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory or VFP When enabled, the DISPC_GLOBAL_BUFFER register is ignored. This bit must be set to zero when the write back channel is used. When DISPC_CONTROL2.GOWB is used BUFFERMERGE MUST be zero. When DISPC_CONTROL2.GOWB is used BUFFERMERGE MUST be zero. WR: immediate 0x0: DMA buffer merge disabled Each DMA buffer is dedicated to one pipeline. 0x1: DMA buffer merge enabled All the DMA buffers are merged into a single one to be used by the single active pipeline.	RW	0
13	TCKTV SELECTION	Transparency color key selection (TV output) wr: EVSYNC 0x0: Destination transparency color key selected 0x1: Source transparency color key selected	RW	0
12	TCKTVENABLE	Transparency color key enabled (TV output) WR: EVSYNC 0x0: Disable the transparency color key for the TV output 0x1: Enable the transparency color key for the TV output	RW	0
11	TCKLCD SELECTION	Transparency color key selection (primary LCD output) wr: VFP start period of primary LCD output 0x0: Destination transparency color key selected 0x1: Source transparency color key selected	RW	0
10	TCKLCDENABLE	Transparency color key enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD	RW	0
9	GAMATABLE ENABLE	For backward compatibility, an enable bit has been added on the 2 additional gamma tables (secondary display and TV). Gamma table of LCD1 is always enabled. 0x0: Gamma table LCD2 and TV are bypassed 0x1: Gamma table LCD2 and TV are enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: AcBias gated disabled 0x1: AcBias gated enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: VSYNC gated disabled 0x1: VSYNC gated enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: HSYNC gated disabled 0x1: HSYNC gated enabled	RW	0

Bits	Field Name	Description	Type	Reset
5	PIXELCLOCK GATED	Pixel Clock Gated Enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: Pixel clock gated disabled 0x1: Pixel clock gated enabled	RW	0
4	PIXELDATAGATED	Pixel data gated enabled (primary LCD output) wr: VFP start period of primary LCD output 0x0: Pixel data gated disabled 0x1: Pixel data gated enabled	RW	0
3	PALETTEGAMMA TABLE	Palette/gamma table selection wr: VFP start period of primary LCD output or VFP start period of secondary LCD output or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the graphics pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory. In case of the table is used as gamma table, it is used for the primary LCD output only. 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0
2:1	LOADMODE	Loading mode for the palette/gamma table wr: VFP start period of primary LCD output or VFP start period of secondary LCD output or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory 0x0: Palette/Gamma Table and data are loaded every frame 0x1: Palette/Gamma Table to be loaded. The user sets the bit when the palette/gamma table has to be loaded. Hardware resets the bit to 0x2 when table has been loaded. (DISPC_GFX_ATTRIBUTES.ENABLE has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 0x2 (Hardware).	RW	0x0
0	PIXELGATED	Pixel gated enable (only for TFT) (primary LCD output) wr: VFP start period of primary LCD output 0x0: Pixel clock always toggles (only in TFT mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in TFT mode)	RW	0

- DISPC Register Summary: [6]

Table 10-177. DISPC_GFX_ATTRIBUTES

Address Offset	0x0000 00A0		
Physical Address	0x5800 10A0	**Instance**	DISPC
Description	The register configures the graphics attributes. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CHANNELOUT2		BURSTTYPE	PREMULTIPLYALPHA	ZORDER		ZORDERENABLE	ANTIFLICKER	RESERVED			SUBSAMPLINGPATTERN			SELFREFRESHAUTO	FORCE1DTILEDMODE	SELFREFRESH	ARBITRATION	ROTATION		BUFPRELOAD	FRAMEPACKINGMODE	NIBBLEMODE	CHANNELOUT	BURSTSIZE		REPLICATIONENABLE	FORMAT				ENABLE

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (should set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. (It does not apply to the palette loading OCP requests using INCR burst only) 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0
28	PREMULTIPLYALPHA	The field configures the DISPC GFX to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	ANTIFLICKER	Antiflicker filtering using a 3-tap filter with hardcoded coefficients (1/4, 1/2, 1/4) 0x0: Antiflicker disabled. 0x1: Antiflicker enabled.	RW	0
23:21	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0
20:18	SUBSAMPLINGPATTERN	Subsampling pattern setting.	RW	0x0
17	SELFREFRESHAUTO	Automatic self-refresh mode 0x0: The transition from Selfrefresh disabled to enabled is controlled by software 0x1: The transition from Selfrefresh disabled to enabled is controlled only by hardware	RW	0
16	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0x0

Bits	Field Name	Description	Type	Reset
15	SELFREFRESH	Enables the self refresh of the graphics window from its own DMA buffer. This bit should be set only after having set the GO bit of the channel and read back a zero in its field. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory. 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics DMA buffer is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
14	ARBITRATION	Determines the priority of the graphics pipeline. When the graphics pipeline is one of the high priority pipelines. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline.	RW	0
13:12	ROTATION	Graphics rotation flag 0x0: No rotation 0x1: Rotation by 90 degrees 0x3: Rotation by 270 degrees 0x2: Rotation by 180 degrees	RW	0x0
11	BUFPRELOAD	Graphics preload value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
10	FRAMEPACKINGMODE	Frame packing mode control. 0x0: Frame Packing mode is disabled 0x1: Nibble mode is enabled	RW	0x0
9	NIBBLEMODE	Graphics nibble mode (only for 1-, 2- and 4 bpp) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled	RW	0
8	CHANNELOUT	Graphics Channel Out configuration: LCD, WB or TV. wr: immediate 0x0: LCD output or WB to the memory selected. bit fields 31 and 30 defines the output associated (primary, secondary or write-back). 0x1: TV output selected	RW	0
7:6	BURSTSIZE	Graphics DMA burst size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
5	REPLICATIONENABLE	Graphics replication enabled: RGB . ARGB, and RGBA formats are converted into ARGB32-8888 using replication of the MSBs or 0s 0x0: Disable graphics replication logic. The conversion to ARGB32-8888 is done by adding 0s for the LSBs 0x1: Enable graphics replication logic. The conversion to ARGB32-8888 is done by duplicating the MSBs for the LSBs	RW	1

Bits	Field Name	Description	Type	Reset
4:1	FORMAT	Graphics format. It defines the pixel format when fetching the graphics picture into memory. 0x6: RGB16-565 0xA: RGBx12-4444 0x7: ARGB16-1555 0xD: RGBA32-8888 0x8: xRGB24-8888 (32-bit container) 0x9: RGB24-888 (24-bit container) 0xB: RGBA12-4444 0x4: xRGB12-4444 0x5: ARGB16-4444 0xF: xRGB15-1555 0xC: ARGB32-8888 0x3: BGRA32-8888 0xE: RGBx24-8888 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	ENABLE	Graphics enable 0x0: Graphics disabled (graphics pipeline inactive and graphics window not present) 0x1: Graphics enabled (graphics pipeline active and graphics window present on the screen)	RW	0

Table 10-189. DISPC_VID1_BA_j

Address Offset	0x0000 00BC + (0x4 * j)	**Index**	j = 0 to 1
Physical Address	0x5800 10BC + (0x4 * j)	**Instance**	DISPC
Description	The register configures the base address of the video buffer for the video window 1 (DISPC_VID1_BA_0 and DISPC_VID1_BA_1 for ping-pong mechanism with external trigger, based on the field polarity otherwise only DISPC_VID1_BA_0 is used). Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Video base address Base address of the video buffer (aligned on pixel size boundary except in case of RGB24 packed format, 4-pixel alignment is required; in case of YUV4:2:2, 2-pixel alignment is required, and YUV4:2:0, byte alignment is supported)). It case of YUV4:2:0 format, it indicates the base address of the Y buffer. When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM.	RW	0x0000 0000

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (should be set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0

Bits	Field Name	Description	Type	Reset
28	PREMULTIPHYALPHA	The field configures the DISPC VID1 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video1 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video vertical resize tap number. The vertical polyphase filter can be configured in 3-tap or 5-tap configuration. According to the number of taps, the maximum input picture width is double while using 3-tap compared to 5-tap. 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0

Bits	Field Name	Description	Type	Reset
19	BUFPRELOAD	Video Preload Value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
18	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
17	SELFREFRESHAUTO	Automatic self-refresh mode 0x0: The transition from SELFREFRESH disabled to enabled is controlled by SW. 0x1: The transition from SELFREFRESH disabled to enabled is controlled only by hardware.	RW	0
16	CHANNELOUT	Video channel out configuration: LCD, WB or TV. wr: immediate 0x0: LCD output or WB to the memory selected. bit fields 31 and 30 defines the output associated (primary, secondary or write-back). 0x1: TV output selected	RW	0
15:14	BURSTSIZE	Video DMA burst size 0x0: 2x128bit bursts 0x1: 4x128bit bursts 0x3: Reserved 0x2: 8x128bit bursts	RW	0x2
13:12	ROTATION	Video rotation flag 0x0: No rotation 0x1: Rotation by 90 degrees 0x3: Rotation by 270 degrees 0x2: Rotation by 180 degrees	RW	0x0
11	FULLRANGE	Color space conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	REPLICATIONENABLE	Replication enable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	1
9	COLORCONVENABLE	Enable the color space conversion. The hardware does not enable/disable the conversion based on the pixel format. The bit field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion YUV to RGB 0x1: Enable Color Space Conversion YUV to RGB	RW	0
8	FRAMEPACKINGMODE	Frame packing mode control. 0x0: Frame Packing mode is disabled 0x1: Nibble mode is enabled	RW	0
7	HRESIZECONF	Write 0s for future compatibility. Reads return 0.	R	0
6:5	RESIZEENABLE	Video Resize Enable 0x0: Disable both horizontal and vertical resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0

Bits	Field Name	Description	Type	Reset
4:1	FORMAT	Video Format. It defines the pixel format when fetching the video 1 picture into memory. 0x6: RGB16-565 0x1: RGB12x-4444 0xA: YUV2 4:2:2 co-sited 0x7: ARGB16-1555 0xD: RGBA32-8888 0x0: NV12 4:2:0 2 buffers (Y + UV) 0x2: RGBA12-4444 0x8: xRGB24-8888 (32-bit container) 0x9: RGB24-888 (24-bit container) 0xB: UYVY 4:2:2 co-sited 0x5: ARGB16-4444 0xF: xRGB15-1555 0xC: ARGB32-8888 0x4: xRGB12-4444 0x3: BGRA32-8888 0xE: RGBx24-8888 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	ENABLE	Video Enable 0x0: Video disabled (video pipeline inactive and window not present) 0x1: Video enabled (video pipeline active and window present on the screen)	RW	0

Table 10-203. DISPC_VID1_PIXEL_INC

Address Offset	0x0000 00DC		
Physical Address	0x5800 10DC	**Instance**	DISPC
Description	The register configures the number of bytes to increment between two pixels for the buffer associated with the video window 2. For more information, see Section 10.2.4.6.5, *Predecimation*.The register is used only when the TILER is not present in the system in order to perform low performance rotation. When the TILER IP is present it is highly recommended to use it for performing the rotation. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD orEVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Video base address Base address of the video buffer (aligned on pixel size boundary except in case of RGB24 packed format, 4-pixel alignment is required; in case of YUV4:2:2, 2-pixel alignment is required, and YUV4:2:0, byte alignment is supported)). In case of YUV4:2:0 format, it indicates the base address of the Y buffer. When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM.	RW	0x0000 0000

Table 10-231. DISPC_VID2_ATTRIBUTES

Address Offset	0x0000 015C		
Physical Address	0x5800 115C	**Instance**	DISPC
Description	The register configures the attributes of the video window 2. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31 30	29	28	27 26	25	24	23	22	21	20	19	18	17	16	15 14	13 12	11	10	9	8	7	6	5	4	3	2	1	0
CHANNELOUT2	BURSTTYPE	PREMULTIPLYALPHA	ZORDER	ZORDERENABLE	SELFREFRESH	ARBITRATION	DOUBLESTRIDE	VERTICALTAPS	FORCE1DTILEDMODE	BUFPRELOAD	RESERVED	SELFREFRESHAUTO	CHANNELOUT	BURSTSIZE	ROTATION	FULLRANGE	REPLICATIONENABLE	COLORCONVENABLE	FRAMEPACKINGMODE	HRESIZECONF	RESIZEENABLE	FORMAT					ENABLE

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (must be set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0

Bits	Field Name	Description	Type	Reset
28	PREMULTIPLYALPHA	The field configures the DISPC VID2 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is only used when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video2 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video Vertical Resize Tap Number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0

Bits	Field Name	Description	Type	Reset
19	BUFPRELOAD	Video Preload Value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
18	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
17	SELFREFRESHAUTO	Automatic self-refresh mode 0x0: The transition from SELFREFRESH disabled to enabled is controlled by SW. 0x1: The transition from SELFREFRESH disabled to enabled is controlled only by hardware.	RW	0
16	CHANNELOUT	Video Channel Out configuration: LCD, WB or TV. wr: immediate 0x0: LCD output or WB to the memory selected. bit fields 31 and 30 defines the output associated (primary, secondary or write-back). 0x1: TV output selected	RW	0
15:14	BURSTSIZE	Video DMA burst size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
13:12	ROTATION	Video Rotation Flag 0x0: No rotation 0x1: Rotation by 90 degrees 0x3: Rotation by 270 degrees 0x2: Rotation by 180 degrees	RW	0x0
11	FULLRANGE	Color space conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	REPLICATIONENABLE	Replication Enable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	1
9	COLORCONVENABLE	Enable the color space conversion. The hardware does not enable/disable the conversion based on the pixel format. The bit field shall be reset when the format is not YUV. 0x0: Disable color space conversion YUV to RGB 0x1: Enable color space conversion YUV to RGB	RW	0
8	FRAMEPACKINGMODE	Frame packing mode control. 0x0: Frame Packing mode is disabled 0x1: Nibble mode is enabled	RW	0
7	HRESIZECONF	Write 0s for future compatibility. Reads return 0.	R	0
6:5	RESIZEENABLE	Video Resize Enable 0x0: Disable both horizontal and vertical resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0

Bits	Field Name	Description	Type	Reset
4:1	FORMAT	Video Format. It defines the pixel format when fetching the video 2 picture into memory. 0x6: RGB16-565 0x1: RGB12x-4444 0xA: YUV2 4:2:2 co-sited 0x7: ARGB16-1555 0xD: RGBA32-8888 0x0: NV12 4:2:0 2 buffers (Y + UV) 0x2: RGBA12-4444 0x8: xRGB24-8888 (32-bit container) 0x9: RGB24-888 (24-bit container) 0xB: UYVY 4:2:2 co-sited 0x5: ARGB16-4444 0xF: xRGB15-1555 0xC: ARGB32-8888 0x4: xRGB12-4444 0x3: BGRA32-8888 0xE: RGBx24-8888 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	ENABLE	VidEnable 0x0: Video disabled (video pipeline inactive and window not present) 0x1: Video enabled (video pipeline active and window present on the screen)	RW	0

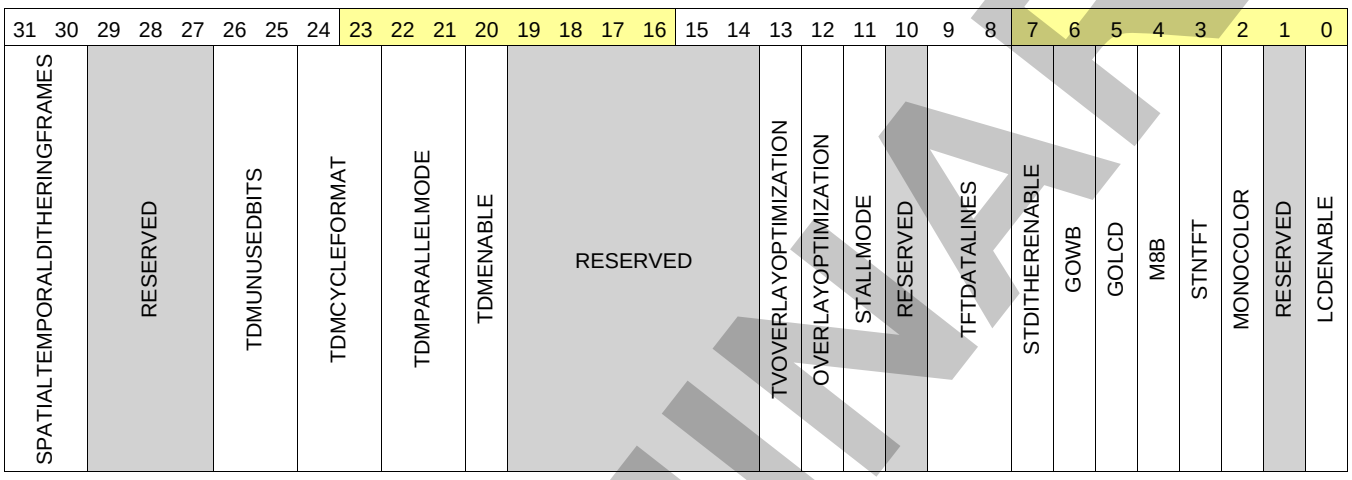
Table 10-283. DISPC_CONTROL2

Address Offset	0x0000 0238		
Physical Address	0x5800 1238	**Instance**	DISPC
Description	The control register configures the Display Controller module for the secondary LCD output. Shadow registers are updated during the VFP start period of the secondary LCD, EVSYNC, or when DISPC_CONTROL2.GOWB is set to 1 by software and the current WB frame is complete (that is, has no more data in the write-back pipeline).		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:30	SPATIALTEMPORAL DITHERINGFRAMES	Spatial/temporal dithering number of frames for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: Spatial only 0x1: Spatial and temporal over 2 frames 0x2: Spatial and temporal over 4 frames 0x3: Reserved	RW	0x0
29:27	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0
26:25	TDMUNUSED BITS	State of unused bits (TDM mode only) for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved	RW	0x0
24:23	TDMCYCLE FORMAT	Cycle format (TDM mode only) for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels	RW	0x0
22:21	TDMPARALLEL MODE	Output Interface width (TDM mode only) for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: 8-bit parallel output interface selected 0x1: 9-bit parallel output interface selected 0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected	RW	0x0

Bits	Field Name	Description	Type	Reset
20	TDMENABLE	Enable the multiple cycle format (TDM mode only used for Active Matrix mode with the RFBI enable bit off) for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: TDM disabled 0x1: TDM enabled	RW	0
19:14	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x00
13	TVOVERLAY OPTIMIZATION	Overlay optimization for the TV output wr: VFP or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory 0x0: All the data for all the enabled pipelines are fetched from memory regardless of the overlay/alpha blending configuration. 0x1: The data not used by the overlay manager because of overlap between layers with no alpha blending between them shall not be fetched from memory in order to optimize the bandwidth.	RW	0
12	OVERLAY OPTIMIZATION	Overlay optimization for the secondary LCD output wr: VFP or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory 0x0: All the data for all the enabled pipelines are fetched from memory regardless of the overlay/alpha blending configuration. 0x1: The data not used by the overlay manager because of overlap between layers with no alpha blending between them shall not be fetched from memory in order to optimize the bandwidth.	RW	0
11	STALLMODE	STALL mode for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: Normal mode selected 0x1: STALL mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output in order to generate a new frame.	RW	0
10	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
9:8	TFTDATALINES	Number of lines of the secondary LCD interface wr: VFP start period of secondary LCD output 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0
7	STDITHER ENABLE	Spatial temporal dithering enable for the secondary LCD output wr: VFP start period of secondary LCD output 0x0: Spatial/Temporal dithering logic disabled 0x1: Spatial/Temporal dithering logic enabled	RW	0

Bits	Field Name	Description	Type	Reset
6	GOWB	GO command for the write-back output. It is used to synchronized the pipelines (graphics and/or video ones) associated with the write-back output to the memory. wr:immediate 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the write-back pipeline using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished to program the shadow registers of the pipeline(s) associated with the write-back pipeline and the hardware can update the internal registers immediately	RW	0
5	GOLCD	GO command for the secondary LCD output. It is used to synchronized the pipelines (graphics and/or video ones) associated with the secondary LCD output. wr:immediate 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: The user has finished to program the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period	RW	0
4	M8B	Mono 8-bit mode of the secondary LCD wr: VFP start period of secondary LCD output 0x0: Reserved 0x1: Reserved	RW	0
3	STNTFT	LCD Display type of the secondary LCD wr: VFP start period of secondary LCD output 0x0: Reserved 0x1: Active or TFT display operation enabled. STN Dither logic and output FIFO bypassed.	RW	0
2	MONOCOLOR	Monochrome/Color selection for the secondary LCD wr: VFP start period of secondary LCD output 0x0: Reserved 0x1: Reserved	RW	0
1	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0
0	LCDENABLE	Enable the secondary LCD output wr:immediate 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled	RW	0

- DISPC Shadow Registers: [0]
- DISPC Logical Register Mapping: [1]
- DISPC Register Summary: [2]

Table 10-299. DISPC_VID3_FIR_COEF_HV_i

Address Offset	0x0000 0314 + (0x8 * i)	**Index**	i = 0 to 7
Physical Address	0x5800 1314 + (0x8 * i)	**Instance**	DISPC
Description	The bank of registers configure the down/up/down-scaling coefficients for the vertical and horizontal resize of the video picture associated with the video window 3 for the phases from 0 to 7. It is used for ARGB and Y setting. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 10-303. DISPC_VID3_ATTRIBUTES

Address Offset	0x0000 0370		
Physical Address	0x5800 1370	**Instance**	DISPC
Description	The register configures the attributes of the video window 3. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory		
Type	RW		

31 30	29	28	27 26	25	24	23	22	21	20	19	18	17	16	15 14	13 12	11	10	9	8	7	6	5	4	3	2	1	0
CHANNELOUT2	BURSTTYPE	PREMULTIPLYALPHA	ZORDER	ZORDERENABLE	SELFREFRESH	ARBITRATION	DOUBLESTRIDE	VERTICALTAPS	FORCE1DTILEDMODE	BUFFPRELOAD	RESERVED	SELFREFRESHAUTO	CHANNELOUT	BURSTSIZE	ROTATION	FULLRANGE	REPLICATIONENABLE	COLORCONVENABLE	FRAMEPACKINGMODE	HRESIZECONF	RESIZEENABLE	FORMAT					ENABLE

Bits	Field Name	Description	Type	Reset
31:30	CHANNELOUT2	It is not used if CHANNELOUT is set to TV. Reserved when CHANNELOUT = 1 (should be set to zero) wr: immediate 0x0: Primary LCD output selected. 0x1: Secondary LCD output selected. 0x2: Third LCD output selected. 0x3: Write-back output to the memory selected.	RW	0x0
29	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0
28	PREMULTIPLYALPHA	The field configures the DISPC VID3 to process incoming data as premultiplied alpha data or non premultiplied alpha data. Default setting is non premultiplied alpha data. 0x0: Non premultiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0

Bits	Field Name	Description	Type	Reset
27:26	ZORDER	Z-Order defining the priority of the layer compared to others when overlaying. It is software responsibility to ensure that each layer connected to the same overlay manager has a different z-order value. If bit 25 is set to 0, the ZORDER bit field is ignored and replaced by the value 0. 0x0: Z-order 0: layer above solid background color and below layer with higher Z-order values. 0x1: Z-order 1: layer above layer with z-order value of 0 and below layers with z-order values of 2 and 3 0x3: Z-order 3: layer above all the other layers 0x2: Z-order 2: layer above layers with z-order value of 0 and 1 and below layer with z-order value of 3	RW	0x0
25	ZORDERENABLE	Z-order Enable. The bit field ZORDER is used only when the Z-order is enabled. 0x0: Z-order disabled. The Z-order of the layer is 0. 0x1: Z-order enabled. The Z-order is defined by the bit field ZORDER (bits 26 and 27).	RW	0
24	SELFREFRESH	Enables the self refresh of the video window from its own DMA buffer only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory. 0x1: The video pipeline does not need anymore to fetch data from memory. Only the DMA buffer associated with the video3 is used. It takes effect after the frame has been loaded in the DMA buffer.	RW	0
23	ARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0
21	VERTICALTAPS	Video vertical resize tap number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. The associated bit fields for the 2 other taps coefficients do not need to be initialized. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0
19	BUFPRELOAD	Video Preload Value 0x0: Hardware prefetches pixels up to the preload value defined in the preload register 0x1: Hardware prefetches pixels up to high threshold value	RW	0
18	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0

Bits	Field Name	Description	Type	Reset
17	SELFREFRESHAUTO	Automatic self-refresh mode 0x0: The transition from SELFREFRESH disabled to enabled is controlled by SW. 0x1: The transition from SELFREFRESH disabled to enabled is controlled only by hardware.	RW	0
16	CHANNELOUT	Video channel out configuration: LCD, WB or TV. wr: immediate 0x0: LCD output or WB to the memory selected. bit fields 31 and 30 defines the output associated (primary, secondary or write-back). 0x1: TV output selected	RW	0
15:14	BURSTSIZE	Video DMA burst size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
13:12	ROTATION	Video rotation flag 0x0: No rotation 0x1: Rotation by 90 degrees 0x3: Rotation by 270 degrees 0x2: Rotation by 180 degrees	RW	0x0
11	FULLRANGE	Color Space Conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	REPLICATIONENABLE	Replication enable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	1
9	COLORCONVENABLE	Enable the color space conversion. The hardware does not enable/disable the conversion based on the pixel format. The bit field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion YUV to RGB 0x1: Enable Color Space Conversion YUV to RGB	RW	0
8	FRAMEPACKINGMODE	Frame packing mode control. 0x0: Frame Packing mode is disabled 0x1: Nibble mode is enabled	RW	0
7	HRESIZECONF	Write 0s for future compatibility. Reads return 0.	R	0
6:5	RESIZEENABLE	Video resize enable 0x0: Disable both horizontal and vertical resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0

Bits	Field Name	Description	Type	Reset
4:1	FORMAT	Video format. It defines the pixel format when fetching the video 3 picture into memory. 0x6: RGB16-565 0x1: RGB12x-4444 0xA: YUV2 4:2:2 co-sited 0x7: ARGB16-1555 0xD: RGBA32-8888 0x0: NV12 4:2:0 2 buffers (Y + UV) 0x2: RGBA12-4444 0x8: RGB24-8888 (32-bit container) 0x9: RGB24-888 (24-bit container) 0xB: UYVY 4:2:2 co-sited 0x5: ARGB16-4444 0xF: xRGB15-1555 0xC: ARGB32-8888 0x4: xRGB12-4444 0x3: BGRA32-8888 0xE: RGBx24-8888 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	ENABLE	Video Enable 0x0: Video disabled (video pipeline inactive and window not present) 0x1: Video enabled (video pipeline active and window present on the screen)	RW	0

Table 10-323. DISPC_VID3_PIXEL_INC

Address Offset	0x0000 0398		
Physical Address	0x5800 1398	**Instance**	DISPC
Description	The register configures the number of bytes to increment between two pixels for the buffer associated with the video window 3. For more information, see Section 10.2.4.6.5, *Predecimation*.The register is used only when the TILER is not present in the system in order to perform low performance rotation. When the TILER IP is present it is highly recommended to use it for performing the rotation. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

Bits	Field Name	Description	Type	Reset
31:19	RESERVED	Write 0s for future compatibility. Reads return 0.	R	0x0000
18	ALIGN	Defines the alignment between HSYNC and VSYNC assertion. 0x0: VSYNC and HSYNC are not aligned. 0x1: VSYNC and HSYNC assertions are aligned.	RW	0
17	ONOFF	HSYNC/VSYNC Pixel clock Control On/Off 0x0: HSYNC and VSYNC are driven on opposite edges of pixel clock than pixel data. 0x1: HSYNC and VSYNC are driven according to bit 16.	RW	0
16	RF	Program HSYNC/VSYNC Rise or Fall 0x0: HSYNC and VSYNC are driven on falling edge of pixel clock (if bit 17 set to 1). 0x1: HSYNC and VSYNC are driven on rising edge of pixel clock (if bit 17 set to 1).	RW	0
15	IEO	Invert output enable 0x0: Ac-bias is active high (active display mode). 0x1: Ac-bias is active low (active display mode).	RW	0
14	IPC	Invert pixel clock 0x0: Data is driven on the LCD data lines on the rising-edge of the pixel clock. 0x1: Data is driven on the LCD data lines on the falling-edge of the pixel clock.	RW	0
13	IHS	Invert HSYNC 0x0: Line clock pin is active high and inactive low. 0x1: Line clock pin is active low and inactive high.	RW	0
12	IVS	Invert VSYNC 0x0: Frame clock pin is active high and inactive low. 0x1: Frame clock pin is active low and inactive high.	RW	0
11:8	ACBI	AC Bias Pin transitions per interrupt Value (from 0 to 15) used to specify the number of AC Bias pin transitions	RW	0x0
7:0	ACB	AC Bias Pin Frequency Value (from 0 to 255) used to specify the number of line clocks to count before transitioning the AC Bias pin. This pin is used to periodically invert the polarity of the power supply to prevent DC charge build-up within the display.	RW	0x00

BA																															

Bits	Field Name	Description	Type	Reset
31:0	BA	Write-back base address Base address of the WB buffer (aligned on pixel size boundary except in case of RGB24 packed format, 4-pixel alignment is required; in case of YUV4:2:2, 2-pixel alignment is required, and YUV4:2;0, byte alignment is supported)). It case of YUV4:2:0 format, it indicates the base address of the Y buffer. When the TILER is addressed, the bits: [28:27] = 0x0 for 8-bit tiled [28:27] = 0x1 for 16-bit tiled [28:27] = 0x2 for 32-bit tiled [28:27] = 0x3 for page mode [31:29] = 0x0 for 0-degree view [31:29] = 0x1 for 180-degree view + mirroring [31:29] = 0x2 for 0-degree view + mirroring [31:29] = 0x3 for 180-degree view [31:29] = 0x4 for 270-degree view + mirroring [31:29] = 0x5 for 270-degree view [31:29] = 0x6 for 90-degree view [31:29] = 0x7 for 90-degree view + mirroring Otherwise the bits indicated the corresponding bit address to access the SDRAM.	RW	0x0000 0000

Table 10-369. DISPC_WB_ATTRIBUTES

Address Offset	0x0000 0570		
Physical Address	0x5800 1570	**Instance**	DISPC
Description	The register configures the attributes of the viwrite back pipeline. Shadow register, updated when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline) when the WB pipeline is directly connected to one of the pipelines (graphics or video), otherwise updated on VFP start period of primary LCD or VFP start period of secondary LCD or VFP start period of the third LCD or EVSYNC depending on which overlay output is selected as an input to the WB pipeline		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDLENUMBER				IDLESIZE	CAPTUREMODE			ARBITRATION	DOUBLESTRIDE	VERTICALTAPS	FORCE1DTILEDMODE	WRITEBACKMODE	CHANNELIN			BURSTSIZE		RESERVED		FULLRANGE	TRUNCATIONENABLE	COLORCONVENABLE	BURSTTYPE	ALPHAENABLE	RESIZEENABLE	FORMAT					ENABLE

Bits	Field Name	Description	Type	Reset
31:28	IDLENUMBER	Determines the number of idles between requests on the L3_MAIN interconnect. It is only used when the write-back pipeline does data transfer from memory to memory. When the output of an overlay is stored in memory through the write-back pipeline in capture mode, the bit field IDLENUMBER is ignored since a timing generator is used to time the transfer. The number of IDLE cycles is IDLENUMBER (from 0 to 15) if IDLESIZE = 0. The number of IDLE cycles is IDLENUMBERx8 (from 0 to 120) if IDLESIZE = 1 and BURSTSIZE = 2. The number of IDLE cycles is IDLENUMBERx4 (from 0 to 60) if IDLESIZE = 1 and BURSTSIZE = 1. The number of IDLE cycles is IDLENUMBERx2 (from 0 to 30) if IDLESIZE = 1 and BURSTSIZE = 0.	RW	0x0
27	IDLESIZE	Determines if the IDLENUMBER corresponds to a number of bursts or singles. 0x0: The number of idles between requests is defined by IDLENUMBER as number of cycles. 0x1: The number of idles between requests is defined by IDLENUMBER multiplied by burst size as number of cycles.	RW	0
26:24	CAPTUREMODE	Defines the frame rate capture. 0x6: Only one out of six frames is captured. The first one is captured then the second one is skipped and so on. 0x1: Only one frame is captured. 0x7: Only one out of seven frames is captured. The first one is captured then the second one is skipped and so on. 0x0: All frames are captures until the write-back channel is disabled or there is no more data generated by the overlay or the pipeline attached to the write-back channel. 0x2: Only one out of two frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x4: Only one out of four frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x5: Only one out of five frames is captured. The first one is captured, and then the second one is skipped, and so on. 0x3: Only one out of three frames is captured. The first one is captured, and then the second one is skipped, and so on.	RW	0x0
23	ARBITRATION	Determines the priority of the write-back pipeline. The write-back pipeline is one of the high priority pipeline. The arbitration gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The write-back pipeline is one of the normal priority pipeline. 0x1: The write-back pipeline is one of the high priority pipeline.	RW	0
22	DOUBLESTRIDE	Determines if the stride for CbCr buffer is the 1x or 2x of the Y buffer stride. It is only used in case of YUV4:2:0. 0x0: The CbCr stride value is equal to the Y stride. 0x1: The CbCr stride value is double to the Y stride.	RW	0

Bits	Field Name	Description	Type	Reset
21	VERTICALTAPS	Video Vertical Resize Tap Number 0x0: 3 taps are used for the vertical filtering logic. The 2 other taps are not used. 0x1: 5 taps are used for the vertical filtering logic.	RW	0
20	FORCE1DTILEDMODE	Force TILED regions access to 1D or 2D. 0x0: 2D accesses for tiled regions 0x1: 1D accesses for tiled regions	RW	0x0
19	WRITEBACKMODE	When connected to the overlay output of a channel the write back can operate as a simple transfer from memory to memory (composition engine) or as a capture channel. 0x0: Capture mode (default mode) 0x1: Memory-to-memory mode	RW	0x0
18:16	CHANNELIN	Video Channel In configuration WR: immediate 0x6: Video3 pipeline output 0x1: Secondary LCD output 0x0: Primary LCD overlay output 0x2: TV overlay output 0x4: Video1 pipeline output 0x5: Video2 pipeline output 0x3: Graphics pipeline output 0x7: Third LCD output	RW	0x0
15:14	BURSTSIZE	Write-back DMA Burst Size 0x0: 2 × 128-bit bursts 0x1: 4 × 128-bit bursts 0x3: Reserved 0x2: 8 × 128-bit bursts	RW	0x2
13:12	RESERVED	Reserved	RW	0x0
11	FULLRANGE	Color Space Conversion full range setting. 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	TRUNCATIONENABLE	It applies only when the input format to the write-back pipeline from the overlay or directly from one of the pipelines is ARGB32. If the format is one of the YUV supported formats, the bit field is ignored. 0x0: Disable truncation logic 0x1: Enable truncation logic from ARGB32 to the pixel format defined in the field FORMAT.	RW	0
9	COLORCONVENABLE	Enable the color space conversion. The hardware does not enable/disable the conversion based on the pixel format. The bit field shall be reset when the format is not YUV. 0x0: Disable Color Space Conversion RGB to YUV 0x1: Enable Color Space Conversion RGB to YUV	RW	0
8	BURSTTYPE	The type of burst can be INCR (incremental) or BLCK (2D block). The 2D block is required when the TILER is targeted by the DMA engine. 0x0: INC burst type is used. 0x1: 2D block burst type is used.	RW	0

Bits	Field Name	Description	Type	Reset
7	ALPHAENABLE	Premultiplied alpha enable Read 0x1: Enabled Read 0x0: Disabled. This bit also disable the logic present in the associated channel out that compute the alpha component sent to the WB pipe. When the WB is configured to copy back one of the output channels (output of overlay), the following configurations are available: 0x1: The WB pipe copies back to memory the premultiplied alpha calculated through the overlay. 0x0: The alpha value is not written back.	RW	0
6:5	RESIZEENABLE	Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing 0x3: Enable both horizontal and vertical resize processing 0x2: Enable the vertical resize processing	RW	0x0
4:1	FORMAT	Write-back format. It defines the pixel format when storing the write-back picture into memory. 0x6: RGB16-565 0x1: RGB12x-4444 0xA: YUV2 4:2:2 co-sited 0x7: ARGB16-1555 0xD: RGBA32-8888 0x0: NV12 4:2:0 2 buffers (Y + UV) 0x2: RGBA12-4444 0x8: xRGB24-8888 (32-bit container) 0x9: RGB24-888 (24-bit container) 0xB: UYVY 4:2:2 co-sited 0x5: ARGB16-4444 0xF: xRGB15-1555 0xC: ARGB32-8888 0x4: xRGB12-4444 0x3: BGRA32-8888 0xE: RGBx24-8888 (24-bit RGB aligned on MSB of the 32-bit container)	RW	0x0
0	ENABLE	Write-back enable. wr: immediate 0x0: Write-back disabled 0x1: Write-back enabled	RW	0

Physical Address	0x5800 1688 + (0x4 * i)	**Instance**	DISPC
Description	The bank of registers configure the down/up/down-scaling coefficients for the vertical resize of the video picture associated with the video window 1 for the phases from 0 to 7. It is used for Crb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the hardware, any value can be used for the bit fields. Shadow register, updated on VFP start period of primary LCD or VFP start period of the secondary LCD or VFP start period of the third LCD or EVSYNC or when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline). The synchronization event is defined based on the output using the pipeline: primary LCD, secondary LCD, third LCD, TV output or write-back to the memory

Description	The register configures the resize accumulator init values for horizontal and vertical up/downsampling of the write back pipeline (DISPC_WB_ACCU2_0 and DISPC_WB_ACCU2_1 for ping-pong mechanism with external trigger, based on the field polarity). It is used for Cb and Cr setting. It is used only when the pixel format at the input of the filter is one of the YUV formats. If the pixel format at the input of the filter is ARGB (all ARGB, RGB, RGBA are converted to ARGB32-8888 by the color space conversion before going to the filter is the color space conversion is done before the filter). When the register is not used by the hardware, any value can be used for the bit fields. Shadow register, updated when DISPC_CONTROL2.GOWB is set to 1 by software and current WB frame is finished (no more data in the write-back pipeline) when the WB pipeline is directly connected to one of the pipelines (graphics or video), otherwise updated on VFP start period of primary LCD or VFP start period of secondary LCD or VFP start period of the third LCD or EVSYNC depending on which overlay output is selected as an input to the WB pipeline

10.3 MIPI Display Serial Interface

This section describes the MIPI® display serial interface (DSI) module for the device.

NOTE: This section contains information that is Copyright © 2005-2008 MIPI Alliance, Inc. All rights reserved.

MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

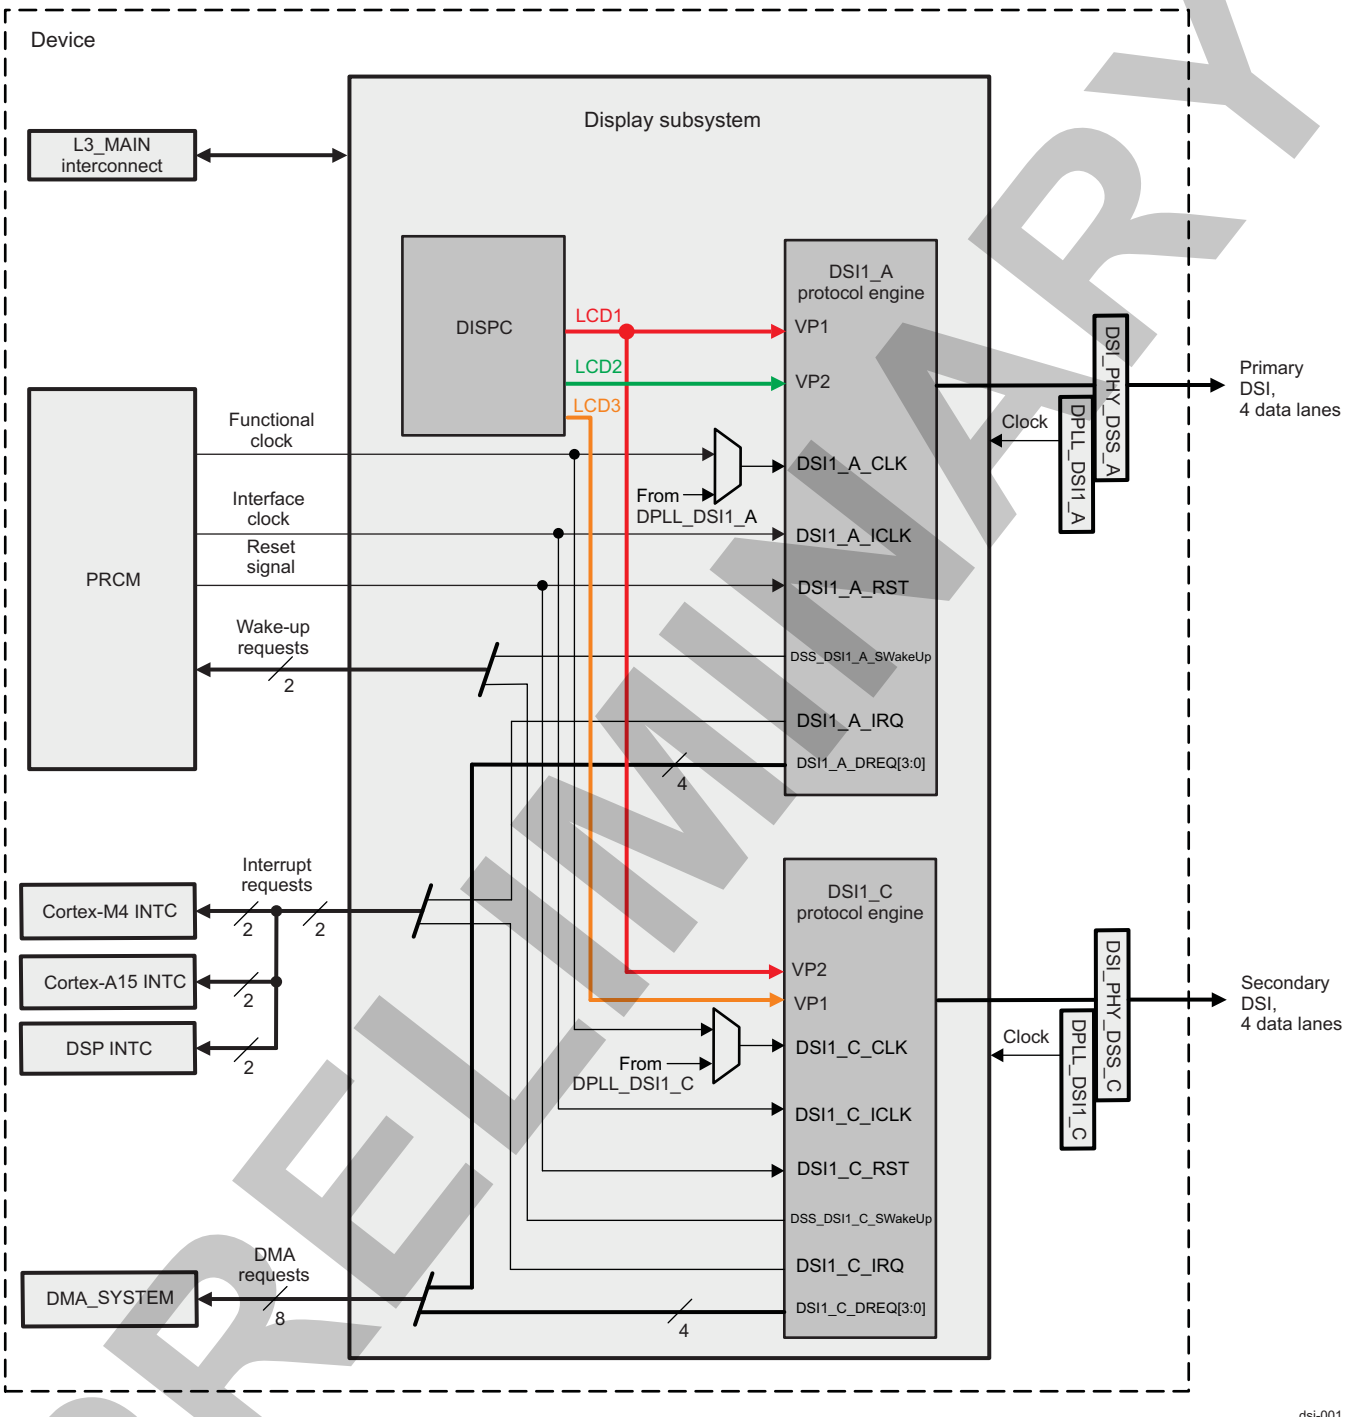
See OMAP5430 MIPI Disclaimer for details.

10.3.1 DSI Overview

The DSI module connects to a DSI display module directly or through an external DSI bridge. The DSI module is connected to DISPC and L3_MAIN interconnect.

Figure 10-92 is a block diagram of the DSI module.

Figure 10-92. DSI Overview



Two DSI modules in the display subsystem provide the following main features:

- MIPI-DSI support (up to four data lanes and one clock lane)
- Video mode and command mode support
- Multiple display (one video mode and one command mode) support. In command mode, pixel data are provided from the level 3 (L3_MAIN) interface or from one of the overlay manager outputs.
- Bidirectional data link support for command mode (only one data lane is used in reverse direction)
- RGB16, RGB18 nonpacked, and RGB24 format support for command mode

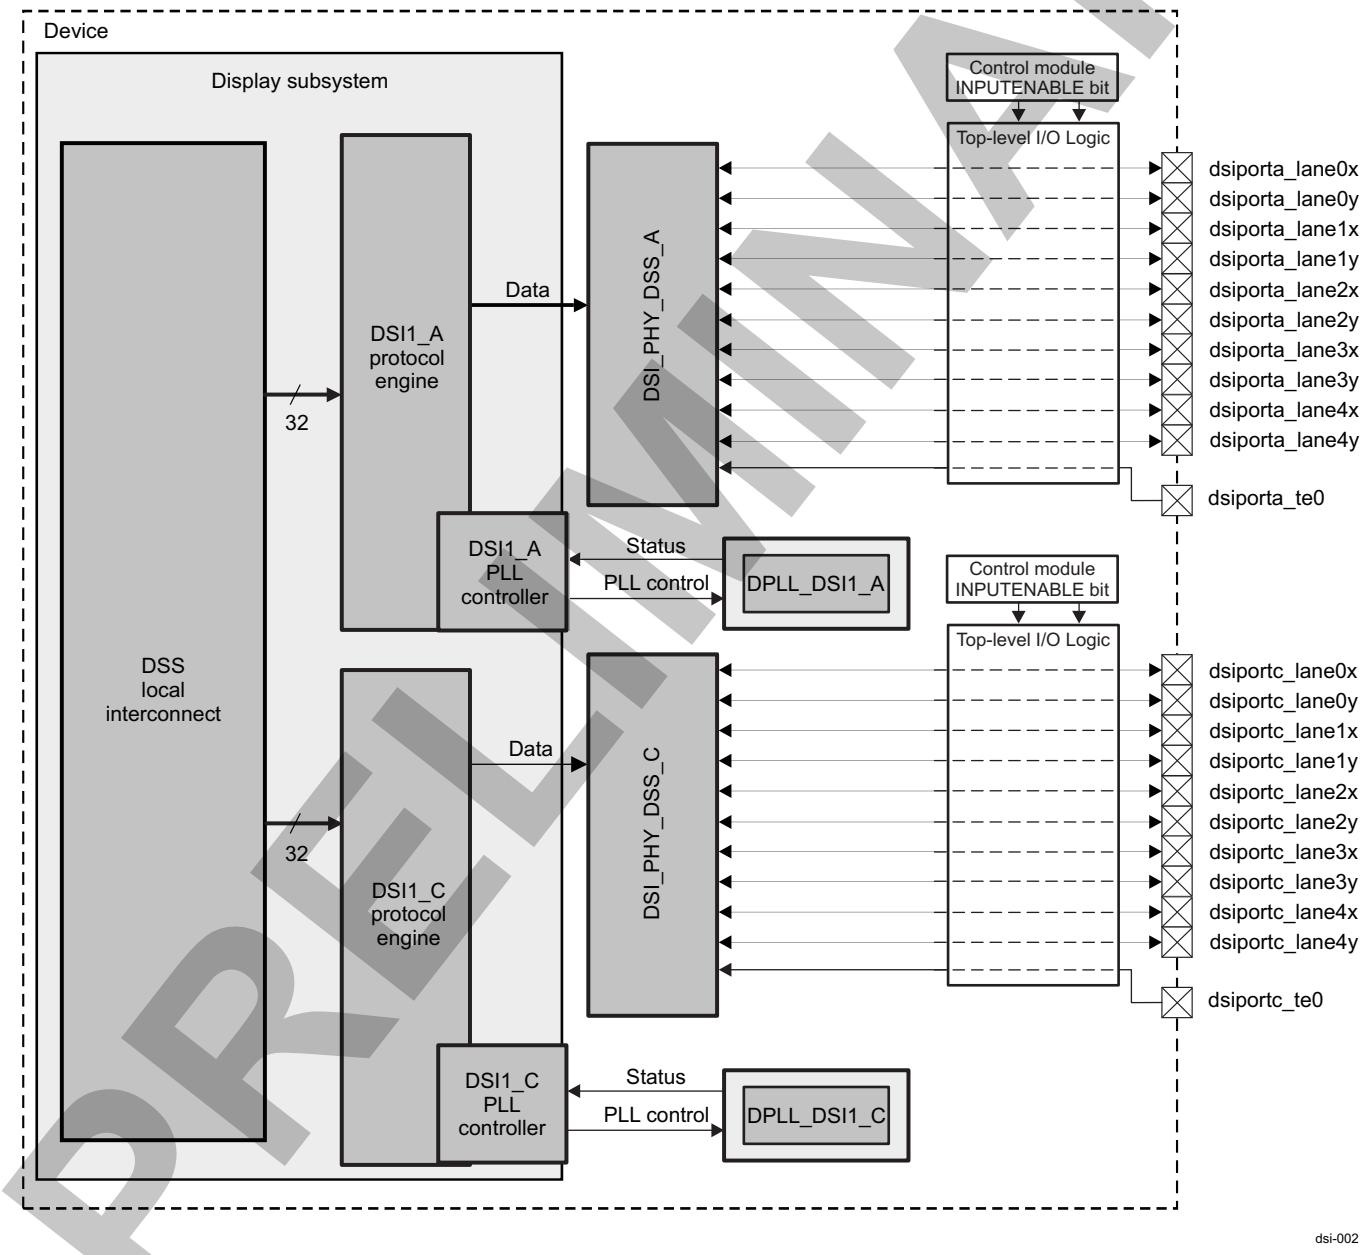
- RGB16, RGB18 packed and nonpacked, and RGB24 format support for video mode
- Burst support for video mode
- Up to four data-configurable lane support, in addition to clock signaling
- Maximum data rate of 1256 Mbps per data pair for four-data lane configuration (627.75MHz at OPP_NOM.)
- Data splitter for 2-, 3-, and 4-data lane configurations
- Data interleaving support for one synchronous stream (video mode) from the DISPC and up to three asynchronous streams (command mode) from the interconnect concurrently, or up to four asynchronous streams (command mode) from the interconnect
- Transfer of pixels and data received on the video port or L3_MAIN interconnect to the display through DSI_PHY_DSS_x
- Serial configuration port (SCP) for the DSI_PHY_DSS_x complex input/output (I/O) and DSI phase-locked loop (PLL)
- Connection to the DSI_PHY_DSS_x DSI PHY through PPI (*MIPI D-PHY Specification v1.01.00 Revision 0.02 compliant*)
- Error-correction code (ECC) and checksum generation
- MIPI DCS support

10.3.2 DSI Environment

This section describes the DSI application fields from an environment point of view (external connections). It describes the DSI connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 10-93 is a block diagram of the DSI environment.

Figure 10-93. DSI Environment

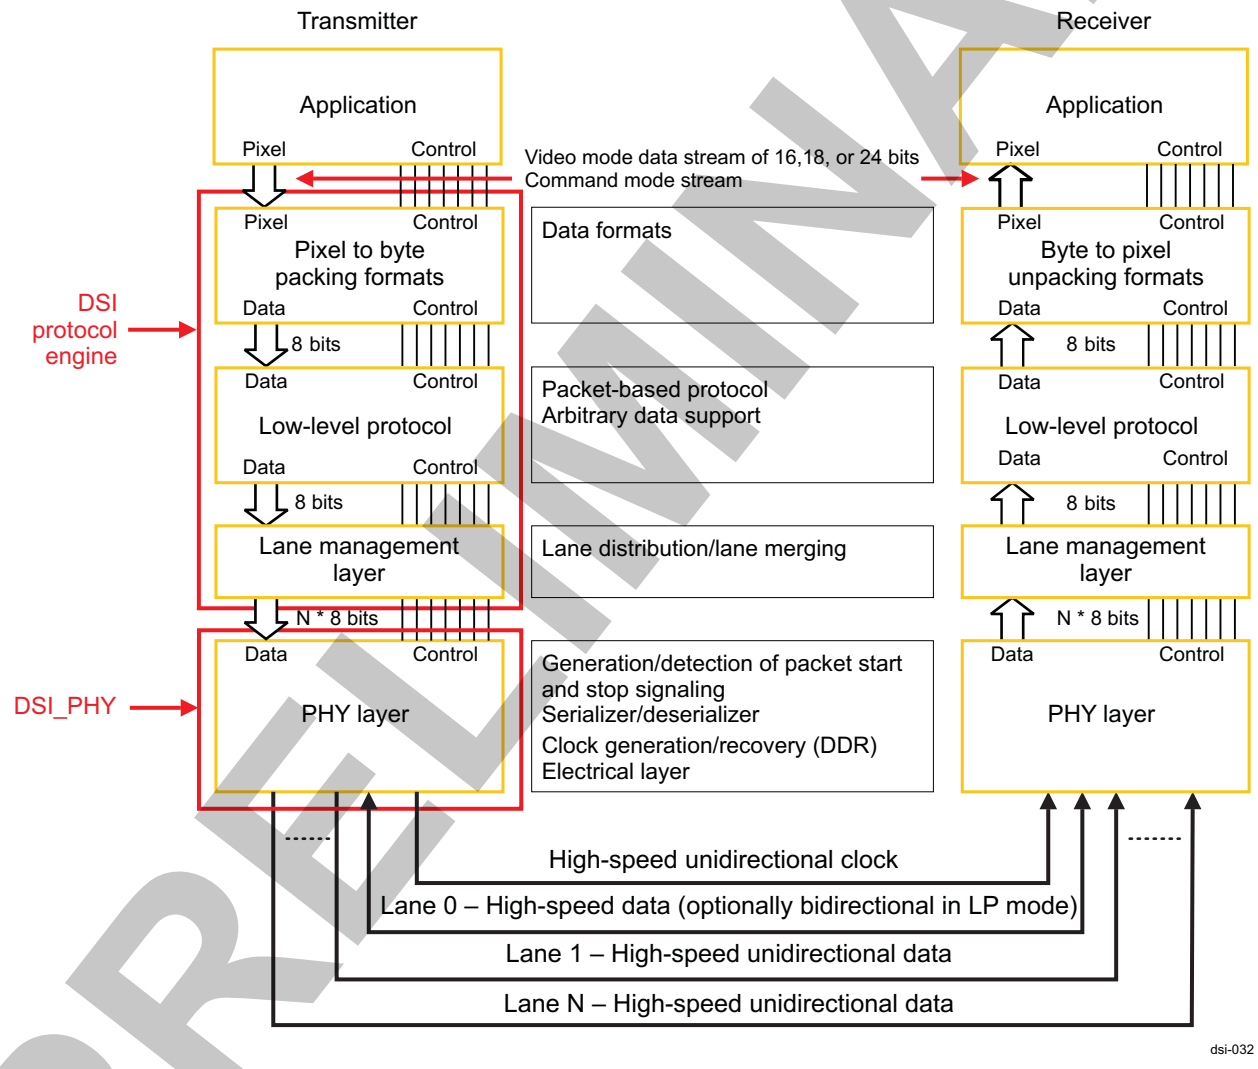


NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

The DSI is a bidirectional differential serial interface with data/clock for the PHY (configured in unidirectional link in case the display module is only unidirectional). The maximum capacity of a DSI data transfer is 1255.5 Mbps for four data lanes. The speed of the link can be configured by software only when the DSI_PHY_DSS_x is in STOP state or ultralow-power state (ULPS).

Figure 10-94 shows the high-level data flow of the DSI transmitter/receiver.

Figure 10-94. DSI Transmitter/Receiver Data Flow



10.3.2.1 DSI PHY

Table 10-509 lists the DSI1_A and DSI1_C I/Os.

Table 10-509. DSI I/O Description of DSI1_A and DSI1_C

Signal Name		I/O[1]	Description	Value at Reset
dsi1portx_dx0	first lane	I/O	Serial data/clock lane	N/A

(1) I = Input; O = Output; I/O = Bidirectional

Table 10-509. DSI I/O Description of DSI1_A and DSI1_C (continued)

Signal Name		I/O[1]	Description	Value at Reset
dsi1portx_dy0				
dsi1portx_dx1 dsi1portx_dy1	second lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx2 dsi1portx_dy2	third lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx3 dsi1portx_dy3	fourth lane	I/O	Serial data/clock lane	N/A
dsi1portx_dx4 dsi1portx_dy4	fifth lane	I/O	Serial data lane only	N/A
dsi1portx_te0	te0	I	DSI1 tearing effect (TE) input 0	N/A

NOTE: Each serial lane can be used as a data lane. The first through fourth can be used as clock lanes (the fifth lane can never be the clock lane). All polarities on all lanes are supported. The MIPI DSI 1.01 protocol requires at least one clock lane and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultralow-power state used between two transmissions
- Off mode: Lane is off.

NOTE: The CONTROL_DSIPHY register in the control module of the device provides the following control over the DSI lanes:

- Enable and disable each lane (the CONTROL_DSIPHY[28:24] DSIPORTA_LANEENABLE and CONTROL_DSIPHY[23:19] DSIPORTC_LANEENABLE bit fields).

For more information, see SYSCTRL_PADCONF_CORE Register Summary, in *Control Module*.

10.3.2.1.1 DSI Data/Clock Configuration

Data-clock signaling consists of one to four data pairs and one clock pair. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit serial data. The DSI transmitter in the host sends the data in-quadrature with the dual data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. The data is transmitted byte-wise least-significant bit (LSB) first.
- The clock signal carries the DDR clock signal in HS transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI_PHY_DSS_x into bytes.

Table 10-510 lists some of the DSI lane configurations.

NOTE: All combinations for the order of the clock and data lanes are supported (except clock cannot be on lane 5) but not explicitly described in Table 10-510.

Table 10-510. DSI Lane Configuration

DSI_PHY_DSS_x Lane Configuration	Data/Clock Lane Position					Description
	1	2	3	4	5	
Mode CLK + DATA1						Single data lane
	CLK	DATA1				
	DATA1	CLK				
Mode CLK + DATA1 + DATA2						Two data lanes
	CLK	DATA1	DATA2			
	CLK	DATA2	DATA1			
	DATA1	CLK	DATA2			
	DATA2	CLK	DATA1			
	DATA1	DATA2	CLK			
	DATA2	DATA1	CLK			
Mode CLK + DATA1 + DATA2 + DATA3						Three data lanes
	CLK	DATA1	DATA2	DATA3		
	CLK	DATA3	DATA2	DATA1		
	DATA1	CLK	DATA2	DATA3		
	DATA1	CLK	DATA3	DATA2		
	DATA2	CLK	DATA1	DATA3		
	DATA2	CLK	DATA3	DATA1		
	DATA3	CLK	DATA1	DATA2		
	DATA3	CLK	DATA2	DATA1		
	DATA3	DATA1	CLK	DATA2		
	DATA3	DATA2	CLK	DATA1		
	DATA3	DATA2	CLK	DATA1		
	DATA1	DATA2	CLK	DATA3		
	DATA2	DATA3	CLK	DATA1		
	DATA1	DATA3	CLK	DATA2		
	DATA1	DATA2	DATA3	CLK		
	DATA3	DATA2	DATA1	CLK		
Mode CLK + DATA1 + DATA2 + DATA3 + DATA4						Four data lanes
	CLK	DATA1	DATA2	DATA3	DATA4	
	DATA3	DATA1	CLK	DATA2	DATA4	
	DATA4	DATA2	CLK	DATA1	DATA3	
	DATA2	DATA1	CLK	DATA3	DATA4	
	DATA4	DATA3	CLK	DATA1	DATA2	
	DATA3	DATA4	CLK	DATA2	DATA1	
	DATA1	DATA2	CLK	DATA4	DATA3	
	DATA1	DATA4	CLK	DATA3	DATA2	
	DATA1	DATA3	CLK	DATA4	DATA2	

NOTE:

- The byte on Dn is sent before the byte on Dn + 1; all combinations of data and clock are supported through programming of the DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL bit fields configure which lane transmits the clock and define its polarity. Eight bit fields (DATA1_POSITION and DATA1_POL, through DATA4_POSITION and DATA4_POL) configure the data lanes and their polarity. The DATA2_POSITION through DATA4_POSITION bit fields can be set to 0; in this case, only the data lane defined in the DATA1_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Because any lane of DSI_PHY_DSS_x can be configured as data lane DATA1, all lanes of the PHY are bidirectional.

10.3.2.1.2 DSI ULPS

Each lane can be put in ULPS by software configuration. ULPS requires the following conditions:

- The lane must be in ULPS.
- For data lanes, no data must be pending in the DSI module.
- For the first data lane, no bus turnaround (BTA) should have been sent. The DSI module must have control of the bus.

For more information about ULPS configuration, see Section 10.3.4.4.16, *DSI ULPS Configuration*.

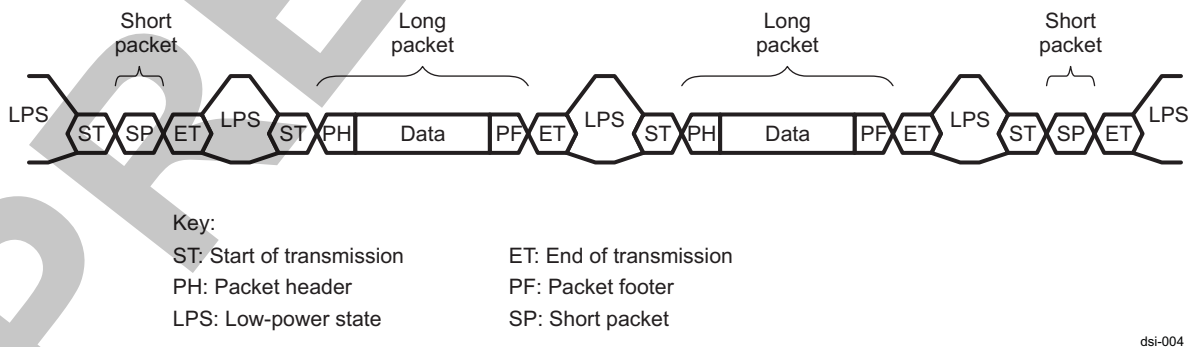
10.3.2.2 DSI Protocol Layer

Low-level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the PHY. Packets can be sent using HS mode or low-speed (LS) mode. LLP is selected through DSI registers. The DSI protocol layer features are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 10-95 shows the protocol layer with short and long packets.

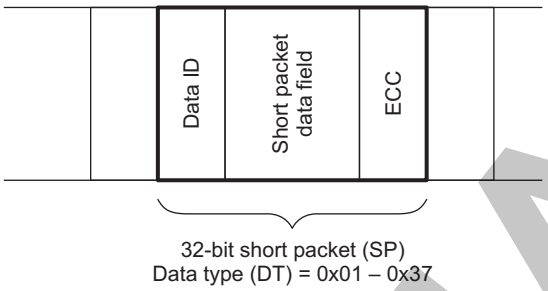
Figure 10-95. DSI Protocol Layer With Short and Long Packets



10.3.2.2.1 DSI Short Packet

Figure 10-96 shows the structure of the short packet. A short packet must contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC. No packet footer (PF) should be present. Short packets must be 4 bytes long. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

Figure 10-96. DSI Short Packet Structure



NOTE: The short packets can be sent in LP mode or HS mode.

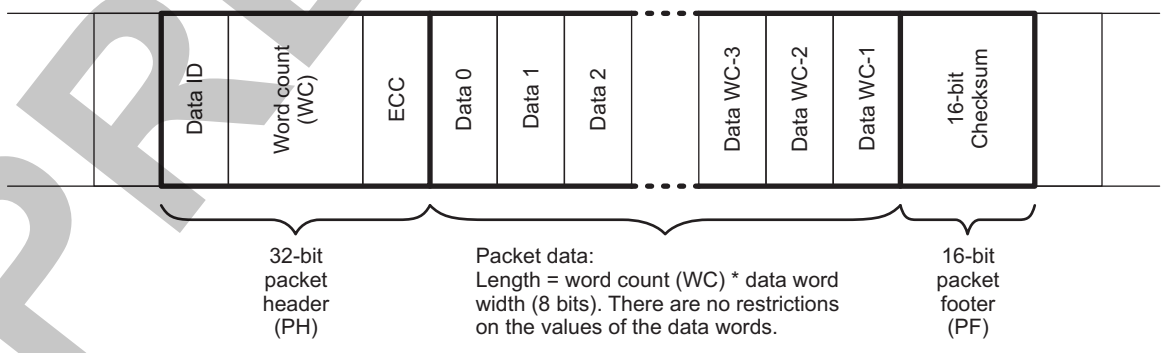
The DSI_VC_SHORT_PACKET_HEADER_i register is used to send only short packets (ECC can be calculated by hardware or by software users for debug purposes). This register is not used for video mode data because the short packets are generated by hardware based on the following events:

- Synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSI_CTRL[18] VP_HSYNC_END
- DSI_CTRL[17] VP_HSYNC_START
- DSI_CTRL[16] VP_VSYNC_END
- DSI_CTRL[15] VP_VSYNC_START
- DSI_CTRL[11] VP_VSYNC_POL
- DSI_CTRL[10] VP_HSYNC_POL
- DSI_VC_CTRL_i[1] SOURCE

10.3.2.2.2 DSI Long Packet

Figure 10-97 shows the structure of the long packet. A long packet must consist of three elements: 32-bit packet header (PH), application-specific data payload with a variable number of bytes, and 16-bit PF.

Figure 10-97. DSI Long Packet Structure



The PH is further composed as follows:

- 8-bit data identifier: The data identifier defines the VC for the data and the DT for the application-

specific payload data.

- 16-bit word count: The word count defines the number of bytes in the data payload between the end of the PH and the start of the PF. The PH and the PF must not be included in the word count.
- 8-bit ECC: The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the PH. This includes the data identifier and the word count fields.

After the end of the PH, the receiver reads the next word count × bytes of the data payload. There are no limitations on the value of a data word within the data payload block (that is, no embedded codes are used). Once the receiver has read the data payload, it reads the checksum in the PF. The host processor must always calculate and transmit a checksum in the PF. Peripherals are not required to calculate a checksum. In the special case of a 0-byte data payload, if the payload length is 0, the checksum calculation results in (0xFFFF). If the checksum is not calculated, the PF must consist of 2 bytes of 0s (0x0000). In the generic case, the length of the data payload must be a multiple of bytes. In addition, each data format can impose additional restrictions on the length of the payload data (that is, a multiple of 4 bytes). Each byte is transmitted LSB first. Payload data can be transmitted in any byte order, restricted only by data format requirements. Multibyte elements, such as word count and checksum, must be transmitted least-significant byte (LSByte) first.

NOTE: Long packets can be sent in LP or HS mode.

The DSI_VC_LONG_PACKET_HEADER_i register provides headers for long packets (ECC is always calculated by hardware). The register is used for video and command modes.

If video mode is enabled for a virtual channel, it is not possible to transfer data concurrently (interleaved in a frame) using long packets received on the video and L3_MAIN interconnect ports because the DSI_VC_LONG_PACKET_HEADER_i register is used by the video mode. The register can be unprogrammed by the user to send long packets received on the L3_MAIN interconnect port only when there is no expected data on the video port. Software must program the register correctly to send sequentially long packets in video and command modes.

The word count (WC) defined in the DSI_VC_LONG_PACKET_HEADER_i register for the VC associated with the video port indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and the size of the line buffer). The total size defined in the WC of the header register cannot exceed the size of the line buffer multiplied by the number of buffer lines.

The DSI_VC_LONG_PACKET_PAYLOAD_i register is used to provide payload data for long packets (checksum is calculated by hardware when the DSI_VC_CTRL_i[7] CS_TX_EN bit is set to 1; otherwise, the value is 0x00). The register is not used in video mode because payload data are provided by the video port.

Software must ensure that the following sequence for write accesses to the header and payload registers (DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i, respectively) is followed:

- A long PH value with WC = 0 written in the DSI_VC_LONG_PACKET_HEADER_i register can be followed by any access.
- A long PH value with WC > 0 written in the DSI_VC_LONG_PACKET_HEADER_i register must be followed by one or more writes to the DSI_VC_LONG_PACKET_PAYLOAD_i register defined by the WC value before writing again to the same DSI_VC_LONG_PACKET_HEADER_i register.

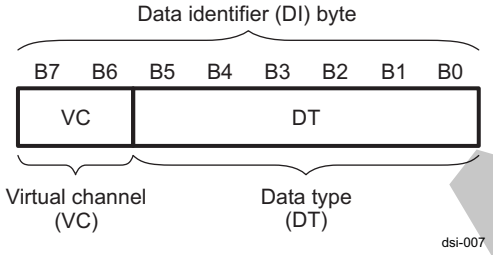
CAUTION

If this sequence is not followed, no error is generated. Access to other DSI registers during this sequence is allowed.

10.3.2.2.3 DSI Data Identifier

The data identifier byte contains the values for the virtual channel ID and data type, as shown in Figure 10-98. The virtual channel ID is contained in the 2 most-significant bits (MSBs) of the data identifier byte and identify the data as directed to one of four virtual channels. The value of the data type is contained in the 6 LSBs of the data identifier byte.

Figure 10-98. DSI Data Identifier Structure

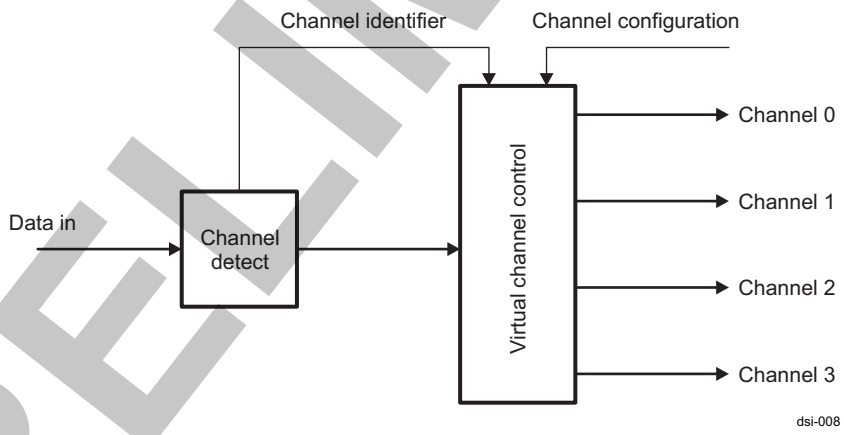


10.3.2.2.3.1 DSI VC ID – VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Each packet sent in a single transmission has its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSI_VC_SHORT_PACKET_HEADER_i and DSI_VC_LONG_PACKET_HEADER_i registers for short and long packets, respectively. It will not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 10-99 shows the VC controller.

Figure 10-99. DSI VC Controller



10.3.2.2.3.2 DSI Data Type Field DT[5:0]

The data type field specifies whether the packet is long or short and identifies the packet format. The data type field, and the word count field for long packets, informs the receiver about how many bytes to expect in the rest of the packet. This is necessary because the beginning and end of a packet are not indicated by special packet start/end sync codes. This permits packets to convey arbitrary data, but it also requires the PH to specify the size of the packet.

10.3.2.2.4 DSI Synchronization Codes

Each frame can be identified by two synchronization codes:

- For the start of the vertical synchronization (VSS) pulse

- For the end of the vertical synchronization (VSE) pulse

Each line can be identified by two synchronization codes:

- For the start of the horizontal synchronization (HSS) pulse
- For the end of the horizontal synchronization (HSE) pulse

The synchronization events are not required by the display (peripheral): they are optional. Users can program which synchronization events are generated to the display from the timings received from the DISPC in video mode. When data are received on the L3_MAIN interconnect port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L3_MAIN interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the DISPC to receive the synchronization events to automatically generate short synchronization packets to the peripheral.

When the DSI protocol engine detects that the VSYNC signal from the DISPC transitions from INACTIVE to ACTIVE state, the VSS short packet replaces the following HSS corresponding to the following HSYNC synchronization short packet (if the generation is enabled).

When the transition from ACTIVE to INACTIVE state is detected, the VSE short packet is generated (if the generation is enabled), replacing the HSE synchronization packet corresponding to the following HSYNC.

When the DSI protocol engine detects that the HSYNC signal from the DISPC transitions from INACTIVE to ACTIVE state, the HSS short packet is generated (if the generation is enabled).

When the transition from ACTIVE to INACTIVE state is detected, the HSE short packet is generated (if generation is enabled).

For the first frame, any HSYNC and data received on the video port before the first VSYNC must be ignored. Because the first VSYNC sent to the display is also recognized as an HSYNC for the first line, there is no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses short packets. Table 10-511 lists the 6-bit DT synchronization code values.

Table 10-511. DSI Synchronization Codes

Synchronization Code	Value	Comments
Vertical sync start code (VSS)	0x1	Optional
Vertical sync end code (VSE)	0x11	Optional
Horizontal sync start code (HSS)	0x21	Optional
Horizontal sync end code (HSE)	0x31	Optional

10.3.2.2.5 DSI Blanking

To keep the DSI link in HS mode while using video mode during blanking periods, long blanking packets are sent to the display. The DSI_VM_TIMINGx (where x = 1 to 8) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

Table 10-512 defines the short packet values for the synchronization packets:

Table 10-512. DSI Sync Short Packet Values

VC ID	Sync Code	Header (First Byte)	Header (Second Byte): Data Field LSB	Header (Third Byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See Note following this table.
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
	0x31	0x91			
0x2	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
	0x31	0xB1			
0x3	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

NOTE:

- If the ECC is enabled by setting the DSI_VC_CTRL_i[8] ECC_TX_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSI_VC_CTRL_i[7] CS_TX_EN bit to 1 for the VC in video mode, the checksum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSI_VC_CTRL_i[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSI_VC_CTRL_i[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, because the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The DSI link (lanes and clock separately) can be put in ULPS. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and t_L are defined in the DSI_VM_TIMING1 through DSI_VM_TIMING8 registers. HSA, HBP, HFP, and t_L are defined using the byte clock unit (TXBYTECLKHS – HS transmit byte clock generated by DSI_PHY_DSS_x) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined by the number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (considering the 4-byte header and the 2-byte checksum).

The configuration of the DISPC timing generator must be used when the DISPC timings are used to generate DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period cannot be used to send any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can be followed only by another HS packet from the same VC, or by a trigger (for example, BTA). When there is no more HS data to send for this VC, the lane is in LPS.

When the blanking period starts with one LP packet from one VC, it can be followed only by another LP packet from the same VC, by another VC, by trigger (BTA, for example), or by extra LP NULL packets. If the trigger is sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. If one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in LPS.

Figure 10-100 and Figure 10-101 show a nonburst transfer in DSI video mode with and without VE and HE, respectively. Figure 10-102 shows a burst transfer in DSI video mode without VE and HE.

Figure 10-100. DSI Video Mode: Nonburst Transfer With VE and HE

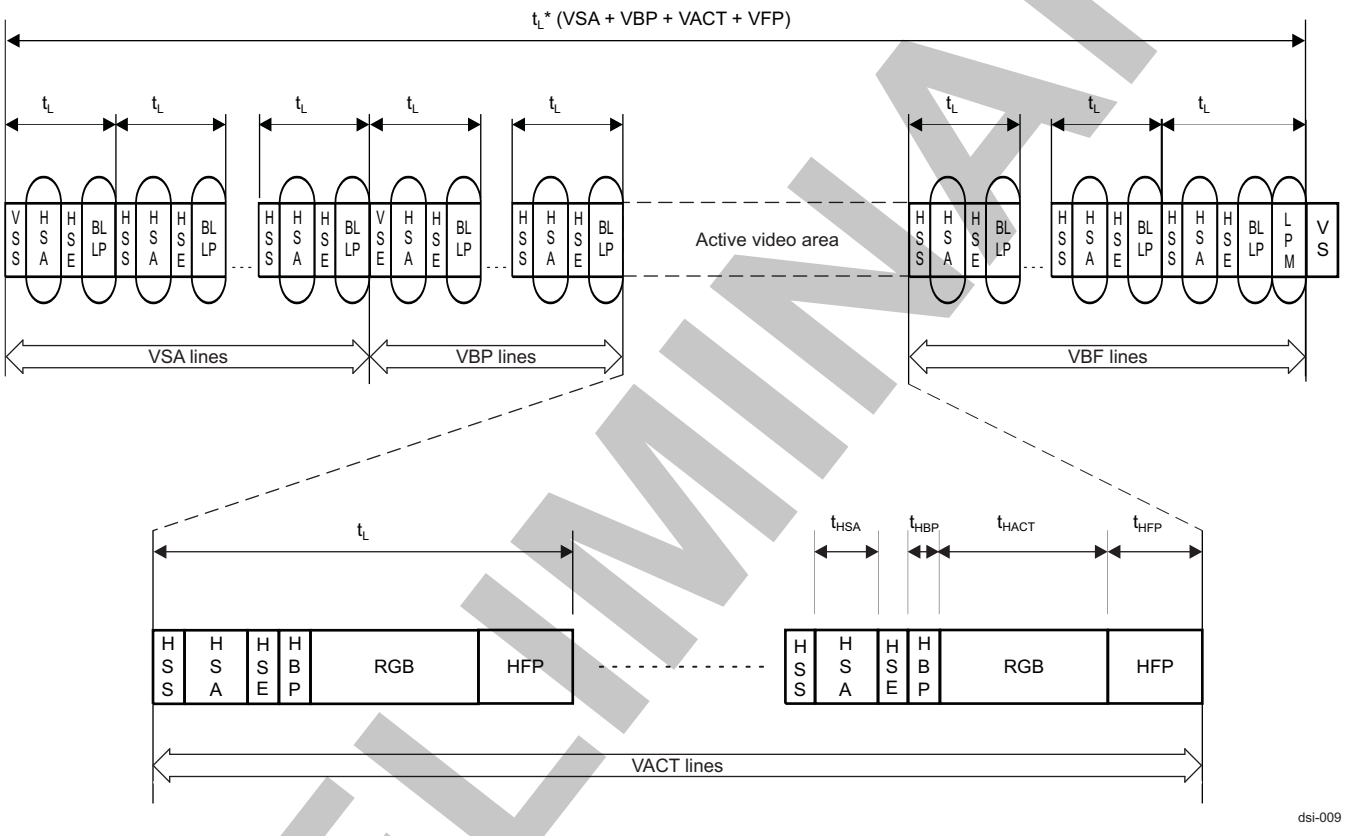


Figure 10-101. DSI Video Mode: Nonburst Transfer Without VE and HE

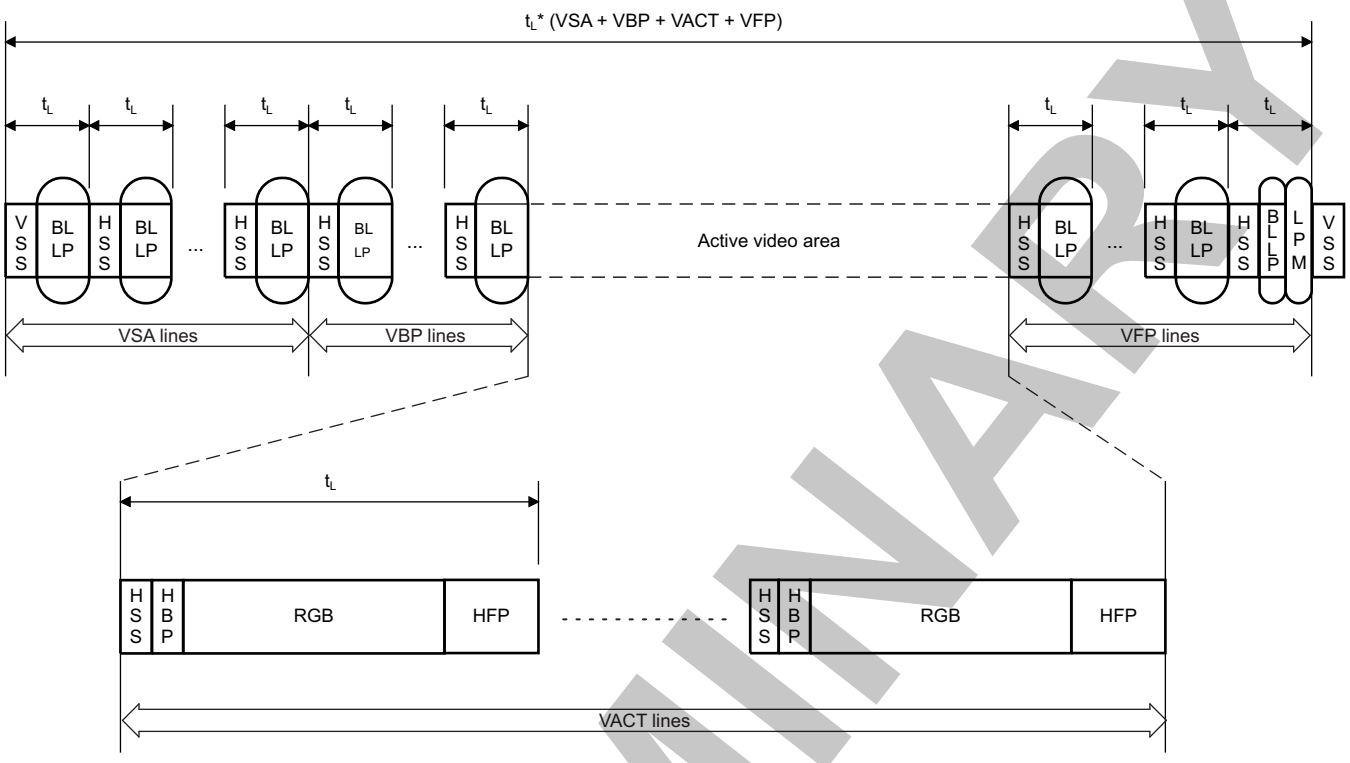
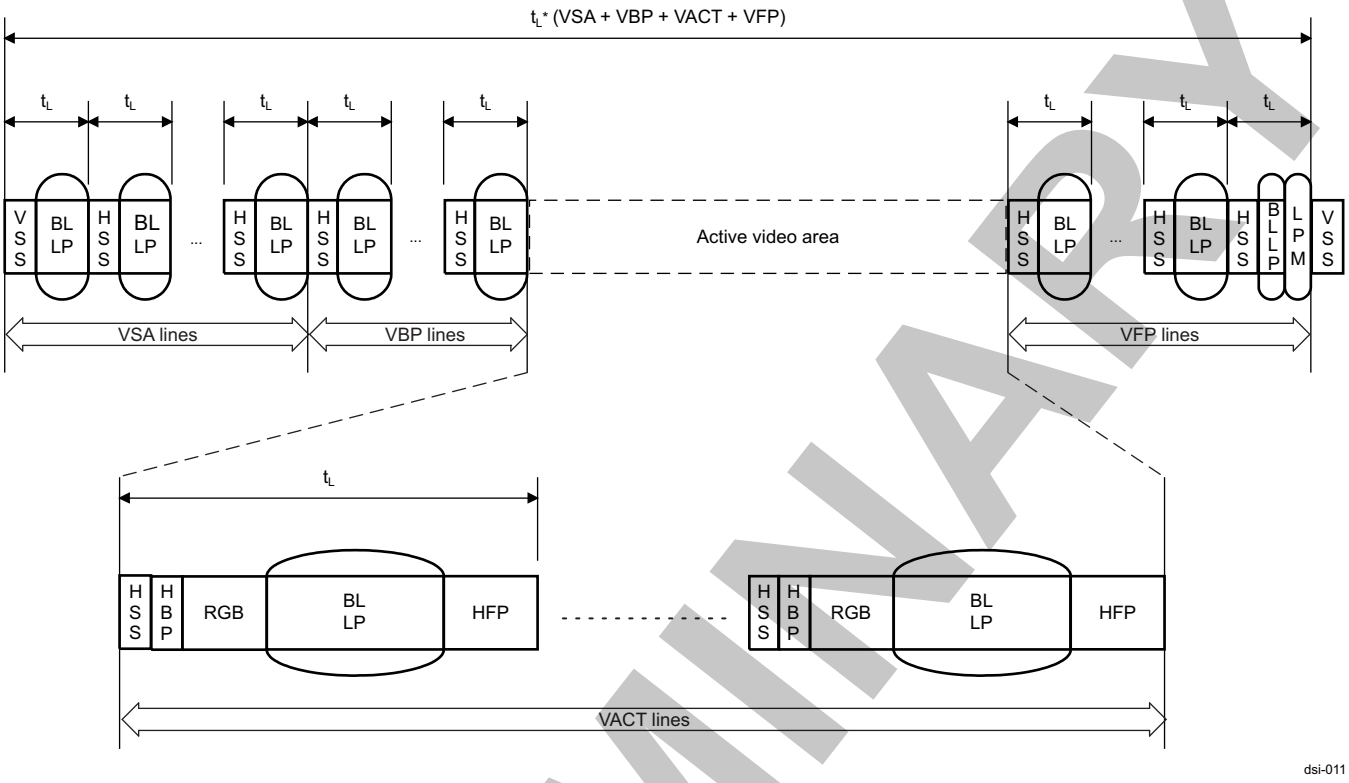


Legend:

- VSS – DSI Sync Event Packet: V sync start
- VSE – DSI Sync Event Packet: V Sync End
- BL LP – DSI Packet : Arbitrary sequence of nonrestricted DSI packets or low-power mode including optional BTA
- HSS – DSI Sync Event Packet: H sync start
- HSA – DSI Blanking Packet: Horizontal sync active or low-power mode, no data
- HSE – DSI Sync Event Packet: H sync end
- HFP – DSI Blanking Packet: Horizontal front porch or low-power mode
- HBP – DSI Blanking Packet: Horizontal back porch or low-power mode
- RGB – DSI Packet: Arbitrary sequence of pixel stream and null packets
- LPM – Low-power mode including optional BTA

NOTE: HSA timing is not used and does not have to be programmed when an HE short packet is not generated.

Figure 10-102. DSI Video Mode: Burst Transfer Without VE and HE



NOTE: HSA timing is not used and does not have to be programmed when an HE short packet is not generated.

In Figure 10-101 and Figure 10-102, if a HSYNC end short packet is not generated (HSA does not exist), HBP must not be 0.

10.3.2.2.6 DSI Frame Structures

NOTE: The figures in this section show only pixel packets and blanking periods; they do not show synchronization packets.

Figure 10-103 shows the DSI general frame structure.

Figure 10-103. DSI General Frame Structure

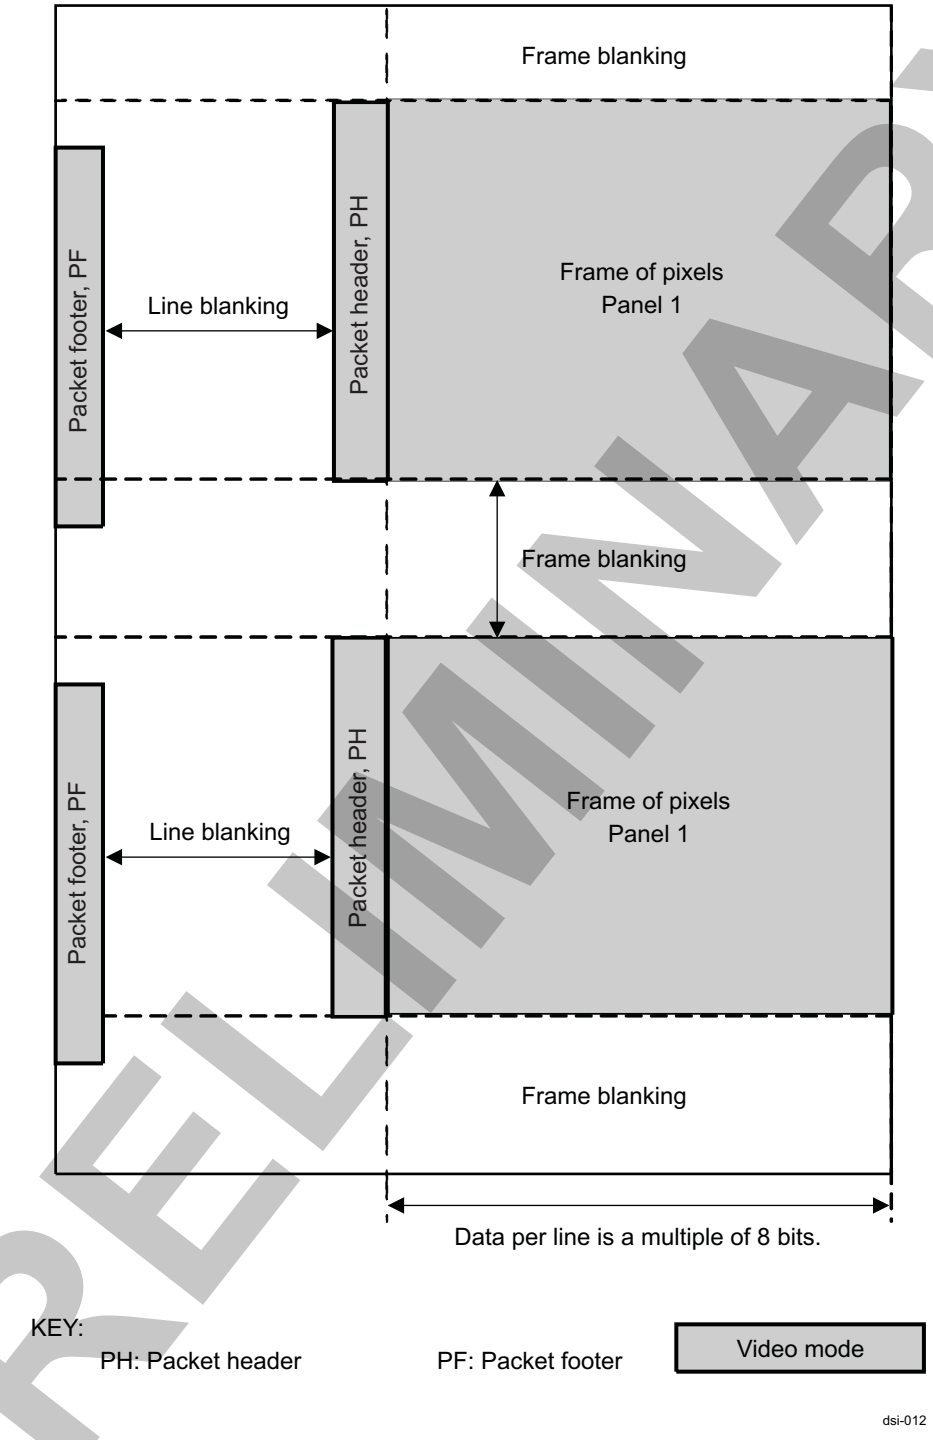


Figure 10-104 shows the general frame structure using burst mode.

Figure 10-104. DSI General Frame Structure Using Burst Mode

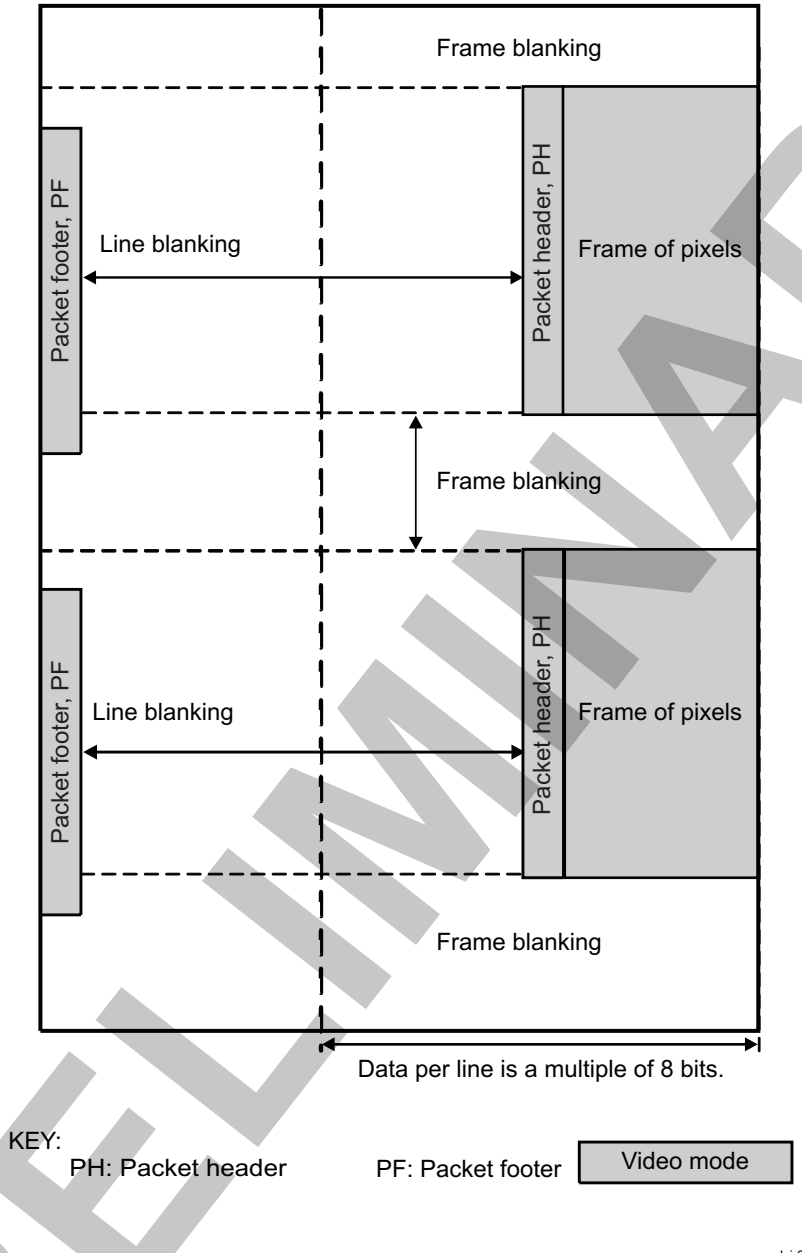

Figure 10-105 shows the general frame structure using burst mode and interleaving.

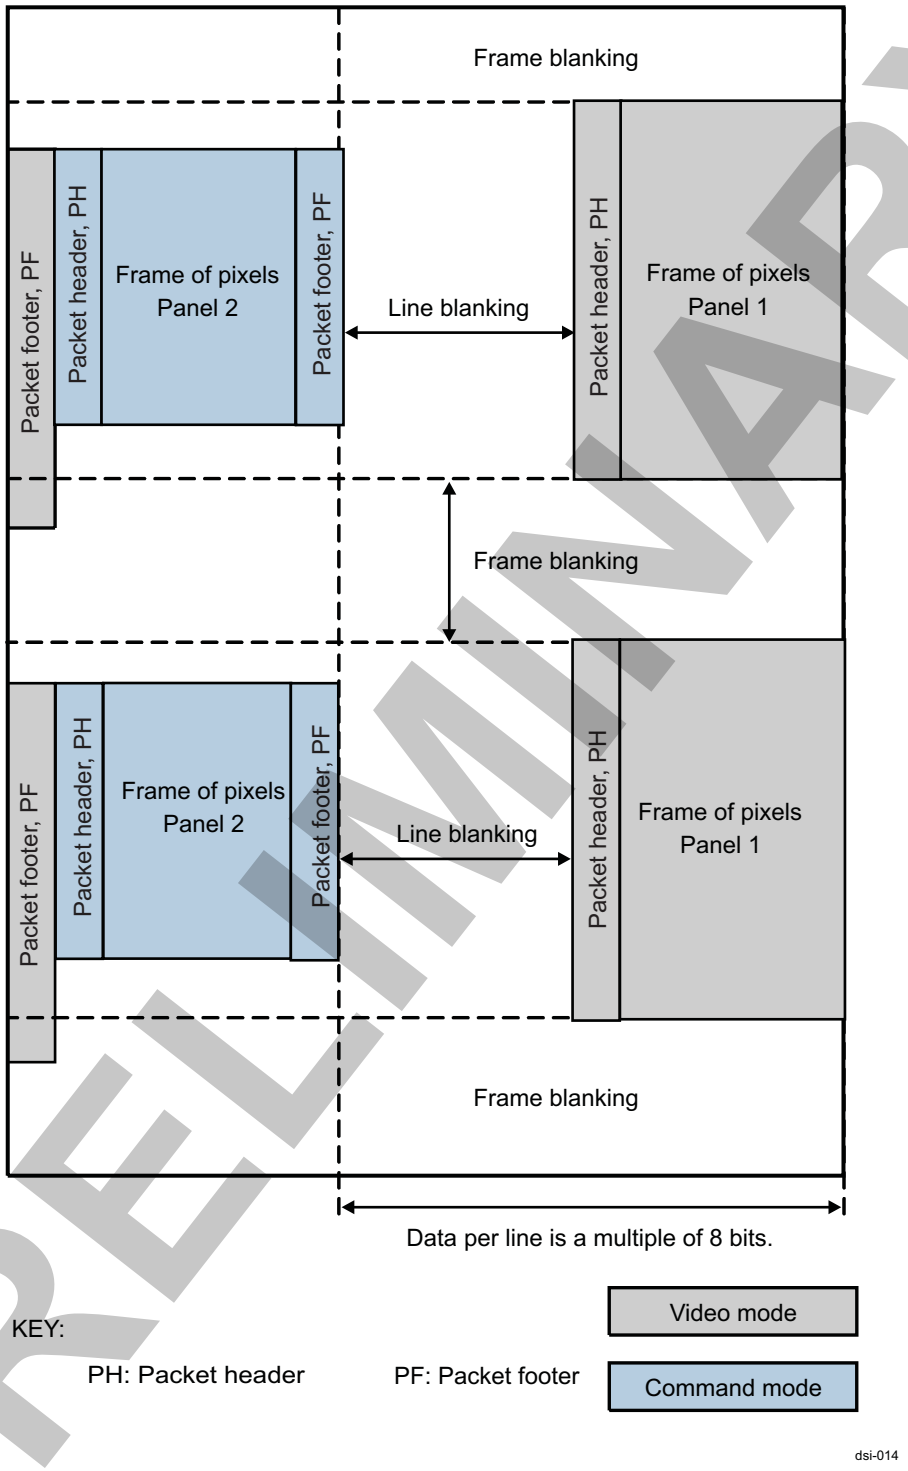
Figure 10-105. DSI General Frame Structure Using Burst Mode and Interleaving



10.3.2.2.7 DSI VCs

The DSI protocol layer transports VCs. VCs separate different data flows, which are interleaved in the same data stream. Each VC is identified by a unique channel identification number in the PH. The channel identification number is encoded in 2 bits. The DSI protocol engine determines the channel identifier number to be used to generate the PH and multiplexes the interleaved data streams. The DSI protocol engine supports up to four concurrent VCs. Table 10-513 summarizes the VC values used for each channel.

Table 10-513. DSI VC Values

VC Number	Value
VC 0	0x0
VC 1	0x1
VC 2	0x2
VC 3	0x3

If multiple displays are connected to a single DSI port on the host, a hub can be used to route the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 is used for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSI_VC_CTRL_i[4] MODE bit):
  - Video mode
  - Command mode
- Data type
- Source (DSI_VC_CTRL_i[1] SOURCE bit)
  - Video port
  - Slave interconnect port
- HS or LP forward transmission
- Automatic BTA generation
  - Short packets (DSI_VC_CTRL_i[2] BTA_SHORT_EN bit)
  - Long packets (DSI_VC_CTRL_i[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
  - DMA request number (DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB bit field for RX FIFO and DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field for TX FIFO)
  - DMA threshold (DSI_VC_CTRL_i[26:24] DMA_RX_THRESHOLD bit field for RX FIFO and DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSI_VC_CTRL_i[9] MODE_SPEED bit)
- ECC transmission (DSI_VC_CTRL_i[8] ECC_TX_EN bit)
- CS transmission (DSI_VC_CTRL_i[7] CS_TX_EN bit)

NOTE: The VC ID is not calculated by the DSI module but is provided while writing into the DSI_VC_SHORT_PACKET_HEADER_i and DSI_VC_LONG_PACKET_HEADER_i registers.

10.3.2.3 DSI Multilane Layer

A layer consists of lane splitter logic to split the incoming byte stream into a serial stream. The bits are sent with the LSB first. The number of active lanes is configurable through a register. The order of the lanes is configurable. The number of lanes can be changed only in ULPS or when all data lanes are in STOP state.

10.3.2.3.1 DSI SoT and EoT in Multilane Configurations

Because a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its valid data signal into lanes for which there is no further data. Although all lanes start simultaneously with parallel start-of-transmissions (SoTs), each lane operates independently and may complete the HS transmission before the other lanes, sending an end-of-transmission (EoT) one cycle (byte) earlier.

10.3.2.3.2 DSI Lane Splitter

The lane splitter can split the byte stream into two, three, or four lanes (for one lane, the splitter is bypassed). Figure 10-106 through Figure 10-109 show the byte position in each serial link for one-, two-, three-, and four-data lane configurations. The byte stream always starts from the first lane. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is used only when packets are sent using HS mode. In LS mode, only the first data lane is used.

Figure 10-106. DSI Four-Data Lane Configuration

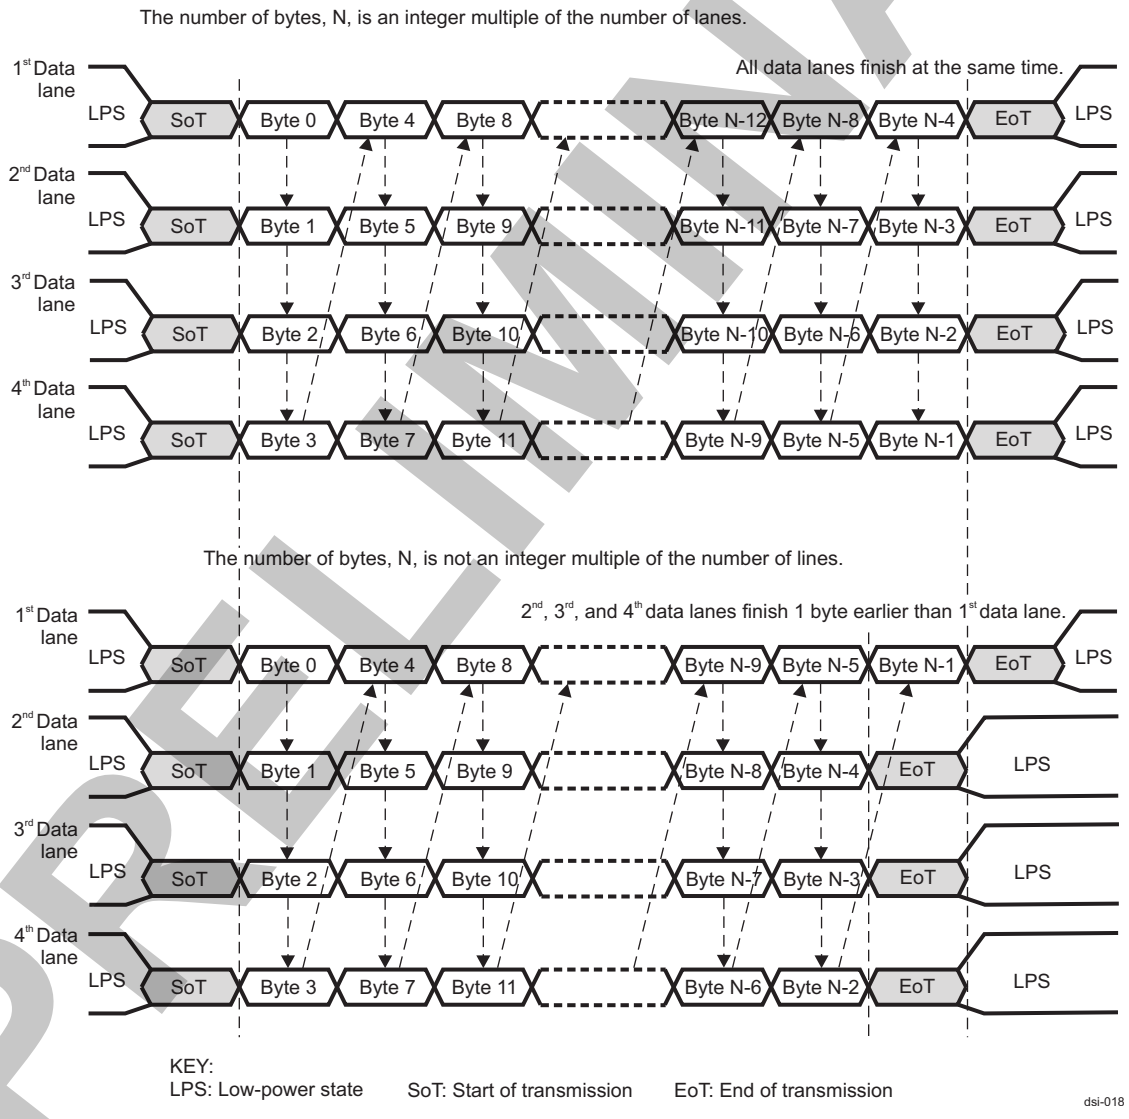


Figure 10-107. DSI Three-Data Lane Configuration

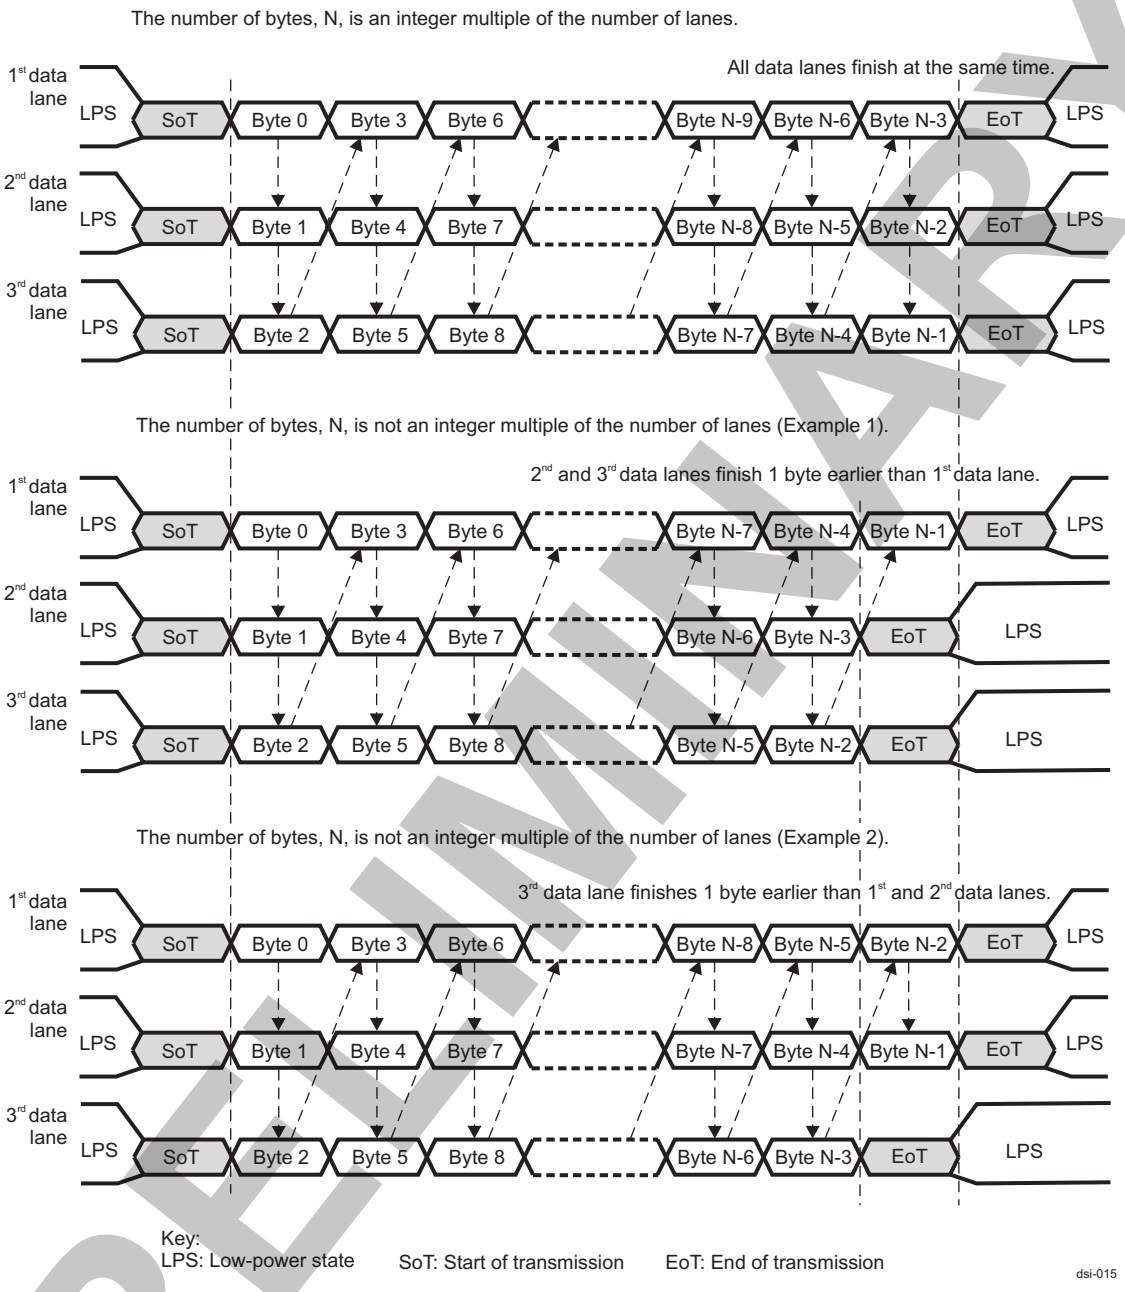

Figure 10-108. DSI Two-Data Lane Configuration

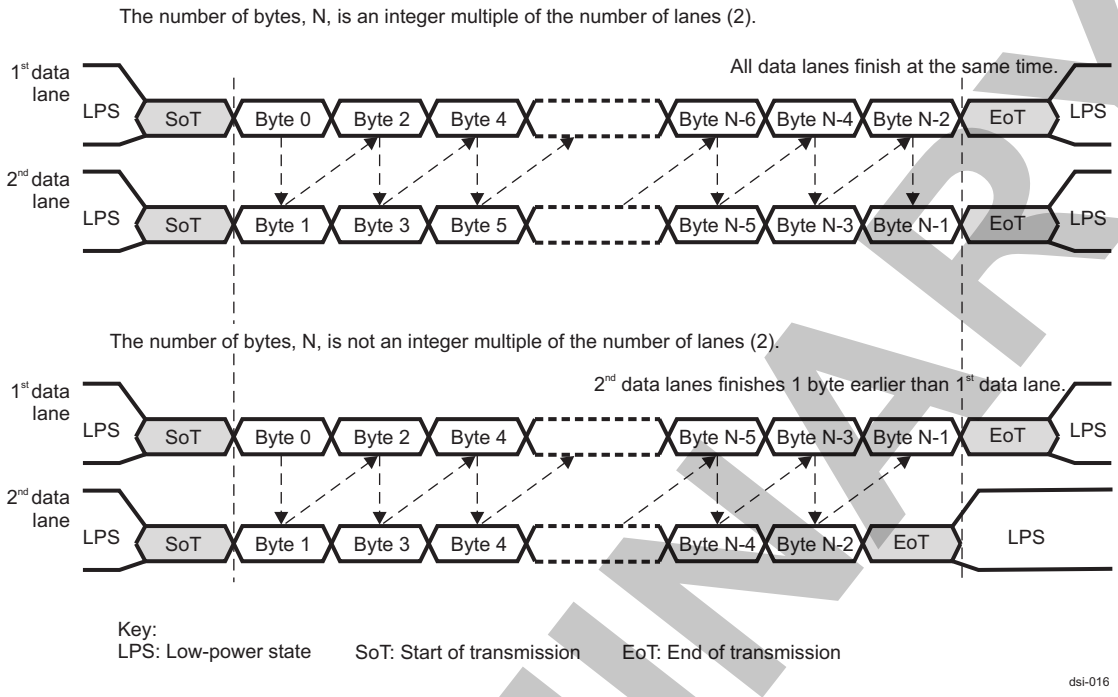

Figure 10-109. DSI One-Data Lane Configuration

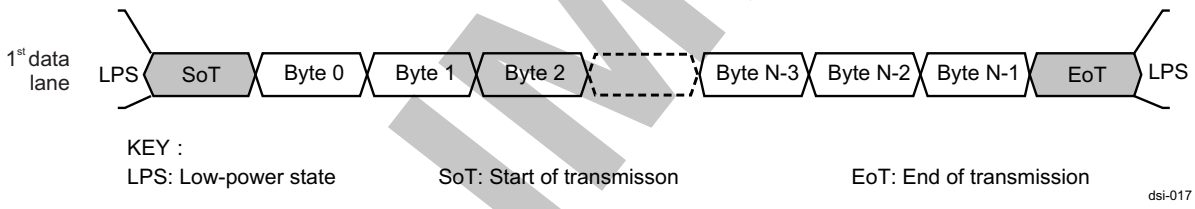
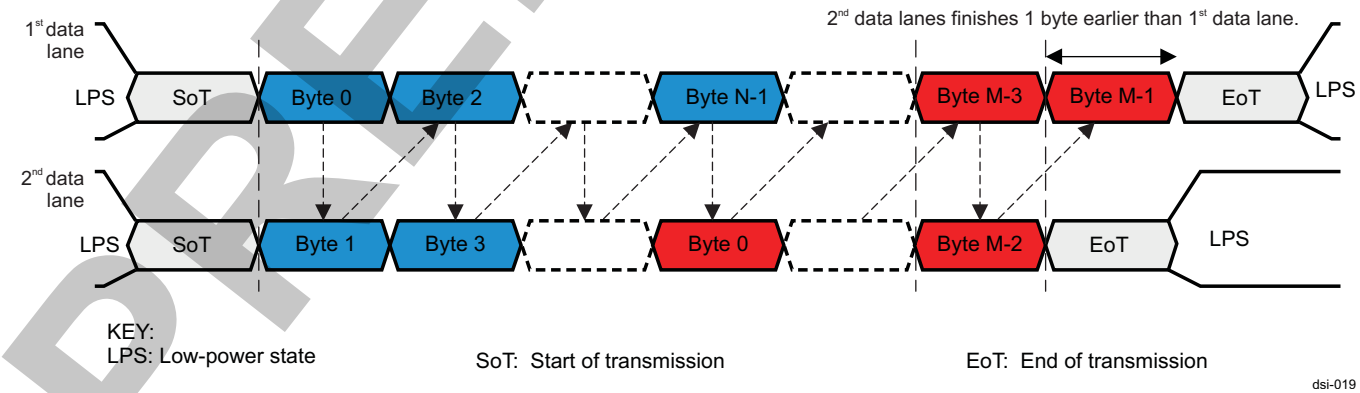


For back-to-back packets, the byte stream is considered as a single packet by the splitter module. Figure 10-110 shows an example of two packets sent back-to-back. N bytes are used for the first packet and M bytes for the second packet.

Figure 10-110. DSI Two Packets Using Two-Data Lane Configuration (Example)



10.3.2.4 DSI Pixel Data Formats

This section describes how the DSI-supported pixel data formats in video mode are transmitted over the serial interface. The DSI protocol engine can cope with all data formats if the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

10.3.2.4.1 DSI Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. Table 10-514 lists the pixel formats supported by the DSI in video mode.

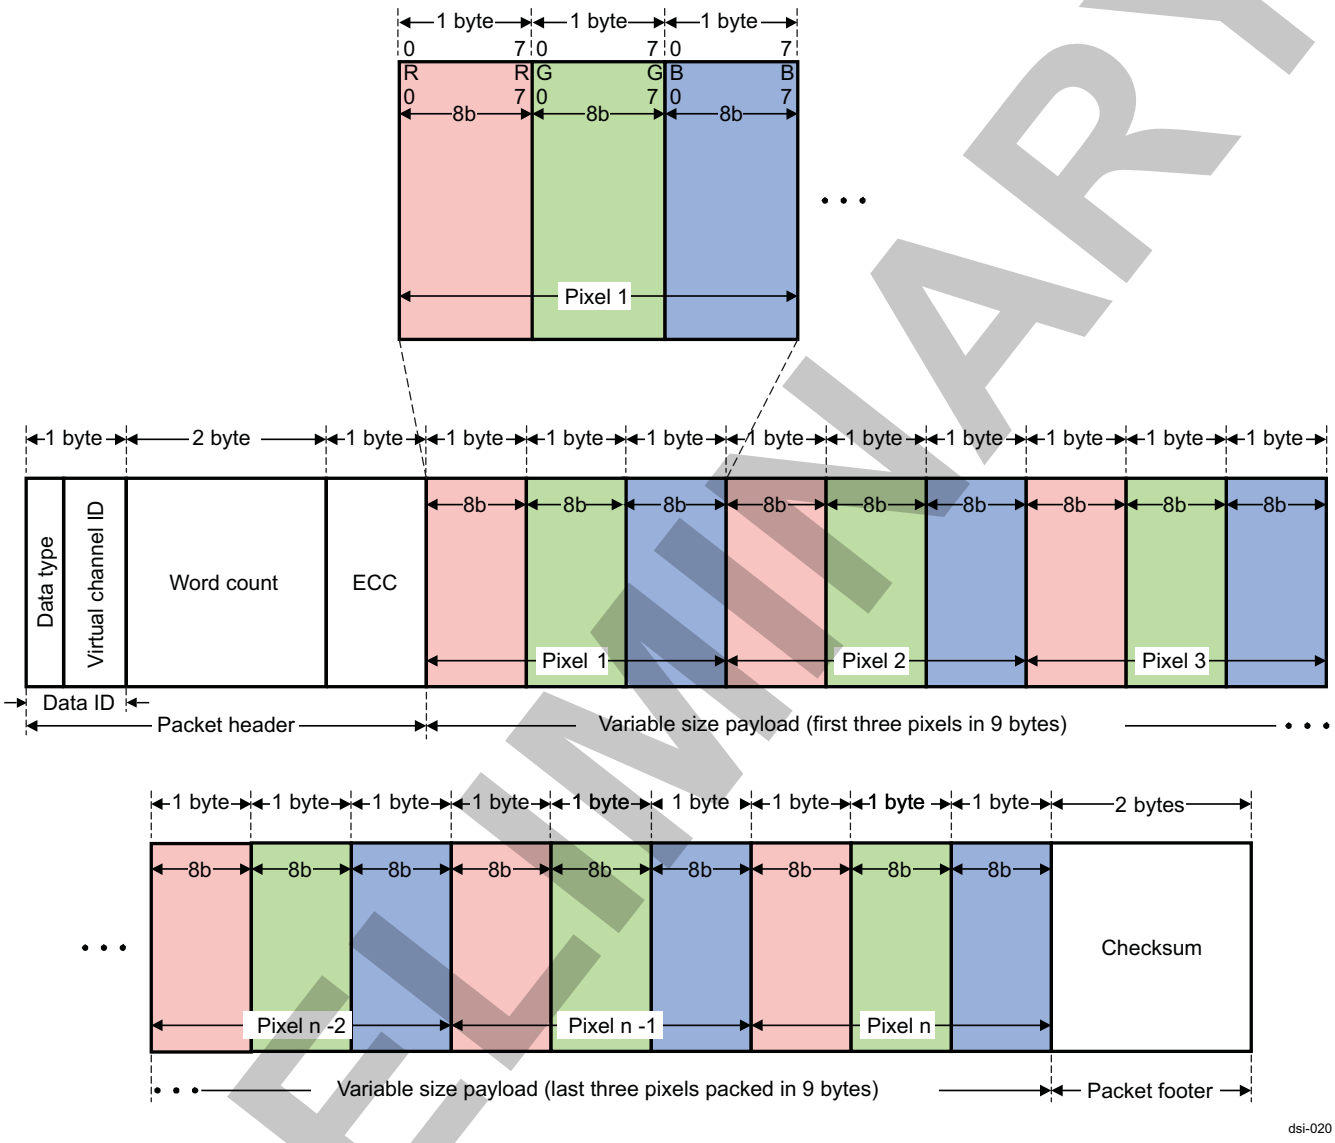
Table 10-514. DSI Pixel Data Format in Video Mode

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

10.3.2.4.2 DSI 24 bpp – RGB Color Format, Long Packet (Video Mode)

Figure 10-111 shows the RGB888 format.

Figure 10-111. DSI 24-bpp RGB Color Format, Long Packet (Video Mode)

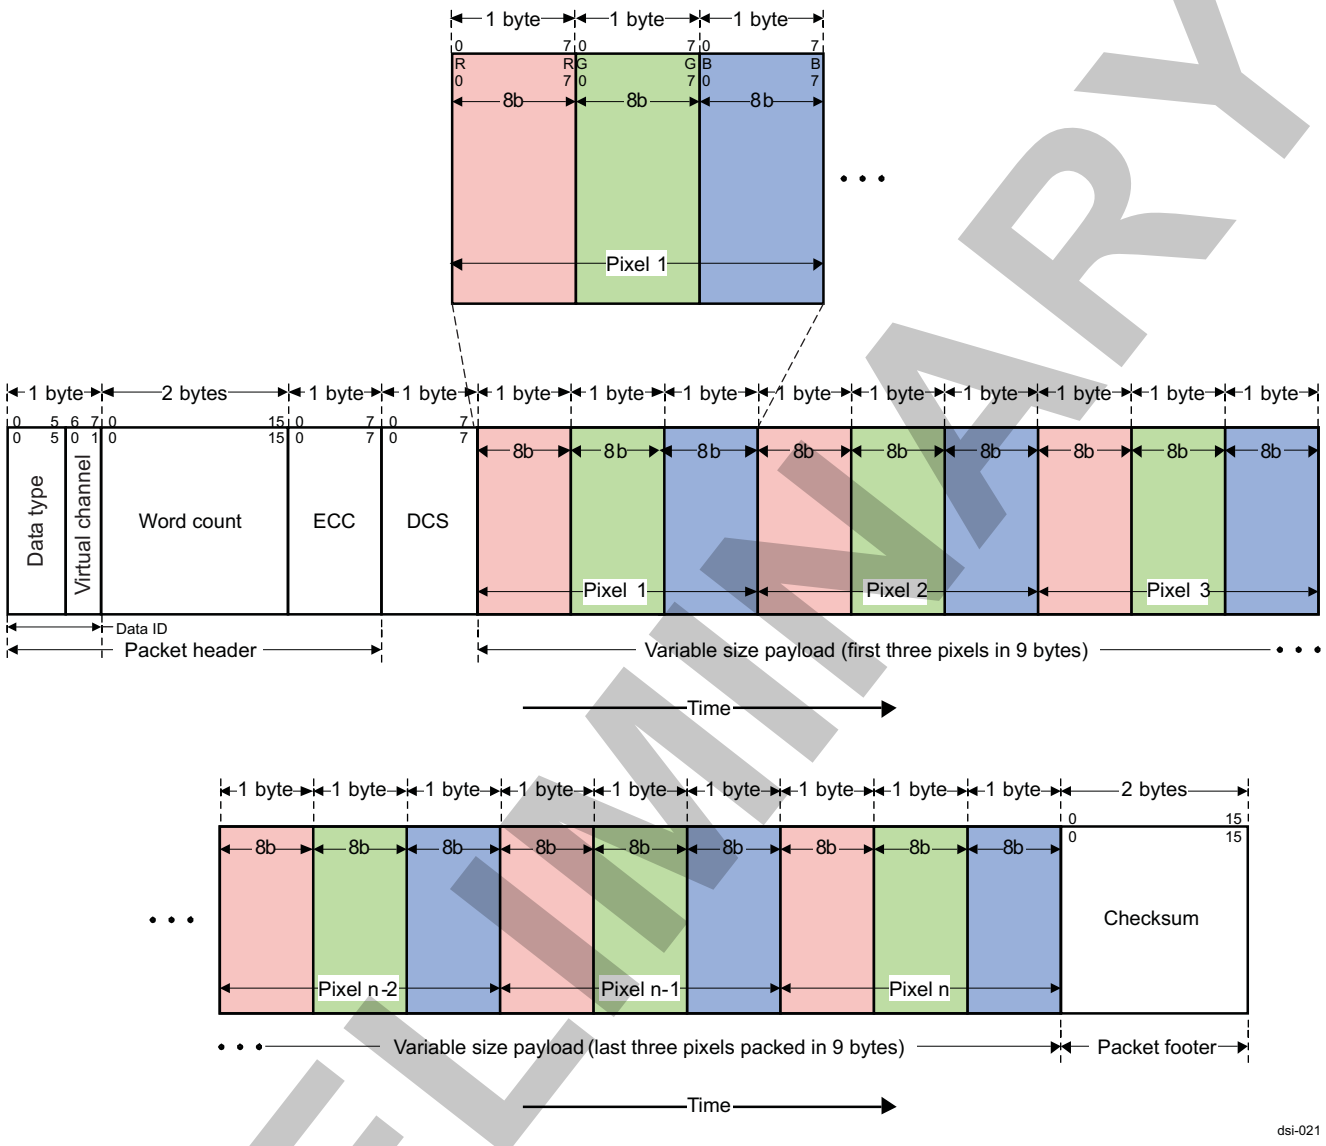


Packed-pixel stream, 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (8 bits), G (8 bits), and B (8 bits), in that order. Each color component occupies 1 byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first and the MSB last.

10.3.2.4.3 DSI 24 bpp - RGB Color Format, Long Packet (Command Mode)

Figure 10-112 shows the RGB888 format.

Figure 10-112. DSI 24-bpp RGB Color Format, Long Packet (Command Mode)

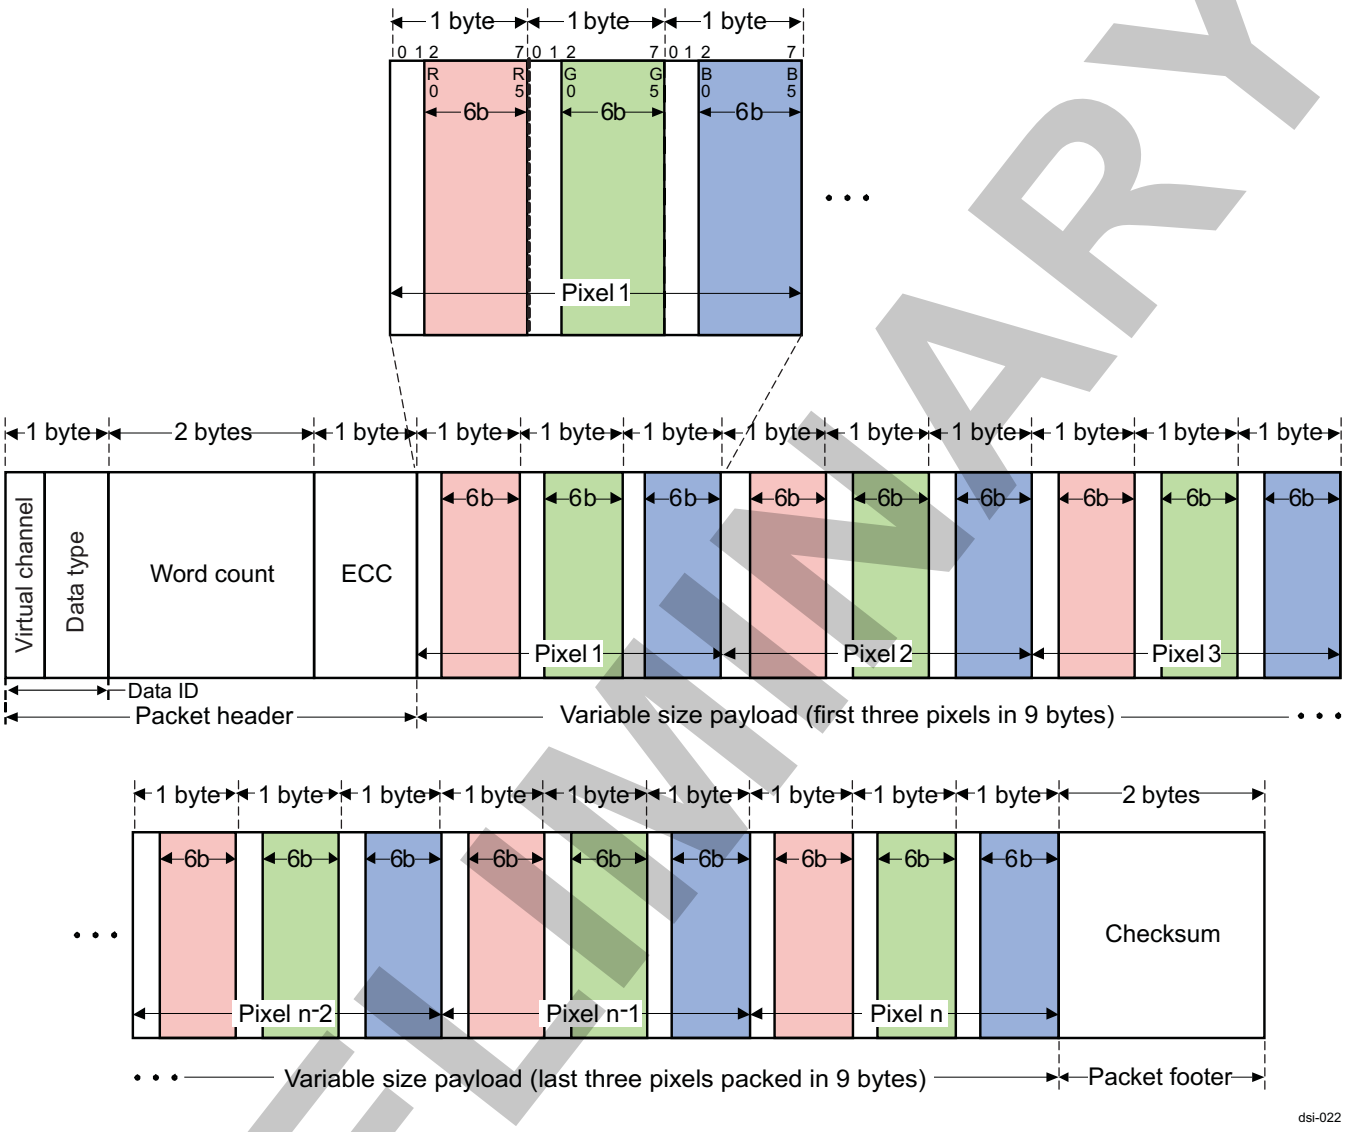


This format is the same as the packed pixel stream format.

10.3.2.4.4 DSI 18 bpp (Loosely Packed) – RGB Color Format, Long Packet (Transparent for DSI Protocol Engine) (Video Mode)

Figure 10-113 shows the RGB666 format.

Figure 10-113. DSI 18-bpp (Loosely Packed) RGB Color Format, Long Packet (Transparent for DSI Protocol Engine) (Video Mode)

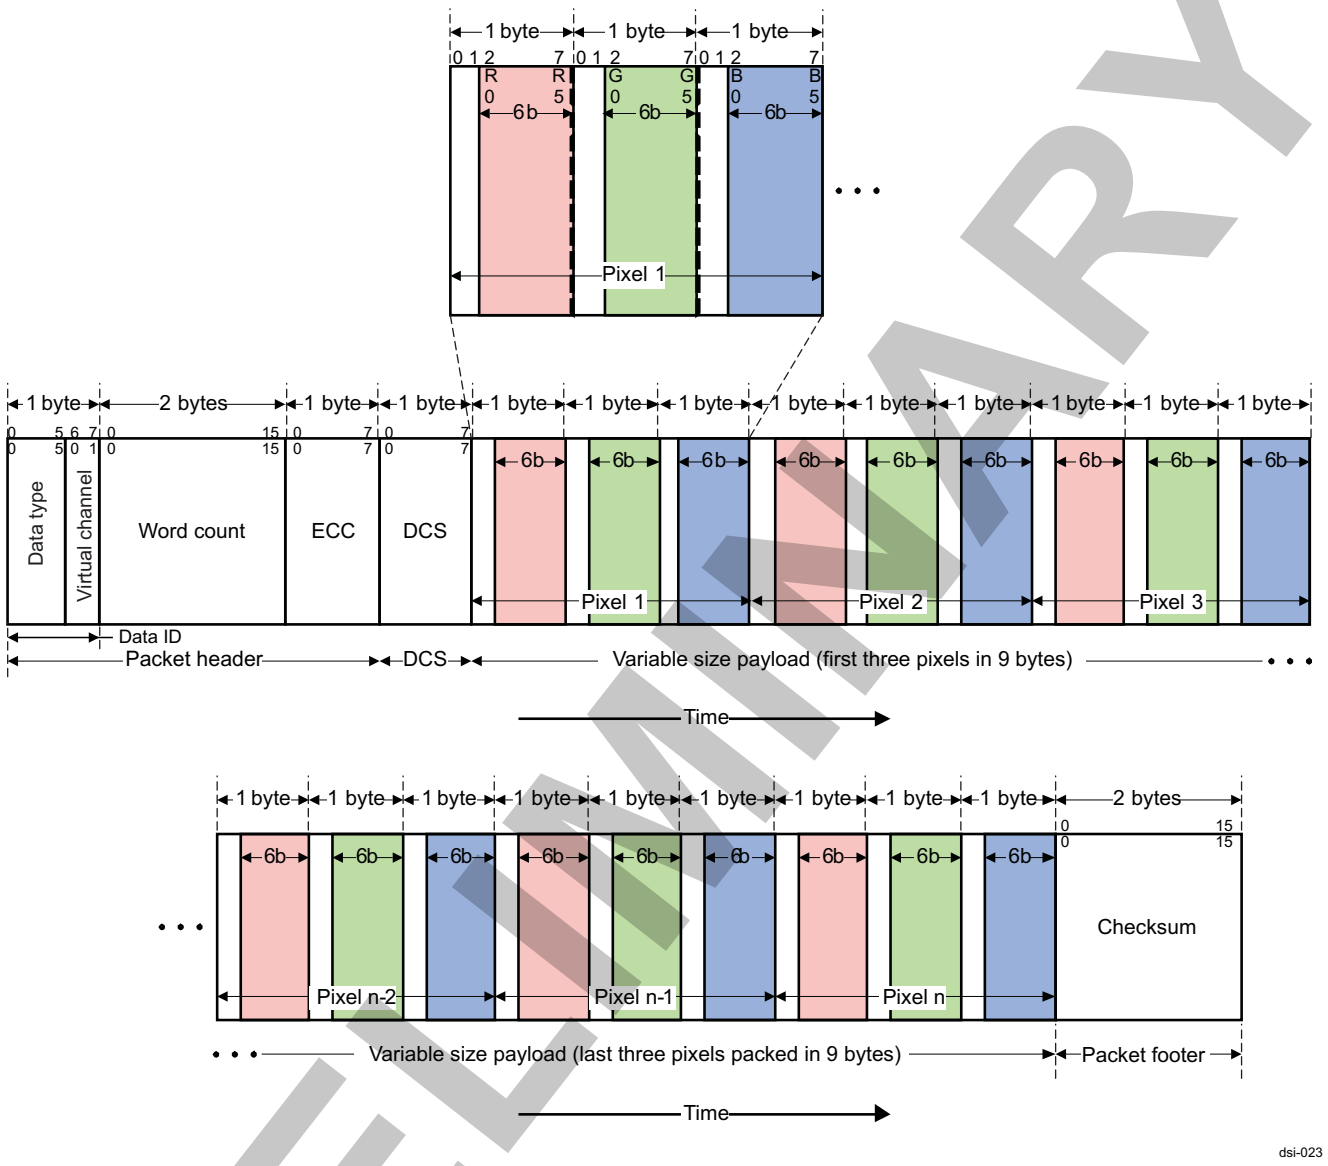


In 18-bit loosely packed pixel format, each R, G, and B color component is 6 bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires 3 bytes as it is transmitted across the link. This requires more bandwidth than packed format but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (6 bits), G (6 bits), and B (6 bits), in that order. Within a color component, the LSB is sent first and the MSB last.

10.3.2.4.5 DSI 18 bpp (Loosely Packed) – RGB Color Format, Long Packet (Command Mode)

Figure 10-114 shows the RGB666 format.

Figure 10-114. DSI 18-bpp (Loosely Packed) RGB Color Format, Long Packet (Command Mode)

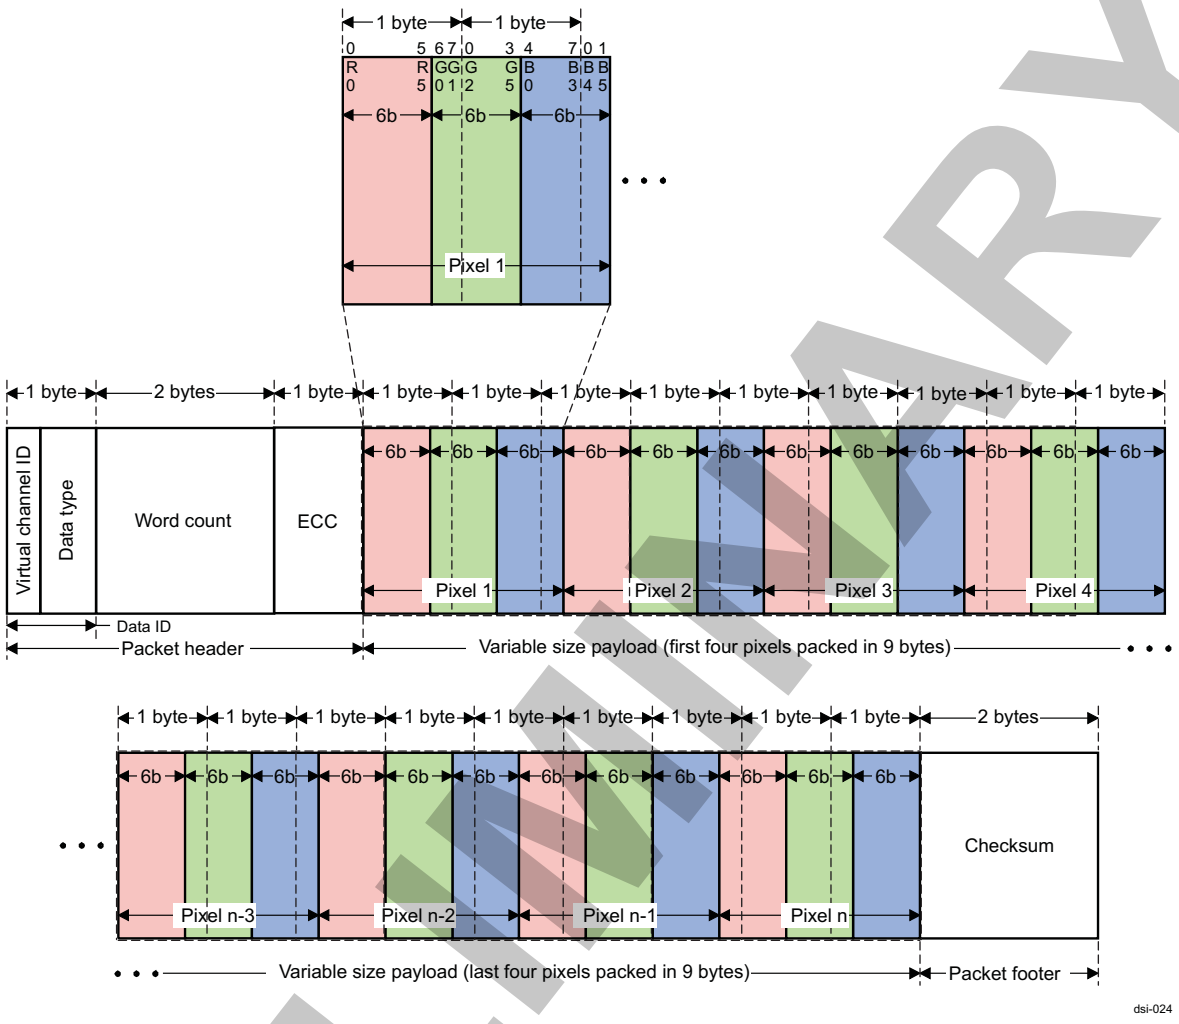


This format is the same as the packed-pixel stream format.

10.3.2.4.6 DSI 18 bpp (Packed) – RGB Color Format, Long Packet (Video Mode)

Figure 10-115 shows the RGB666_PACKED format.

Figure 10-115. DSI 18-bpp (Packed) RGB Color Format, Long Packet (Video Mode)

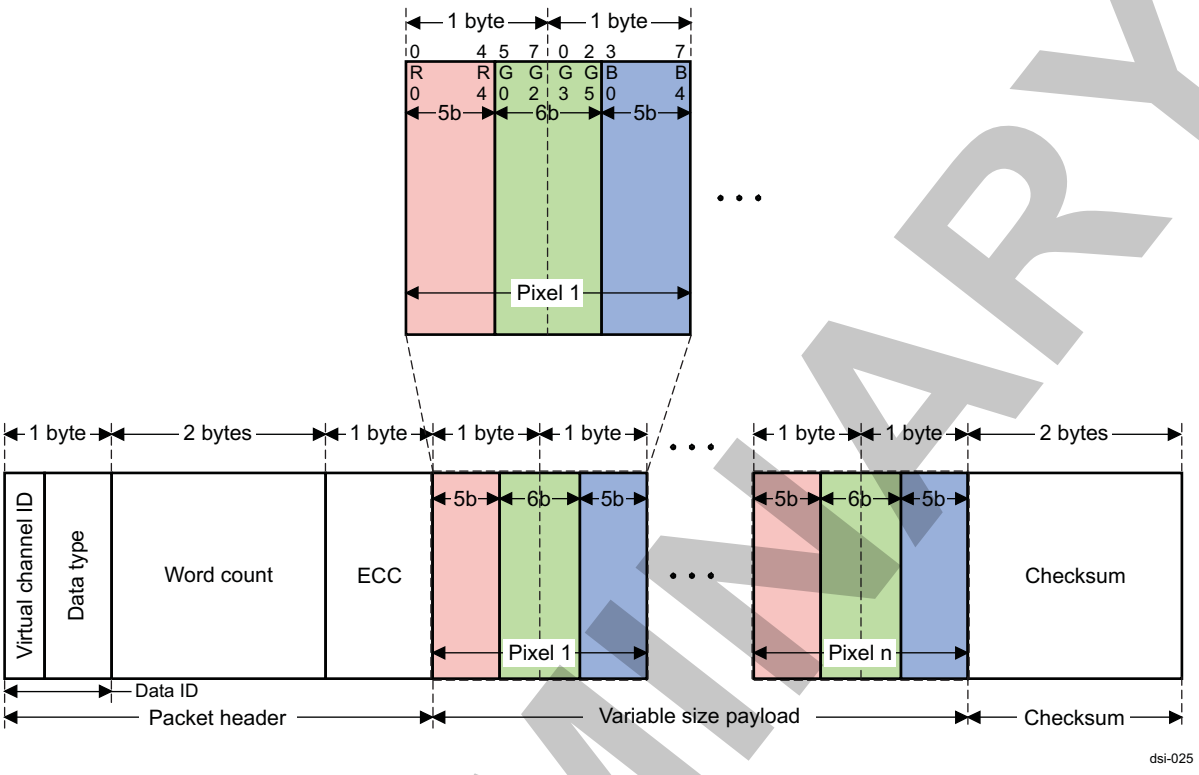


Packed pixel stream 18-bit format is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (6 bits), G (6 bits), and B (6 bits), in that order. Within a color component, the LSB is sent first and the MSB last. With this format, it is strongly recommended that the total line width be a multiple of 4 pixels (9 bytes). This format is not supported in command mode.

10.3.2.4.7 DSI 16 bpp – RGB Color Format, Long Packet (Video Mode)

Figure 10-116 shows the RGB565 format.

Figure 10-116. DSI 16-bpp RGB Color Format, Long Packet (Video Mode)

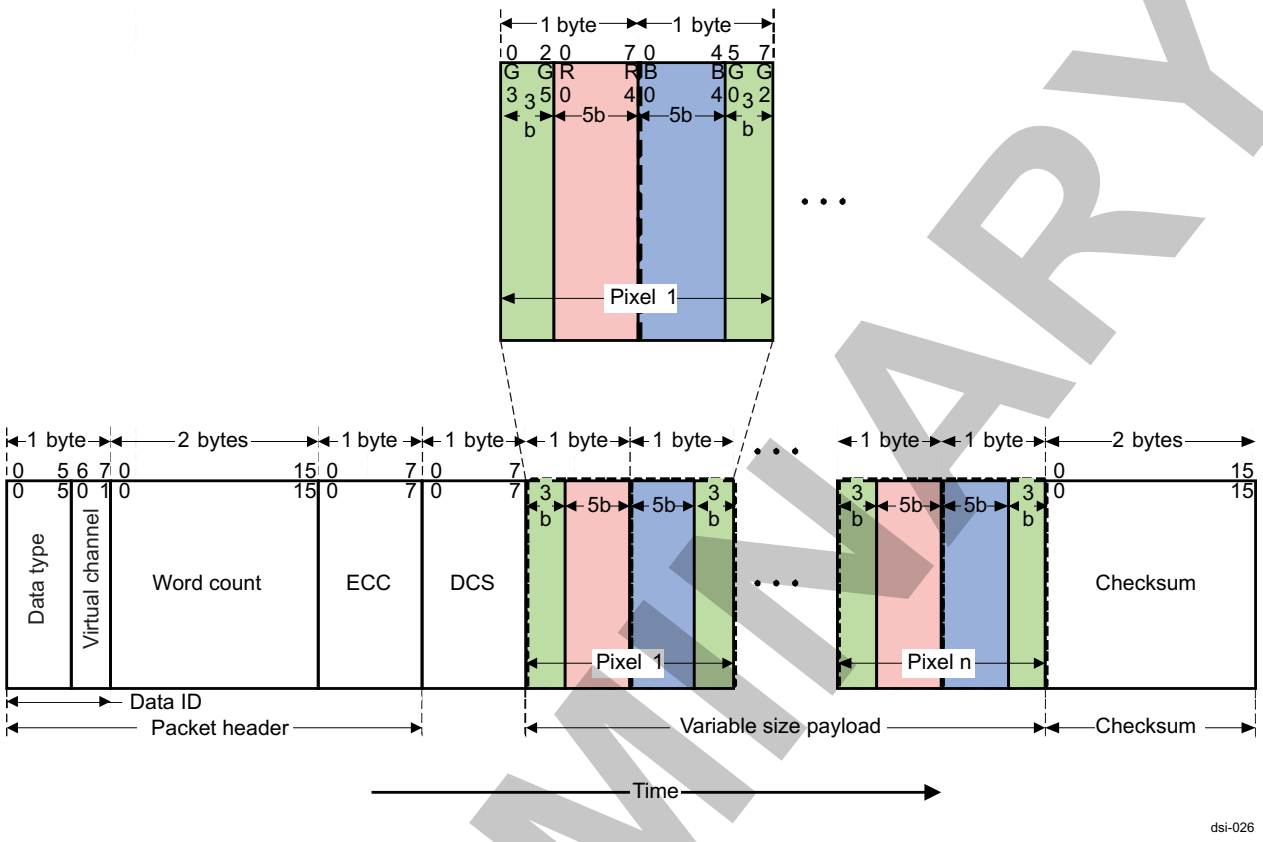


Packed-pixel stream, 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the data ID byte, a 2-byte WC, an ECC byte, a payload of length WC bytes, and a 2-byte checksum. The pixel format is R (5 bits), G (6 bits; split across 2 bytes), and B (5 bits), in that order. Within a color component, the LSB is sent first and the MSB last.

10.3.2.4.8 DSI 16 bpp – RGB Color Format, Long Packet (Command Mode)

Figure 10-117 shows the RGB565 format.

Figure 10-117. DSI 16-bpp RGB Color Format, Long Packet (Command Mode)



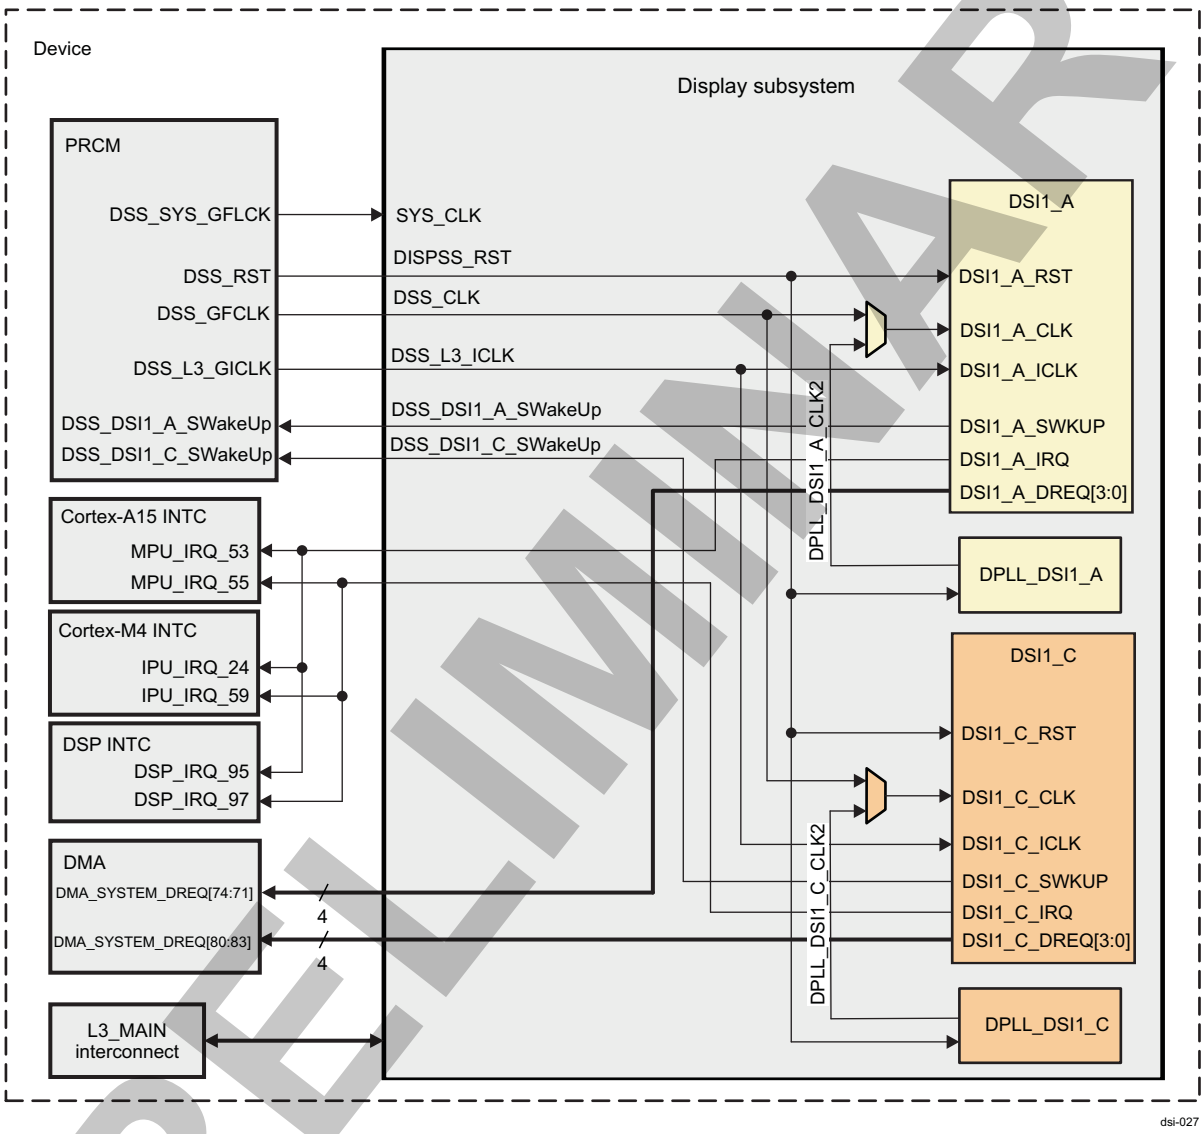
This is the opposite byte order from the packed pixel stream format. To retain flexibility, the byte order is made programmable using the DSI_VC_CTRL_i[12] RGB565_ORDER bit, with this order the default for command mode through the video port.

10.3.3 DSI Integration

This section describes the integration of the DSI in the device, including information about clocks, resets, and hardware requests.

Figure 10-118 shows the integration of the DSI in the device.

Figure 10-118. DSI Integration



NOTE: For more information about the wake-up request, see , *Module-Level Clock Management*, in *Chapter 3, Power, Reset, and Clock Management*.

Table 10-515 through Table 10-518 summarize the integration of the DSI module in the device.

Table 10-515. DSI Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MIPI DSI1_A	PD_DSS	L3_MAIN for data and configuration
MIPI DSI1_C	PD_DSS	L3_MAIN for data and configuration

Table 10-516. DSI Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
	SYS_CLK	DSS_SYS_GFLCK	PRCM module	Functional clock for the DSI PLLs
MIPI DSI1_A	DSI1_A_CLK	DSS_CLK DPLL_DSI1_A_CLK2	PRCM module DPLL_DSI1_A	Functional clock
	DSI1_A_ICLK	DSS_L3_MAIN_ICLK	PRCM module	Interface clock
MIPI DSI1_C	DSI1_C_CLK	DSS_CLK DPLL_DSI1_C_CLK2	PRCM module DPLL_DSI1_C	Functional clock
	DSI1_C_ICLK	DSS_L3_MAIN_ICLK	PRCM module	Interface clock
Resets				
MIPI DSI1_A	DSI1_A_RST	DISPSS_RST	PRCM module	Nonretention reset
MIPI DSI1_C	DSI1_C_RST	DISPSS_RST	PRCM module	Nonretention reset

NOTE: For information about clock distribution and configuration inside the module, see Section 10.3.4.2, *DSI Clock Configuration*.

Table 10-517. DSI Interrupt Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
MIPI DSI1_A	DSI1_A_IRQ	DSP_IRQ_95	DSP INTC	Display DSI1_A interrupt request
	DSI1_A_IRQ	MPU_IRQ_53	Cortex-A15 INTC	Display DSI1_A interrupt request
	DSI1_A_IRQ	IPU_IRQ_24	Cortex-M4 INTC	Display DSI1_A interrupt request
MIPI DSI1_C	DSI1_C_IRQ	DSP_IRQ_97	DSP INTC	Display DSI1_C interrupt request
	DSI1_C_IRQ	MPU_IRQ_55	Cortex-A15 INTC	Display DSI1_C interrupt request
	DSI1_C_IRQ	IPU_IRQ_59	Cortex-M4 INTC	Display DSI1_C interrupt request

NOTE: For a description of the interrupt source, see Section 10.3.4.3, *DSI Interrupt Requests*.

Table 10-518. DSI DMA Requests

DMA Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
MIPI DSI1_A	DSI1_A_DREQ_0	DMA_SYSTEM_DREQ_71	DMA_SYSTEM	DSI1_A DMA request 0
	DSI1_A_DREQ_1	DMA_SYSTEM_DREQ_72	DMA_SYSTEM	DSI1_A DMA request 1
	DSI1_A_DREQ_2	DMA_SYSTEM_DREQ_73	DMA_SYSTEM	DSI1_A DMA request 2
	DSI1_A_DREQ_3	DMA_SYSTEM_DREQ_74	DMA_SYSTEM	DSI1_A DMA request 3
MIPI DSI1_C	DSI1_C_DREQ_0	DMA_SYSTEM_DREQ_80	DMA_SYSTEM	DSI1_C DMA request 0
	DSI1_C_DREQ_1	DMA_SYSTEM_DREQ_81	DMA_SYSTEM	DSI1_C DMA request 1
	DSI1_C_DREQ_2	DMA_SYSTEM_DREQ_82	DMA_SYSTEM	DSI1_C DMA request 2
	DSI1_C_DREQ_3	DMA_SYSTEM_DREQ_83	DMA_SYSTEM	DSI1_C DMA request 3

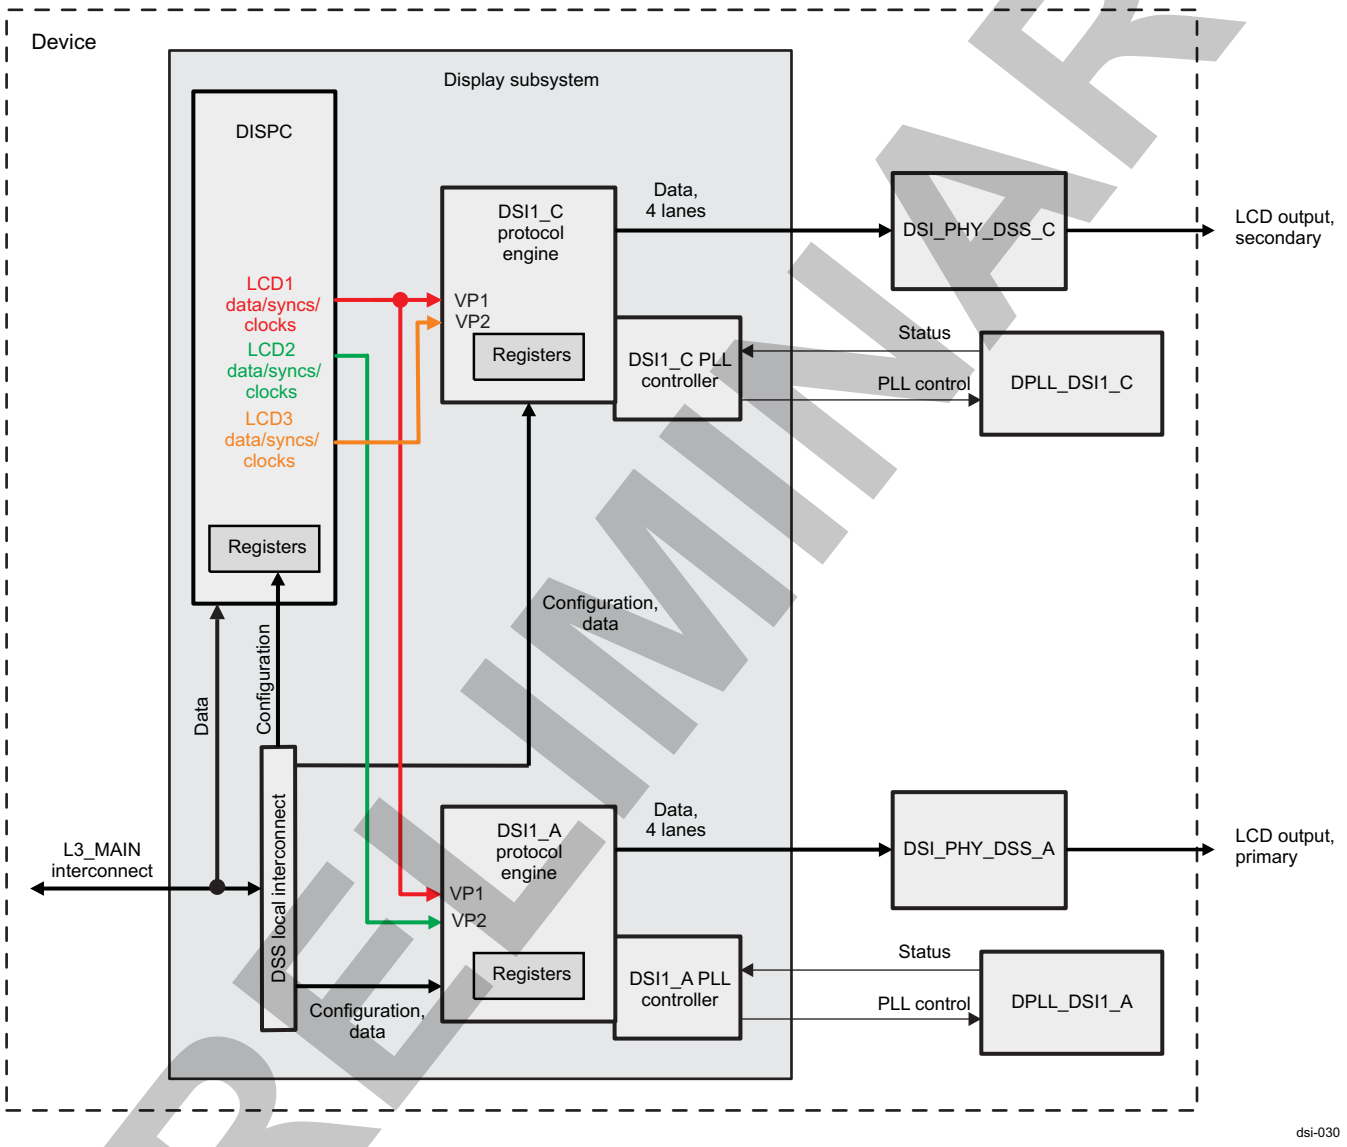
10.3.4 DSI Functional Description

This section describes the functions of the DSI1_A and DSI1_C modules.

10.3.4.1 DSI Block Diagram

Figure 10-119 is a schematic of DSI1_A and DSI1_C.

Figure 10-119. DSI Schematic



10.3.4.2 DSI Clock Configuration

Figure 10-120 shows the clock tree for DSI1_A and DSI1_C.

Figure 10-120. DSI Clock Tree

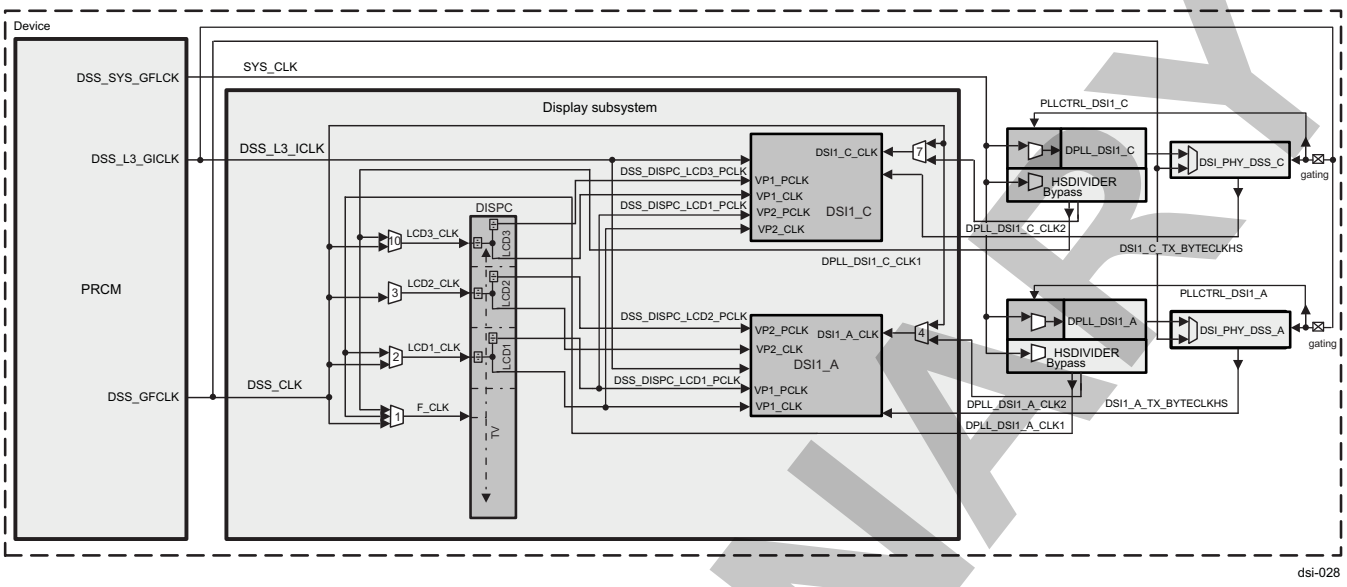


Table 10-519 shows the controls for clock multiplexers.

Table 10-519. DSI Multiplexer Controls

Destination	Source Signal Name	Source	Multiplexer Number	DSS_CTRL Bits
DISPC functional clock (F_CLK)	DSS_CLK	PRCM external PER_PLL	1	[9:7] FCK_CLK_SWITCH
	DPLL_DSI1_A_CLK1	DPLL_DSI1_A		
	DPLL_DSI1_C_CLK1	DPLL_DSI1_C		
	DPLL_HDMI_CLK1	DPLL_HDMI		
DISPC LCD1 functional clock (LCD1_CLK)	DSS_CLK	PRCM external PER_PLL	2	[0] LCD1_CLK_SWITCH
	DPLL_DSI1_A_CLK1	DPLL_DSI1_A		
DISPC LCD2 functional clock (LCD2_CLK)	DSS_CLK	PRCM external DPLL_PER	3	[12] LCD2_CLK_SWITCH
DISPC LCD3 functional clock (LCD3_CLK)	DSS_CLK	PRCM external DPLL_PER	10	[19] LCD3_CLK_SWITCH
	DPLL_DSI1_C_CLK1	DPLL_DSI1_C		
DSI1_A protocol engine functional clock (DSI1_A_CLK)	DSS_CLK	PRCM external DPLL_PER	4	[1] DSI1_A_CLK_SWITCH
	DPLL_DSI1_A_CLK2	DPLL_DSI1_A		
DSI1_A protocol engine interface clock (DSI1_A_ICLK)	DSS_L3_MAIN_ICLK	PRCM external DPLL_CORE	N/A	N/A
DSI1_A protocol engine pixel clock	DSS_DISPC_LCD1_PCLK	DISPC	N/A	N/A
DSI1_A protocol engine byte clock	DSI1_A_TX_BYTECLKHS	DPLL_DSI1_A	N/A	N/A
DSI1_C protocol engine functional clock (DSI1_C_CLK)	DSS_CLK	PRCM external DPLL_PER	7	[18] DSI1_C_CLK_SWITCH
	DPLL_DSI1_C_CLK2	DPLL_DSI1_C		
DSI1_C protocol engine interface clock (DSI1_C_ICLK)	DSS_L3_MAIN_ICLK	PRCM external DPLL_CORE	N/A	N/A
DSI1_C protocol engine pixel clock	DSS_DISPC_LCD3_PCLK	DISPC	N/A	N/A

Table 10-519. DSI Multiplexer Controls (continued)

Destination	Source Signal Name	Source	Multiplexer Number	DSS_CTRL Bits
DSI1_C protocol engine byte clock	DSI1_C_TX_BYTECLKHS	DPLL_DSI1_C	N/A	N/A

NOTE: For more information about the DSI1_A and DSI1_C video port clocks (VPn_CLK and VPn_PCLK, where n = 1 or 2), see Section 10.3.4.4.5, *DSI Video Port Interface*

NOTE: For the frequency ratings of the various DSI clocks, see Display Subsystem Clocks, in *Display Subsystem*.

NOTE: To enable the bypass input for the DSI_PHY_DSS_A or DSI_PHY_DSS_C module, set the DSI_PLL_CONFIGURATION2[15] BYPASSEN bit to 1.

10.3.4.3 DSI Interrupt Requests

The DSI protocol engine requires a single interrupt line. The DSI_IRQSTATUS register indicates the general interrupt events. Each VC and PHY has a dedicated interrupt register: DSI_VC_IRQSTATUS_i and DSI_COMPLEXIO_IRQSTATUS, respectively.

Table 10-520 lists the DSI global interrupt events.

Table 10-520. DSI Global Interrupts

IRQ Name	Description
RESYNCHRONIZATION_IRQ	Resynchronization in video mode
TA_TO_IRQ	Turnaround timer expired
SYNC_LOST_IRQ	Synchronization with video port is lost (video mode only).
ACK_TRIGGER_IRQ	Acknowledge trigger is received.
TE_TRIGGER_IRQ	TE PHY trigger is received.
WAKEUP_IRQ	Occurs when the SWakeUp signal is asserted.
HS_TX_TO_IRQ	HS TX time-out interrupt
LP_RX_TO_IRQ	LS RX time-out interrupt
COMPLEXIO_ERR_IRQ	Error signaling from DSI PHY: The interrupt is triggered when an error is received from the DSI PHY (events are defined in DSI_COMPLEXIO_IRQSTATUS).
PLL_RECAL_IRQ	PLL recalibration event (assertion of DSIRecal signal from the DSI PLL control module)
PLL_UNLOCK_IRQ	PLL unlock event (deassertion of DSILock signal from the DSI PLL control module)
PLL_LOCK_IRQ	PLL lock event (assertion of DSILock signal from the DSI PLL control module)
VIRTUAL_CHANNEL3_IRQ	VC 3 error signaling from DSI VC 3: The interrupt is triggered when an error is received from DSI VC 3 (events are defined in DSI_VC_IRQENABLE_i where i = 3).
VIRTUAL_CHANNEL2_IRQ	VC 2 error signaling from DSI VC 2: The interrupt is triggered when an error is received from DSI VC 2 (events are defined in DSI_VC_IRQENABLE_i where i = 2).
VIRTUAL_CHANNEL1_IRQ	VC 1 error signaling from DSI VC 1: The interrupt is triggered when an error is received from DSI VC 1 (events are defined in DSI_VC_IRQENABLE_i where i = 1).
VIRTUAL_CHANNEL0_IRQ	VC 0 error signaling from DSI VC 0: The interrupt is triggered when an error is received from DSI VC 0 (events are defined in DSI_VC_IRQENABLE_i where i = 0).
TE0_LINE_IRQ	TE detected on TE0 CMOS input signal
TE1_LINE_IRQ	TE detected on TE1 CMOS input signal

NOTE: For information about other internal DSI interrupt events, see Table 10-538 and Table 10-547 .

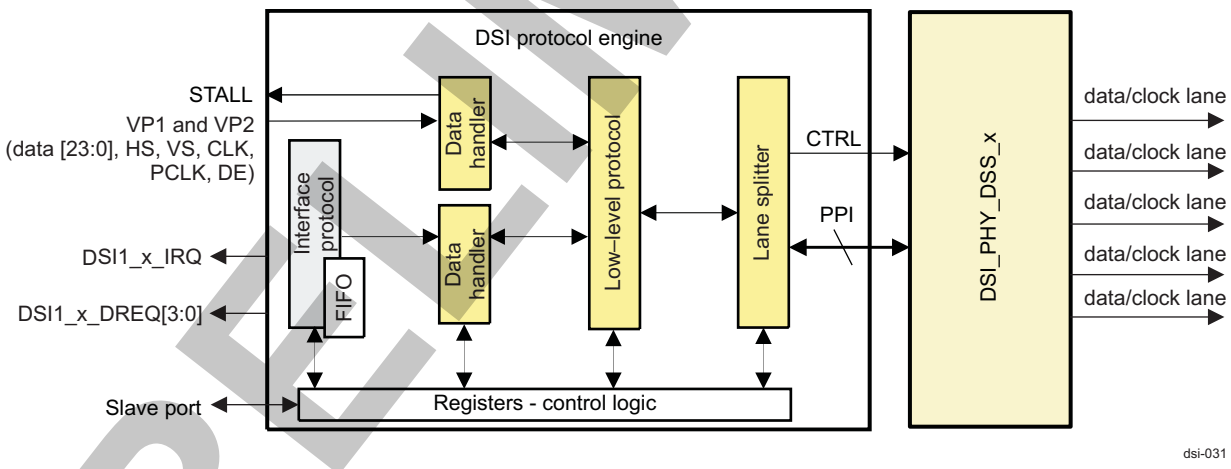
10.3.4.4 DSI Protocol Engine

The DSI protocol engine integrates the DSI with the display through the DSI_PHY_DSS_x module, local interconnect interface, and video interface from the DISPC. The DSI_PHY_DSS_x module is described in Section 10.3.4.6, *DSI PHY*. The DSI transmitter (protocol engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL control module described in Section 10.3.4.5, *DSI PLL Controllers*. The DSI transmitter port can be used in video mode or/and command mode.

10.3.4.4.1 DSI Protocol Overview

The DSI protocol engine receives data from the DISPC video port and/or the L3_MAIN interconnect slave port, encapsulates them with the VC ID, generates the ECC and checksum, and splits the data into byte streams to the DSI_PHY_DSS_x to be sent using LS or HS protocol. The DSI protocol engine receives data and acknowledges from the panel using the same DSI link in case of bidirectional panel. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. Figure 10-121 shows the DSI protocol engine, with an example of data lane and clock lane ordering. It is possible to configure other orders through registers as described in Section 10.3.2.1.1, *Data/Clock Configuration*.

Figure 10-121. DSI Protocol Engine



NOTE: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be clock or data. DSI PHY receives the configuration for the pin order and the differential ± in a pair from the settings in the DSI_COMPLEXIO_CFG1 register.

10.3.4.4.2 DSI Global Register Controls

Before receiving data from the DSI PHY, the DSI_PHY_DSS_x SCP registers in the DSI PHY must be configured. Table 10-521 lists the register access width limitations for all the DSI modules.

Table 10-521. DSI Register Access Width Limitations

Register Name	Register Access Width
All DSI PHY registers (DSI_PHY_DSS_x SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VC_LONG_PACKET_HEADER_i	32-bit only
DSI_VC_SHORT_PACKET_HEADER_i	32-bit only
DSI_VC_LONG_PACKET_PAYLOAD_i	16- and 32-bit
All other DSI protocol engine registers	8-, 16-, and 32-bit

CAUTION

If a different access width than listed in Table 10-521 is used, an interface error is generated in response to the write using SResp = ERR.

The DSI protocol engine is globally controlled by the DSI_CTRL register. The interface to the DSI PHY is enabled by setting the DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSI_CTRL[0] IF_EN bit is set to 1, the pending packets are sent to the DSI PHY, and the data transfer from the video port is ignored until the first vertical sync event is received.

When the DSI_CTRL[0] IF_EN bit is reset by software, the DSI protocol engine must finish the transfer of the pending data in the TX FIFO and wait for a response if BTA has been sent (the protocol engine is in receive mode); hardware then resets the DSI_CTRL[0] IF_EN bit. When using video mode, the VC associated with the video port must be enabled before enabling the interface according to the following sequence:

1. The DSI_CTRL[0] IF_EN bit is equal to 0.
2. Enable the VC associated with video mode by setting the DSI_VC_CTRL_i[0] VC_EN bit.
3. Set the DSI_CTRL[0] IF_EN bit to 1.

10.3.4.4.3 DSI Transfer Modes

Two main transfer modes are supported by the DSI modules:

- Video mode: Pixels are received from the video port (VP1 or VP2.) There are some real-time constraints (pixels must be sent at the pixel frequency required by the panel module).
- Command mode: Pixels can be received from the video port or from the L3_MAIN interconnect slave port. There are no real-time constraints except that the TE must be avoided by starting the transfer at the correct time during the scan of the display and that it must be fast enough.

10.3.4.4.3.1 DSI Video Mode

Video mode refers to the MIPI display pixel interface (DPI) standard. The sync events and pixels must be sent according to the display mode timings. Data is received from the video ports. The DISPC fetches the data from the system memory and provides it to the DSI protocol engine through VP1 or VP2. The short packets used for the sync event use precalculated 32-bit values. The long packets are constructed using the header defined in the DSI_VC_LONG_PACKET_HEADER_i registers. In case of synchronization short packets for video mode, because hardware generates short packets without using the DSI_VC_SHORT_PACKET_HEADER_i register, if the DSI_VC_CTRL_i[8] ECC_TX_EN bit is set, the ECC is calculated; otherwise, 0 is used. This feature is used to generate incorrect ECC for debugging purposes and to ease the check of the link and peripheral error detection and correction.

The DSI_VM_TIMING1 through DSI_VM_TIMING8 registers define the timings of the video mode.

The DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

The DSI_CTRL[20] BLANKING_MODE bit defines whether long blanking packets or LPS are used during the blanking periods (except HFP, HBP, and HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. Software must ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSI_VC_CTRL_i[9] MODE_SPEED bit is set to 1 (HS mode) to keep the video mode transfer in HS mode during blanking periods (except for the last blanking period, because it is required to go to LPS at least once per frame).

The following bits define whether during these blanking packets data from TX FIFO or long blanking packets are sent:

- DSI_CTRL[21] HFP_BLANKING_MODE
- DSI_CTRL[22] HBP_BLANKING_MODE
- DSI_CTRL[23] HSA_BLANKING_MODE

To ensure that the writes to the DSI_VC_LONG_PACKET_HEADER_i register are handled correctly as header information for video mode long packets, the following registers must be programmed:

- DSI_VC_CTRL_i[0] VC_EN bit set to 0
- DSI_VC_CTRL_i[4] MODE bit set to 1
- DSI_VC_LONG_PACKET_HEADER_i register access
- DSI_VC_CTRL_i[0] VC_EN bit set to 1

NOTE: The hardware ignores the DSI_VC_CTRL_i[1] SOURCE and DSI_VC_CTRL_i[9] MODE_SPEED bits when video mode is selected (the DSI_VC_CTRL_i[4] MODE bit is set to 1).

The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ interrupt events indicate whether or not the DSI protocol engine has been able to resynchronize the video port timing to its own timing base. The RESYNCHRONIZATION_IRQ indicates to the software user that the video port works but the configuration of the timings for the DISPC and for DSI protocol engine may need to be modified to avoid the resynchronization. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events, respectively, can be monitored in the DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

10.3.4.4.3.2 DSI Command Mode

The command mode refers to the MIPI display command set (DCS) standard. The commands, parameters, and pixels are sent to the display module with limited real-time constraints (as defined in Section 10.3.4.4.3.1, *Video Mode*). The pixels can be provided on one of the two video ports by the DISPC or on the L3_MAIN interconnect slave port.

The DSI_VC_LONG_PACKET_HEADER_i registers are used for the header of long packets; the DSI_VC_SHORT_PACKET_HEADER_i registers are used for short packets.

For the payload, the DSI_VC_LONG_PACKET_PAYLOAD_i register is used. Each 32-bit payload data is written to the DSI_VC_LONG_PACKET_PAYLOAD_i register from the MPU subsystem or DMA_SYSTEM. It is buffered to send packets with a higher rate than the L3_MAIN interconnect frequency can provide. If the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit is set to 1, the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is used to determine the number of bytes to be sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register minus the size of the DCS command header added by the protocol engine at the beginning of the payload (also sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register). If the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit is set to 0, the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is used to determine the number of bytes to be sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register.

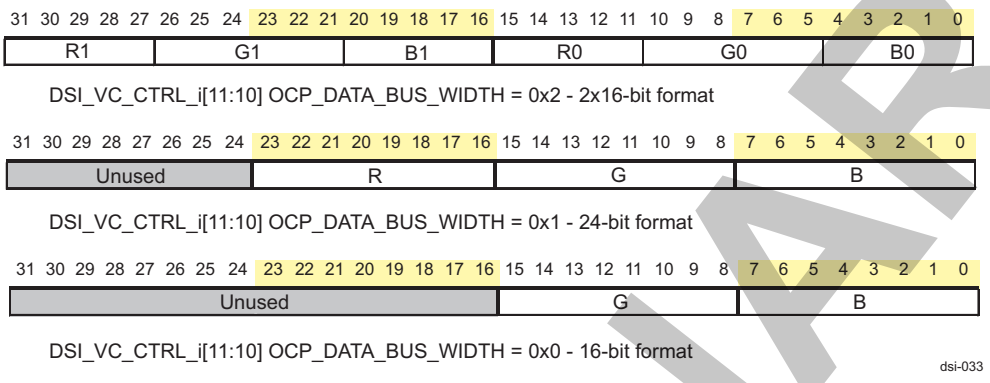
The DSI_VC_CTRL_i[11:10] OCP_DATA_BUS_WIDTH bit field is used to define the size of the data on the L3_MAIN interconnect slave port for the write access (read access to the RX FIFO is not affected by the bit field value):

- 0x0: 16-bit data width (LSB of the 32-bit interface port data bus)
- 0x1: 24-bit data width (LSB of the 32-bit interface port data bus)

- 0x2: 2 × 16-bit data width (first pixel on the LSB of the 32-bit interface port data bus and second pixel on the MSB of the 32-bit interface port data bus for the same interface access)
- 0x3: 32-bit data width (no bit, no byte, no pixel manipulation)

Figure 10-122 shows the different data width configurations of the L3_MAIN interconnect slave port.

Figure 10-122. DSI Interface Data Configuration



NOTE: To provide 18-bit pixel loosely packed format to the L3_MAIN interconnect slave port, the DSI_VC_CTRL_i[11:10] OCP_DATA_BUS_WIDTH bit field must be set to 0x1. The 18-bit pixel packed format is not supported in case of command mode on the L3_MAIN interconnect slave port.

The write into the DSI_VC_LONG_PACKET_HEADER_i register is required before accessing the DSI_VC_LONG_PACKET_PAYLOAD_i register. The DSI protocol engine must extract the length of the payload and discard the extra data sent using the DSI_VC_LONG_PACKET_PAYLOAD_i register. Writes into the DSI_VC_LONG_PACKET_HEADER_i register are valid only if the VC is enabled; otherwise, the write is ignored. When receiving pixels on the video port, only the DSI_VC_LONG_PACKET_HEADER_i register is used. The video port pixels are used for the payload.

10.3.4.4.3.2.1 DSI Command Mode TX FIFO

The single TX FIFO is used to store data from the L3_MAIN interconnect before sending it to the panel. The configuration of the FIFO for a specific VC must be done only when the VC is disabled.

The VC must not be enabled when data is still pending in the TX FIFO for the corresponding space allocated for the VC from the previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated registers (DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i) are used to provide data for long packets. The DSI_VC_SHORT_PACKET_HEADER_i register is used to provide data for short packets (32 bits long).

For each long packet, the DSI_VC_LONG_PACKET_HEADER_i register must be written first, followed by the DSI_VC_LONG_PACKET_PAYLOAD_i register. The only exception is when the word count defined in the header equals 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header must be written into the DSI_VC_LONG_PACKET_HEADER_i register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests for each VC to the TX FIFO are kept in order while sending the data to the DSI_PHY_DSS_x inside the VC requests. The only exception is the last 32-bit write for the last bytes of the payload data, because it can be 1, 2, 3, or 4 bytes.

When the last transfer is a 32-bit write, but the number of valid bytes is only 1, 2, or 3 (calculated using the header word count and the number of bytes are received for the payload), hardware stores the 32-bit value into the TX FIFO but the invalid bytes are not sent and are discarded.

When the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is not a multiple of the request threshold value defined in the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes are discarded by hardware to store in FIFO only the exact number of valid bytes.

The triggering event to send data to the DSI link is one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (the threshold value is bigger than the space left in the TX FIFO for the VC).
- When the VC is disabled, the remaining bytes in the FIFO are sent to the DSI link.

NOTE: In case video mode is active, the blanking period must be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (DSI_CTRL[3] TX_FIFO_ARBITRATION = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets must be sent to HS mode, to ensure that there is no LP transition between them, at least one of the following conditions must be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To stop a transfer immediately when packets are being transferred from the TX FIFO to DSI_PHY_DSS_x, a flush of the FIFO is necessary. It can be required in a dead-lock situation to flush the FIFO even if bytes are still in the FIFO. In that case, it is necessary to ensure having a known state of the whole DSI protocol engine module (software reset may be required) to the start of a new transfer through the TX FIFO.

To flush the FIFO (discard the data) for some pending bytes:

1. Change the size of the space of FIFO to 0 by writing DSI_TX_FIFO_VC_SIZE VCi_FIFO_SIZE bit fields (where i is the VC number from 0 to 3).
2. Disable the VC by resetting the DSI_VC_CTRL_i[0] VC_EN bit to 0.
3. Wait for DSI_VC_CTRL_i[15] VC_BUSY = 0 (VC_BUSY is set to 0 after TX FIFO flush is done).

It is necessary to check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant DSI_VC_CTRL_i[15] VC_BUSY bit or by using the interrupt PACKET_SENT_IRQ. This interrupt is monitored by reading the DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ status bit.

The DSI_CTRL[3] TX_FIFO_ARBITRATION bit defines the arbitration scheme:

- Round-robin between enabled VCs with pending ready requests (that is, all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC that has the lowest VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" is evaluated after the end of each packet.

To use in-order for all requests for all channels, a single VC must be used. (The VC ID defined in the header provided to the hardware using the DSI_VC_LONG_PACKET_HEADER_i or DSI_VC_SHORT_PACKET_HEADER_i register is not used and not modified by the DSI protocol engine.)

The DSI_TX_FIFO_VC_SIZE register defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO is defined by the DSI_TX_FIFO_VC_SIZE register VCi_FIFO_SIZE bit field. It must be a multiple of the threshold defined in the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field. To change the size of the space of the memory allocated for a specific VC, the VC must be disabled by setting the DSI_VC_CTRL_i[0] VC_EN bit to 0. The whole FIFO cannot be used by all the VCs at the same time because a VC can be disabled to change one or multiple parameters. Software users must configure the start address and size for each VC correctly.

Table 10-522 lists the corresponding values for the size of the space allocated in the FIFO.

Table 10-522. DSI VC TX FIFO Size Values

DSI_TX_FIFO_VC_SIZE.VCi_FIFO_SIZE (where i = 0, 3)	Space Size (up to the size of the FIFO)
0	0 × 33 bits
1	32 × 33 bits
2	64 × 33 bits
3	96 × 33 bits
4	128 × 33 bits

NOTE: TX FIFO is 128 × 33 bits. Therefore, the sum of all VC FIFO allocations cannot exceed 128 × 33 bits.

CAUTION

Bit 32 of each location in the FIFO is used by the DSI protocol engine to tag the data in the TX FIFO. It is for internal use only.

Table 10-523 lists the start address of the space in the FIFO.

Table 10-523. DSI VC TX FIFO Start Address

DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD (where x = 0, 2)	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

The different VC spaces must not overlap.

When the TX FIFO is full:

- The overflow interrupt (FIFO_TX_OVF_IRQ) is generated in the DSI_VC_IRQSTATUS_i[3] FIFO_TX_OVF_IRQ status bit.
- There is no L3_MAIN interconnect error generated.
- The interface commands are accepted but the data are not written into the FIFO.

To ensure that all writes are stored correctly in the TX FIFO, the FIFO must not be full. The room in the space allocated for the VC in the TX FIFO is given in the DSI_TX_FIFO_VC_EMPTINESS register. When no space is allocated in the TX FIFO for the VC, the DSI_TX_FIFO_VC_EMPTINESS register indicates a value of 0 for the VC space emptiness.

While waiting to receive the first VSYNC event on the video port to start video mode on the DSI link, no command data from TX FIFO is sent on the interface. This is required to ensure that when receiving the VSYNC event there is no ongoing command mode transfer that could delay the start of video mode on the DSI link.

10.3.4.4.3.2.2 DSI Command Mode RX FIFO

The RX FIFO stores the data received from the DSI PHY. The data are always packed in the RX FIFO (single or multiple packets received during single or multiple BTA periods).

The read requests (single or burst) can be less than, equal to, or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transferred. In that case, the logic keeps the VC information to provide the rest of the data during the next read request(s).

The DSI_RX_FIFO_VC_SIZE register defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs are considered.

To change the size of the memory space allocated for a specific VC, the VC must be disabled by resetting the DSI_VC_CTRL_i[0] VC_EN bit to 0. The entire FIFO cannot be used by the entire VC at the same time because a VC can be disabled to change one or multiple parameters. Software users must configure the start address and size for each VC correctly.

Table 10-524 lists the corresponding values for the size of the space allocated in the FIFO:

Table 10-524. DSI VC RX FIFO Size Values

DSI_RX_FIFO_VC_SIZE.VCi_FIFO_SIZE (where i = 0, 3)	Space Size (up to the size of the FIFO)
0	0 × 33 bits
1	32 × 33 bits
2	64 × 33 bits
3	96 × 33 bits
4	128 × 33 bits

NOTE: RX FIFO is 128 × 33 bits. Therefore, the sum of all VC FIFO allocations cannot exceed 128 × 33 bits.

CAUTION

Bit 32 of each location in the FIFO is used by the DSI protocol engine to tag the data in the RX FIFO. It is for internal use only.

Table 10-525 lists the start address of the space in the FIFO.

Table 10-525. DSI VC RX FIFO Start Address

DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD (where x = 0, 2)	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

The different VC spaces must not overlap.

While reading the received bytes in the RX FIFO, only the DSI_VC_SHORT_PACKET_HEADER_i register is used, because hardware does not keep track of the header position for long packets and the start/end of each packet. Software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_LONG_PACKET_PAYLOAD_i registers are not used.

The ECC is used only by the first header when receiving multiple packets during the same LP RX transfer from the peripheral because the DSI protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the checksum is not enabled because hardware checks the checksum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, hardware does not detect a header and cannot check and/or detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- No interface error is generated.
- Commands are accepted and the data for the responses are 0s.

10.3.4.4.3.2.3 DSI Command Mode DMA Requests

The DMA requests (DSI_DMA_REQ) are used to allow automatic transfer by the DMA_SYSTEM or MPU (with less efficiency and throughput capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable through the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD and DSI_VC_CTRL_i[26:24] DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO, respectively. DMA requests are asserted on the threshold value. The size of the space allocated in TX FIFO for each VC must be a multiple of the value of the DSI_VC_CTRL_i[19:17] DMA_TX_THRESHOLD bit field.

In the case of TX FIFO, if all the bytes defined by the word count field in the DSI_VC_LONG_PACKET_HEADER_i register are received, the DMA request is no longer asserted. Even during the last transfer, less than the DMA_TX_THRESHOLD number of bytes are received because the word count is not a multiple of the DMA_TX_THRESHOLD value.

In the case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the DMA_SYSTEM must be programmed to read the exact number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSI_VC_SHORT_PACKET_HEADER_i register is performed until the DSI_VC_CTRL_i[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The only exception is when the LP data transfer finishes and the threshold value is not reached. In this case, the DMA request is asserted. The drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

The use of each DMA request is programmable by software. The DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field is dedicated to DMA request numbering for the TX FIFO. The DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB bit field is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO that BTA has received from the peripheral, which indicates an end of the transfer from the peripheral to the host for a transfer to the system memory, the DMA request that corresponds to the VC ID is generated.

The DMA_SYSTEM transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (the user must know the number of expected received bytes to program the DMA_SYSTEM correctly). When the DMA_SYSTEM transfers a multiple number of threshold values, the DSI protocol engine sends 0s for the data when there is no more received data in the RX FIFO for the VC. Software users must parse the data and determine the valid bytes.

The size of the DMA transfer can be determined by reading the DSI_RX_FIFO_VC_FULLNESS register. The BTA interrupt (BTA_IRQ) must be used to determine when to read the number of received bytes. The BTA interrupt must be monitored by reading the DSI_VC_IRQSTATUS_i[5] BTA_IRQ status bit. The DMA request must not be enabled until the DMA_SYSTEM is programmed with the correct number of data to read from RX FIFO.

This method must also be used when the RX FIFO space for the VC is expected to overflow because the expected number of data to be received is greater than the space allocated for the VC. Instead, the DMA request is asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: For the most efficient transfer, the size of the request (read or write, single or burst) must be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

10.3.4.4.3.3 DSI Video + Command Mode

The two modes can be interlaced to send two DSI streams to two types of panels: video and command. The number of concurrent video streams is limited to one. The number of concurrent command mode streams is limited to four when there is no video stream, and three when there is a video stream.

- For DSI1_A and DSI1_C, which have two video ports (see Section 10.3.4.4.5, *DSI Video Port Interface*), it is possible to send video or command mode streams from DISPC to DSI1_x primary video port (VP1), and a command stream on the secondary VP (VP2) for interleaving. In addition, it is also possible to send concurrently a command mode stream on the L3_MAIN Interconnect slave port for interleaving.

10.3.4.4.3.4 DSI Burst Mode

Frequency and transparent burst modes are supported:

- Frequency burst mode is used to reduce the HS period by increasing the clock frequency on the DSI link. In some cases, it reduces power consumption on the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine must buffer a full line before sending the HS packets for the line. A double-buffering mechanism is required to send a line while the following one is being received on the video port. For more information about double-buffering, see Section 10.3.4.4.5.4, *Ping-Pong Buffer*.
- The transparent burst mode is used by increasing the pixel clock frequency generated by the DISPC with an increase of the horizontal blanking period.

10.3.4.4.3.5 DSI Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L3_MAIN interconnect during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as HS packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into LPS during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into LPS during the gap on the PPI link. If LPS is set during a gap, the DSI module performs interleaving during that period.

Two sets of registers are available for:

- HS interleaving (when HS command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

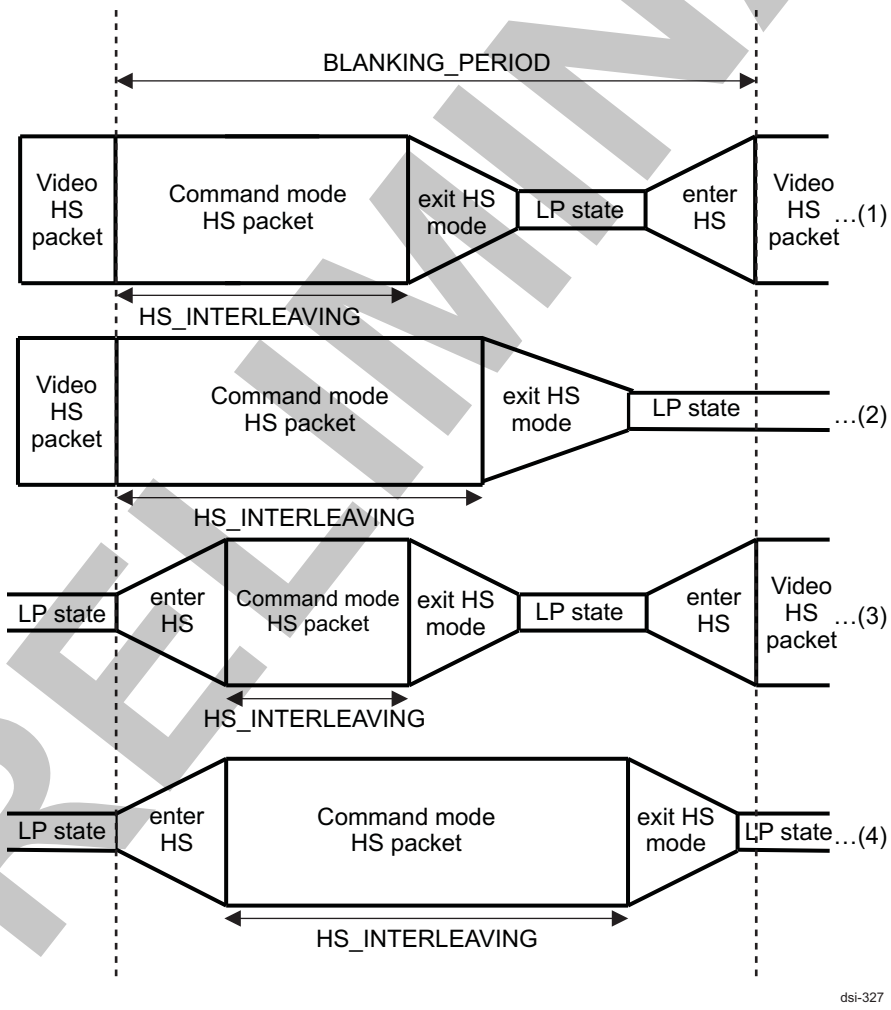
10.3.4.4.3.5.1 DSI HS Command Mode Interleaving

Figure 10-123 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TXBYTECLKHS clock cycles used for interleaving in HS command mode packets.

- The DSI_VM_TIMING6[31:16] BL_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The DSI_VM_TIMING4[7:0] HBP_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The DSI_VM_TIMING4[15:8] HFP_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The DSI_VM_TIMING4[23:16] HSA_HS_INTERLEAVING bit field defines the number of TXBYTECLKHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 10-123. DSI HS Command Mode Interleaving



NOTE: For calculations and equations, the following abbreviations are used: EXIT_CLK_HS_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations:

$$EXIT\_CLK\_HS\_MODE = T_{CLK\text{-}TRAIL} + TH_{S\text{-}EXIT}$$

NOTE: For more information about other timing parameters used in the following equations, see Section 10.3.4.4.4.1, *Timing Parameters for an LP-to-HS Transaction*, and Section 10.3.4.4.4.2, *Timing Parameters for an HS-to-LP Transaction*.

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the following bit fields, depending on the blanking type:

- BL_HS_INTERLEAVING
- HSA_HS_INTERLEAVING
- HBP_HS_INTERLEAVING
- HFP_HS_INTERLEAVING

In each scenario, two calculations are present, depending on the value of the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit:

- DDR_CLK_ALWAYS_ON = 1: Clock lane is always active.
- DDR_CLK_ALWAYS_ON = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.

CAUTION

When the DDR_CLK_ALWAYS_ON bit is programmed to 1, the following must be considered:

- LPS can be achieved on the PPI link only if the data lane has enough time to go out from HS mode and enter a new HS mode during a period inside which the PPI link is meant to be in LPS. This can be expressed with the following equation:

  EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1 ≤ BLANKING_PERIOD
- If the equation cannot be satisfied, because the LPs period is too short, software must program the DSI module in a way that during this blanking period a HS blanking packet is sent.

When the DDR_CLK_ALWAYS_ON bit is programmed to 0, the following must be considered:

- LPS can be achieved on the PPI link only if the data and clock lanes have enough time to go out from HS mode and enter a new HS mode during a period inside which the PPI link is meant to be in LPs. This can be expressed with the following equations:

  EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1 ≤ BLANKING_PERIOD

  DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE + ENTER_HS_MODE_LATENCY(data lane) + 1 ≤ BLANKING_PERIOD
- If both equations cannot be satisfied, because the LPS period is too short, software must program the DSI module in a way that during this blanking period a HS blanking packet is sent.

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + max{

ENTER_HS_MODE_LATENCY, 2} + 1)

HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + 1)

HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LPS.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 3)

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_POST + EXIT_CLK_HS_MODE + 3)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}
- Scenario 3: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ ENTER_HS_MODE_LATENCY, 2} + 1)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + max{ENTER_HS_MODE_LATENCY, 2} + 1)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + DDR_CLK_PRE+ ENTER_HS_MODE_LATENCY + 1)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}
- Scenario 4: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  - DDR_CLK_ALWAYS_ON = 1

    HS_INTERLEAVING = BLANKING_PERIOD – (ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)
  - DDR_CLK_ALWAYS_ON = 0

    HS_INTER1 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + EXIT_HS_MODE_LATENCY + 3)

    HS_INTER2 = BLANKING_PERIOD – (DDR_CLK_PRE + ENTER_HS_MODE_LATENCY + DDR_CLK_POST + EXIT_CLK_HS_MODE + 1)

    HS_INTERLEAVING = min{HS_INTER1, HS_INTER2}

10.3.4.4.3.5.2 DSI LP Command Mode Interleaving

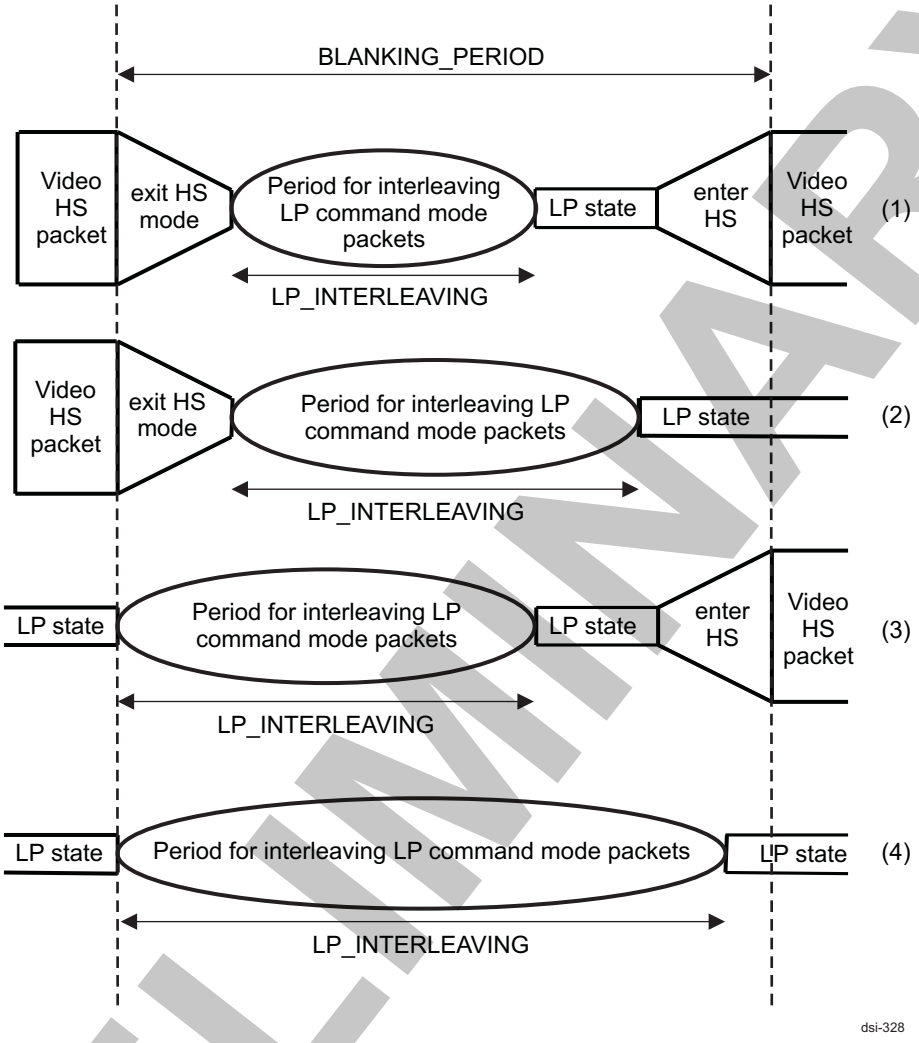
Figure 10-124 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of bytes of LP command mode packets that can be sent during a blanking period.

- The DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during a BLLP gap.
- The DSI_VM_TIMING5[7:0] HBP_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HBP gap.
- The DSI_VM_TIMING5[15:8] HFP_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HFP gap.
- The DSI_VM_TIMING5[23:16] HSA_LP_INTERLEAVING bit field defines the number of bytes of LP command mode packets that can be sent during an HSA gap.

These values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane HS and low-power mutually exclusive control. Clock lanes can be in HS mode while the data lanes are in HS data transfer mode, low-power data transfer mode, or in LPS.

According to this scenario, different equations must be considered to calculate register values.

Figure 10-124. DSI LP Command Mode Interleaving



For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The LP_INTERLEAVING period represents the maximal period in LP command mode packets. Its value is set in the following bit fields, depending on the blanking type.

- BL_LP_INTERLEAVING
- HSA_LP_INTERLEAVING
- HBP_LP_INTERLEAVING
- HFP_LP_INTERLEAVING

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TXBYTECLKHS clock cycles during which LP interleaving can appear.

To calculate the LP_INTERLEAVING value:

1. Calculate how many TXBYTECLKHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the value of LP_INTERLEAVING according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY +

max{ENTER_HS_MODE_LATENCY, 2} + 1)

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LPS.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (EXIT_HS_MODE_LATENCY + 1)
- Scenario 3: The gap for interleaving starts with the LPS and ends with a regular video stream HS packet.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – (max{ENTER_HS_MODE_LATENCY, 2} + 1)
- Scenario 4: The gap for interleaving starts with LPS and ends with a regular video stream HS packet.
  ALLOWED_HSBYTE_CLOCKS_FOR_LP = BLANKING_PERIOD – 1

After finishing Step 1, the time period available for LP interleaving is known:

$T_{lp\_available}$ = ALLOWED_HSBYTE_CLOCKS_FOR_LP *T TXBYTECLKHS

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$LP\_INTERLEAVING < \left\lfloor \frac{\frac{Tlp\_available - 8*Thsbyte\_clk - 5*Tdsif\_clk}{Ttxclkesc}}{16} - 26 \right\rfloor$$

dsi-E124

Thsbyte_clk: Period of TXBYTECLKHS clock of the DSI_PHY_DSS_x module

Tdsif_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

10.3.4.4.4 DSI Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even if there is no data to send for displays that require continuous clock. It is software-programmed through the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit: This bit can be programmed only when the interface is disabled (the DSI_CTRL[0] IF_EN bit set to 0).

The peripheral can use two different kinds of clocks. The first is the DDR clock provided on the clock lane. The second clock is some transitions on the first data lane even if there is no valid data to send using LP mode.

The LP clock (TxClkEsc) frequency provided to the DSI PHY is from 67 percent to 150 percent of the peripheral low-power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field. The LP clock generated from the DSI functional clock must be from 20 MHz to 32 kHz. The duty cycle must be 50/50 (minimum high time = 24 ns). LP clock frequency visible on the pads (DP x or DN) is half the frequency of TxClkEsc.

The DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is used to enable or disable the clock. When disabled, the value of the DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR bit field is ignored and does not have to be programmed by software users.

10.3.4.4.4.1 DSI Timing Parameters for an LP-to-HS Transaction

Figure 10-125 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 10-526 lists the LP to HS timing parameters.

Figure 10-125. DSI LP-to-HS Timing

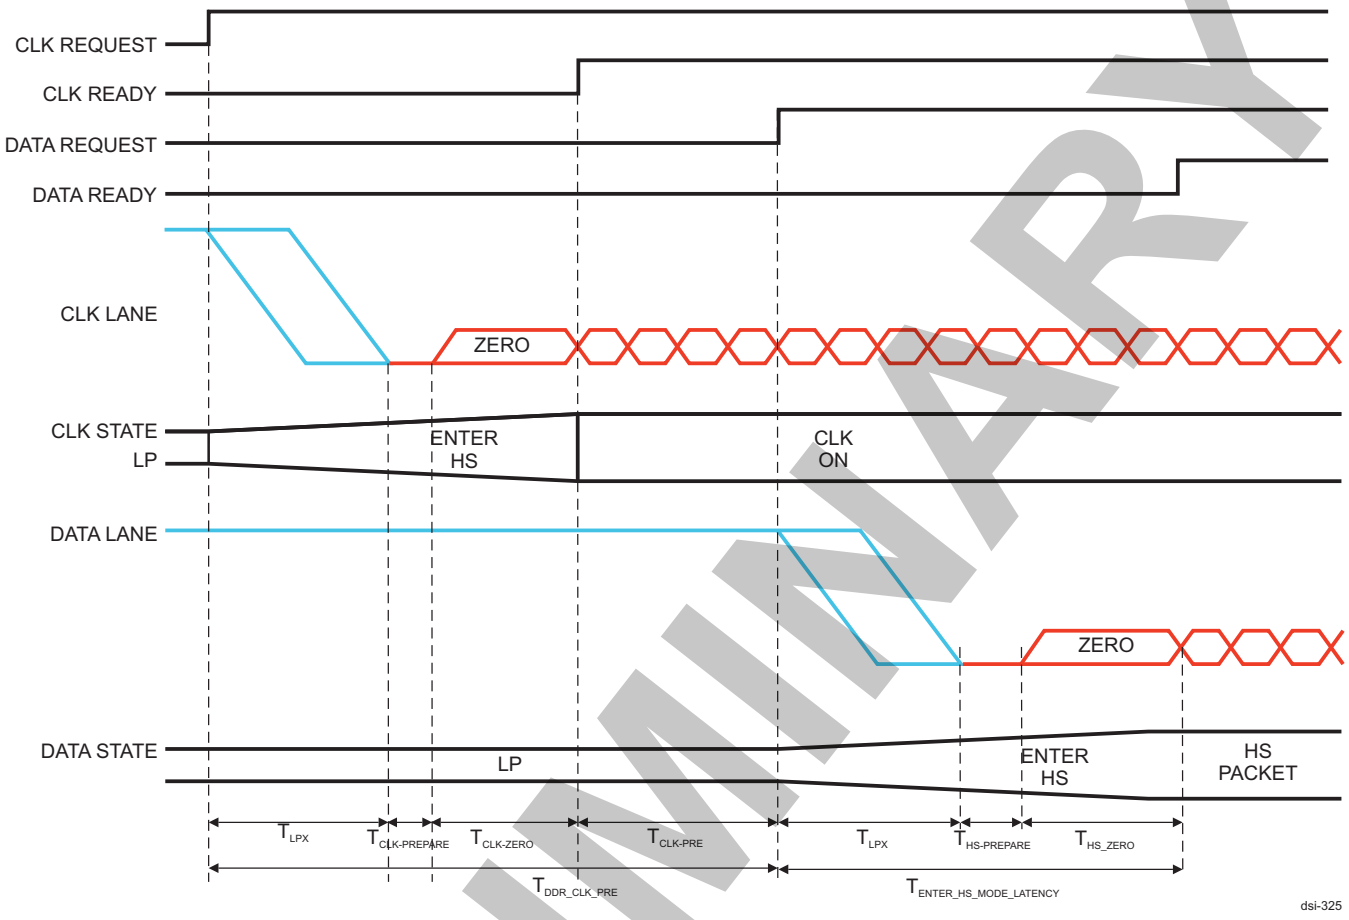


Table 10-526. DSI LP-to-HS Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{LPX}	Length of any low-power state period	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2 The value set in this bit field is half of the T_{LPX}	CEIL (25 ns / DDR_Clock_Period)	CEIL (2 * REG_TLPXBY2/4) * 4 * DDR_Clock_Period
$T_{CLK-PREPARE}$	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	CEIL (65 ns / DDR_Clock_Period)	REG_TCLKPREPARE * DDR_Clock_Period + (~–25– + 5 ns)
$T_{CLK-ZERO}$	Time to drive the CLK lane to HS-0 state, before starting the clock	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	CEIL (265 ns / DDR_Clock_Period)	{CEIL [(REG_TCLKZERO + 3)/4] * 4 + CEIL (REG_TCLKPREPARE/ 4) * 4 – REG_TCLKPREPARE + 2} * DDR_Clock_Period + (~ 0–+ 5 ns)
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode	N/A	N/A	DDR_CLK_PRE - T_{LPX} - $T_{CLK-PREPARE}$ - $T_{CLK-ZERO}$
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL (70 ns / DDR_Clock_Period) + 2	REG_THSPREPARE * DDR_Clock_Period + (–26.5–+ 4 ns)
$T_{HS-ZERO}$ + $T_{HS-PREPARE}$	$T_{HS-ZERO}$: Time to drive the data lane to HS-0 state before the synchronous sequence	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	CEIL (175 ns / DDR_Clock_Period) + 2	{CEIL [(N + 3)/4] * 4 + CEIL (M/4) * 4 + 3} * DDR_Clock_Period + (~ –29–0 ns). Where: N = REG_THSPREPARE_THSZERO – REG_THSPREPARE M = REG_THSPREPARE
$T_{DDR\_CLK\_PRE}$	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING[15:8] DDR_CLK_PRE	CEIL [(T_{LPX} + $T_{CLK-PREPARE}$ + $T_{CLK-ZERO}$ + $T_{CLK-PRE}$) / $T_{TXBYTECLKHS}$] (1) (2)	
$T_{ENTER\_HS\_MODE\_LATENCY}$ (3)	Time to enter data lane into HS mode	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	CEIL [(T_{LPX} + $T_{HS-PREPARE}$ + $T_{HS-ZERO}$) / $T_{TXBYTECLKHS}$] (1)	

(1) The timings seen on the line should be used to determine the register value.
(2) See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.
(3) ENTER_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 10-527, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz.

Table 10-527. DSI LP-to-HS Timing Parameters Example for 400-MHz DDR Clock

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line
T_{LPX}	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	10	50 ns

Table 10-527. DSI LP-to-HS Timing Parameters Example for 400-MHz DDR Clock (continued)

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line
$T_{CLK-PREPARE}$	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	26	40–70 ns
$T_{CLK-ZERO}$	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	106	280–285 ns
$T_{CLK-PRE}$ (1)	N/A	N/A	80 ns
$T_{HS-PREPARE}$	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	30	48.5–79 ns
$T_{HS-ZERO}$	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	72	178.5–207.5 ns
$T_{DDR\_CLK\_PRE}$	DSI_CLK_TIMING[15:8] DDR_CLK_PRE	45–49 (2)	450–490 ns
$T_{ENTER\_HS\_MODE\_LATENCY}$	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	24 * TXBYTECLKHS or 112 * DDR_CLOCK 34 * TXBYTECLKHS or 136 * DDR_CLOCK (2)	277–336.5 ns

(1) See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.
(2) Register setting calculated based on the values in the Timing Seen on the Line column.

10.3.4.4.4.2 DSI Timing Parameters for an HS-to-LP Transaction

Figure 10-126 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Table 10-528 lists the HS-to-LP timing parameters.

Figure 10-126. DSI HS-to-LP Timing

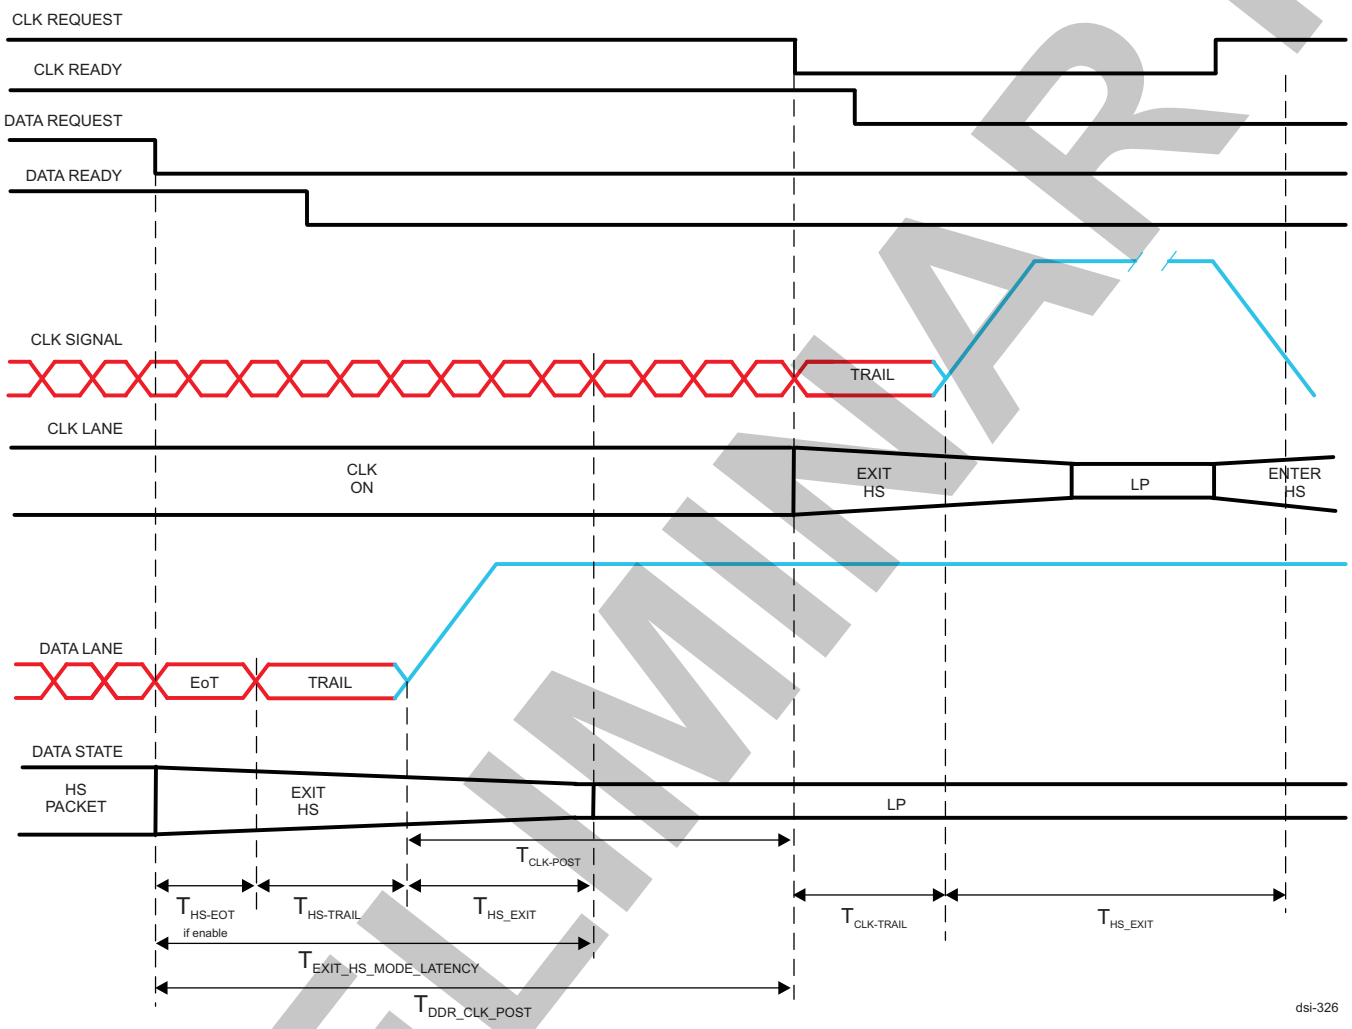

Table 10-528. DSI HS-to-LP Timing Parameters

Timings	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{HS-EOT}	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes.	N/A	N/A	DIVROUNDUP (4, NB_DATA_LANES) Thus: One data lane = Four DDR clocks Two data lanes = Two DDR clocks
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of an HS transmission burst	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	CEIL (60 ns / DDR_Clock_Period) + 5	{CEIL [(REG_THSTRAIL + 3)/4] * 4 – 2.75} * DDR_Clock_Period + (~ 0– 5 ns)
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	CEIL (145 ns / DDR_Clock_Period)	[CEIL (REG_THSEXIT/4) * 4] * DDR_Clock_Period – (~ 3–45 ns)
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	N/A	N/A	DDR_CLK_POST - T_{HS-EOT} (1) - $T_{HS-TRAIL}$
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of an HS transmission burst	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	CEIL (60 ns / DDR_Clock_Period) + 2	{CEIL [(REG_TCLKTRAIL + 3)/4] * 4 – 1.5} * DDR_Clock_Period + (~ 0– 5 ns)
$T_{DDR\_CLK\_POST}$	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: DDR_CLK_POST ≥ $T_{HS-TRAIL}$ + T_{HS-EOT} + $T_{CLK-POST}$	DSI_CLK_TIMING[7:0] $T_{DDR\_CLK\_POST}$	CEIL [($T_{HS-TRAIL}$ + T_{HS-EOT} (1) + $T_{CLK-POST}$) / $T_{TXBYTECLKHS}$] (2) (3)	
$T_{EXIT\_HS\_MODE\_LATENCY}$ (4)	Time to exit HS mode	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	CEIL [($T_{HS-TRAIL}$ + $T_{HS-EXIT}$ + T_{HS-EOT} (1)) / $T_{TXBYTECLKHS}$] (2)	

(1) If T_{HS-EOT} is enabled
(2) The timings seen on the line should be used to determine the register value.
(3) See the MIPI D-PHY specification for the$T_{CLK-POST}$ value.
(4) EXIT_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in Table 10-529, the DDR clock = 400 MHz; TxByteClkHS = 100 MHz; two data lanes.

Table 10-529. DSI HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
T_{HS-EOT}	N/A	N/A	5 ns	N/A
$T_{HS-TRAIL}$	DSI_PHY_REGISTER0 [15:8] REG_THSTRAIL	29	73.125–78.125 ns	73.125–78.125 ns

Table 10-529. DSI HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes (continued)

Timings	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
$T_{HS-EXIT}$	DSI_PHY_REGISTER0 [7:0] REG_THSEXIT	58	105–147 ns	105–147 ns
$T_{CLK-POST}$ (1)	N/A	N/A	585 ns	580 ns
$T_{CLK-TRAIL}$	DSI_PHY_REGISTER1 [15:8] REG_TCLKTRAIL	26	76.25–81.25 ns	76.25–81.25 ns
DDR_CLK_POST	DSI_CLK_TIMING[7:0] DDR_CLK_POST	66 * TxByteClkHS or 264 * DDR_CLOCK 67 * TxByteClkHS or 268 * DDR_CLOCK (2)	658.125–663.125 ns	653.125–658.125 ns
EXIT_HS_MODE_ LATENCY	DSI_VM_TIMING7[15: 0] EXIT_HS_MODE_LAT ENCY	19 * TxByteClkHS or 76 * DDR_CLOCK 24 * TxByteClkHS or 96 * DDR_CLOCK (2)	183.125–230.125 ns	178.125–225.125 ns

(1) See the MIPI D-PHY specification.
(2) Register setting calculated based on the values in Timing Seen on the Line (T_{HS-EOT} Enabled) column.

10.3.4.4.4.3 DSI Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last LS transfer. The same value is used for all the VCs sending packets in LS mode.

The size of the payload is defined by the DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE bit field. The header value depends on the size of the payload as described in Table 10-530 and Table 10-531.

NOTE: In Table 10-530 and Table 10-531, ECC and checksum are enabled.

Table 10-530. DSI Extra NULL PH

VC ID	Payload Size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_ PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F

10.3.4.4.5 DSI Video Port Interface

NOTE: The signals described in this section are internal and not bounded outside the device. This section describes the internal connections between the DISPC and the DSI protocol engine.

Table 10-532 and Table 10-533 summarize the video interface signals. DSI1_A and DSI1_C have two video ports (VP1 and VP2). These interfaces connect the DISPC outputs to the DSI protocol engine to send real-time data streams. For video mode, only the active matrix timings are supported by the DSI protocol engine.

- DSI1_A has two video ports (VP1 and VP2)
  - VP1 is connected to the LCD1 output of DISPC.
  - VP2 is connected to the LCD2 output of DISPC.
- DSI1_C has two video ports (VP1 and VP2)
  - VP1 is connected to the LCD1 output of DISPC.
  - VP2 is connected to the LCD3 output of DISPC.

Table 10-532. DSI Video Port 1 Signals for DSI1_A and DSI1_C Protocol Engines

Signal Name	Type(1)	Description
VP1_HSYNC	I	Horizontal synchronization signal
VP1_VSYNC	I	Vertical synchronization signal
VP1_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP1_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP1_CLK. The VP1_PCLK is generated from VP1_CLK through division inside the DISPC. The clock ratio is indicated in the DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DISPC_DIVISOR1[7:0] PCD bit field for DISPC LCD1 output, and the DISPC_DIVISOR2[7:0] PCD bit field for DISPC LCD2 output). The source of the VP1_PCLK for DSI1_A is the DSS_DISPC_LCD1_PCLK. The source of the VP1_PCLK for DSI1_C is DSS_DISPC_LCD3_PCLK. For more information, see DISPC Clock Configurationin *Display Controller*, and , *DSI Clock Configuration*.
VP1_DE	I	Data enable
VP1_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)

(1) I = Input; O = Output

Table 10-532. DSI Video Port 1 Signals for DSI1_A and DSI1_C Protocol Engines (continued)

Signal Name	Type[1]	Description
VP1_CLK	I	DISPC internal clock. It is a free-running clock. The source of VP1_CLK for DSI1_A is LCD1_CLK, divided down. The source of VP1_CLK for DSI1_C is LCD3_CLK, divided down. For more information, see DISPC Clock Configurationin *Display Controller*, and , *DSI Clock Configuration*

Table 10-533. DSI Video Port 2 Signals for DSI1_A and DSI1_C Protocol Engines

Signal Name	Type[1]	Description
VP2_HSYNC	I	Horizontal synchronization signal
VP2_VSYNC	I	Vertical synchronization signal
VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP2_CLK. The VP2_PCLK is generated from VP2_CLK through division inside the DISPC. The clock ratio is indicated in the DSI_CTRL2[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DISPC_DIVISOR2[7:0] PCD bit field for DISPC LCD2 output). The source of the VP2_PCLK for DSI1_A is the DSS_DISPC_LCD2_PCLK. The source of the VP2_PCLK for DSI1_C is LCD1_PCLK. For more information, see DISPC Clock Configuration in *Display Controller*, and , *DSI Clock Configuration*.
VP2_DE	I	Data enable
VP2_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP2_CLK	I	DISPC internal clock. It is a free-running clock. The source of the VP2_CLK for DSI1_A is LCD2_CLK, divided down. The source of the VP2_CLK for DSI1_C is LCD1_CLK, divided down. For more information, see DISPC Clock Configuration in *Display Controller*, and , *DSI Clock Configuration*.

(1) I = Input; O = Output

NOTE:

- The polarities of VP_HSYNC and VP_VSYNC are programmable by setting the DSI_CTRL and DSI_CTRL2 registers.
- Clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port (the width of the data bus) is defined in the DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.
- For the 18-bit pixel format using 24 bits on the DSI link, the format to be used by the DSI protocol engine is 24-bit, because the DISPC must convert the 18-bit pixels into 24-bit pixels. There is no logic inside the DSI protocol engine to convert from 18-bit format to 24-bit format.

The data received on the video port can be stored in the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the DISPC.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, cannot be used. Only transparency burst mode is supported.

NOTE: The DSI_CTRL[13:12] LINE_BUFFER and DSI_CTRL2[13:12] LINE_BUFFER bit fields define the number of lines to be used for transferring data from the video port to the DSI1_A and DSI1_C links.

10.3.4.4.5.1 DSI Video Port Used for Video Mode

If the video port is used for video mode, VP_STALL is not used. Table 10-534 and Table 10-535 list the active signals on the video port.

Table 10-534. DSI Video Port 1 for DSI1_A and DSI1_C in the Context of Video Mode

Signal Name	Type[1]	Description
VP1_HSYNC	I	Horizontal synchronization signal
VP1_VSYNC	I	Vertical synchronization signal
VP1_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP1_PCLK	I	Pixel clock
VP1_DE	I	Data enable
VP1_CLK	I	A free-running clock used as the DISPC functional clock

(1) I = Input; O = Output

Table 10-535. DSI Video Port 2 for DSI1_A and DSI1_C in the Context of Video Mode

Signal Name	Type[1]	Description
VP2_HSYNC	I	Horizontal synchronization signal
VP2_VSYNC	I	Vertical synchronization signal
VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	Pixel clock
VP2_DE	I	Data enable
VP2_CLK	I	A free-running clock used as the DISPC functional clock

(1) I = Input; O = Output

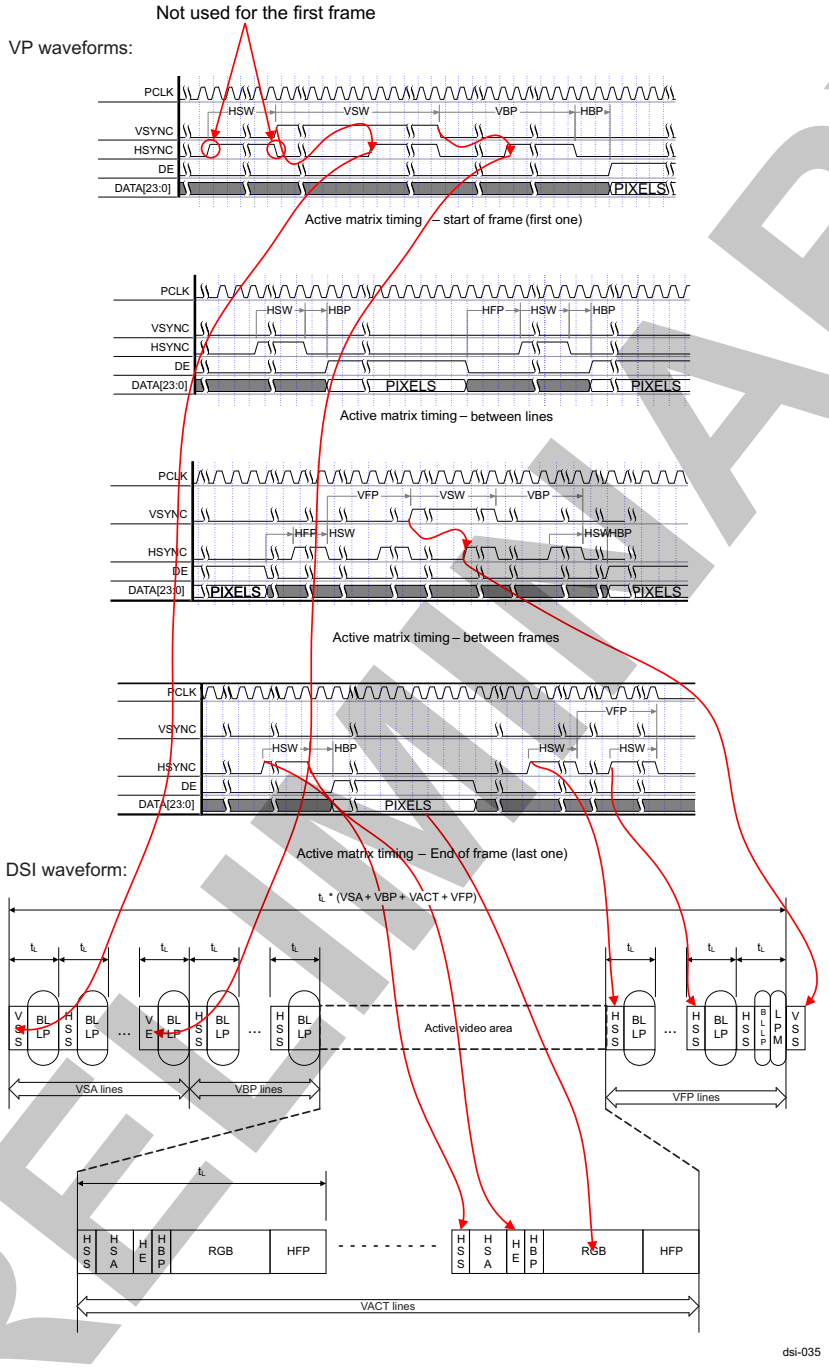
Three video modes are available:

- No-line buffer: The data received on the video port are directly output to the DSI port without buffering. The ratio of VP_PCLK and the DSI HS clock period must ensure the same throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide this configuration).
- One-line buffer:
  - The data can be transferred as described in the no-line buffer configuration.
  - The data are first stored in the line buffer; and then when all the data for one line are received, the DSI protocol engine sends the entire line. Software must adjust timings to let enough time for storing all line data into the line buffer before sending to DSI outputs. The synchronization packets are never stored in the line buffer.
- Two-line buffers:
  - The data can be transferred as described in the one-line buffer configuration.
  - One line is stored when the second line is output on the DSI port. This allows burst capability. While receiving the first line of the frame, no RGB packets are sent, because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored in the line buffer.

NOTE: If more active lines are received on the video port than the number of lines defined in the DSI_VM_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

Figure 10-127 through Figure 10-129 show these three video modes.

Figure 10-127. DSI Video Mode Without Burst (No-Line Buffer)



Legend:

- VSS – DSI Sync Event Packet: V sync start
- VSE – DSI Sync Event Packet: V Sync End
- BL LP – DSI Packet : Arbitrary sequence of nonrestricted DSI packets or low-power mode including optional BTA
- HSS – DSI Sync Event Packet: H sync start
- HSA – DSI Blanking Packet: Horizontal sync active or low-power mode, no data
- HSE – DSI Sync Event Packet: H sync end
- HFP – DSI Blanking Packet: Horizontal front porch or low-power mode
- HBP – DSI Blanking Packet: Horizontal back porch or low-power mode
- RGB – DSI Packet: Arbitrary sequence of pixel stream and null packets
- LPM – Low-power mode including optional BTA

Figure 10-128. DSI Video Mode Without Burst (One-Line Buffer)

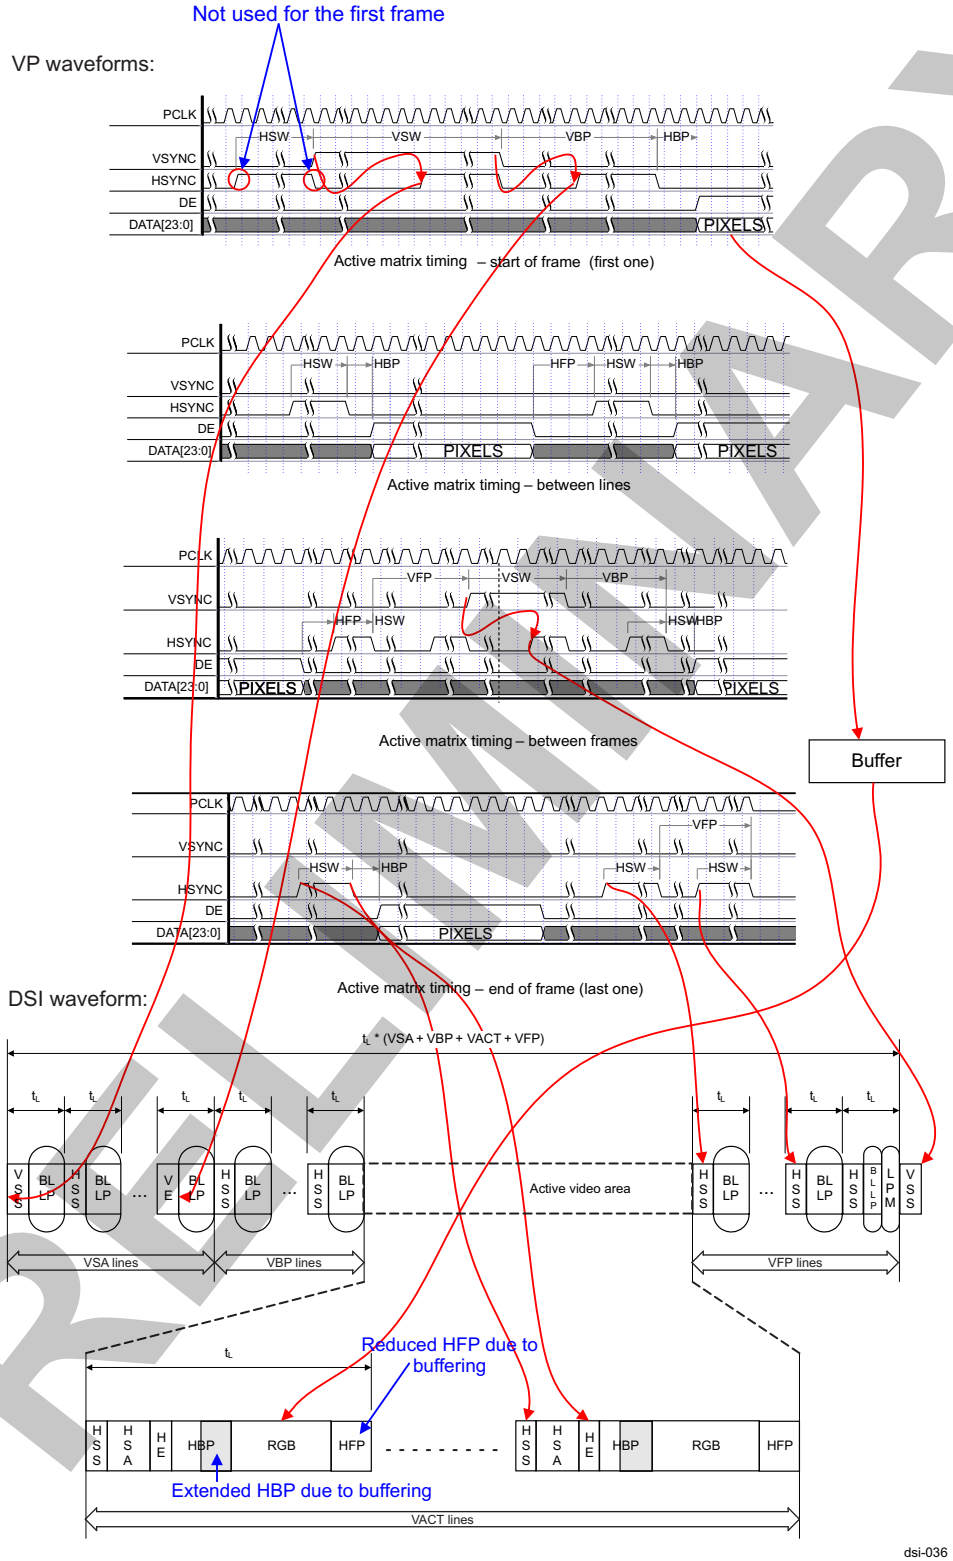


Figure 10-129. DSI Video Mode With Burst (Two-Line Buffers)

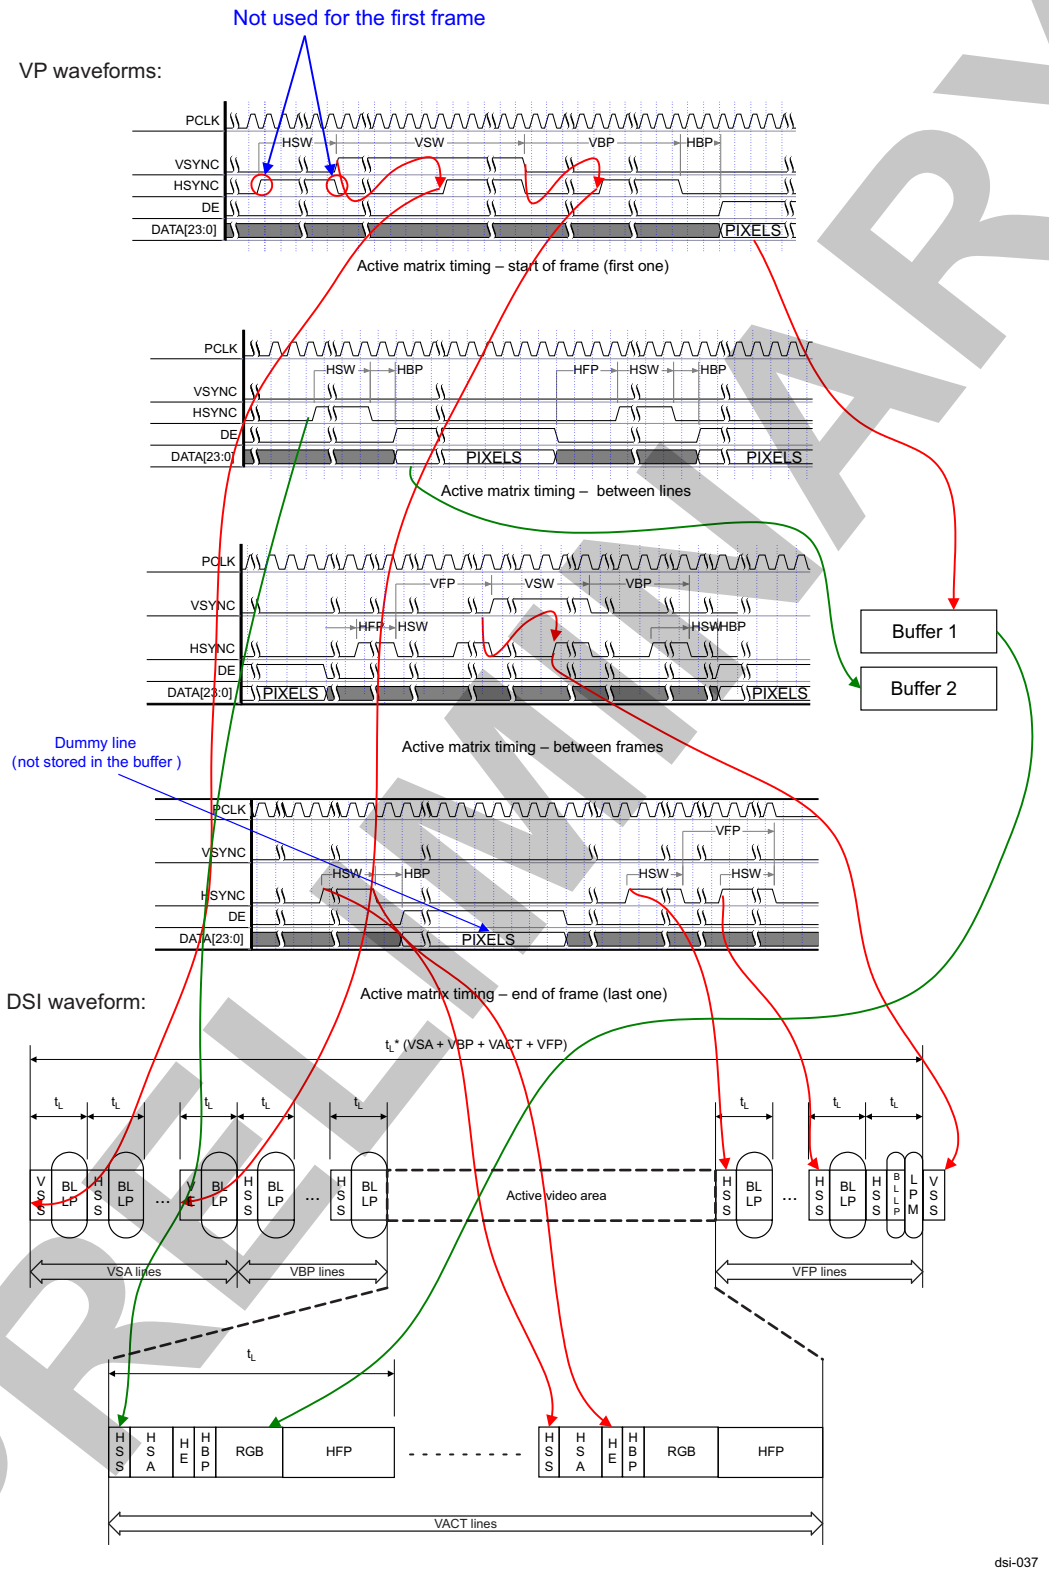

NOTE: In Figure 10-127 through Figure 10-129:

- When HSYNC start and HSYNC end short packets are not generated (HSA does not exist), the HBP signal must not be 0.
- Software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible:
  - The lane remains in ULPS, and the DSI_CTRL[20] BLANKING_MODE bit is set to 0x0.
  - Dummy bytes are sent during LP with the DSI_CTRL[20] BLANKING_MODE bit set to 0x1; the number of sent bytes is determined by the DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field.

In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

If the VP_DE signal is not asserted during enough VP_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP_DE signal is asserted for too many VP_PCLK cycles, the module stops capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS checks that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync is generated and the interface is disabled (the DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field.

10.3.4.4.5.2 DSI Video Port Used for Command Mode

If the video port is used for command mode, the VP_HSYNC, VP_VSYNC, and VP_DE signals are not used. Table 10-536 and Table 10-537 describe the active signals on video port 1 and video port 2, respectively.

Table 10-536. DSI Video Port 1 for DSI1_A and DSI1_C in the Context of Command Mode

Signal Name	Type(1)	Description
VP1_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP1_PCLK	I	One pulse is generated every time new data is output on the data bus.
VP1_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP1_CLK	I	DISPC internal clock. A free-running clock used as the DISPC functional clock.

(1) I = Input; O = Output

Table 10-537. DSI Video Port 2 for DSI1_A and DSI1_C in the Context of Command Mode

Signal Name	Type(1)	Description
VP2_DATA[23:0]	I	Parallel output data: Bits [23:0]
VP2_PCLK	I	One pulse is generated every time new data is output on the data bus.
VP2_STALL	O	The STALL signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the DISPC is configured in stall mode; in that mode, HSYNC and VSYNC are not generated.)
VP2_CLK	I	DISPC internal clock. A free running-clock used as the DISPC functional clock.

(1) I = Input; O = Output

NOTE: The STALL signal must be deasserted to receive pixels and asserted to stop receiving pixels.

Figure 10-130 and Figure 10-131 show the VP_STALL signal assertion and deassertion on rising and falling edges, respectively.

Figure 10-130. DSI Stall Timing With Pixel on Rising Edge

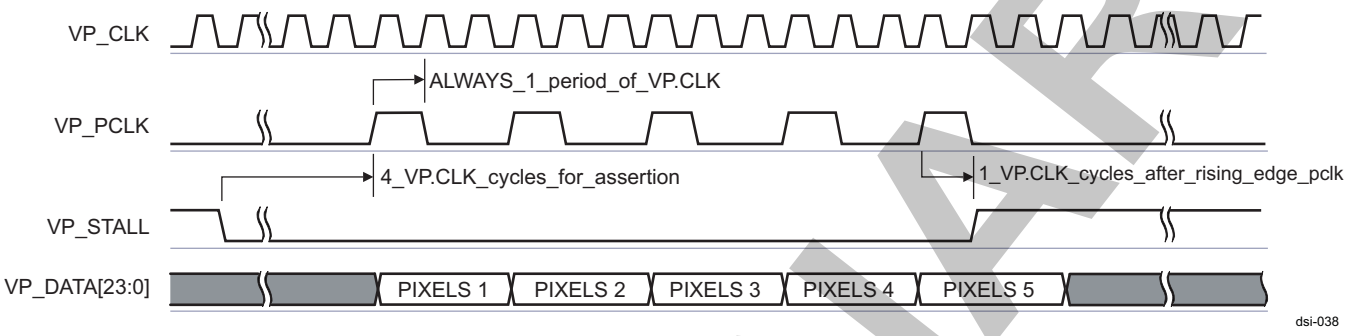

Figure 10-131. DSI Stall Timing With Pixel on Falling Edge

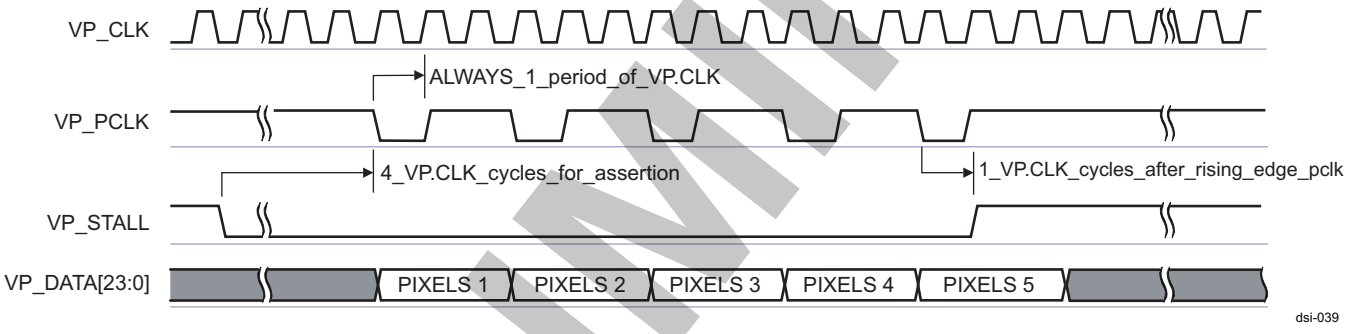


The VP_STALL signal is asserted to stop the transfer when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through registers in the DISPC. Data output on the falling edge of VP_PCLK is supported by the DSI protocol engine.

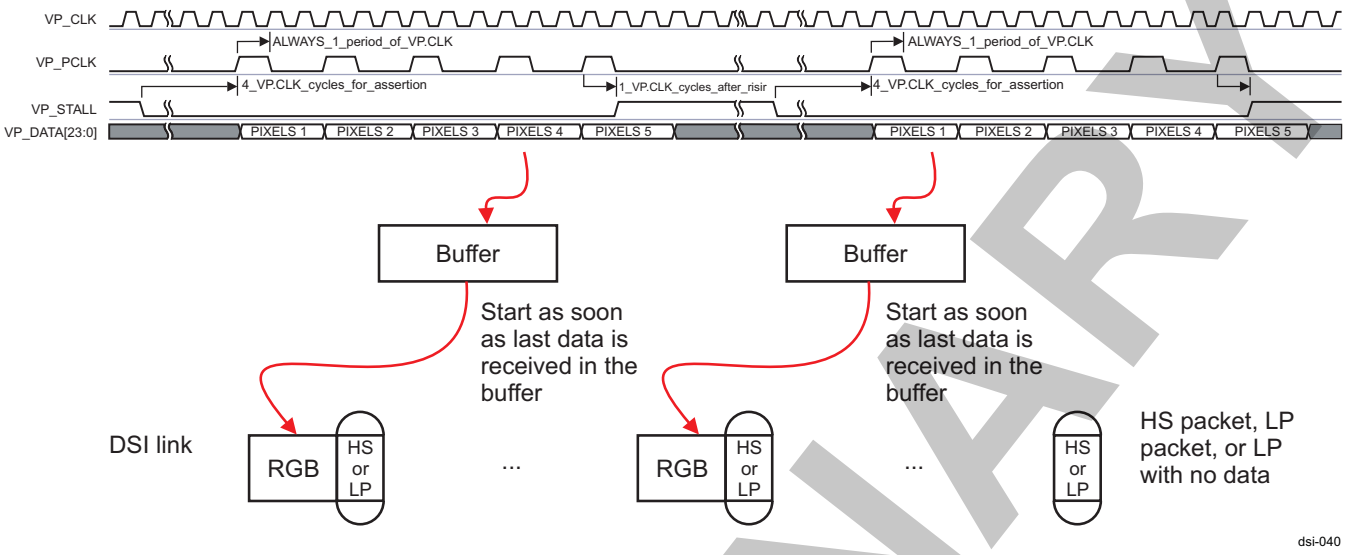
The VP_PCLK clock is generated from VP_CLK; these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on the rising edge of VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the DISPC. For more information, see DISPC Overview, in *Display Controller*. In the DSI protocol engine, the information is defined in the DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the DISPC configuration.

Deassertion of the VP_STALL signal occurs at least four VP_CLK cycles before assertion of VP_PCLK. Assertion of VP_STALL occurs one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the DISPC under software control. It can be kept running between assertion and deassertion of VP_STALL.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field for video port 1 and the DSI_CTRL2[7:6] VP_DATA_BUS_WIDTH bit field for video port 2.

Figure 10-132 shows the data flow in command mode using the video port.

Figure 10-132. DSI Data Flow in Command Mode Using the Video Port



Two command modes are available:

- One-line buffer: The data are stored in the line buffer before being sent.
- Two-line buffers: The two lines are used if the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register is bigger than the line size; otherwise, one-line buffer must be used.

NOTE: In command mode, the video port can be used only in one- or two-line buffer configuration. No-line buffer configuration is not allowed.

The packets can be sent using high speed or low speed.

The DCS command in the payload can be inserted automatically using the DSI_VC_CTRL_i[30] DCS_CMD_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and th DCS Write Continue command for all subsequent packets. The DSI_VC_CTRL_i[31] DCS_CMD_CODE bit is ignored.

10.3.4.4.5.3 DSI Burst Mode

When burst mode is enabled, the video port receives data from the DISPC at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer size). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. Burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second line buffer is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the entire video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by an internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

NOTE: The line buffers are used to store only the pixels. The synchronization codes are not stored in the line buffers; they must be sent according to the video port timings.

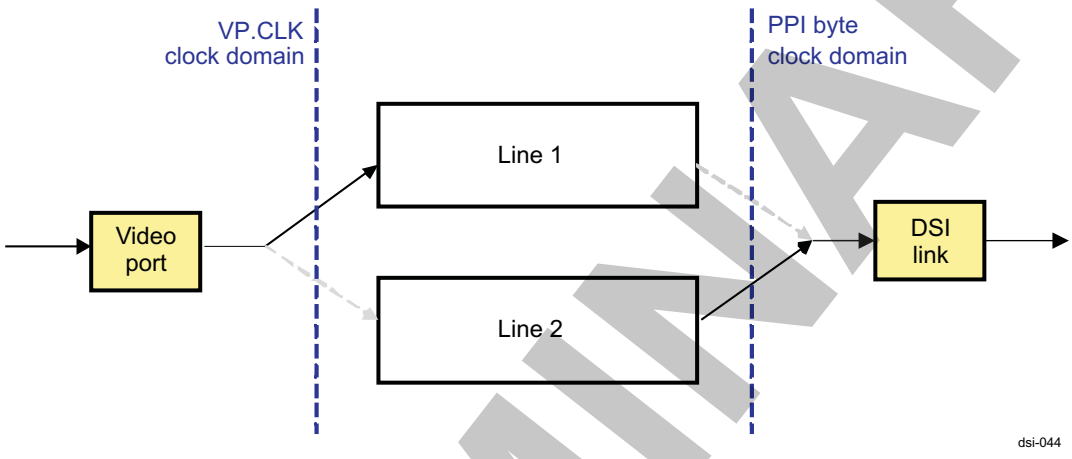
NOTE: The number of line buffers to be used while receiving data on the video port can be selected by setting the DSI_CTRL[13:12] LINE_BUFFER bit field.

10.3.4.4.5.4 DSI Ping-Pong Buffer

The ping-pong buffer stores data incoming from the DISPC in one of the two line buffers. When one line buffer is used to store the pixels received on the video port, the other line buffer is used to provide data on the DSI link. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 × 32 bits for VP2 of DSI1_A and DSI1_C, and 960 × 32 bits for VP1 of DSI1_A and DSI1_C). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

Figure 10-133 shows the video port used in ping-pong mode .

Figure 10-133. DSI Ping-Pong Mode



The ping-pong buffer status can be checked by the DSI_VC_CTRL_i[14] PP_BUSY bit.

- When PP_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, a new header cannot be updated.
- When PP_BUSY equals 0, at least one line buffer is empty; therefore, a new header can be updated. PP_BUSY is then set to 0x1. If both line buffers are empty, two headers can be written, one following the other. PP_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after the second header is written.

An IRQ is available to update header on events. The IRQ is enabled by setting the DSI_VC_IRQENABLE_i[8] PP_BUSY_CHANGE_IRQ bit to 0x1, and its status is accessible on the DSI_VC_IRQSTATUS_i[8] PP_BUSY_CHANGE_IRQ bit.

10.3.4.4.6 DSI SCP Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL control module and to the DSI PHY. It spends several cycles to serialize the data to be sent. Software users must consider the delay in processing the transfer of the data from/to the L3_MAIN interconnect slave port to/from the module.

10.3.4.4.6.1 DSI Shadowing Register

The first three SCP registers for the DSI PHY address map must be implemented as shadow registers. The shadowing mechanism is enabled and disabled using the DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the three first local interconnect port registers into the first three registers of the DSI PHY (DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2) is done only when the DISPC_UPDATE_SYNC signal from the DISPC is active and the DSI_COMPLEXIO_CFG1[30] GOBIT bit is set to 1. If there is no pending update for the three registers when the DISPC_UPDATE_SYNC signal is asserted, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware and there is no SCP transfer.
  - If only one register needs to be updated, only the corresponding new value is transferred. The

second and third registers in the DSI PHY are not updated. When the transfer completes, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware.

– If two registers need to be updated, the register with the lower address is transferred first, followed by the second register. When the transfers complete, the DSI_COMPLEXIO_CFG1[30] GOBIT bit is reset by hardware.

– If three registers need to be updated, the register with the lowest address is transferred first, and then the other registers are transferred according to incremental address. When the transfers complete, the GOBIT bit is reset by hardware.

When there is an ongoing transfer (read or write) to any SCP register, the transfer must complete before updating the shadowing registers.

- When setting the DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the first two DSI PHY registers has already started, it should be finished.

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI PHY are returned.

10.3.4.4.6.2 DSI Busy Signal

The SCPBusy signal indicates there is still activity using the SCPClk clock provided by the PRCM module. The SCPClk clock is then divided by the DSS_L3_MAIN_ICLK/4 clock.

10.3.4.4.7 DSI Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX, and TurnRequests timers generate interrupts immediately when the timer value is null. The ForceTxStopMode timer ends counting instantly and ForceTxStopMode is not asserted.

10.3.4.4.7.1 DSI T_{wakeup} Timer

The T_{WakeUp} timer is not implemented in the DSI protocol engine. The general-purpose (GP) timer must be used to handle wakeup. This timer is used for exiting ULPS for the active lanes (clock and/or data lanes). The sequence to exit ULPS is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt that indicates all lanes with TxULPSExit ACTIVE have acknowledged by asserting ULPSActiveNot. This is done by reading the ULPSACTIVENOT_ALLi_IRQ bit field (where i = 0 or 1) in the DSI_COMPLEXIO_IRQSTATUS register.
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

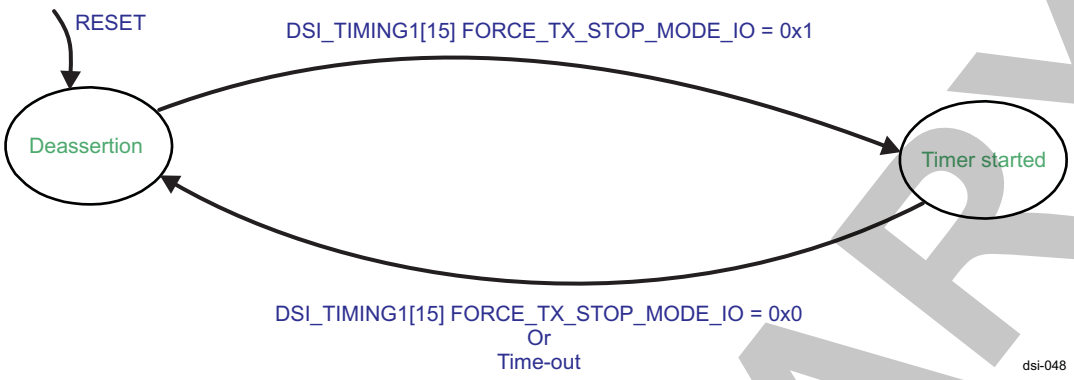
NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS for the clock lane, the state of TxUlpsClk must be changed to ACTIVE. To enter ULPS for the data lane, the state of TxRequestEsc must be changed to ACTIVE (also TxUlpsEsc, if it is not already in ACTIVE state).

10.3.4.4.7.2 DSI ForceTxStopMode FSM

The ForceTxStopMode signal is used at initialization time (DSI PHY). Figure 10-134 shows the ForceTxStopMode finite state-machine (FSM) to assert and deassert the ForceTxStopMode signal.

Figure 10-134. DSI ForceTxStopMode FSM



The DSI protocol engine asserts the ForceTxStopMode signal by setting the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows the lanes to be initialized. The lanes are in STOP state when the ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, STOP_STATE_X4_IO, and STOP_STATE_X16_IO bit fields in DSI_TIMING1[14:0] register. The DSI_TIMING1[15:0] FORCE_TX_STOP_MODE_IO bit field is reset by hardware when the time is reached.

This bit can be reset by software.

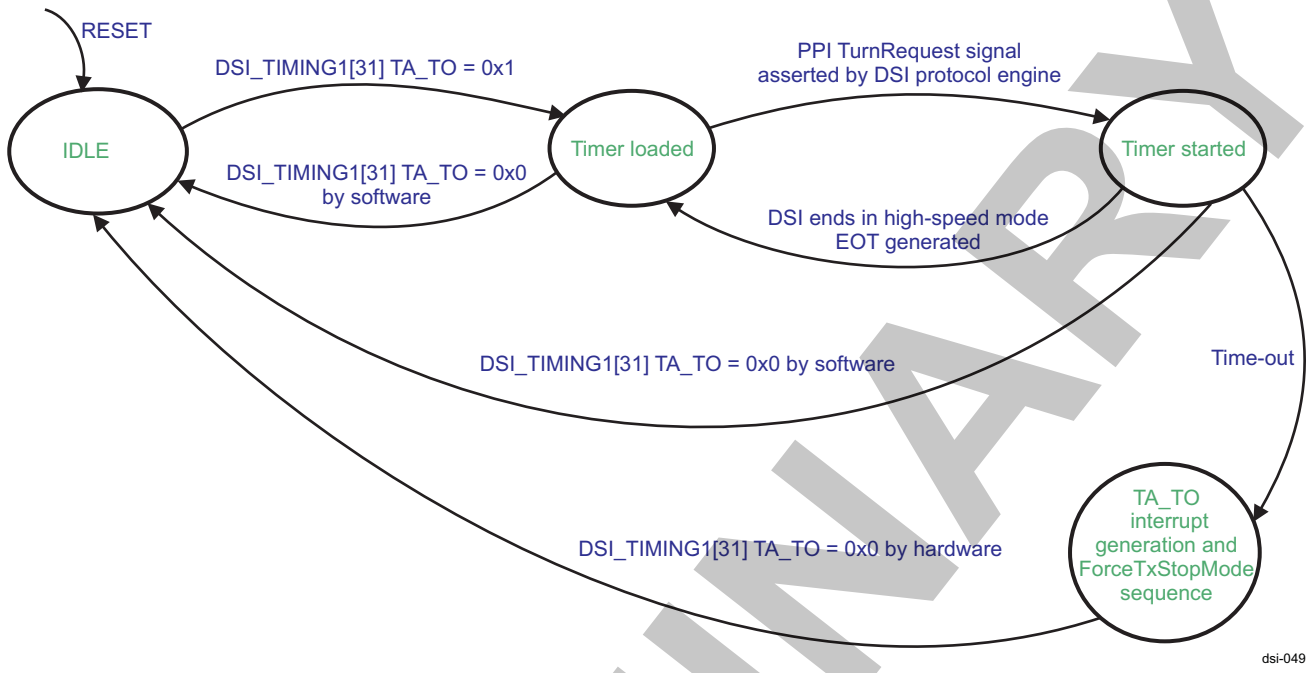
The calculation of the number of DSI_CLK functional clock cycles assertion period is defined by:

Total period in DSI_FCLK cycles = STOP_STATE_COUNTER_IO × ((STOP_STATE_X16_IO x 15) + 1) × ((STOP_STATE_X4_IO × 3))

10.3.4.4.7.3 DSI TurnRequest FSM

The TurnRequest signal is used to request a turnaround. It is valid only for the first data lane, because the other data lanes cannot be used in reverse direction to receive data from the DSI receiver. When the TurnRequest signal is asserted, the TA_TO timer is started. Figure 10-135 shows the TurnRequest FSM to assert and deassert the TurnRequest signal.

Figure 10-135. DSI TurnRequest FSM



The DSI protocol engine asserts the TurnRequest signal during one TxClkEsc cycle when turnaround is enabled through the DSI_VC_CTRL_i[6] BTA_EN bit (for more information, see Section 10.3.4.4.8, *Bus Turnaround*). The DSI_TIMING1[31] TA_TO bit is set/reset by software to enable or disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time-out occurs.

The timer is loaded with the value in the number of DSI_FCLK cycles:

DSI_TIMING1[28:16] TA_TO_COUNTER × ((DSI_TIMING1[30] TA_TO_X16 × 15) + 1) × ((DSI_TIMING1[29] TA_TO_X8 × 7) + 1)

When the TA_TO_IRQ interrupt is generated (the turnaround timer expired and the procedure failed), hardware automatically resets the DSI_TIMING1[31] TA_TO bit and asserts the ForceTXStopMode signal (see Section 10.3.4.4.7.2, *ForceTxStopMode FSM*) for the DSI_PHY_DSS_x to drive the LP-11 STOP state. The ForceTXStopMode timer is used to define the minimum duration of the LP-11 state. The STOP state can be longer if there is no activity.

Hardware resets the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit, followed by an internal logic reset except for all register values and TX FIFO content, and then resets the DSI_CTRL[0] IF_EN bit. Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_CTRL[0] IF_EN bit to be reset to 0 before starting the recovery sequence.

10.3.4.4.7.4 DSI Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Instead, a GP timer must be used in case of reset of the peripheral to determine when the peripheral is ready to operate again.

10.3.4.4.7.5 DSI HS TX Timer

The HS TX timer is used to detect when the host is in TX mode too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of HS transmission occurs. It is enabled and disabled by software through the DSI_TIMING2[31] HS_TX_TO bit. The HS_TX_TO_IRQ interrupt is generated when the timer expires. The DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

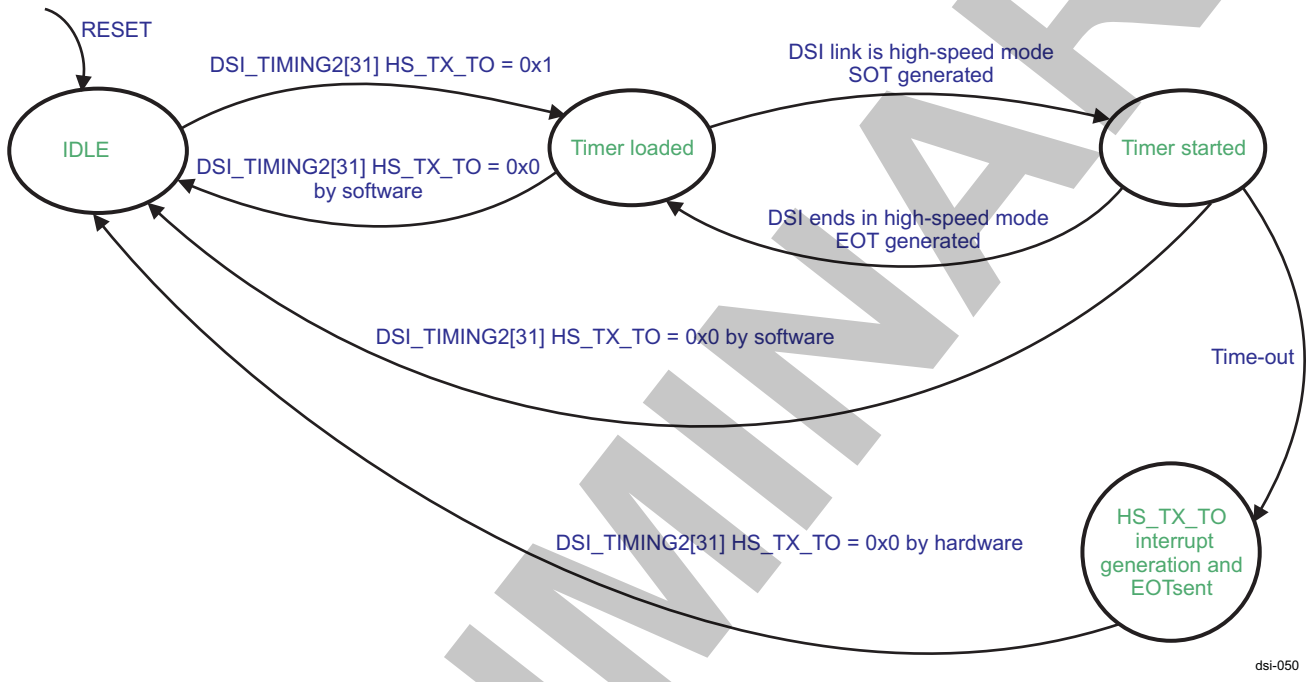
The maximum time supported is 20 ms. It can be used to determine that at least once per frame in video mode, the HS mode is stopped to enter ULPS.

The timer is loaded with the value in the number of TXBYTECLKHS:

DSI_TIMING2[28:16] HS_TX_TO_COUNTER × (1 + (DSI_TIMING2[30] HS_TX_TO_X64 × 63)) × (1 + (DSI_TIMING2[29] HS_TX_TO_X16 × 15))

Figure 10-136 shows the HS TX timer FSM.

Figure 10-136. DSI HS TX Timer FSM



When the time-out occurs, hardware sends an EOT request for the DSI PHY to drive LP-11 STOP state. This is followed by the generation of the interrupt. Hardware performs an internal logic reset including the TX FIFO content but excluding the register values, and then resets the DSI_CTRL[0] IF_EN bit.

Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action.

10.3.4.4.7.6 DSI LP RX Timer

When the host is in low-power receive mode after a BTA, the LP RX timer is loaded. When the timer expires, the host requests the DSI PHY to drive LP-11. The LP_RX_TO_IRQ interrupt is generated when the timer expires. The DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

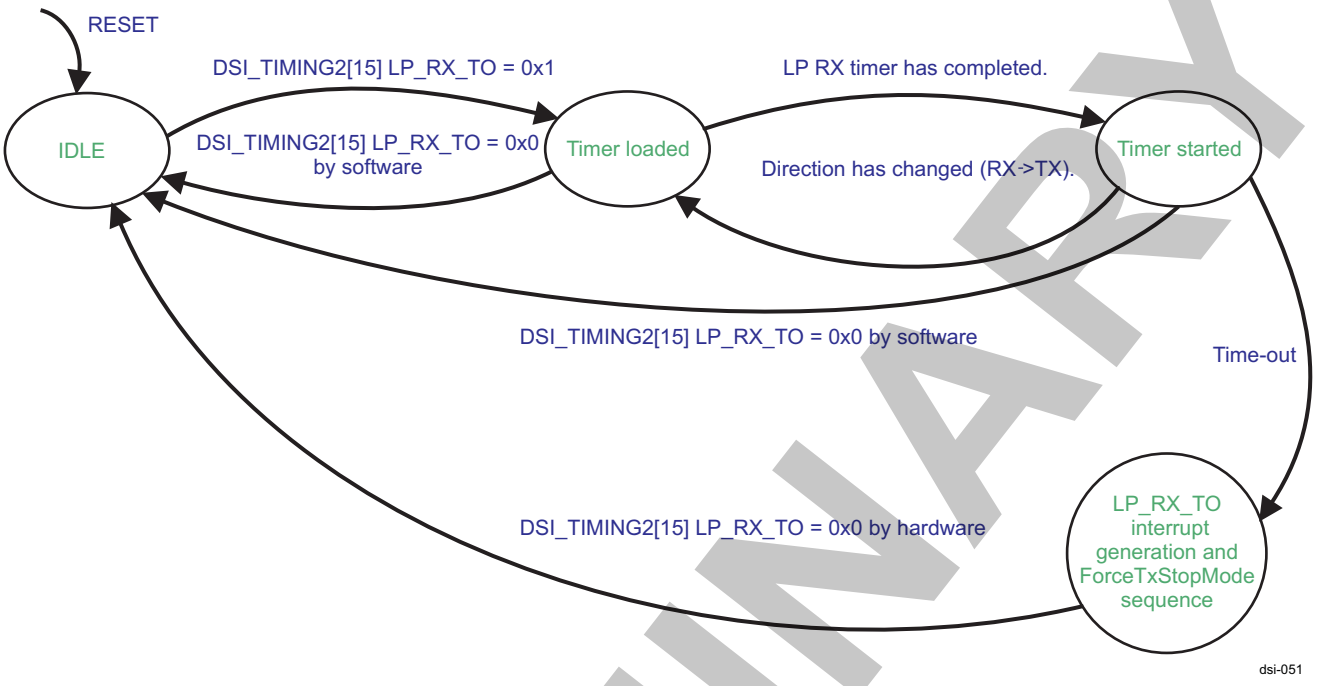
The DSI_TIMING2[15] LP_RX_TO bit is set and reset by software to enable or disable the timer.

The timer is loaded with the value in the number of DSI_CLK functional clock cycles:

DSI_TIMING2[12:0] LP_RX_TO_COUNTER × ((DSI_TIMING2[14] LP_RX_TO_X16 × 15) + 1) × ((DSI_TIMING2[13] LP_RX_TO_X4 × 3) + 1)

Figure 10-137 shows the LP RX timer FSM.

Figure 10-137. DSI LP RX Timer FSM



When the interrupt is generated, hardware automatically resets the DSI_TIMING2[15] LP_RX_TO bit and then asserts ForceTXStopMode for the DSI PHY to drive LP-11 STOP state. The ForceTXStopMode timer is used to define the minimum duration of the LP-11 state. The STOP state can be longer if there is no activity.

Hardware resets the FORCE_TX_STOP_MODE bit, followed by an internal logic reset except for all register values and TX FIFO content, and then resets the DSI_CTRL[0] IF_EN bit. Software must take action to recover (for example, by resetting the peripheral if it is not responding). It must wait for the DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when the DSI_VC_CTRL_i[0] VC_EN is set to 1).

10.3.4.4.8 DSI Bus Turnaround

The BTA is not automatically sent by default after each packet is sent to the panel(s). It is programmable independently for each VC ID. BTA generation can be enabled when the DSI_VC_CTRL_i[6] BTA_EN bit is set to 1 by software. Software must ensure that when the BTA is sent to the peripheral, enough time is allocated for the response and for the BTA from the peripheral to the host. For more information about possible DSI PHY timing adjustments during the turnaround procedure, see Section 10.3.4.6.5.3, *Turnaround Request in Transmit Mode*, and Section 10.3.4.6.5.4, *Turnaround Request in Receive Mode*.

When setting the DSI_VC_CTRL_i[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

Acknowledgment from the peripheral for successful BTA is indicated by asserting the BTA_IRQ interrupt, if it is enabled in the DSI_VC_IRQENABLE_i[5] BTA_IRQ_EN bit. To monitor the BTA interrupt, the user must read the DSI_VC_IRQSTATUS_i[5] BTA_IRQ status bit.

CAUTION

The BTA should be sent when the RX FIFO is empty. Users must empty the RX FIFO before sending the BTA to the peripheral to ensure that when receiving new data from the peripheral, the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packet transmission, if the DSI_VC_CTRL_i[2] BTA_SHORT_EN or DSI_VC_CTRL_i[3] BTA_LONG_EN bit is set to 1.

Two modes can be used for each VC ID:

- Automatic: After each packet, a BTA is sent. To determine the size of the long packet, the protocol engine on the host side reads the word count defined in the header (in the DSI_VC_LONG_PACKET_HEADER_i register) and uses it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. The BTA is then sent to the peripheral. The word count is also used to determine how many bytes are to be transferred from the 32-bit write access to the payload register (DSI_VC_LONG_PACKET_PAYLOAD_i).
- Manual:
  - Data transfer through L3_MAIN interconnect: When transferring data using the L3_MAIN interconnect port, while all data have been provided to the DSI protocol engine, users can select the BTA for the last packet provided to the L3_MAIN interconnect port only by setting the DSI_VC_CTRL_i[6] BTA_EN bit, or for the last packets and the following ones by setting automatic mode.
  - Data transfer through video port: In the case of data transfer using the video port, the DSI_VC_CTRL_i[6] BTA_EN bit can be selected at any time during the transfer of the packet.
- For video mode packets (data and synchronization events), it is not possible to determine when the BTA is sent; therefore, it is highly recommended to use manual BTA mode only in command mode. It is possible, however, to use the BTA for a VC in video mode.

  For data provided on the video port, an interrupt for end of packet transfer PACKET_SENT_IRQ is provided to indicate when the packet is completely sent by the DSI PHY. PACKET_SENT_IRQ can be monitored in the DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ status bit. The BTA is available even if the space allocated in the TX FIFO for the corresponding VC is empty. It must be sent later even if no packet was sent before the BTA request. The DSI_VC_CTRL_i[6] BTA_EN bit must be reset if the BTA request was sent, even if automatic mode for this specific type of packets is enabled.

The BTA is supported for video and command mode packets. It is not possible to send the BTA during the blanking periods of video mode when HS blanking packets should be sent; that is, when one of the following bits is set to 1:

- DSI_CTRL[20] BLANKING_MODE
- DSI_CTRL[21] HFP_BLANKING_MODE
- DSI_CTRL[22] HBP_BLANKING_MODE
- DSI_CTRL[23] HSA_BLANKING_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

When the TurnRequest signal is asserted (always only for the first data lane), the TA_TO timer is started. If the direction signal is not changed according to the turnaround request, the TA_TO interrupt is generated. When the direction signal is in output mode, any data on the input data bus is ignored because the DSI is in transmission mode (data and triggers must be ignored). For more information about the TA_TO timer, see Section 10.3.4.4.7.3, *TurnRequest FSM*.

10.3.4.4.9 DSI PHY Triggers

The DSI protocol engine uses three triggers that are supported only for the first data lane:

- Reset trigger from host to display
- TE trigger from display to host
- Acknowledge trigger from display to host

CAUTION

Each trigger is associated with a dedicated user-configurable receive or transmit pattern, which is loaded in the DSI_PHY_REGISTER3 or DSI_PHY_REGISTER4 register. The default (reset) values of the bit fields are aligned with the *MIPI D-PHY Specification v1.01.00 Revision 0.02*. If any of these values need to be changed, the following must be considered:

- If any of the bit fields is written with a nondefault value, the other bit fields in the same register must also be configured with different values. This ensures that two different trigger bit fields are not programmed with the same pattern.
- If two or more bit fields are written with equal values, unpredictable behavior of the DSI PHY module may occur.

10.3.4.4.9.1 DSI Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY_DSS_x to send a reset to the display. The reset trigger pattern is configurable through the DSI_PHY_REGISTER3[31:24] REG_TXTRIGGERESC3 bit field. To send the reset pattern to the peripheral, the DSI_CTRL[5] TRIGGER_RESET bit must be set to 1. When software requires the trigger reset pattern to be sent, the DSI protocol engine resets its own logic, but not the registers. Software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already considered for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on the DSI link and those already scheduled are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is valid only if a VC is using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on the video port after the current frame are ignored.

To select reset mode, the DSI_CTRL[14] TRIGGER_RESET_MODE bit must be programmed.

NOTE: For both reset modes, the DSI protocol engine flushes the FIFOs, synchronization buffers, and line buffers before resetting the DSI_CTRL[0] IF_EN bit.

10.3.4.4.9.2 DSI Tearing Effect

TE on the display is avoided by having synchronization information from the display. It is used only in command mode and is not functional in video mode.

The two types of TE triggers are:

- DSI PHY TE trigger
- CMOS TE line (one of the two input signals can be selected for the TE trigger of a VC; the signal is asynchronous)

Software must set and send the appropriate sequence to receive the TE trigger pattern from the peripheral on the DSI link, or use the CMOS TE line. The value of the expected TE trigger pattern can be configured through the DSI_PHY_REGISTER4[23:16] REG_RXTRIGGERESC2 bit field.

When the TE PHY trigger pattern is received, the DSI protocol engine generates the TE_TRIGGER_IRQ interrupt with a TE event if the interrupt is enabled. To enable the interrupt, the DSI_IRQENABLE[16] TE_TRIGGER_IRQ_EN bit must be set to 1. The DSI_IRQSTATUS[16] TE_TRIGGER_IRQ status bit indicates whether the interrupt event has been generated.

When using the TE CMOS signal, the DSI protocol engine generates the TE0_LINE or TE1_LINE interrupt, if it is enabled, depending on which line is used. One or multiple VCs can be synchronized using the same TE line. Both lines can be active at the same time for different VCs.

The DSI_VC_TE_i[30] TE_EN bit must be set and the DSI_VC_TE_i[29] TE_LINE bit must be reset to indicate that hardware must use the TE PHY trigger to start the transfer of the data from the related VC. TE_EN is reset when all the data are sent to the peripheral.

The DSI_VC_TE_i[30] TE_EN, DSI_VC_TE_i[29] TE_LINE, and DSI_VC_TE_i[28] TE_LINE_NB bits must be set to select between the TE0 and TE1 line to indicate that hardware must use the TE0 or TE1 line to start the transfer of the data from the related VC. The bits are reset when all the data are sent to the peripheral.

The DSI_TE_VSYNC_WIDTH_j, DSI_TE_HSYNC_WIDTH_j, and DSI_TE_HSYNC_NUMBER_j registers indicate which mode is used to detect the start of the transfer:

- If DSI_TE_HSYNC_NUMBER_j[10:0] LINE_NUMBER = 0, DSI_TE_HSYNC_WIDTH_j is ignored. When a pulse on the TE line is detected to be wider than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field, data transfer starts from the protocol engine to the peripheral at the falling edge of the TE CMOS line.
- If the DSI_TE_HSYNC_NUMBER_j[10:0] LINE_NUMBER bit field is greater than 0, DSI_TE_HSYNC_WIDTH_j is used. The DSI protocol engine waits until it detects a pulse wider than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field, and then counts each pulse wider than DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH, but smaller than DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH. When the number of HSYNC pulses is reached, data transfer from the DSI protocol engine to the peripheral starts. In case the number of HSYNC pulses is not reached due to a new VSYNC pulse being detected, the counter of HSYNC pulses restarts from 0.

NOTE: The DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH is always programmed with a value smaller than the DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH bit field.

NOTE: The following must always be set before the DSI_VC_TE_i[30] TE_EN bit is enabled:

- DSI_TE_HSYNC_WIDTH_j[19:8] MIN_HSYNC_PULSE_WIDTH
- DSI_TE_VSYNC_WIDTH_j[19:8] MIN_VSYNC_PULSE_WIDTH
- DSI_VC_TE_i[29] TE_LINE
- DSI_VC_TE_i[28] TE_LINE_NB

The DSI_VC_TE_i[31] TE_START bit must be used when automatic mode is disabled (the DSI_VC_TE_i[30] TE_EN bit is set to 0). It lets users start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSI_VC_TE_i[23:0] TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include checksum) sent on the DSI link. The register content must not be modified by software during a transfer. The DSI_VC_TE_i[23:0] TE_SIZE bit field must be set first to indicate that the following accesses to the DSI_VC_LONG_PACKET_HEADER_i register must be used for TE transfer.

The data can be provided from two sources (select by setting the DSI_VC_CTRL_i[1] SOURCE bit):

- L3_MAIN interconnect slave port using DMA request: The DMA request DSI_DMA_REQi must be asserted only when the TE trigger is received or when the DSI_VC_TE_i[31] TE_START bit is set by the user and must no longer be asserted when all the bytes defined in the DSI_VC_TE_i[23:0] TE_SIZE bit field are sent on the DSI link. The VC is associated with a DMA request by programming the number in the DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB bit field. The DSI_VC_LONG_PACKET_PAYLOAD_i register is used to provide the number of bytes defined by the DSI_VC_TE_i[23:0] TE_SIZE bit field (the checksum value is not provided in the DSI_VC_LONG_PACKET_PAYLOAD_i register). The size of the header is not considered in the number of bytes to transfer. The DSI_VC_SHORT_PACKET_HEADER_i register is not used.

NOTE: All DMA requests associated to a VC must be disabled when they are not used (DSI_VC_CTRLi[23:21] DMA_TX_REQ_NB = 0x4).

- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. If no line buffer is instantiated (that is, the DSI_CTRL[13:12] LINE_BUFFER bit field is set to 0), it is not possible to use the video port to provide data. The line buffer is filled according to the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register header. The value must be written before the TE trigger event is received or before the DSI_VC_TE_i[31] TE_START bit is set to 1 by software. If the total number of bytes defined by the DSI_VC_TE_i[23:0] TE_SIZE bit field is not a multiple of the word count defined in the DSI_VC_LONG_PACKET_HEADER_i register, all the packets are the same size defined by the WC of the header, except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Because the DSI_VC_TE_i[23:0] TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of the DSI_VC_TE_i[23:0] TE_SIZE bit field before the last transfer (the header and the payload checksum sizes are not included in the DSI_VC_TE_i[23:0] TE_SIZE bit field).

When the transfer completes, the value of the DSI_VC_TE_i[23:0] TE_SIZE bit field is equal to 0. Software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to the TE transfer. Any data in the TX FIFO that must be sent before the reception of the TE trigger must be sent before the TE. This is done by not enabling the TE trigger until all data for the corresponding VC are sent to the peripheral. Software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSI_VC_CTRL_i[5] TX_FIFO_NOT_EMPTY status bit.

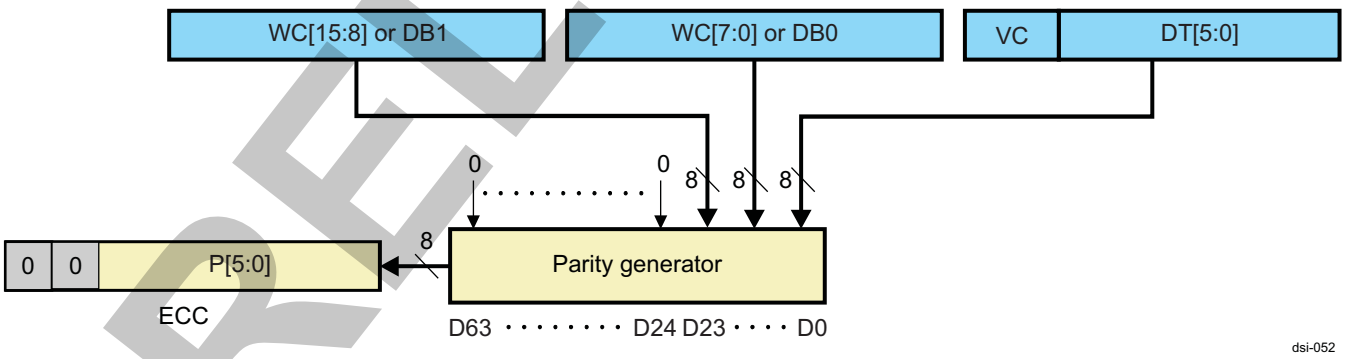
10.3.4.4.9.3 DSI Acknowledge

The corresponding acknowledge interrupt (ACK_TRIGGER_IRQ) is generated when the acknowledge trigger is received. The value of the expected acknowledge trigger pattern can be configured through the DSI_PHY_REGISTER4[15:8] REG_RXTRIGGERESC1 bit field. To enable the acknowledge interrupt, set the DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

10.3.4.4.10 DSI ECC Generation

The DSI protocol uses a 4-byte PH. Because ECC generation requires a fixed word length of 64-bits, the packet headers must be padded with additional bits to form a full 8-byte value for ECC generation and checking. The PH minus the ECC byte should occupy bits D[23:0], and the pad bits should occupy bits D[63:24]. All padding bits must be 0 to generate the ECC byte. ECC can be generated using a parallel approach, as shown in Figure 10-138.

Figure 10-138. DSI 64-Bit ECC Generation on TX Side



The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSI_CTRL[2] ECC_RX_EN bit enables and disables ECC generation in the receive direction.
- The DSI_VC_CTRL_i[8] ECC_TX_EN bit enables and disables ECC generation in the transmit direction

The ECC can be provided while writing the ECC value directly into the DSI_VC_LONG_PACKET_HEADER_i and DSI_VC_SHORT_PACKET_HEADER_i registers. The DSI_VC_CTRL_i[8] ECC_TX_EN bit indicates whether the ECC value will be calculated or whether the value written in the register will be used instead for command and video modes.

10.3.4.4.11 DSI Checksum Generation for Long Packet Payloads

Long packets consist of a PH protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. For the special case of a 0-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can indicate only the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations, because the peripheral has no way to report errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals; it is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation must transmit 2 bytes with a value of 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor must disable checksum checking for received long packets from peripherals that do not support checksum generation.

Checksum must be realized as a 16-bit CRC with a generator polynomial of $x^{16} + x^{12} + x^5 + x^0$. The LSByte is sent first, followed by the MSByte. Within the byte, the LSB is sent first.

Figure 10-139 shows the checksum transmission.

Figure 10-139. DSI Checksum Transmission

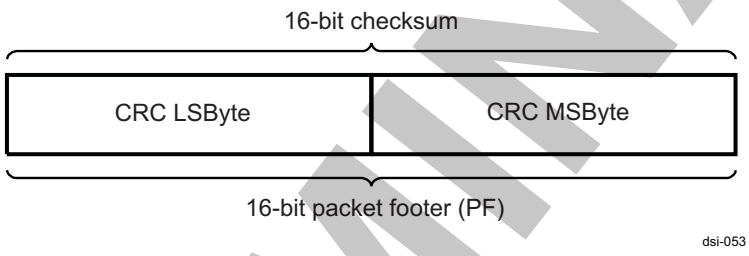


Figure 10-140 shows the CRC implementation. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the PH then enters as a bitwise data stream from the left, LSB first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the MSB of the checksum, and C0 contains the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

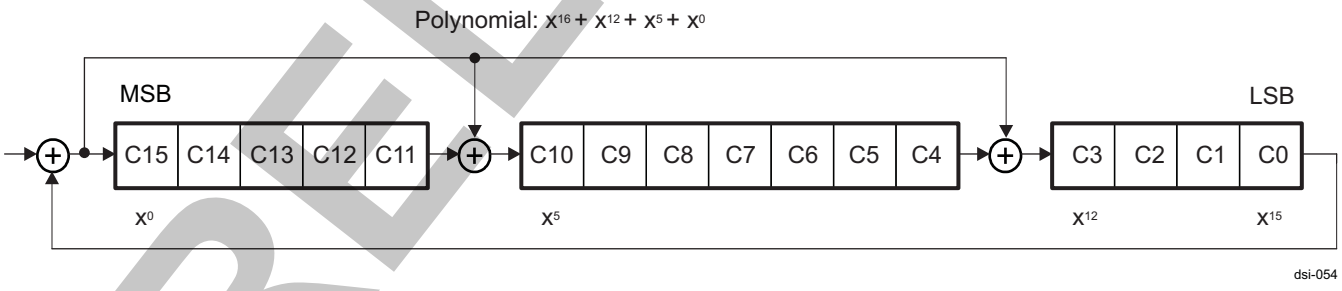
Figure 10-140. DSI 16-Bit CRC Generation Using a Shift Register



Checksum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSI_CTRL[1] CS_RX_EN bit enables and disables checksum generation in the receive direction.
- The DSI_VC_CTRL_i[7] CS_TX_EN bit enables and disables checksum generation in the transmit direction.

10.3.4.4.12 DSI EOT Packet

A new packet type allows the DSI protocol (rather than the DSI_PHY_DSS_x) at the display to detect the HS EOT. This is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the DSI_CTRL[19] EOT_ENABLE bit.

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more that one data lane is used, the EOT packet bytes are distributed across the multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through as any other packet, but no internal decode or use is made of the EOT information.

10.3.4.4.13 DSI Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSI_SYSCONFIG[1] SOFT_RESET bit to 1. Software can monitor the DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the reset to complete. If after five reads the DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional because a hardware reset is always performed on the DSI protocol engine at device reset.

10.3.4.4.14 DSI Power Management

The power-management behavior of the DSI protocol engine is controlled by the DSI_SYSCONFIG register. This register controls the way the module interacts with the PRCM module. The DSI_SYSCONFIG[0] AUTO_IDLE bit must be set to 1 (default value) to enable automatic clock gating in the module.

The DSI protocol engine implements a handshake protocol on the L3_MAIN interconnect slave port with the PRCM module. The protocol engine provides control signal CIO_CLK_ICG to gate the SCPClk (DSS_L3_MAIN_ICLK/4). It allows the reduction of power consumption of the DSI PHY when the DSI link is not in use (the DSI_CLK_CTRL[14] CIO_CLK_ICG bit).

10.3.4.4.15 DSI Power Control of DSI PHY and DSI PLL

The DSI protocol engine can control and send power commands for the DSI PHY and DSI PLL controller modules.

10.3.4.4.15.1 DSI PHY Control Commands

10.3.4.4.15.1.1 DSI PHY Control Commands

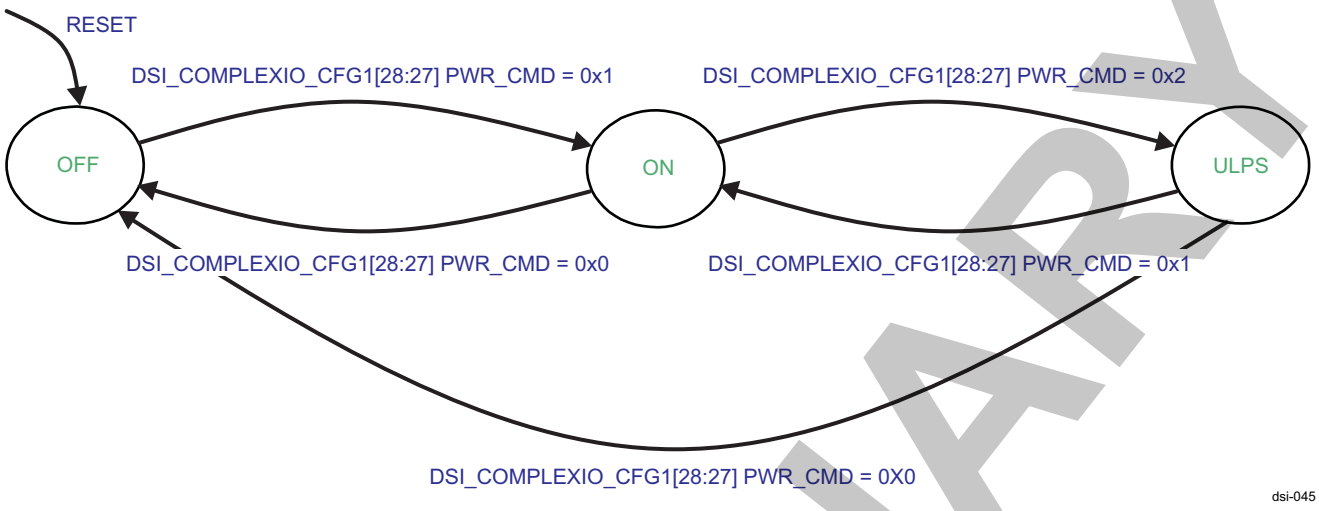
The DSI PHY can be set in three modes:

- OFF: In this power state, the complete DSI_PHY_DSS_x circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY_DSS_x circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes that are in receive ULPS. For the lanes that are in transmit ULPS, the circuitry for weak pulldown is ON. ULPS must be used only when all three lanes are in ULPS (transmit or receive).

10.3.4.4.15.1.2 DSI PHY Power FSM

Figure 10-141 shows the FSM to control the power state of the DSI PHY

Figure 10-141. DSI PHY Power FSM



The following commands control the state transition of the DSI PHY:

- PwrCmdOff
- PwrCmdUlp
- PwrCmdOn

The DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field allows the state to be modified. The allowed transitions are: OFF–ON, ON–ULPS, and ULPS–OFF. The DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the DSI PHY.

CAUTION

- In automatic mode, software must ensure that the DSI PHY is in ON state (that is, ON command already sent) before sending requests to the DSI PHY.
- In a command request to change to a state that is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PHY).
- To change the state to ULPS, all ULPSActiveNot signals must be low. The ULPSActiveNot_ALL0_IRQ interrupt indicates the state of the ULPSActiveNot signals. The change from ULPS to ON state is required before starting the ULP exit sequence (for more information, see Section 10.3.4.4.7.1, *T_{wakeup} Timer*).

10.3.4.4.15.2 DSI PLL Power Control Commands

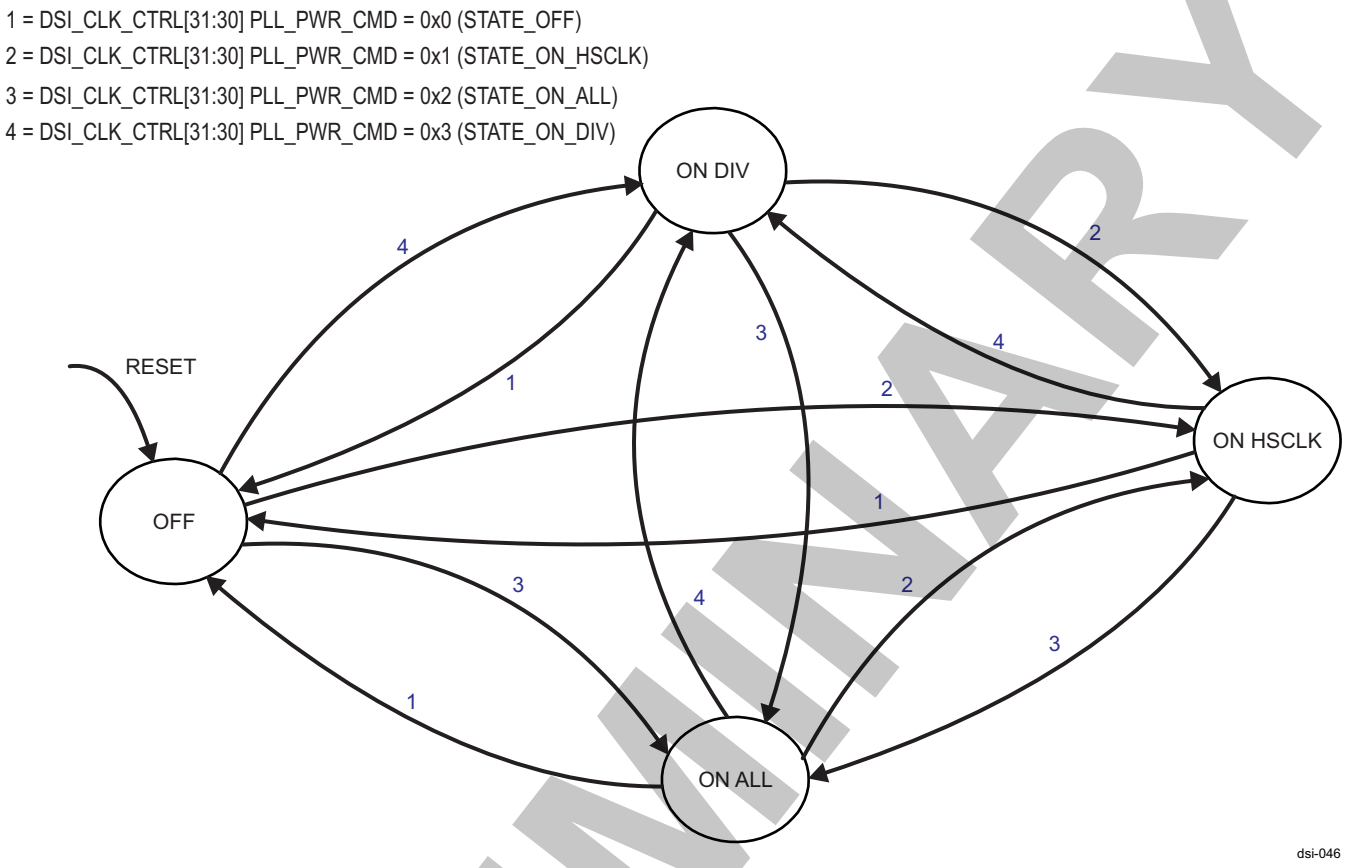
The DSI PLL controller module can be set in four modes:

- OFF: DSI PLL and HSDIVIDER are OFF.
- ON ALL: DSI PLL and HSDIVIDER are ON. The CLKIN2DDR clock is provided to the DSI PHY, and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The CLKIN2DDR clock is provided to the DSI PHY, but the second clock output is not provided to the HSDIVIDER.
- ON DIV: DSI PLL and HSDIVIDER are ON. The CLKIN2DDR clock is not provided to the DSI PHY, but the second clock output is provided to the HSDIVIDER.

10.3.4.4.15.2.1 DSI PLL Power FSM

Figure 10-142 shows the power state of the DSI PLL.

Figure 10-142. DSI PLL Power FSM



The following commands control the state transition of the DSI PLL control module:

- PLLPwrCmdOff
- PLLPwrCmdOnAll
- PLLPwrCmdOnDIV
- PLLPwrCmdOnHSClk

Setting the DSI_CLK_CTRL[31:30] PLL_PWR_CMD bit field modifies the state. The DSI_CLK_CTRL[29:28] PLL_PWR_STATUS bit field gives a status on the current state of the DSI PLL controller.

NOTE: If a command requests to change to a state that is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL control module).

10.3.4.4.15.2.1.1 DSI PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI protocol engine does not need to use HS mode and the PLL HS output (CLKIN2DDR clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the DISPC, because that must result in the PLL HS output being stopped.

When the interface is disabled (the DSI_CTRL[0] IF_EN bit set to 0) and the clock lane is stopped (DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON = 0), the DSIStopClk signal is asserted.

Assertion of DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is no longer required). For deassertion of TxRequestHS, the following conditions are required:

- The DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer must be ongoing or already scheduled.
- No VC ACTIVE in video mode. No VC using the video mode is enabled. If the VC is enabled, the mode is command mode only (the DSI_VC_CTRL_i[0] VC_EN bit set to 1 and the DSI_VC_CTRL_i[4] MODE bit set to 0).
- No command mode requiring HS transfer (one or more VCs using command mode can be active)
- Or the DSI_CTRL[0] IF_EN bit is reset to 0 (the previous conditions are not all required, except the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be set to 0 after resetting the DSI_CTRL[0] IF_EN bit)

Deassertion of DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required).
- One video mode VC ACTIVE
- At least one VC in command mode requiring HS transfer
- The DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSI_CTRL[0] IF_EN bit must be reset to 0 for updating the value of the DDR_CLK_ALWAYS_ON bit).

Automatic assertion/deassertion is enabled by using the DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

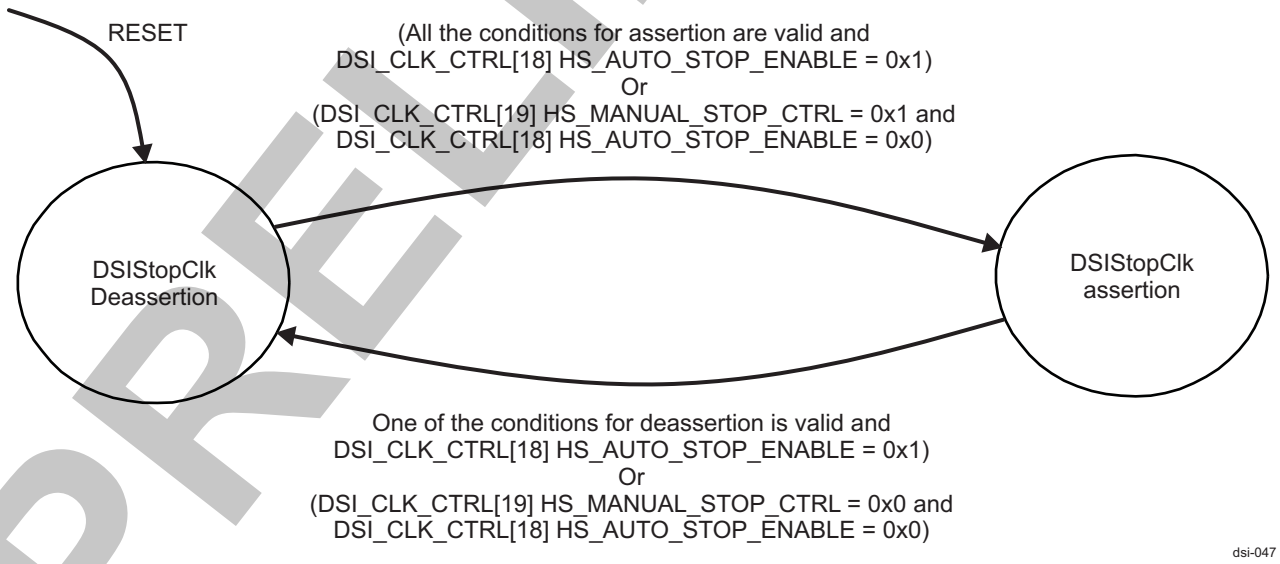
Manual mode can be used by setting and resetting the DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert or deassert the DSIStopClk signal.

NOTE: Setting the DSI_CTRL[24] DISPC_UPDATE _SYNC bit to 0x1 enables the use of the Dispc_Update_Sync signal to synchronize.

10.3.4.4.15.2.1.2 DSI PLL HS Clock FSM

Figure 10-143 shows the DSI PLL HS clock FSM.

Figure 10-143. DSI PLL HS Clock FSM



When DSIStopClk is used, there is a latency through other modules (DSI PLL controller and DSI_PHY_DSS_x) before TXBYTECLKHS is stopped. This latency must be considered to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field. This timer is programmed in a number of periods of the DSI protocol functional clock (DSI_CLK). At the reset value, the timer is programmed with the value 0x80 (128).

CAUTION

The programmed value in the DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field must be greater than ((3 × L3_MAIN_ICLK period) + (5 × CLKIN2DDR period)) / (DSI_CLK period).

10.3.4.4.16 DSI ULPS Configuration

This section describes how to enter and exit ULPS.

NOTE: The DSI_COMPLEXIO_CFG2[9:0] LANEx_ULPS_SIGy bit field (***where x*** = 1 to 5, corresponding to the five lanes of DSI1_A, and DSI1_C; ***and where y*** = 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This considers low TxClkEsc frequencies.

10.3.4.4.16.1 DSI Entering ULPS

To enter ULPS for a clock lane, the following sequence is required:

1. Wait for the DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and ensure that the DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is 0.
2. The state of TxUlpsClk changes from INACTIVE to ACTIVE by setting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait until all TX_FIFOs for all VCs working in HS are empty, video mode is not active, and the DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition for the first data lane, the DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0).
2. The state of TxRequestEsc changes from INACTIVE to ACTIVE by setting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 1.

10.3.4.4.16.2 DSI Exiting ULPS

To exit ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is done by monitoring the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the state of the TxUlpsClk signals to INACTIVE for the clock lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
6. Reset the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit to 0.

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a clock lane, in case the DSI PHY is in OFF state (the DSI protocol engine sends the DSI PHY to OFF state [PWROFF command] by setting DSI_COMPLEXIO_CFG1[28:27] PWR_CMD = 0x0), the sequence is:

1. Change the state of the TxUlpsClk signals to INACTIVE for the clock lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.

2. Change the state of TxUlpsExit for clock lane to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0. This step is necessary only when a PWROFF command (the command for power control of the DSI PHY) is issued while the sequence for exiting is in progress (the TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2[9:5] and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit ACTIVE have acknowledged by asserting UlpsActiveNot. This is done by monitoring the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the state of the TxRequestEsc signals to INACTIVE for the data lane by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
6. Reset the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0.

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bit fields must be read back to confirm they are effective before proceeding.

To exit ULPS for a data lane, in case the DSI PHY is in OFF state (the DSI protocol engine sends the DSI PHY into OFF state by setting DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field to 0x0), the sequence is:

1. Change the state of the TxRequestEsc signals to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 bit field to 0.
2. Change the state of TxUlpsExit to INACTIVE by resetting the DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit field to 0. This step is necessary only when a PWROFF command is issued while the sequence for exiting is in progress (the TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSI_COMPLEXIO_CFG2[9:5] LANEx_ULPS_SIG2 and DSI_COMPLEXIO_CFG2[4:0] LANEx_ULPS_SIG1 bit fields are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering or exiting ULPS is started for specific lanes, users must wait for the completion of the sequence before changing the state of the same or other lanes.

10.3.4.4.17 DSI Interrupts

A single interrupt request (IRQ) is generated by each DSI: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ into a single IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSI_IRQENABLE: This register enables and disables interrupt event reporting for the VCs. Each event for the VC is configured in the DSI_VC_IRQENABLE_i register dedicated to the VC number. In addition, it includes 1 bit to enable error reporting for the DSI PHY. The interrupt is triggered when any error is received from the DSI PHY.
- DSI_IRQSTATUS: The register flags which VC(s) have generated an interrupt. Based on the VC number, the DSI_VC_IRQSTATUS_i register indicates the event generating the interrupt. In addition, it

includes 1 bit for the status of error reporting for the DSI PHY.

Table 10-538 lists the DSI VC interrupt events

Table 10-538. DSI VC Interrupts

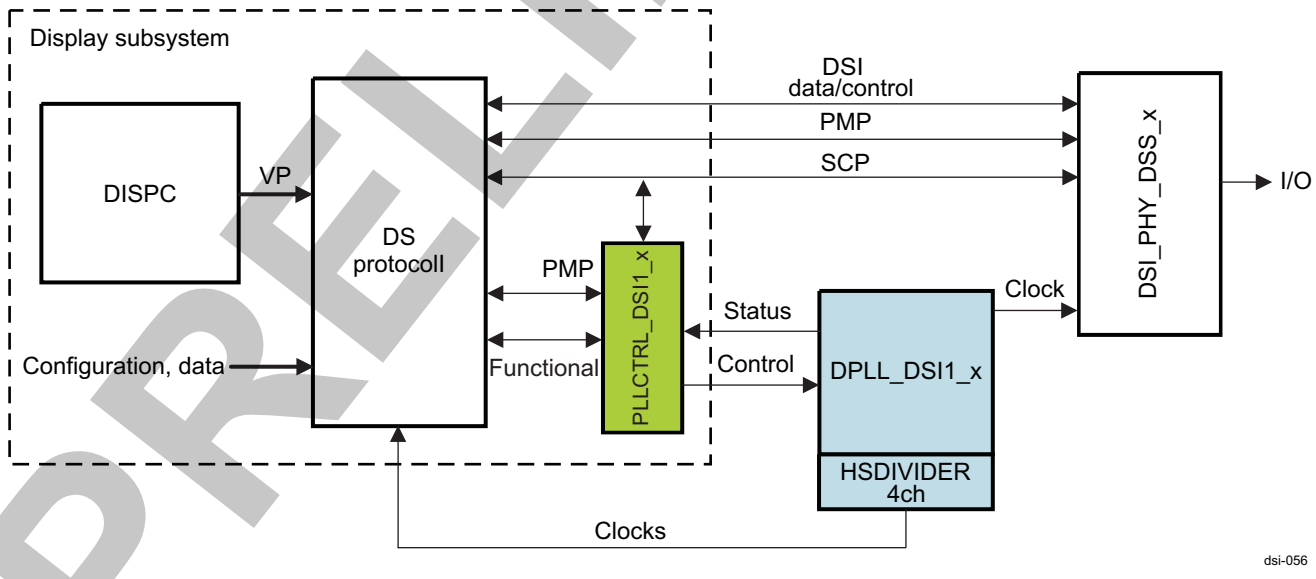
IRQ Name	Description
ECC_CORRECTION_IRQ	Indicates whether a 1-bit error correction has occurred using ECC (short and long packets)
PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used.
CS_IRQ	Virtual channel. Checksum of the payload mismatch detection.
FIFO_RX_OVF_IRQ	RX FIFO overflow. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the DSI link has overflowed.
FIFO_TX_OVF_IRQ	TX FIFO overflow. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the interface slave port has overflowed.
BTA_IRQ	BTA is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral will be used to determine which VC will be used to flag the interrupt).
ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error.
FIFO_TX_UDF_IRQ	TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L3_MAIN interconnect slave port has underflowed in the middle of a packet transfer.

10.3.4.5 DSI PLL Controllers

10.3.4.5.1 DSI PLL Controllers Overview

Two DSI PLL controller modules are part of the display subsystem. They use the SCP (see Section 10.3.4.4.6, *Serial Configuration Port Interface*) and power-management port (PMP) as the primary interfaces to the DSI protocol engines. The SCP interface sets the configuration of the digital phase-locked loop (DPLL) and HSDIVIDER modules, primarily the various counter values. The PMP controls the power state of the DPLL and HSDIVIDER modules. Figure 10-144 is an overview of a single DSI PLL controller module in the display subsystem.

Figure 10-144. DSI PLL Controller Overview



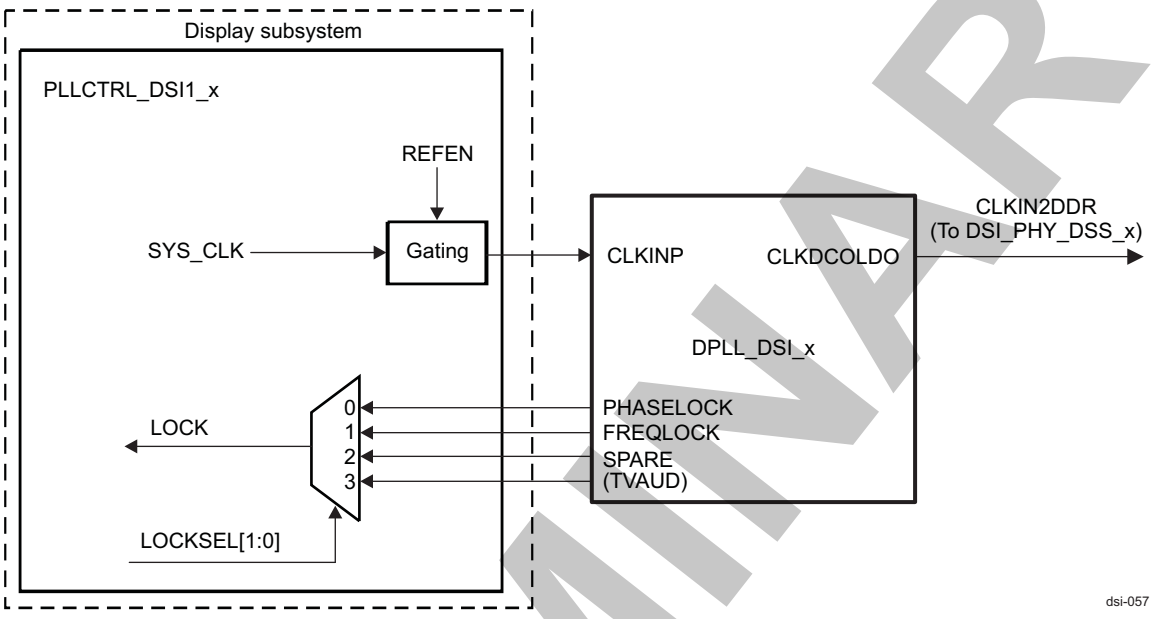
NOTE: The DSI PLL controller modules do not have an interface to L3_MAIN interconnect. The programmable features are managed by registers mapped into the DSI protocol engines.

10.3.4.5.2 DSI PLL Controllers Architecture

The DSI PLLs use type-A instances of the DPLL modules. For information regarding DPLL types, see , *Generic DPLL Overview*, in Chapter 3, PRCM. The pixel clock (PCLK) frequency range is up to 103 MHz.

Figure 10-145 shows the internal reference diagram of a single DSI PLL.

Figure 10-145. DSI PLL Reference Diagram

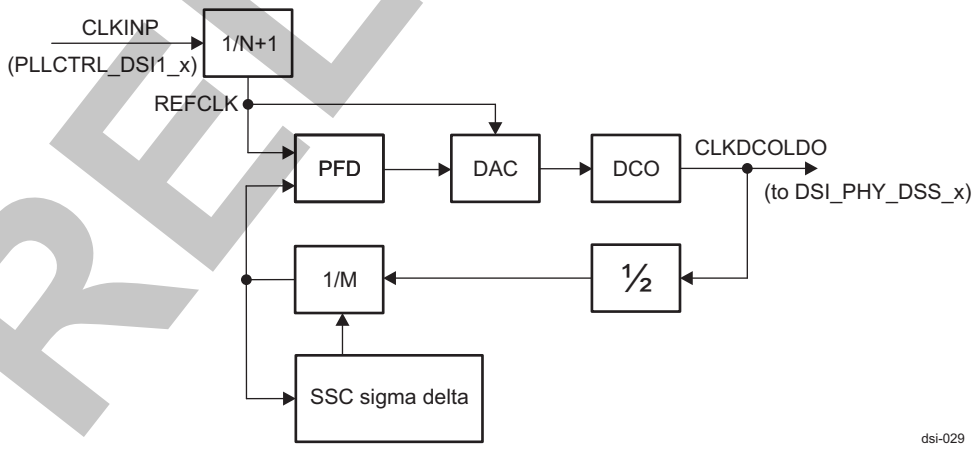


The DSI PLL clock output (CLKDCOLDO) corresponds to the CLKIN2DDR clock of a DSI PHY (DSI_PHY_DSS_x) module.

Only the SYS_CLK clock is used as an input reference clock for the DPLL. The DSI PLL controller can gate this clock by setting the DSI_PLL_CONFIGURATION2[13] PLL_REFEN bit.

Figure 10-146 is a simplified block diagram of the ADPLLM instance used for the DSI modules.

Figure 10-146. DSI DPLL Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field. The frequency range for the CLKINP and REFCLK clocks is as below:

Table 10-539. DSI PLL CLKINP and REFCLK frequency range

Clock	Type	Min Frequency	Max Frequency
CLKINP	Input	0.032MHz	52MHz
REFCLK when DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	Input	0.15MHz	52MHz
REFCLK when DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	Input	0.032MHz	1MHz

The output clock CLKDCOLDO is synthesized by a digitally controlled oscillator (the DCO block) that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP * 2 * M / (N + 1). For that purpose the feedback multiplier M must be configured through the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL module also supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm), that is, [{10*$\log_{10}$(df/fm)} – 10] dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df) (that is, dM / M = df / Fout).

Since this is in band modulation for the DSI PLL, the modulation frequency (fm) is required to be within the bandwidth of the PLL loop (lowest BW of REFCLK/70; that is, REFCLK must be > fm*70). A higher modulation frequency results in less spreading in the output clock.

The SSC can be enabled and disabled by asserting the DSI_PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the DSI_PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value of ModFreqDivider programmed in the DSI_PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK / (4 * fm). The ModFreqDivider is split into Mantissa and $2^{Exponent}$(ModFreqDivider = ModFreqDividerMantissa *$2^{ModFreqDividerExponent}$).

- The Mantissa is controlled by bits [29:23] of the MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), M must be controlled as previously explained. To define M, the step size of M for each REFCLK during the triangular pattern bust be programmed (that is, M = ModFreqDivider * DeltaMStep). DeltaMStep is controlled by the DSI_PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field and the PLL_SSC_CONFIGURATION2[30] DELTAM2 bit. DeltaMStep is split into an integer part and a fractional part:

- The integer part is controlled by bits [19:18] of the DELTAM bit field.
- The fractional part is controlled by bits [17:0] of the DELTAM bit field.

The frequency spread achieved, however, has an overshoot of 20% or an inaccuracy of +20%.

If the DSI_PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for the overshoot, as previously described).

NOTE: There is a restriction in the range of M values. The restriction is that (M – dM) must be >= 20.Also, M + dM should be <= 2045. If the DSI_PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, then (M – 2*dM) should be >= 20 and M <= 2045.

10.3.4.5.3 DSI PLL Operations

The DSI PLL configuration signals operate according to Table 10-540, which indicates the operation when the PLLs are not locked.

Table 10-540. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop Mode Low Power[1]	Stop Mode Fast Relock[1]	Idle Bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
DSI_PLL_CONFIGURATION2[0] PLL_IDLE	0	0	1
DSI_PLL_CONFIGURATION2[6] PLL_LOWCURRSTBY	1	0	1

(1) This mode must be used for better performance.

When locked, the PLL output frequency is: Input frequency × 2 × M / (N + 1), where:

- M multiplier is programmed in the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- N divider is programmed in the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

NOTE: When the PLL_REGM bit-field is set to 1, the PLL enters a MN-Bypass mode. This is a low power mode, where the PLL gates its internal clocks and powers down the analog blocks. The CLKDCOLDO clock output goes low and remains like that, until the PLL comes out of the MN-Bypass mode (by changing the PLL_REGM bit-field to a value other than 0 or 1).

10.3.4.5.4 DSI PLL Controllers Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register spaces using the SCP interface. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations can optionally be updated in synchronization with the DISPC and DSI protocol engines. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must be written before this signal is asserted. For more information, see Section 10.3.4.4.6.1, *Shadowing Register*.

10.3.4.5.5 DSI PLL Error Handling

The PLL lock and recalibration signals can be monitored to detect the loss of lock or the requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DSI_PLL_STATUS[1] PLL_LOCK status bit gives the DSI PLL lock state.
- The DSI_PLL_STATUS[2] PLL_RECAL status bit informs whether the PLL must be uncalibrated.

These signals can also generate interrupts at the DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.

- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored:

- The DSI_PLL_STATUS[3] PLL_LOSSREF status bit informs whether the DSI PLL has lost the reference.

10.3.4.5.6 DSI PLL Software Reset

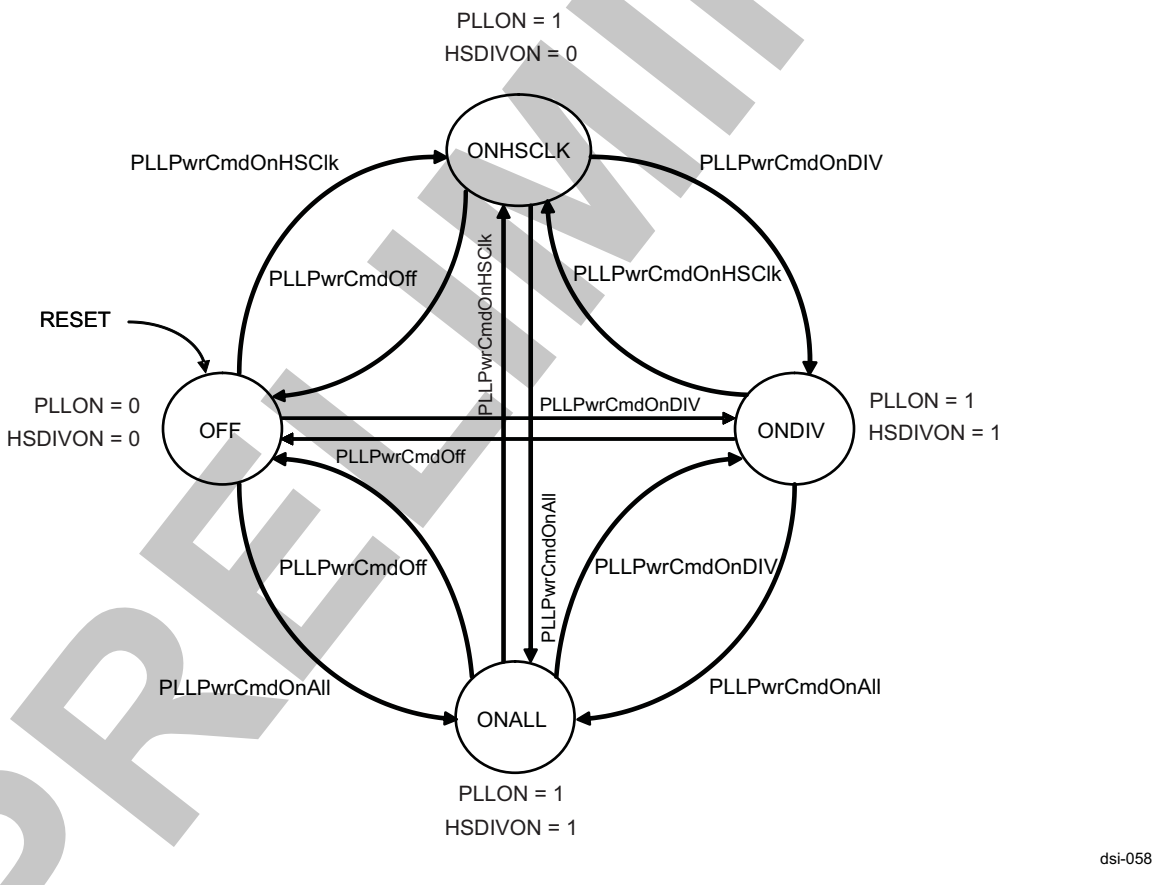
The DSI PLL control modules do not have their own software reset. They are reset by the global DSS_RST signal at PRCM module level. See Display Subsystem Resets, in *Display Subsystem*. Nevertheless, software users can monitor the reset statuses of the DSI PLL control modules by reading the DSI_PLL_STATUS[0] PLLCTRL_RESET_DONE status bits.

10.3.4.5.7 DSI PLL Power Management

PLLCTRL manages only the LDO power of the DPLL and HSDIVIDER; this is done by overriding the SYSRESET signals. All other power-management signals are integrated with the display subsystem power management.

Figure 10-147 shows the power states that are controlled through the PMP.

Figure 10-147. DSI PLL Power State Diagram



10.3.4.5.8 DSI PLL HSDIVIDER Loading Operation

In manual mode (PLL_CONTROL[0] PLL_AUTOMODE = 0), it is possible to update the configuration values of HSDIVIDER without starting the DPLL locking sequence. Once all the configuration values have been programmed into the registers, the PLL_GO[1] HSDIVLOAD bit must be set. The TENABLEDIV output is driven high for six SCP clock periods while the TINITZ and TENABLE signals remain unchanged. The HSDIVLOAD bit is cleared at the end of the sequence.

The TENABLEDIV signal is shared with the DPLL and HSDIVIDER so the DPLL M2 divider is loaded at the same time. The SCPBUSY signal is high during the sequence until the HSDIVLOAD bit is cleared, thus indicating that there is pending activity in the SCPClk domain. SCPClk must be kept running while this signal is asserted.

The HSDIVIDER sequence and the GO sequence (Section 10.3.4.5.11, *DSI PLL Go Sequence*) cannot be performed at the same time. If one of the two sequences is running and the trigger bit of the other sequence is set, PLLCTRL finishes the first sequence and then immediately starts the other sequence.

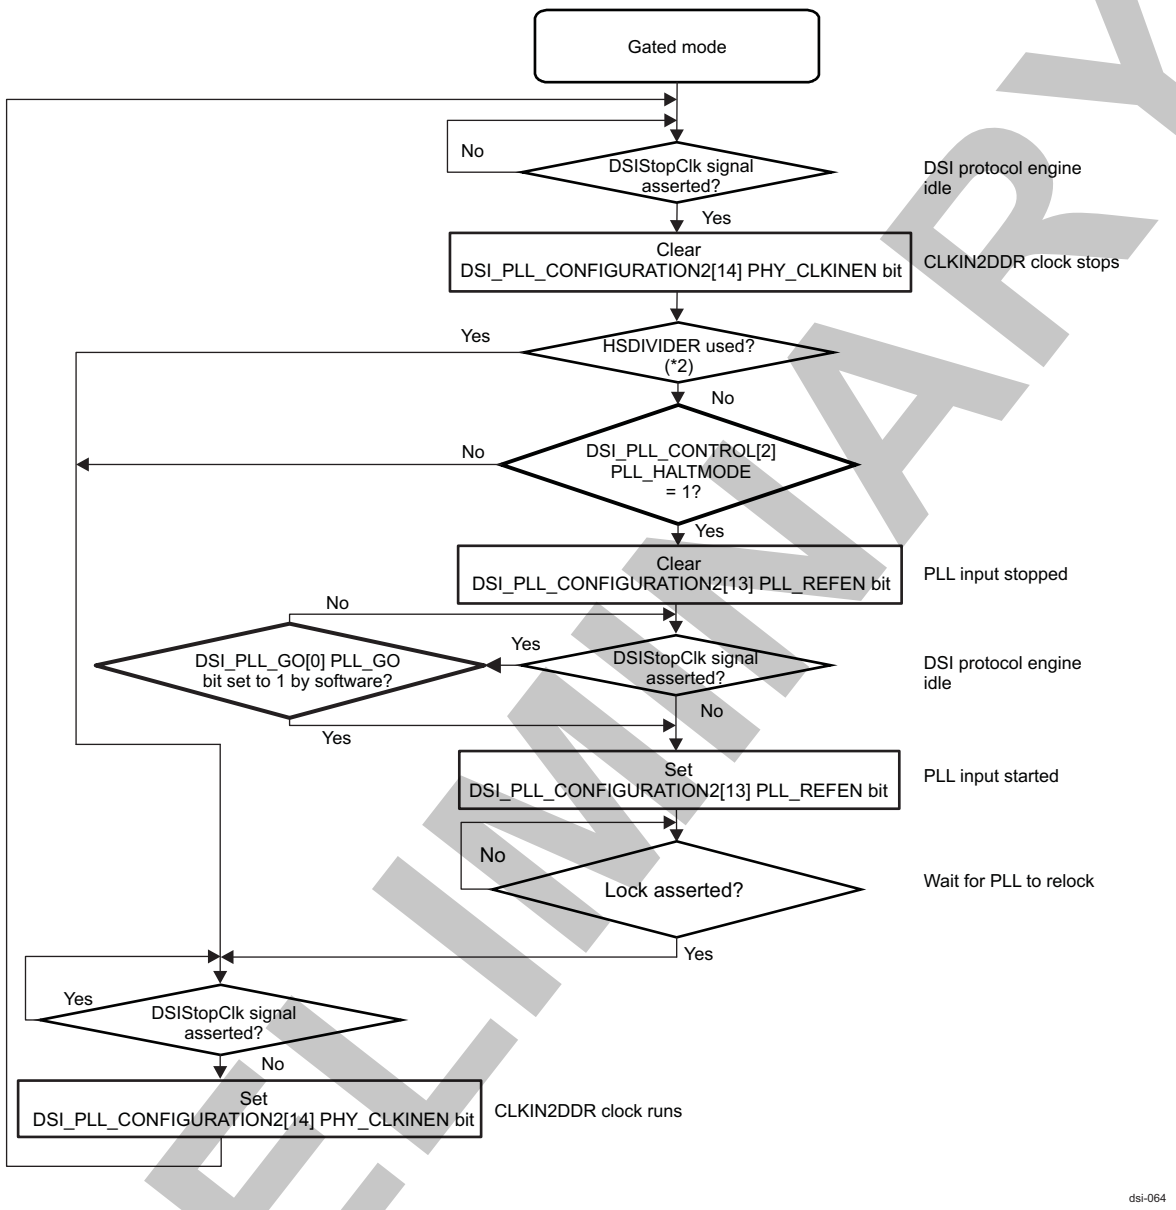
10.3.4.5.9 DSI PLL Clock-Gating Sequence

Clock gating can be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engines must verify when the PLLs have restarted by inspecting the LOCK signal (the DSI_PLL_STATUS[1] PLL_LOCK status bit), because the TXBYTECLKHS clocks are stopped when the CLKIN2DDR clocks generated by the DSI PLL are stopped. This eliminates the need for any explicit feedback that the clock has restarted. This flow chart shown in Figure 10-148 should run even if the DSI_PLL_GO[0] PLL_GO bit is not set.

Figure 10-148 shows the DSI PLL gated mode sequence.

Figure 10-148. DSI PLL Gated Mode Sequence



(1) All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

(2) HSDIVIDER is used if one of the following bits is set to 1:

- DSS_CTRL[12] LCD2_CLK_SWITCH
- DSS_CTRL[0] LCD1_CLK_SWITCH
- DSS_CTRL[18] DSI1_C_CLK_SWITCH
- DSS_CTRL[1] DSI1_A_CLK_SWITCH

(3) For more information, see Display Subsystem Overview, in *Display Subsystem*.

Table 10-541. DSI PLL Register Call Summary for Gated Mode Sequence

Register Name	Register Name	Register Name
DSI_PLL_CONFIGURATION2	DSI_PLL_CONTROL	DSI_PLL_GO

10.3.4.5.10 DSI PLL Clock Sequence

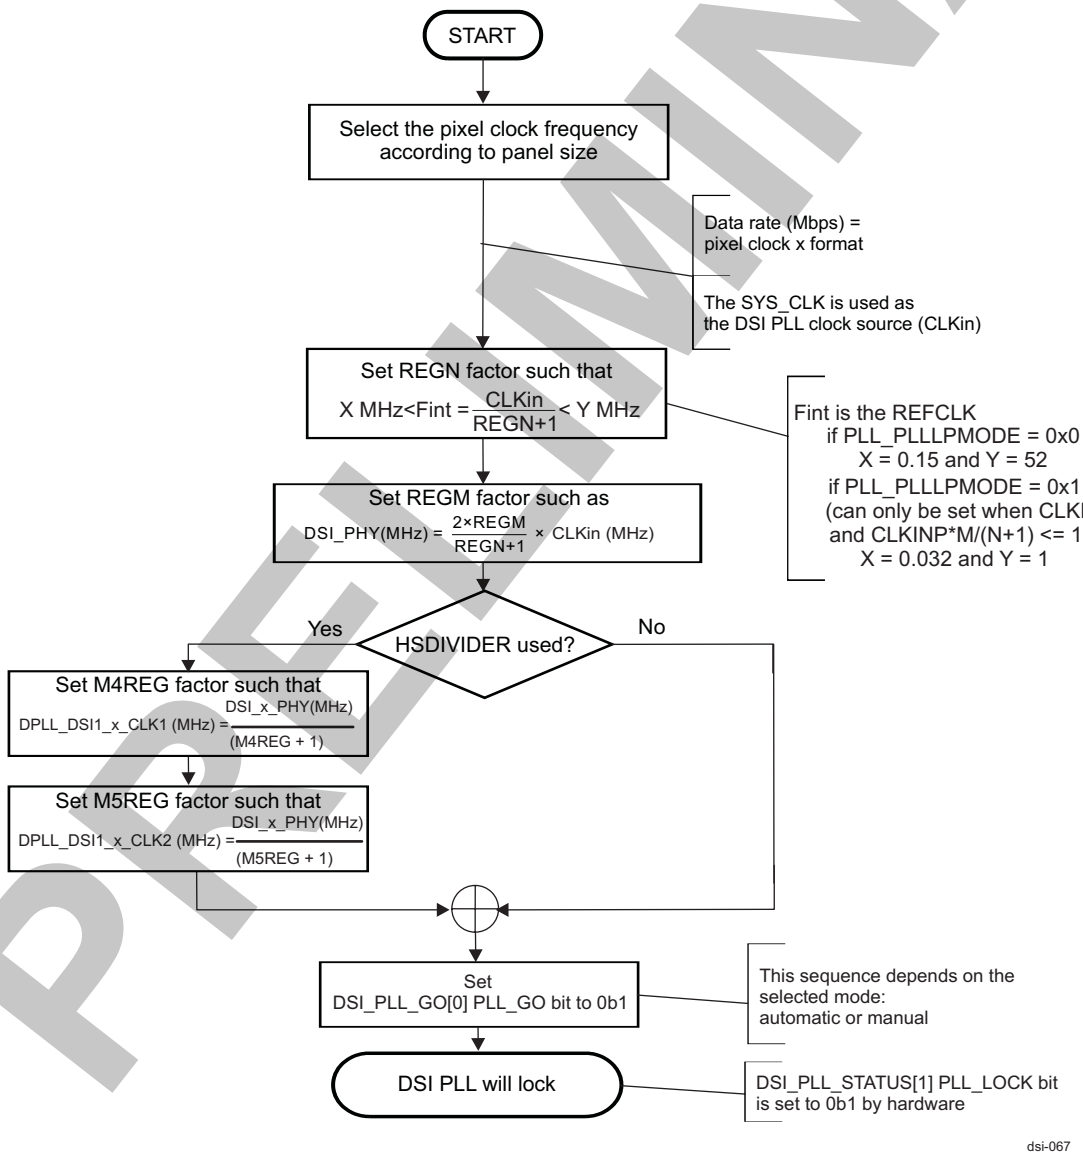
The two DSI PLLs generate the CLKIN2DDR clocks. Each HSDIVIDER outputs two clocks: DPLL_DSI1_x_CLK1, connected to the DISPC, and DPLL_DSI1_x_CLK2, connected to the DSI protocol engine (where x is the dedicated DSI PLLs [A or C]). If these two clocks are not used, the HSDIVIDER functions are not required.

The CLKIN2DDR clocks are twice the DSI output clock frequency, which is equal to the data rate. The DSI PLL factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by the DSI_PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- REGN factor is programmed by the DSI_PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- M4REG factor is programed by the DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV bit field, and applies to DPLL_DSI1_x_CLK1.
- M5REG factor is programmed by the DSI_PLL_CONFIGURATION1[30:26] M5_CLOCK_DIV bit field, and applies to DPLL_DSI1_x_CLK2.

Figure 10-149 shows the programming sequence.

Figure 10-149. DSI PLL Programming Sequence



NOTE:

- The M4REG and M5REG factors must be set respecting the following conditions:
  - The DPLL_DSI1_x_CLK1 frequency must be a multiple of PCLK frequency (for proper settings of the PCD and LCD factors in the DISPC).
  - The DPLL_DSI1_x_CLK1 and DPLL_DSI1_x_CLK2 frequencies must be lower than 200 MHz. For more information about clock frequency ratings, see Display Subsystem Clocks, in Chapter 10, *Display Subsystem*.
- Most of the other DSI PLL programming values are available for software flexibility, but it is not recommended to update the values in normal use. For the recommended DSI PLL values, see Section 10.3.4.5.12, *DSI PLL Recommended Values*.

Table 10-542. DSI Register Call Summary for DSI PLL Programming Sequence

Register Name	Register Name	Register Name
DSI_PLL_CONFIGURATION2	DSI_PLL_GO	DSI_PLL_STATUS

10.3.4.5.11 DSI PLL Go Sequence

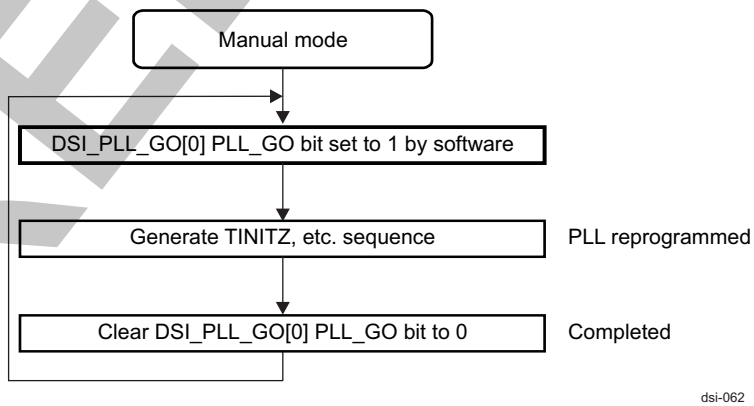
In manual mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 0), the DPLL requires a sequence on TINITZ, TENABLE, and TENABLEDIV to update the configuration values and start the locking sequence.

When all the configuration values are programmed into the registers, the GO bit must be set. The appropriate sequence is then sent on the TINITZ, TENABLE, and TENABLEDIV pins, respecting the timing requirements of the DPLL. The DSI_PLL_GO[0] PLL_GO bit is cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module so that it is programmed at the same time. In this mode, software must deassert CLKINEN by setting the DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN bit to 0 and assert HSDIVBYPASS correctly by setting the DSI_PLL_CONFIGURATION2[20] HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting DSI_PHY_DSS_x and the display subsystem during PLL locking. In manual mode, the shadow register is updated anyway so that valid values are present when later selecting automatic mode.

Figure 10-150 shows the DSI PLL Go flow chart in manual mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 0).

Figure 10-150. DSI PLL Go Sequence (Manual Mode)

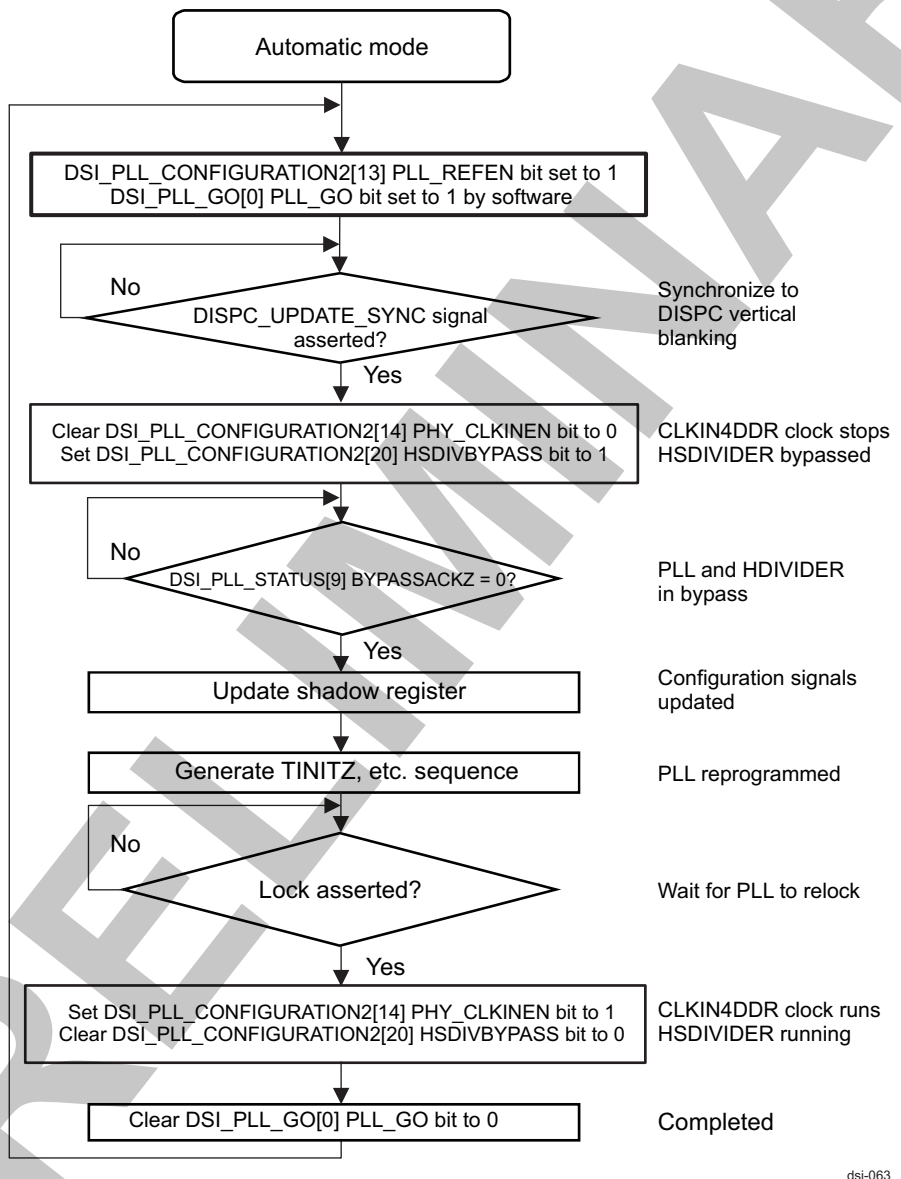


NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 1), the TINITZ, TENABLE, and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register are deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode, CLKINEN, HSDIVBYPASS, and REFEN are automatically controlled and the register value is overridden.

Figure 10-151 shows the DSI PLL Go flow chart in automatic mode (the DSI_PLL_CONTROL[0] PLL_AUTOMODE bit is set to 1).

Figure 10-151. DSI PLL Go Sequence (Automatic Mode)



NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

Table 10-543. DSI Register Call Summary for DSI PLL Go Sequence (Automatic Mode)

Register Name	Register Name	Register Name
DSI_PLL_CONFIGURATION2	DSI_PLL_STATUS	DSI_PLL_GO

10.3.4.5.12 DSI PLL Recommended Values

Table 10-544 shows the DSI PLL recommended values.

Table 10-544. DSI PLL Recommended Programming Values

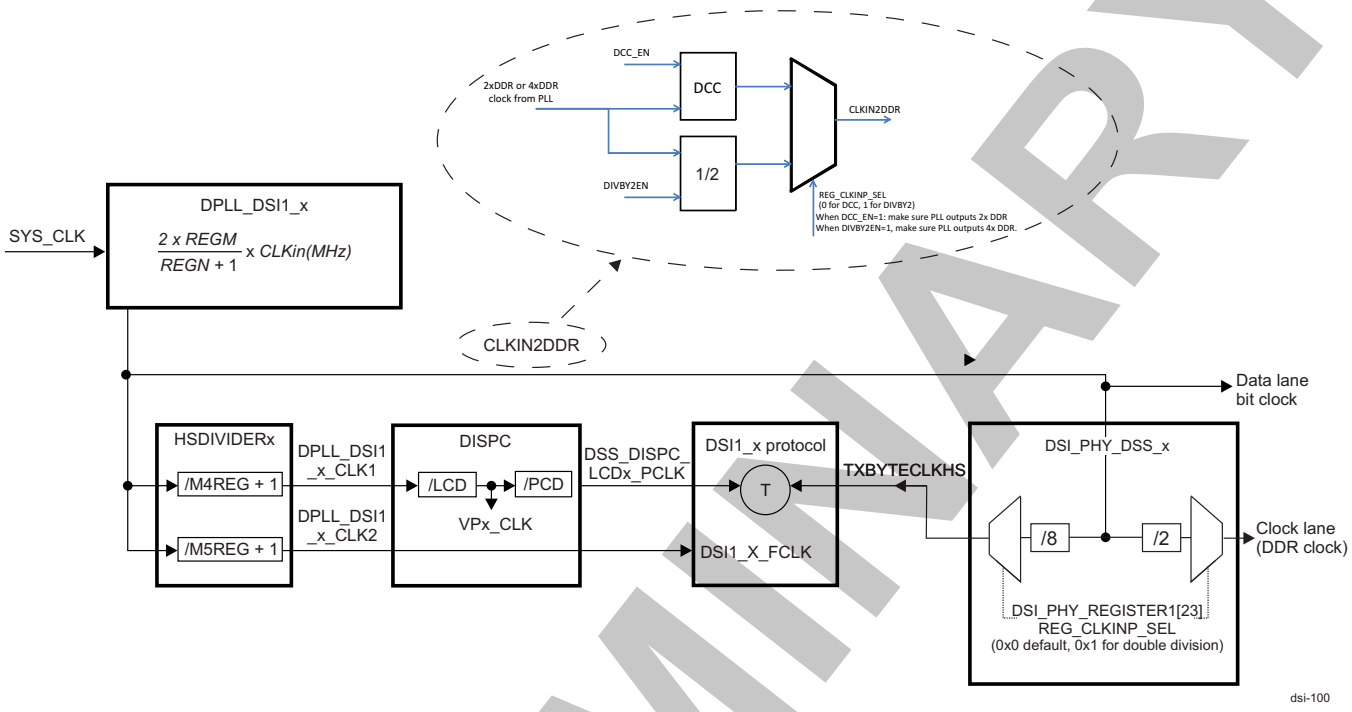
Field Name	Value	Description
DSI_PLL_CONTROL[4] HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_CONTROL[3] PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_CONTROL[2] PLL_HALTMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_CONTROL[1] PLL_GATEMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_CONTROL[0] PLL_AUTOMODE	–	For information, see Section 10.3.4.5.9, *DSI PLL Clock-Gating Sequence*.
DSI_PLL_GO[0] PLL_GO	1–>0	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.
DSI_PLL_CONFIGURATION1[30:36] M5_CLOCK_DIV	See (1).	DSI protocol engine clock divider
DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV	See (1).	DSS clock divider
DSI_PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DSI_PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
DSI_PLL_CONFIGURATION2[20] HSDIVBYPASS	0	PLL controls HSDIVIDER bypass
DSI_PLL_CONFIGURATION2[18] M5_CLK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PLL_CONFIGURATION2[16] M4_CLOCK_EN	1	If PLL/HSDIVIDER is used as the clock source
DSI_PLL_CONFIGURATION2[15] BYPASSEN	0	To use PLL as the clock source. For small displays, it may be possible to use the display subsystem functional clock, DSS_CLK, in which case this bit must be set to 1. See Section 10.3.4.2, *DSI Clock Configuration*.
DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN	1	Enable CLKIN2DDR clock
DSI_PLL_CONFIGURATION2[13] PLL_REFEN	1	Enable PLL reference
DSI_PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_CONFIGURATION2[8] PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt must be used to decide when to perform a PLL uncalibration. No automatic uncalibration is performed.
DSI_PLL_CONFIGURATION2[6] PLL_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current. Set to 1 for leakage level standby current, but longer unlock time.
DSI_PLL_CONFIGURATION2[5] PLL_PLLLPMODE	0	Normal operation. For smaller display sizes, it may be possible to set to 1.
DSI_PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active

(1) The value of the bit field must be set according to the desired clock frequency.

10.3.4.5.13 DSI How to Configure the DSI PLL in Video Mode

Figure 10-152 is a global overview of the DSI1_A and DSI1_C clock trees when used in video mode.

Figure 10-152. DSI Clock Tree in Video Mode



The settings of the DSI PLL registers can be summarized by the following equations.

Equation 1

$$N \times T_{VP\_CLK} = T_L \times T_{TXBYTECLKHS}$$

dsi-e101

where

- $T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + ceiling((WC + 6) / NDL) + HBP_{DSI}$
- N is an integer.
- NDL: Number of data lanes
- WC: Word count or payload in bytes
- HSA_{DSI} is HSA period in video mode.
- HBP_{DSI} is HBP period in video mode.
- HFP_{DSI} is HFP period in video mode.

T_{HS} is the length of HSYNC start short packet in the number of byte clock cycles (TXBYTECLKHS).

- The generation of this packet can be enabled by setting the DSI_CTRL[17] VP_HSYNC_START bit to 1.
- T_{HS} is equal to ceiling(4 / NDL), if VP_HSYNC_START = 1; else, it is 0.

T_{HE} is the length of HSYNC end short packet in the number of byte clock cycles (TXBYTECLKHS).

- The generation of this packet can be enabled by setting the DSI_CTRL[18] VP_HSYNC_END bit to 1.
- T_{HE} is equal to 1, if (VP_HSYNC_START = 1, VP_HSYNC_END = 1, HSA_{DSI} = 0, and NDL = 3), else
- T_{HE} is equal to ceiling(4 / NDL), if (VP_HSYNC_START = 1 and VP_HSYNC_END = 1); else, it is 0.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

$$R = T_{TXBYTECLKHS} / T_{VP\_PCLK}$$

dsi-e102

To synchronize the DISPC and DSI protocol engines, users must follow the ratio R between TXBYTECLKHS and VP_PCLK, as listed in Table 10-545.

Table 10-545. DSI Ratio R

Number of Data Lanes (Up to 4 Data Lanes for DSI1_A and DSI1_C)	Pixel Format	Ratio R
1	16-bit pixel	1/2
1	18-bit pixel	4/9
1	24-bit pixel	1/3
2	16-bit pixel	1
2	18-bit pixel	8/9
2	24-bit pixel	2/3
3	16-bit pixel	3/2
3	18-bit pixel	4/3
3	24-bit pixel	1
4	16-bit pixel	2
4	18-bit pixel	16/9
4	24-bit pixel	4/3

All cases are covered by:

$$F_{VP\_PCLK} \times bits\_per\_pixel = F_{TXBYTECLKHS} \times NDL \times 8$$

dsi-e110

NOTE: Table 10-545 defines the strict ratio values to be used for no line buffer configuration (where DSI burst mode is not supported).

In case of two (or one) line buffers configuration (where DSI burst mode is supported), the ratio R = TTXBYTECLKHS / TVP_PCLK is not limited to the values in Table 10-545. It can be set to other values by ensuring that the line lengths on DISPC and DSI match Equation 3.

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP\_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) \times T_{TXBYTECLKHS}$$

dsi-e103

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} \times bits\_per\_pixel)/(NDL \times 8)) - (2/NDL)$$

dsi-e109

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888
- 1-data lane
- LCD size 480 × 640 with $HSA_{DISP} = HFP_{DISP} = HBP_{DISP} = 20$, $VSA_{DISP} = VFP_{DISP} = VBP_{DISP} = 2$

Step 1. Determine REGM and REGN.

To obtain correct stability, F_{int} must be kept between 0.032 MHz and 52 MHz. In this case, F_{int} is maintained at 2 MHz. For more information, see Section 10.3.4.5.2, *DSI PLL Controllers Architecture*,

Section 10.3.4.5.10, *DSI PLL Clock Sequence*, and Section 10.3.5.2.1.1, *Main Sequence – DSI PLL Setup*.

$$REGN = (F_{SYS\_CLK} / F_{int}) - 1$$
$$REGN = 12$$
$$REGM = (REGN + 1) \times F_{CLKIN2DDR} / (2 \times F_{SYS\_CLK})$$
$$REGM = 75$$

dsi-e113

where

- SYS_CLK = 26 MHz is used as a reference clock.

Step 2. Determine VP_PCLK and TXBYTECLKHS clocks.

TXBYTECLKHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12.5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{VP\_PCLK} / (HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times (VSA_{DISPC} + LPP + VBP_{DISPC})$$
$$\text{Frame rate} = 12.5\ \text{MHz} / (540) \times (646)$$
$$\text{Frame rate} = 35.83\ \text{frame/sec}$$

dsi-e123

Step 3. Determine LCD, PCD, and M4REG.

$$T_{CLKIN2DDR} = T_{TXBYTECLKHS}/8 = T_{DSS\_DISPC\_LCDx\_PCLK}/((M4REG + 1) \times LCD \times PCD)$$
$$((M4REG + 1) \times LCD \times PCD) = 8 \times 3$$

dsi-e115

If LCD and PCD are set to 1 and 3, respectively, M4REG is equal to 7.

Step 4. Verify N as integer.

First, TL must be determined:

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP\_PCLK} / T_{TXBYTECLKHS} = T_L = 1620$$

dsi-e116

From **Equation 1** follows:

$N \times T_{VP\_CLK} = T_L \times T_{TXBYTECLKHS}$

$N = T_{TXBYTECLKHS} \times T_L / T_{VP\_CLK} = T_L / (R \times PCD)$

$N = 14580$

N is an integer.

Step 5. Determine HFP and HBP of the DSI protocol engine.

From **Equation 3** follows:

$$((HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) \times T_{VP\_PCLK} / T_{TXBYTECLKHS}) - (4/NDL + (WC + 6)/NDL) = HFP_{DSI} + HBP_{DSI}$$
$$HFP_{DSI} + HBP_{DSI} = 170$$

dsi-e117

From **Equation 4** follows:

$$HFP_{DSI} = ((HFP_{DISP} \times bits\_per\_pixel)/NDL \times 8)) - (2/NDL)$$
$$HFP_{DSI} = 58$$
$$HBP_{DSI} = 170 - 58 = 112$$

dsi-e121

10.3.4.6 DSI PHY

10.3.4.6.1 DSI PHY Overview

DSI_PHY_DSS_x is a DSI PHY with five unidirectional (HS) lane modules. This includes four data lane modules and one clock lane module. Each lane module has two data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using a point-to-point interconnect.

Lane modules support HS burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes can be used for low-power data transmission, among other things.

The maximum data rate supported in HS mode is 1 Gbps for up to four data lanes. The lane module function and position are configurable; that is, any lane module can be chosen as a clock lane module, and the DX/DY data pad for each lane module can be configured as a DP or DN pin defined by the D-PHY specification.

DSI_PHY_DSS_x interacts with the higher layers of the DSI link through the PPI. DSI_PHY_DSS_x does not include a PLL; a high-frequency clock input is expected in HS mode (CLKIN2DDR). DSI_PHY_DSS_x also supports the SCP interface to set various configuration and control registers.

10.3.4.6.2 DSI PHY Software Reset

The clock domain using the TXBYTECLKHS byte clock from the DSI PHY has dedicated reset-done information in the DSI_COMPLEXIO_CFG1[29] RESET_DONE bit. The DSI_SYSCONFIG[1] SOFT_RESET bit is used to reset the byte clock power domain. A dummy read using the SCP interface to any DSI_PHY_DSS_x register is required after DSI_PHY_DSS_x reset to complete the reset of the DSI PHY.

10.3.4.6.3 DSI PHY Reset-Done Bits

The DSI PHY has several clock domains. The reset status for each clock domain is provided in the DSI_PHY_REGISTER5 register:

- DSI_PHY_REGISTER5[31] RESETDONETXBYTECLK bit: Reset done for the TXBYTECLK domain.
- DSI_PHY_REGISTER5[28:24] RESETDONETXCLKESCi bit field: Reset done for the TXCLKESC domain for lane i (where i = 0 to 4).
- DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP FSM. When the reset sequence completes, the RESETDONESCPCLK signal goes high, and software users can read again the DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit to ensure that the value is now 1.

  NOTE: Software must not write in the DSI_PHY_DSS_x SCP registers before the DSI_PHY_REGISTER5[30] RESETDONESCPCLK bit is set to 1.

- DSI_PHY_REGISTER5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR FSM is complete when the RESETDONEPWRCLK signal goes high.

10.3.4.6.4 DSI PHY Pad Configuration

The number of lanes is configurable through the DSI_COMPLEXIO_CFG1 register.

It is not allowed to change:

- The position on the fly (by modifying DATAx_POSITION, where x = 1 through 4, and CLOCK_POSITION fields)
- The P/N order (positive/negative order of the differential pair by modifying DATAy_POL, where y = 1 through 4, and CLOCK_POL)
- The number of active data lanes (by modifying the DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION, DSI_COMPLEXIO_CFG1[14:12] DATA3_POSITION, and DSI_COMPLEXIO_CFG1[18:16]

DATA4_POSITION bit fields).

To add or remove the second, third, or fourth lanes, the DSI PHY must be in off mode.

The configuration of the DSI PHY (number of data lanes, position, differential order) must not be changed while the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For hardware to recognize a new configuration of the DSI PHY (done in the DSI_COMPLEXIO_CFG1 register), the following sequence must be followed. If the sequence is not followed, the DSI PHY configuration is undetermined.

1. Set the DSI_CTRL[0] IF_EN bit to 1.
2. Reset the DSI_CTRL[0] IF_EN bit to 0.
3. Set the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit to 1.
4. Set the DSI_CTRL[0] IF_EN bit again to 1.

The minimum requirement for the number of lanes is one clock lane and one data lane. By default, the second, third, and fourth data lanes are not connected (the reset value of the DATAx_POSITION bit field is 0).

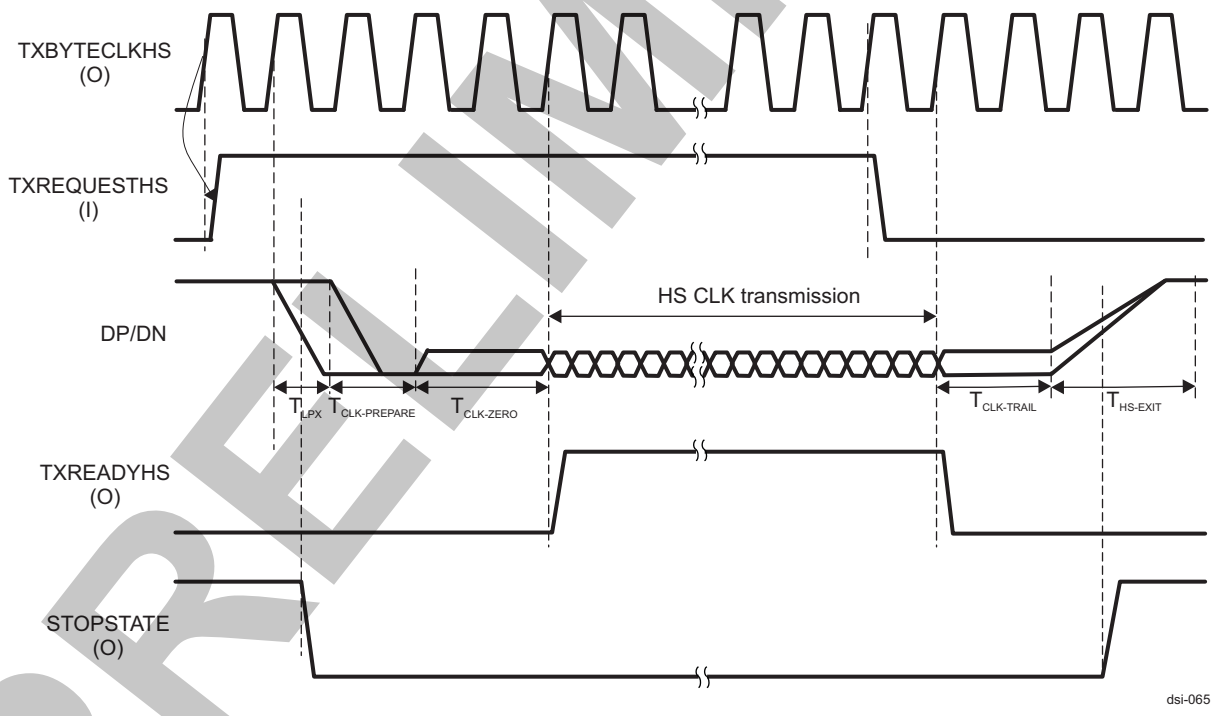
10.3.4.6.5 DSI PHY Display Timing Configuration

Depending on the CLKIN2DDR clock frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI PHY registers.

10.3.4.6.5.1 DSI PHY HS Clock Transmission

Figure 10-153 shows an example of HS clock transmission.

Figure 10-153. DSI PHY HS Clock Transmission



TXBYTECLKHS is an output clock derived by dividing CLKIN2DDR by 8.

NOTE: DSI_PHY_DSS_X can work with 2x DDR from PLL, compared to the 4x clock required in previous devices. The slower clock requirement saves power inside PLL and PHY. A duty cycle corrector (DCC) is used inside PHY to correct the duty cycle and allow use of 2x clock. 4x clock mode (legacy) is also supported. The default setting for the PHY is 2x clock. The 2x clock is only supported from data rate of 500Mbps to 1,255.5 Mbps. Below 500Mbps data rates, the DCC must be bypassed and PLL be programmed to 4x clock.

The TXBYTECLKHS clock is driven by DSI_PHY_DSS_x when:

- CLKIN2DDR is running and the DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN bit is set to 1.
- DSI_PHY_DSS_x is in ON power state (the DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field is set to 1) and at least one lane is enabled.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXBYTECLKHS. The PHY detects this signal on the next rising edge, after which it initiates the LP SoT procedure.

During an HS clock transmission, these parameters are defined in multiples of CLKIN2DDR and are programmed by the following bit fields:

- TLPX timing is programmed by DSI_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE timing is programmed by DSI_PHY_REGISTER0[31:24] THSPREPARE.
- TCLK-ZERO timing is programmed by DSI_PHY_REGISTER1[7:0] TCLKZERO.

TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The DSI_PHY_DSS_x detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

DSI_PHY_DSS_x then goes through the LP EoT procedure. The TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN2DDR and are programmed by the following bit fields:

- TCLK-TRAIL timing is programmed by DSI_PHY_REGISTER1[15:8] TCLKTRAIL.
- THS-EXIT timing is programmed by DSI_PHY_REGISTER0[7:0] THSEXIT.

DSI_PHY_DSS_x completes the SoT and EoT procedures, once begun, regardless of any change in the PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

The HS clock must be present for a period of time before (TCLK-PRE) and after (TCLK-POST) HS data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature phase with respect to a toggling bit sequence on any data lane, and a rising edge in the center of the first transmitted bit of each data byte. These relations are not described in the timing diagram.

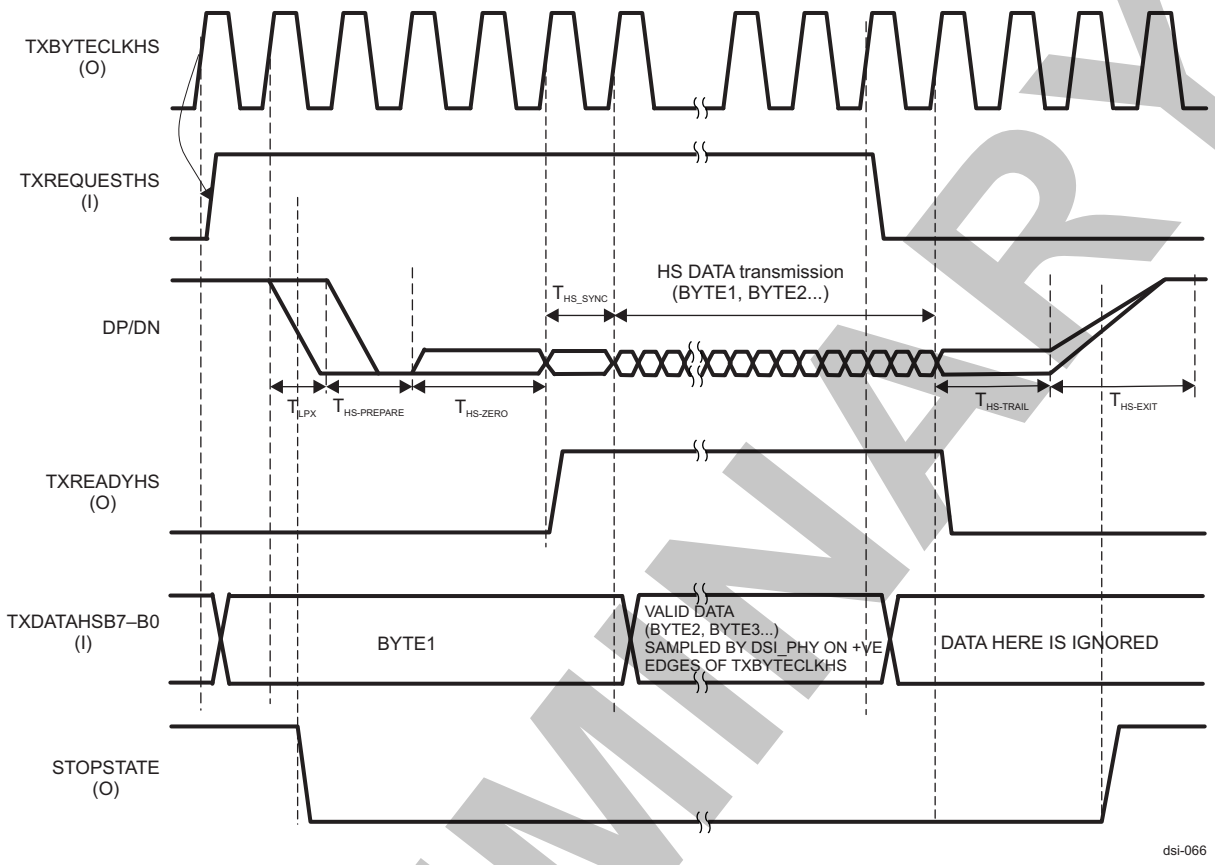
CLKIN2DDR can be shut off 300 ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN2DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after the TxRequestHS falling edge is received by DSI_PHY_DSS_x.

The DSI protocol engine must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

10.3.4.6.5.2 DSI PHY HS Data Transmission

Figure 10-154 shows an example of HS data transmission.

Figure 10-154. DSI PHY HS Data Transmission



To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXBYTECLKHS. It also makes TXREQUESTHS high on the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXBYTECLKHS, following which it initiates the LP SoT procedure.

During an HS data transmission, these timings are multiples of CLKIN2DDR and are programmed by the following bit fields:

- TLPX timing is programmed by DSI_PHY_REGISTER1[20:16] TLPXBY2.
- THS-PREPARE + THS-ZERO timing is programmed by DSI_PHY_REGISTER0[23:16] THSPRPR_THSZERO.

THS-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXBYTECLKHS cycles. THS-SYNC corresponds to the length of the sync pattern (8 HS bits), and can be configured through the DSI_PHY_REGISTER2[31:24] HSSYNCPATTERN bit field.

Toward the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXBYTECLKHS and then starts accepting data from TXDATAHS from the next positive edge onward. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXBYTECLKHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS data transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXBYTECLKHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP EoT procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN2DDR and are programmed by the following bit fields:

- THS-TRAIL timing is programmed by DSI_PHY_REGISTER0[15:8] THSTRAIL.
- THS-EXIT timing is programmed by DSI_PHY_REGISTER0[7:0] THSEXIT.

The PHY completes the SoT and EoT procedures, once begun, regardless of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY starts the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low-power receivers. This signal is not synchronized with TXBYTECLKHS.

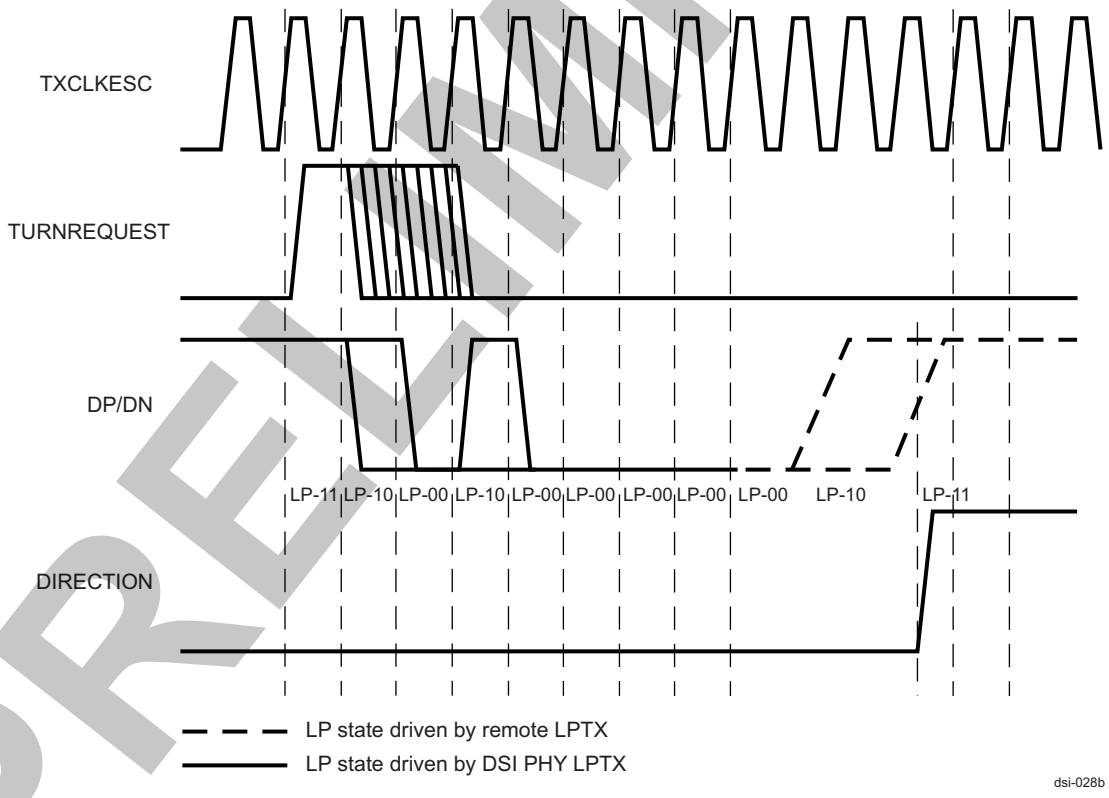
The protocol must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

10.3.4.6.5.3 DSI PHY Turnaround Request in Transmit Mode

When the DSI PHY is in transmit mode, the DSI protocol engine can request a turnaround by making the TurnRequest signal high for at least one clock cycle of TxClkEsc (see Section 10.3.4.4.7.3, *TurnRequest FSM*).

The DSI PHY transmits the turnaround request pattern (LP 11-10-00-10-00-00-00-00) (see Figure 10-155). The number of 00 states at the end of the pattern is defined by the T_{TA-GO} timing parameter and is programmable through the DSI_PHY_REGISTER1[31:29] REG_TTAGO bit field, in number of TxClkEsc clocks. Following the transmission of the pattern, the DSI PHY disables its LP transmitters and waits for an acknowledgment from the remote device. The remote device detects the turnaround request and acknowledges it by driving LP-10, followed by the STOP state. When this acknowledgment is received (BTA_IRQ is asserted, as described in Section 10.3.4.4.8, *DSI Bus Turnaround*), the DSI PHY switches to receive mode and indicates the completion of the turnaround procedure by changing the direction (BTA_EN = 0).

Figure 10-155. DSI PHY Turnaround Request in Transmit Mode

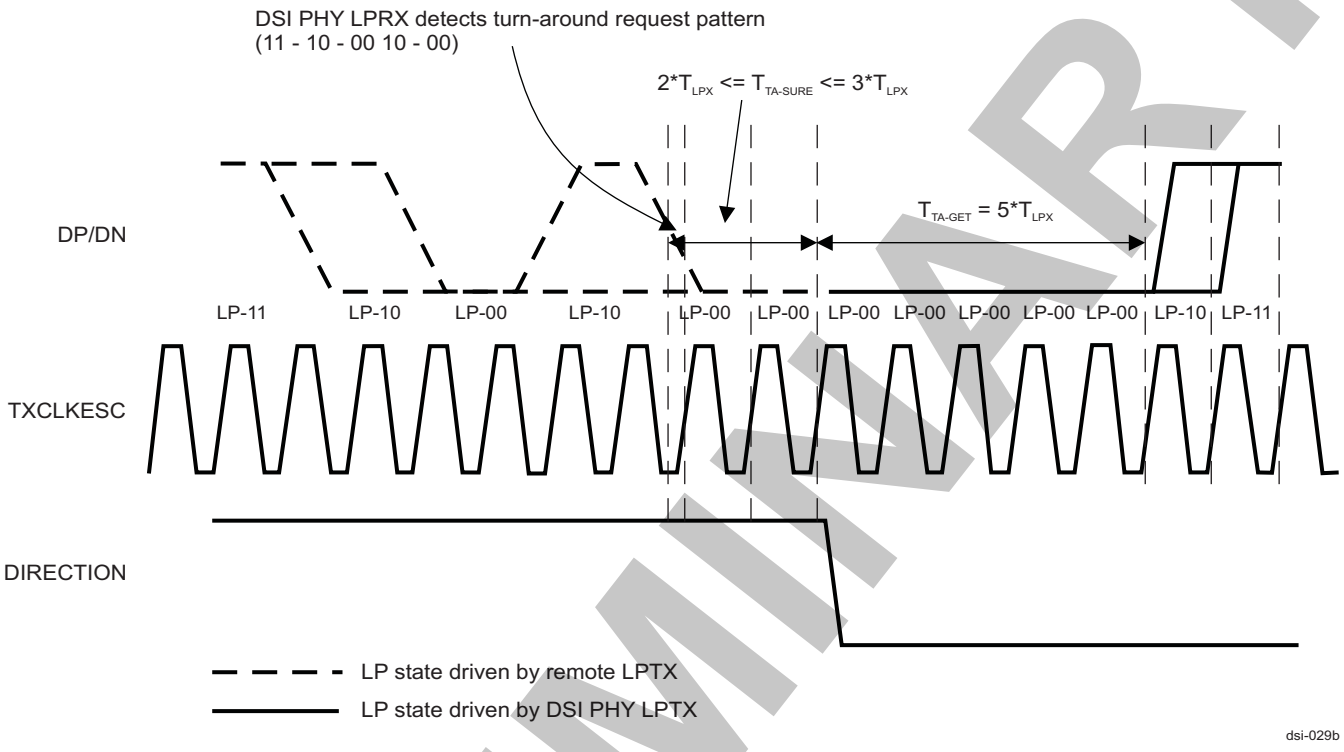


The DSI protocol engine must not stop TxClkEsc after the turnaround process completes (the DSI_CLK_CTRL[20] LP_CLK_ENABLE bit must be kept at 1), because TxClkEsc is also used in handling a turnaround request transmitted by a remote slave device (see Section 10.3.4.6.5.4, *Turnaround Request in Receive Mode*).

10.3.4.6.5.4 DSI PHY Turnaround Request in Receive Mode

When DSI PHY is in receive mode, an LP pattern of 11-10-00-10-00 on DP/DN lines indicates a turnaround request from the remote device (see Figure 10-156).

Figure 10-156. DSI PHY Turnaround Request in Receive Mode



If the line stays in LP-00 for a time $T_{TA-SURE}$, the DSI PHY accepts the turnaround request, changes the direction, transmits LP-00 for a time T_{TA-GET}, and then transmits the acknowledgment pattern LP-10, followed by the STOP state.

This completes the turnaround procedure. The $T_{TA-SURE}$ and T_{TA-GET} timing parameters are programmable through DSI_PHY_REGISTER1 in number of TxClkEsc clocks:

- $T_{TA-SURE}$ can be configured in the [28:27] REG_TTASURE bit field.
- T_{TA-GET} can be configured in the [26:24] REG_TTAGET bit field.

10.3.4.6.5.5 DSI PHY Transmission and Reception

The timings of the following sequences defined in the DSI_PHY_DSS_x protocol cannot be programed by the user:

- Low-power data transmission
- Escape mode trigger command transmission
- ULPS command transmission on data lanes
- ULPS transmission on clock lane
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULPS command on clock lane in receive mode
- ULPS command on data lane in receive mode

10.3.4.6.6 DSI PHY Power Management

Power management of the DSI_PHY_DSS_x analog circuitry is done through the internal power FSM, which is controlled by the subsystem. The control interface is a basic command and acknowledge protocol. The subsystem is the master of the interface. There is a dedicated command pin for each power state of DSI_PHY_DSS_x and a common acknowledge pin. The subsystem sends the power command and clock. The internal FSM does the sequencing and control generation of internal power domains. It then asserts the acknowledge, which signals the completion of the power state transition. The internal power control FSM is powered by a constant power supply.

The main features of the power control interface are:

- One dedicated command line per power state
- Only one command line can be asserted at a time.
- One acknowledge signal common to all command lines
- The command line cannot be cleared unless the acknowledge has been returned.
- All the command lines and the acknowledge signal must be cleared before triggering a new command.

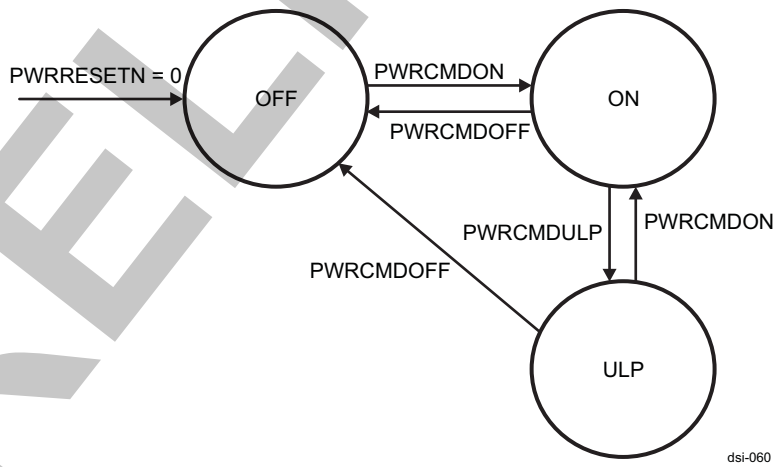
DSI_PHY_DSS_x supports three power states:

- OFF/GPIO mode (OFF): The entire analog circuit is powered down. Internal LDO is off. All analog circuitry on 1.8-V supply is powered down. The ULPS exit detection circuit power switch is off. DSI_PHY_DSS_x takes leakage level current.
- ON: Complete analog circuit is powered on and functional. LDO is on. (DSI_PHY_DSS_x calibrates every time the module enters power on state.)
- ULPS: Only the ULPS exit-detection circuit power switch in DSI_PHY_DSS_x mode is on. All the other analog circuitry is switched off. LDO is off.

NOTE: ULPS must be entered only when all used lane modules go into ULPS. The PHY power state must be returned to ON power state when any one of the used modules goes out of ULPS. No PPI signal except TXULPSEXIT must be toggled when in this power state.

Figure 10-157 shows the power states of the DSI PHY

Figure 10-157. DSI PHY Power State Diagram



10.3.4.6.6.1 DSI PHY Power Saving in DSIPHY From PLL Clock

DSIPHY can work with the 2X clock from PLL. A duty cycle corrector (DCC) is used inside DSIPHY to correct the duty cycle and allow the use of the 2X clock. Compared to legacy devices, a slower clock saves power in the PLL. Therefore, the default setting for DSIPHY is to use the 2X clock. The 2X clock is supported only from a data rate of 500 Mbps to 1,255.5 Mbps. For data rates less than 500 Mbps, the DCC must be bypassed and PLL must be programmed to the 4X clock. The DSI_PHY_DSS_x_REGISTER1 register setting for this is explained in Table 10-546.

Table 10-546. DSI PHY PLL Clock Select Register Control

DSI_PHY_DSS_x_REGISTER1 Bits	Functionality	Comment
REG_DCCEN	Enable DCC.	For higher data rates, DCC must be enabled. The default value is 1 or DCC is enabled.
REG_CLKINP_SEL	Select DCC or divby2 output.	The default value is 0 or DCC output is selected.
REG_CLKPINP_DIVBY2EN	Enable divby2.	For lower data rates, 500 Mbps and below must be used.

10.3.4.6.7 DSI PHY Error Handling

A dedicated register for the DSI PHY (DSI_COMPLEXIO_IRQSTATUS) indicates the state of each error provided by the DSI PHY error signals. The DSI_PHY_DSS_x reports the following errors:

- DSI_COMPLEXIO_IRQSTATUS[9:5] ERRESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS[4:0] ERRSYNCESCi_IRQ: If the number of bits received during a low-power data transmission is not a multiple of 8 when the transmission ends, ERRSYNCESC is made high and remains high until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS[14:10] ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turnaround request or escape mode request is immediately followed by a STOP state instead of the required bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the lane module detects a contention situation on lines DX and DY, respectively, while trying to drive the lines low. Contention is detected only if it lasts at least 50 ns.
- DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the lane module detects a contention situation on lines DX and DY, respectively, while trying to drive the lines high. Contention is detected only if it lasts at least 50 ns.

The ULPSACTIVENOT signal goes low, which indicates to the protocol that the PHY has entered ULPS. When all the ULPSActiveNot signals are low, the DSI_COMPLEXIO_IRQSTATUS[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in the DSI_COMPLEXIO_IRQSTATUS register occur, the DSI_IRQSTATUS[10] COMPLEXIO_ERR_IRQ bit is set to 1 at the DSI protocol engine level.

Table 10-547 lists the DSI PHY interrupt events.

Table 10-547. DSI PHY Interrupts

IRQ Name	Description
ULPSActiveNot_ALL0_IRQ	All ULPSActiveNOT signals are 0.
ULPSActiveNot_ALL1_IRQ	All ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high.
STATEULPM5_IRQ	Fifth lane n ULPS
STATEULPM4_IRQ	Fourth lane in ULPS
STATEULPM3_IRQ	Third lane in ULPS
STATEULPM2_IRQ	Second lane in ULPS
STATEULPM1_IRQ	First lane in ULPS
ERRCONTROL5_IRQ	Control error for fifth lane
ERRCONTROL4_IRQ	Control error for fourth lane
ERRCONTROL3_IRQ	Control error for third lane
ERRCONTROL2_IRQ	Control error for second lane

Table 10-547. DSI PHY Interrupts (continued)

IRQ Name	Description
ERRCONTROL1_IRQ	Control error for first lane
ERRESC5_IRQ	Escape entry error for fifth lane (edge trigger interrupt)
ERRESC4_IRQ	Escape entry error for fourth lane (edge trigger interrupt)
ERRESC3_IRQ	Escape entry error for third lane (edge trigger interrupt)
ERRESC2_IRQ	Escape entry error for second lane (edge trigger interrupt)
ERRESC1_IRQ	Escape entry error for first lane (edge trigger interrupt)
ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for first lane
ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for first lane
ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for second lane
ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for second lane
ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for third lane
ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for third lane
ERRCONTENTIONLP1_4_IRQ	Contention LP1 error for fourth lane
ERRCONTENTIONLP0_4_IRQ	Contention LP0 error for fourth lane
ERRCONTENTIONLP1_5_IRQ	Contention LP1 error for fifth lane
ERRCONTENTIONLP0_5_IRQ	Contention LP0 error for fifth lane
ERRSYNCESC5_IRQ	Low-power data transmission synchronization error for fifth lane
ERRSYNCESC4_IRQ	Low-power data transmission synchronization error for fourth lane
ERRSYNCESC3_IRQ	Low-power data transmission synchronization error for third lane
ERRSYNCESC2_IRQ	Low-power data transmission synchronization error for second lane
ERRSYNCESC1_IRQ	Low-power data transmission synchronization error for first lane

Software must take appropriate action when receiving the interrupt indicating the error from the DSI PHY. The action can be:

- Reset the DSI protocol engine module.
- Reset the peripheral through the reset trigger or directly drive the hardware reset pin of the display module.
- Ignore the error.

10.3.5 DSI Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the DSI module.

10.3.5.1 DSI Global Initialization

10.3.5.1.1 DSI Surrounding Modules Global Initialization

This section describes the requirements to initialize the surrounding modules when the DSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DSI. For more information, see Section 10.3.3, *DSI Integration*, and Section 10.3.2, *DSI Environment*.

Table 10-548 describes the global initialization of the surrounding modules.

Table 10-548. DSI Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	DSI module interface and functional clocks must be enabled. The module power management (idle and sleep modes) must be configured. For more information, see , *Module-Level Clock Management*, in *Chapter 3, Power, Reset, and Clock Management*.
MPU INTC	MPU interrupt controller (INTC) configuration must be done to enable interrupts from the DSI module. For more information about the module configuration, see , *Interrupt Controllers Overview*, in Chapter 17, *Interrupt Controllers*.
DSP INTC	DSP INTC configuration must be done to enable interrupts from the DSI module. For more information about the module configuration, see , *DSP Subsystem Overview*, in *Chapter 5, DSP Subsystem*.
DMA_SYSTEM	DMA configuration must be done to enable DSI module DMA channel requests. For more information about the configuration, see , *DMA_SYSTEM Module Overview*, in *Chapter 16, System DMA*.
L3_MAIN interconnect	For information about the interconnect configuration, see , *L3 Interconnect*, in *Chapter 14, Interconnects*.

10.3.5.1.2 DSI Global Initialization

10.3.5.1.2.1 DSI Main Sequence – DSI Global Initialization

This procedure initializes the DSI after a power on or software reset.

Table 10-549 summarizes the DSI global initialization.

Table 10-549. DSI Global Initialization

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Set clock activity.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	x
Configure power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	x
Reset DSI protocol engine.	DSI_SYSCONFIG[1] SOFT_RESET	0x1
Wait until five reads of reset status?	Software test condition	
Read reset status.	DSI_SYSSTATUS[0] RESET_DONE	
IF: Is reset ongoing?	DSI_SYSSTATUS[0] RESET_DONE	= 0x0
Error occurred during reset stage		
ENDIF		

10.3.5.2 DSI Operational Modes Configuration

10.3.5.2.1 DSI Video Mode Using the DISPC Video Port

10.3.5.2.1.1 DSI Main Sequence – DSI PLL Setup

Table 10-550 lists the steps required to configure the DSI PLL.

Table 10-550. DSI PLL Configuration Registers

Steps	Registers	Value
Turn on/off the PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	x
Wait until the status of the PLL is set (value according to the previous step)?	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	= x
Set the divider value for DSI protocol engine clock source M5REG.	DSI_PLL_CONFIGURATION1[30:26] M5_CLOCK_DIV	x
Set the divider value for clock source M4REG.	DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV	x
Set the value for M divider for the PLL.	DSI_PLL_CONFIGURATION1[20:9] DSI_PLL_REGM	x
Set the value for N divider for the PLL.	DSI_PLL_CONFIGURATION1[8:1] DSI_PLL_REGN	x
Enable/disable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] M5_CLOCK_EN	x
Enable/disable M4 clock source divider.	DSI_PLL_CONFIGURATION2[16] M4_CLOCK_EN	x
Enable/disable DSI PHY clock.	DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN	x
Enable/disable PLL reference clock.	DSI_PLL_CONFIGURATION2[13] PLL_REFEN	x
Set PLL automatic update mode.	DSI_PLL_CONTROL[0] PLL_AUTOMODE	x
Request PLL locking sequence.	DSI_PLL_GO[0] PLL_GO	0x1
Read until PLL_GO bit = 0?	DSI_PLL_GO[0] PLL_GO	= 0x0
Wait until PLL is locked?	DSI_PLL_STATUS[1] PLL_LOCK	= 0x1
Set the ratio for the LP clock.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	x
Enable/disable DSS_L3_MAIN_ICLK clock gating to DSI_PHY_DSS_x and PLL module.	DSI_CLK_CTRL[14] CIO_CLK_ICG	x
Enable/disable the automatic assertion/deassertion of DSIStopClk.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	x
Configure the DSI functional clock synchronization and clock speed.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	x
Turn on/off PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	x

10.3.5.2.1.2 DSI Main Sequence – Set Up DSI Protocol Engine

10.3.5.2.1.2.1 DSI Set Up DSI Control Registers

Table 10-551 lists the steps to set up the DSI control registers. Table 10-552 lists the steps to set up the DSI PHY registers.

Table 10-551. DSI Control Registers

Steps	Registers	Value
Enable the interrupt event for lost synchronization with the video port.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable interrupt event for sent packet on desired VC.	DSI_VC_IRQENABLE_i[2] PACKET_SENT_IRQ_EN	x
Enable HSYNC END pulse detection (short packet generation).	DSI_CTRL[17] VP_HSYNC_START	0x1
Enable VSYNC START pulse detection (short packet generation).	DSI_CTRL[15] VP_VSYNC_START	0x1
Select trigger reset mode.	DSI_CTRL[14] TRIGGER_RESET_MODE	x

Table 10-551. DSI Control Registers (continued)

Steps	Registers	Value
Set the number of line buffers.	DSI_CTRL[13:12] LINE_BUFFER	x
Set video port HSYNC signal polarity.	DSI_CTRL[10] VP_HSYNC_POL	x
Set video port VSYNC signal polarity.	DSI_CTRL[11] VP_VSYNC_POL	x
Set video port data enable signal polarity.	DSI_CTRL[9] VP_DE_POL	x
Set the size of the video port data bus.	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	x
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO.	DSI_CTRL[3] TX_FIFO_ARBITRATION	x
Enable/disable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 10-552. DSI PHY Registers

Steps	Registers	Value
Configure synchronized update on the shadow register.	DSI_COMPLEXIO_CFG1[30] GOBIT	x
Set the DSI PHY power state.	DSI_COMPLEXIO_CFG1[28:27] PWR_CMD	x
Set the position of the first data lane.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	x
Set the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	x
Clear the interrupt status register.	DSI_COMPLEXIO_IRQSTATUS	0xFFFF FFFF
Disable all interrupt events.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable the DSI protocol engine.	DSI_CTRL[0] IF_EN	0x1
Disable the DSI protocol engine.	DSI_CTRL[0] IF_EN	0x0
Wait until the interface is disabled?	DSI_CTRL[0] IF_EN	= 0x0
Enable the low-power clock (TXCLKESC).	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Wait until reset is done?	DSI_COMPLEXIO_CFG1[29] RESET_DONE	= 0x1
Check if power control is ON?	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	= 0x1
Wait until internal module reset is complete?	DSI_SYSSTATUS[0] RESETDONE	= 0x1

10.3.5.2.1.2.2 DSI Configure DSI Timing and VCs

Table 10-553 lists the steps to configure DSI timing and the VCs.

Table 10-553. DSI Timing Registers

Steps	Registers	Value
Determine the number of DSI_CLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x-
Determine the number of BYTE_CLK clock cycles for the HS RX timer.	DSI_TIMING2[28:16] HS_TX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 16 for the number of BYTE_CLK clock cycles for the HS TX timer.	DSI_TIMING2[29] HS_TX_TO_X16	0x-
Determine the number of DSI_CLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 16 for the number of DSI_CLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x-
Set the horizontal sync active period.	DSI_VM_TIMING1[31:24] HSA	0x-
Set the horizontal front porch.	DSI_VM_TIMING1[23:12] HFP	0x-
Set the horizontal back porch.	DSI_VM_TIMING1[11:0] HBP	0x-
Set the number of BYTE clock cycles for the sync window.	DSI_VM_TIMING2[27:24] WINDOW_SYNC	0x-

Table 10-553. DSI Timing Registers (continued)

Steps	Registers	Value
Set the vertical sync active period.	DSI_VM_TIMING2[23:16] VSA[(1)]	0x-
Set the vertical front porch.	DSI_VM_TIMING2[15:8] VFP	0x-
Set the vertical back porch.	DSI_VM_TIMING2[7:0] VBP	0x-
Set the line length.	DSI_VM_TIMING3[31:16] TL	0x-
Set the number of active lines.	DSI_VM_TIMING3[15:0] VACT	0x-
Set the number of TXBYTECLKHS clock cycles for entering HS mode.	DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY	0x-
Set the number of TXBYTECLKHS clock cycles for exiting HS mode.	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	0x-
Set the number of TXBYTECLKHS clock cycles between the start of the DDR clock and the assertion of the data request signal.	DSI_CLK_TIMING[15:8] DDR_CLK_PRE	0x-
Set the number of TXBYTECLKHS clock cycles after the data request signal is deasserted and the DDR clock is stopped.	DSI_CLK_TIMING[7:0] DDR_CLK_POST	0x-
Configure the RX FIFO DMA request.	DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB	0x-
Configure the TX FIFO DMA request.	DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB	0x-
Enable/disable the ECC generation for the transmit header.	DSI_VC_CTRL_i[8] ECC_TX_EN	0x-
Enable/disable the checksum generation for the transmit payload.	DSI_VC_CTRL_i[7] CS_TX_EN	0x-
Select video mode.	DSI_VC_CTRL_i[4] MODE	0x-

(1) In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

10.3.5.2.1.3 DSI Main Sequence – Configure DSI_PHY_DSS_x

Table 10-554 summarizes the timing in the functions of DDR_CLK_P. For more information about the timing calculation, see Section 10.3.4.4.4, *DSI Clock Requirements*.

Table 10-554. DSI Calculate DSI_PHY_DSS_x Timing

Steps	Registers	Value
Settings of the DSI protocol timing. For a complete description of the timing specifications, see Section 10.3.4.4.4, *DSI Clock Requirements*.	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_PRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25 ns/DDR clock period)

10.3.5.2.1.4 DSI Main Sequence – Drive STOP State

Table 10-555 lists the steps to drive STOP state.

Table 10-555. DSI Drive STOP State

Steps	Registers	Value
Force TX stop mode.	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0?	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	= 0x0

10.3.5.2.1.5 DSI Main Sequence – Enable Video Mode

Table 10-555 lists the steps to enable video mode.

Table 10-556. DSI Enable Video Mode

Steps	Registers	Value
Set up long packet header.	DSI_VC_LONG_PACKET_HEADER_i	0x-
Enable desired VC.	DSI_VC_CTRL_i[1] VC_EN	0x1
Enable DSI module.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN = 1?	DSI_CTRL[0] IF_EN	= 0x1

10.3.5.2.2 DSI Command Mode Using the DISPC Video Port

This section explains the basic programming model of command mode using the DISPC video port.

10.3.5.2.2.1 DSI Main Sequence – Configure DSI PLL

Table 10-557 lists the steps required to configure the DSI PLL.

Table 10-557. DSI Configure DSI PLL

Steps	Register/Bit Field/Programming	Value
Set PLL and HSDIVIDER to ON state.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2
Wait until PLL and HSDIVIDER are enabled?	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	= 0x2
Set the M5REG value.	DSI_PLL_CONFIGURATION1[30:26] M5_CLK_DIV	x
Set the M4REG value.	DSI_PLL_CONFIGURATION1[25:21] M4_CLOCK_DIV	x
Set the REGN value.	DSI_PLL_CONFIGURATION1[8:1] PLL_REGN	x
Set the REGM value.	DSI_PLL_CONFIGURATION1[20:9] PLL_REGM	x
Enable/disable PLL reference clock control.	DSI_PLL_CONFIGURATION2[13] PLL_REFEN	x
Enable/disable CLKIN2DDR control.	DSI_PLL_CONFIGURATION2[14] PHY_CLKINEN	x
Enable/disable DSS clock divider.	DSI_PLL_CONFIGURATION2[16] M4_CLOCK_EN	x
Enable/disable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] M5_CLOCK_EN	x
Configure synchronization of configuration update with DISPC_UPDATE_SYNC.	DSI_PLL_CONTROL[0] PLL_AUTOMODE	x
Start PLL locking sequence.	DSI_PLL_GO[0] PLL_GO	0x1
Wait until there is no pending action?	DSI_PLL_GO[0] PLL_GO	= 0x0
Check whether PLL is locked?	DSI_PLL_STATUS[1] PLL_LOCK	= 0x1
Set the LP mode clock ratio.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	x
Configure DSS_L3_MAIN_ICLK clock to the DSI PHY.	DSI_CLK_CTRL[14] CIO_CLK_ICG	x
Enable/disable the automatic assertion/deassertion of the DSIStopClk signal.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	x
Define the DSI functional clock value and synchronization.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	x
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2

10.3.5.2.2.2 DSI Main Sequence – Switch to DSI PLL Clock Source

Table 10-558 lists the steps to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 10-558. DSI witch to DSI PLL Clock Source

Steps	Reference	Value
Switch DISPC clock to PLL1_CLK1.	For more information, see Display Subsystem Integration, in *Display Subsystem*.	
Switch DSI clock to DPLL_DSI1_A_CLK2.	For more information, see Display Subsystem Integration, in *Display Subsystem*.	

10.3.5.2.2.3 DSI Main Sequence – Configure DSI Protocol Engine

10.3.5.2.2.3.1 DSI Set Up DSI Control Registers

Table 10-559 lists the steps required to set up the DSI control registers. Table 10-560 lists the steps to set up the DSI PHY registers.

Table 10-559. DSI Control Registers

Steps	Register/Bit Field/Programming	Value
Enable IRQ for lost synchronization with video port.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on desired VC.	DSI_VC_IRQENABLE_i[2] PACKET_SENT_IRQ_EN	0x1
Set the trigger reset mode.	DSI_CTRL[14] TRIGGER_RESET_MODE	x
Configure the number of active line buffers.	DSI_CTRL[13:12] LINE_BUFFER	x
Set the size of the video port data bus.	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	x
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	x
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO.	DSI_CTRL[3] TX_FIFO_ARBITRATION	x
Enable/disable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	x

Table 10-560. DSI PHY Registers

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	x
Set the position of data lane 1.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	x
Configure the power state of the DSI PHY.	DSI_COMPLEXIO_CFG1[28:27] PWR_CMD	x
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear the DSI PHY IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xFFFF FFFF
Disable all DSI PHY IRQ events.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable the DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x1
Disable the DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x0
Wait until interface is disabled?	DSI_CTRL[0] IF_EN	= 0x0
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Check whether internal reset is complete?	DSI_COMPLEXIO_CFG1[29] RESET_DONE	= 0x1
Check whether power state of DSI PHY is ON?	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	= 0x1
Check whether reset is complete?	DSI_SYSSTATUS[0] RESETDONE	= 0x1

10.3.5.2.2.3.2 DSI Configure DSI Timing and VCs

Table 10-561 lists the steps to configure DSI timing and the VCs.

Table 10-561. DSI Timing Registers

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x-
Enable/disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x-
Enable/disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x-
Clear turnaround timer settings.	DSI_TIMING1[30:16]	0x0
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x-
Enable/disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x-
Determine the number of BYTE_CLK clock cycles for the HS RX timer.	DSI_TIMING2[28:16] HS_TX_TO_COUNTER	0x-
Enable/disable the multiplication factor of 16 for the number of BYTE_CLK clock cycles for the HS TX timer.	DSI_TIMING2[29] HS_TX_TO_X16	0x-
Enable/disable the multiplication factor of 64 for the number of BYTE_CLK clock cycles for the HS TX timer.	DSI_TIMING2[30] HS_TX_TO_X64	0x-
Set the number of TXBYTECLKHS clock cycles	DSI_CLK_TIMING[15:8] DDR_CLK_PRE and DSI_CLK_TIMING[7:0] DDR_CLK_POST	0x-
Configuration of VCi		
Select source of data and enable VP_STALL.	DSI_VC_CTRL_i[1] SOURCE	0x1
Enable/disable the checksum generation for the transmit payload.	DSI_VC_CTRL_i[7] CS_TX_EN	0x-
Enable/disable the ECC generation for the transmit header.	DSI_VC_CTRL_i[8] ECC_TX_EN	0x-
Enable/disable HS mode to send short and long packets to the peripheral.	DSI_VC_CTRL_i[9] MODE_SPEED	0x-
Configure DMA request for TX FIFO.	DSI_VC_CTRL_i[23:21] DMA_TX_REQ_NB	0x-
Configure DMA request for RX FIFO.	DSI_VC_CTRL_i[29:27] DMA_RX_REQ_NB	0x-
Configuration TX and RX FIFO		
Set size of the RX FIFO allocated for used VC.	DSI_RX_FIFO_VC_SIZE	0x-
Set size of the TX FIFO allocated for used VC.	DSI_TX_FIFO_VC_SIZE	0x-

10.3.5.2.2.4 DSI Main Sequence – Configure DSI_PHY_DSS_x Timing

Table 10-562 summarizes DSI_PHY_DSS_x timing settings. For more information about timing calculation, see Section 10.3.4.4.4, *DSI Clock Requirements*.

Table 10-562. DSI Configure DSI_PHY_DSS_x Timing

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 10.3.4.4.4, *Clock Requirements*.	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	ceil(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	ceil(60n s/DDR clock period) + 5
	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2	ceil(25 ns/DDR clock period)

10.3.5.2.2.5 DSI Main Sequence – Drive STOP State

Table 10-563 lists the steps to drive the STOP state.

Table 10-563. DSI Drive STOP State

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	0x1
Wait until the end of TX stop mode assertion?	DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO	= 0x1

10.3.5.2.2.6 DSI Main Sequence – Enable Command Mode Using DISPC Video Port

Table 10-564 lists the steps to enable DISPC to send frames continuously. Two BTAs must be generated:

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 10-564. DSI Enable Command Mode and Automatic TE

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue/start code.	DSI_VC_CTRL_i[31] DCS_CMD_CODE	0x-
Enable/disable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_VC_CTRL_i[30] DCS_CMD_ENABLE	0x-
Enable used VC.	DSI_VC_CTRL_i[0] VC_EN	0x1
Enable DSI protocol engine interface.	DSI_CTRL[0] IF_EN	0x1
Wait until interface is enabled?	DSI_CTRL[0] IF_EN	= 0x0
Send the sequence to receive the TE trigger from the peripheral.	DSI_VC_SHORT_PACKET_HEADER_i[31:0] HEADER	0x-
Wait until packet is sent?	DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ	= 0x1
Write 1 to reset the status bit.	DSI_VC_IRQSTATUS_i[2] PACKET_SENT_IRQ	0x1

NOTE: Keep reserved bits at reset value in DSI_PHY_REGISTER1 and DSI_PHY_REGISTER2.

10.3.5.2.2.7 DSI Main Sequence – Send Frame Data to LCD Panel Using Automatic TE

Table 10-565 summarizes the steps to send a frame data to the LCD panel using automatic TE.

Table 10-565. DSI Send Frame Data to LCD Panel Using Automatic TE

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	For more information, see DISPC Clock Configuration, in*Display Controller*.	
Specify the number of bytes to send. When DCS insertion is used, word count (WC) must include this one DCS byte.	DSI_VC_TE_i[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header.	DSI_VC_LONG_PACKET_HEADER_i[31:0] HEADER	0x-
Enable/disable TE control.	DSI_VC_TE_i[30] TE_EN	0x1
Wait until RX FIFO is empty?	DSI_VC_CTRL_i[20] RX_FIFO_NOT_EMPTY	= 0x0
Wait until TX FIFO is not full?	DSI_VC_CTRL_i[16] TX_FIFO_FULL	= 0x0
Enable first BTA to give bus possession to the display module.	DSI_VC_CTRL_i[6] BTA_EN	0x1
Wait until BTA IRQ event occurs?	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	= 0x1
Write 1 to clear BTA IRQ status bit.	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	0x1
Enable the second BTA to get the TE trigger.	DSI_VC_CTRL_i[6] BTA_EN	0x1
Wait until BTA IRQ event occurs?	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	= 0x1
Write 1 to clear BTA IRQ status bit.	DSI_VC_IRQSTATUS_i[5] BTA_IRQ	0x1
Wait until transfer is complete?	DSI_VC_TE_i[30] TE_EN	= 0x0

10.3.6 DSI Register Manual

This section describes the DSI module registers.

10.3.6.1 DSI Instance Summary

Table 10-566 summarizes the DSI module instances.

Table 10-566. DSI Instance Summary

Module Name	L3_MAIN Base Address	Size
DSI1_A	0x5800 4000	512 bytes
DSI_PHY_DSS_A	0x5800 4200	64 bytes
DPLL_DSI1_A	0x5800 4300	64 bytes
DSI1_C	0x5800 9000	512 bytes
DSI_PHY_DSS_C	0x5800 9200	64 bytes
DPLL_DSI1_C	0x5800 9300	64 bytes

10.3.6.2 DSI Registers

10.3.6.2.1 DSI Register Summary

Table 10-567. DSI1_A Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	DSI1_A L3_MAIN Physical Address

Table 10-579. DSI_CTRL

Address Offset	0x0000 0040		
Physical Address	0x5800 4040 0x5800 9040	**Instance**	DSI1_A DSI1_C
Description	Global control register – This register controls the DSI protocol engine module. This register mustnot be modified dynamically (except IF_EN bit fields).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DISPC_UPDATE_SYNC	HSA_BLANKING_MODE	HBP_BLANKING_MODE	HFP_BLANKING_MODE	BLANKING_MODE	EOT_ENABLE	VP_HSYNC_END	VP_HSYNC_START	VP_VSYNC_END	VP_VSYNC_START	TRIGGER_RESET_MODE	LINE_BUFFER	VP_VSYNC_POL	VP_HSYNC_POL	VP_DE_POL	VP_CLK_POL	VP_DATA_BUS_WIDTH		TRIGGER_RESET	VP_CLK_RATIO	TX_FIFO_ARBITRATION	ECC_RX_EN	CS_RX_EN	IF_EN

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	DISPC_UPDATE_SYNC	Determines whether the Dispc_Update_Sync signal from the display controller is used 0x0: Dispc_Update_Sync signal is not used. 0x1: Dispc_Update_Sync signal is used.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0

Bits	Field Name	Description	Type	Reset
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE, and HFP_BLANKING_MODE, respectively) when there is no command mode data in TX FIFO ready to be sent. Thus, blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE, and HFP_BLANKING_MODE, respectively) regardless of the packets present in the TX FIFO ready to be sent.	RW	0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS-to-LP transitions.	RW	0
18	VP_HSYNC_END	HSYNC end pulse 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0
16	VP_VSYNC_END	VSYNC end pulse 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0
15	VP_VSYNC_START	VSYNC start pulse 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.(1)	RW	0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: The mode is valid only if there is virtual channel using the video mode and it is active. The principal is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: All pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. The valid values are from 0 to DSI_GNQ[17:16] VP1_NB_LINE_BUFFER. 0x0: No line buffer 0x1: One line buffer 0x2: Two line buffers	RW	0x0

(1) In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

Bits	Field Name	Description	Type	Reset
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI protocol engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI protocol engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bit data width (LSB of the 24-bit video port data bus) 0x1: 18-bit data width (LSB of the 24-bit video port data bus) 0x2: 24-bit data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: Reads: Reset trigger generation is complete. It is reset by hardware when it completes. Writes: Cancellation of the request for reset trigger generation (may be too late because it is already ongoing) 0x1: Reads: Generation of the reset trigger has been requested by the user (may be ongoing but not yet complete). Writes: Request for reset trigger to be sent to the peripheral	RW	0
4	VP_CLK_RATIO	The field indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is used only when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3 , 5, 7, ...).	RW	0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the virtual channel pending ready requests in the TX FIFO 0x0: Round-robin scheme is used. 0x1: Sequential scheme is used.	RW	0
2	ECC_RX_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all virtual channel ids) 0x0: Disabled 0x1: Enabled	RW	0
0	IF_EN	Enables the module. When the module is disabled, the signals from the DSI PHY are gated (no updates of the interrupt status register). It is not possible to change the bit fields in the DSI_CTRL register except when IF_EN is enabled. All the other registers can be changed except those that require DSI_VC_CTRL_i[0] VC_EN to be equal to 0 to be modified. 0x0: The interface is disabled. If one of the virtual channels uses the video mode with the video port to receive data, the DSI protocol engine is disabled when the next VSYNC is received and all the data in the FIFO for the other virtual channels in command mode are sent to the peripherals (if BTA_EN is enabled, the DSI protocol must wait for the response and BTA from the peripheral before disabling all the internal logic, because an acknowledge is requested). 0x1: The interface is enabled immediately, and the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the slave port FIFO (command mode).	RW	0

- DSI Register Description: [2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24] [25] [26] [27] [28] [29]

Table 10-583. DSI_COMPLEXIO_CFG1

Address Offset	0x0000 0048		
Physical Address	0x5800 4048 0x5800 9048	**Instance**	DSI1_A DSI1_C
Description	Complexio configuration register for the DSI PHY. This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals and the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SHADOWING	GOBIT	RESET_DONE	PWR_CMD		PWR_STATUS		RESERVED					DATA4_POL	DATA4_POSITION			DATA3_POL	DATA3_POSITION			DATA2_POL	DATA2_POSITION			DATA1_POL	DATA1_POSITION			CLOCK_POL	CLOCK_POSITION		

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration 0x0: Disabled. The writes to the DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSI_PHY_REGISTER0 through DSI_PHY_REGISTER2 registers are done only when the GOBIT is set and when the signal DISPCUpdataSync from the display controller module is active.	RW	0
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPCUpdateSync is active. 0x0: Resets the GOBIT. The hardware has finished the update of the shadow SCP registers. The bit is reset by hardware. The software can reset the bit if the user decides to abort it. There is no guarantee that the software reset is done before the transfer of the values to the DSI PHY. 0x1: Set the GOBIT. Only when the transfer of the new values for the three first registers is completed (3, 2, 1, or 0 transfers are performed based on the number of registers to update), the GOBIT is reset. The DISPCUpdateSync signal is used to synchronize the update. The bit must be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the TXBYTECLKHS clock from the DSI PHY Read 0x0: Internal module reset is ongoing. Read 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the DSI PHY 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ULTRALOW-POWER state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the DSI PHY Read 0x0: DSI PHY in OFF state Read 0x1: DSI PHY in ON state Read 0x2: DSI PHY in ULTRALOW-POWER state	R	0x0
24:20	RESERVED	Reserved	R	0x0

Bits	Field Name	Description	Type	Reset
19	DATA4_POL	± differential pin order of the fourth data lane 0x0: ± pin order (DSI.DX = + and DSi.DY = –) 0x1: ± pin order (DSI.DX= – and DSi.DY = +)	RW	0
18:16	DATA4_POSITION	Position and order of the fourth data lane 0x0: Not used/connected 0x1: The fourth data lane is at the first position (first lane is lane 0). 0x2: The fourth data lane is at the second position (second lane is lane 1). 0x3: The fourth data lane is at the third position (third lane is lane 2). 0x4: The fourth data lane is at the fourth position (fourth lane is lane 3). 0x5: The fourth data lane is at the fifth position (fifth lane is lane 4).	RW	0x0
15	DATA3_POL	± differential pin order of the third data lane 0x0: ± pin order (DSI.DX = + and DSi.DY = –) 0x1: ± pin order (DSI.DX = – and DSi.DY = +)	RW	0
14:12	DATA3_POSITION	Position and order of the third data lane 0x0: Not used/connected 0x1: The third data lane is at the first position (first lane is lane 0). 0x2: The third data lane is at the second position (second lane is lane 1). 0x3: The third data lane is at the third position (third lane is lane 2). 0x4: The third data lane is at the fourth position 4 (fourth lane is lane 3). 0x5: The third data lane is at the fifth position (fifth lane is lane 4).	RW	0x0
11	DATA2_POL	± differential pin order of the seond data lane 0x0: ± pin order (DSI.DX = + and DSi.DY = –) 0x1: ± pin order (DSI.DX = – and DSi.DY = +)	RW	0
10:8	DATA2_POSITION	Position and order of the second data lane 0x0: Not used/connected 0x1: The second data lane is at the first position (first lane is lane 0). 0x2: The second data lane is at the second position (second lane is lane 1). 0x3: The second data lane is at the third position (third lane is lane 2). 0x4: The second data lane is at the fourth position (fourth lane is lane 3). 0x5: The second data lane is at the fifth position (fifth lane is lane 4).	RW	0x0
7	DATA1_POL	± pin differential pin order of the first data lane 0x0: ± pin order (DSI.DX = + and DSi.DY = –) 0x1: ± pin order (DSI.DX = – and DSi.DY = +)	RW	0

Bits	Field Name	Description	Type	Reset
6:4	DATA1_POSITION	Position and order of the first data lane. The first data lane s always present. 0x0: Not used/connected 0x1: The first data lane is at the first position (first lane is lane 0). 0x2: The first data lane is at the second position (second lane is lane 1). 0x3: The first data lane is at the third position (third lane is lane 2). 0x4: The first data lane is at the fourth position (fourth lane is lane 3). 0x5: The first data lane is at the fifth position (fifth lane is lane 4).	RW	0x0
3	CLOCK_POL	± differential pin order of the clock lane 0x0: ± pin order (DSI.DX = + and DSi.DY = –) 0x1: ± pin order (DSI.DX = – and DSi.DY = +)	RW	0
2:0	CLOCK_POSITION	Position and order of the clock lane; 0, 5, 6, and 7 are reserved. The clock lane is always present but cannot be at the fifth position even if the DSI PHY consists of five lanes. 0x0: Not used/connected 0x1: Clock lane is at the first position (first lane is lane 0). 0x2: Clock lane is at the second position (second lane is lane 1). 0x3: Clock lane is at the third position (third lane is lane 2). 0x4: Clock lane is at the fourth position (fourth lane is lane 3). 0x5: Reserved 0x6: Reserved 0x7: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
31	ULPSACTIVENOT_ALL1_IRQ	All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high. 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
30	ULPSACTIVENOT_ALL0_IRQ	All signals ULPSActiveNOT are 0 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
29	ERRCONTENTIONLP1_5_IRQ	Contention LP1 error for the fifth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
28	ERRCONTENTIONLP0_5_IRQ	Contention LP0 error for the fifth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
27	ERRCONTENTIONLP1_4_IRQ	Contention LP1 error for the fourth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
26	ERRCONTENTIONLP0_4_IRQ	Contention LP0 error for the fourth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
25	ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for the third lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
24	ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for the third lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Bits	Field Name	Description	Type	Reset
23	ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for the second lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
22	ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for the second lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
21	ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for the first lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
20	ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for the first lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
19	STATEULPS5_IRQ	the fifth lane in ULTRALOW-POWER State 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
18	STATEULPS4_IRQ	the fourth lane in ultralow-power mode 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
17	STATEULPS3_IRQ	the third lane in ULTRALOW-POWER state 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
16	STATEULPS2_IRQ	the second lane in ULTRALOW-POWER state 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
15	STATEULPS1_IRQ	the first lane in ULTRALOW-POWER state 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
14	ERRCONTROL5_IRQ	Control error for the fifth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
13	ERRCONTROL4_IRQ	Control error for the fourth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Bits	Field Name	Description	Type	Reset
12	ERRCONTROL3_IRQ	Control error for the third lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
11	ERRCONTROL2_IRQ	Control error for the second lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
10	ERRCONTROL1_IRQ	Control error for the first lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
9	ERRESC5_IRQ	Escape entry error for the fifth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
8	ERRESC4_IRQ	Escape entry error for the fourth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
7	ERRESC3_IRQ	Escape entry error for the third lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
6	ERRESC2_IRQ	Escape entry error for the second lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
5	ERRESC1_IRQ	Escape entry error for the first lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
4	ERRSYNCESC5_IRQ	Low power Data transmission synchronization error for the fifth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
3	ERRSYNCESC4_IRQ	Low power Data transmission synchronization error for the fourth lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Bits	Field Name	Description	Type	Reset
2	ERRSYNCESC3_IRQ	Low power Data transmission synchronization error for the third lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
1	ERRSYNCESC2_IRQ	Low power Data transmission synchronization error for the second lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
0	ERRSYNCESC1_IRQ	Low power Data transmission synchronization error for the first lane 0x0: Reads: Event is false. Writes: Status bit unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Address Offset	0x0000 0054		
Physical Address	0x5800 4054 0x5800 9054	**Instance**	DSI1_A DSI1_C
Description	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL_PWR_CMD		PLL_PWR_STATUS		RESERVED						LP_RX_SYNCHRO_ENABLE	LP_CLK_ENABLE	HS_MANUAL_STOP_CTRL	HS_AUTO_STOP_ENABLE	LP_CLK_NULL_PACKET_SIZE		LP_CLK_NULL_PACKET_ENABLE	CIO_CLK_ICG	DDR_CLK_ALWAYS_ON	LP_CLK_DIVISOR										

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	Command for power control of the DSI PLL Control module 0x0: Command to change to OFF state 0x1: Command to change to ON state for PLL only (HSDIVISER is OFF) 0x2: Command to change to ON state for both PLL and HSDIVISER 0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI PHY)	RW	0x0
29:28	PLL_PWR_STATUS	Status of the power control of the DSI PLL Control module Read 0x0: DSI PLL Control module in OFF state Read 0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF) Read 0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER Read 0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI PHY)	R	0x0
27:22	RESERVED		R	0x00

Bits	Field Name	Description	Type	Reset
21	LP_RX_SYNCHRO_ENABLE	Defines if the functional is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.	RW	0
20	LP_CLK_ENABLE	Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR is not used and does not need to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR is used and needs to be programmed.	RW	0
19	HS_MANUAL_STOP_CTRL	In case HS_AUTO_STOP_ENABLE=0, the bit field allows manual control of the assertion/de-assertion of the signal DSIStopClk by the user. 0x0: DSIStopClk de-assertion unconditionally. 0x1: DSIStopClk assertion unconditionally.	RW	0
18	HS_AUTO_STOP_ENABLE	Enables the automatic assertion/de-assertion of DSIStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled.	RW	0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0
14	CIO_CLK_ICG	Gates SCPClk clock provided to DSI_PHY_DSS_x and PLL-CTRL module. 0x0: Disabled. SCPClk is not generated. It remains at 0. 0x1: Enabled. SCPClk is generated (OCP_CLK/4)	RW	0
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low-power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LS mode).	RW	0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency shall be in the range between 20 MHz and 32 kHz.	RW	0x0001

Table 10-591. DSI_TIMING1

Address Offset	0x0000 0058		
Physical Address	0x5800 4058 0x5800 9058	**Instance**	DSI1_A DSI1_C
Description	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL[0] IF_EN is set to '1'. It is used to indicate the number of DSI1_A_CLK and DSI1_A_CLK functional clocks cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER													FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO												

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0
30	TA_TO_X16	Multiplication factor for the number of DSI_CLK functional clocks cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	1
29	TA_TO_X8	Multiplication factor for the number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_CLK functional clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	1

Bits	Field Name	Description	Type	Reset
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_CLK function clock to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.	RW	0x1FFF
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal 0x0: Deassertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The software can reset the bit in order to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode	RW	0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_CLK functional clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 1x 0x1: The number of DSI_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 16x	RW	1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_CLK functional clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_CLK functional clock cycles defined in STOP_STATE _COUNTER is multiplied by 1x 0x1: The number of DSI_CLK functional clock cycles defined in STOP_STATE _COUNTER_IO is multiplied by 4x	RW	1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_CLK function clock to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

Table 10-593. DSI_TIMING2

Address Offset	0x0000 005C		
Physical Address	0x5800 405C 0x5800 905C	**Instance**	DSI1_A DSI1_C
Description	TIMING2 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL[0] IF_EN is set to '1'. It is used to indicate the number of DSI_FCLK clock cycles for the timer LP_RX_TIMER and the number of BYTE_CLK functional clock cycles for the timer HS_TX_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_TX_TO	HS_TX_TO_X64	HS_TX_TO_X16	HS_TX_TO_COUNTER													LP_RX_TO	LP_RX_TO_X16	LP_RX_TO_X4	LP_RX_TO_COUNTER												

Bits	Field Name	Description	Type	Reset
31	HS_TX_TO	Enables the HS TX timer. 0x0: Time-out counter is disabled. 0x1: Time-out counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0
30	HS_TX_TO_X64	Multiplication factor for the number of BYTE_CLK functional clock cycles defined in HS_TX_COUNTER bit field. BYTE_CLK is a high speed transmit byte clock signal generated by the DSI_PHY_DSS_x. 0x0: The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 64x	RW	1
29	HS_TX_TO_X16	Multiplication factor for the number of BYTE_CLK functional clock cycles defined in HS_TX_COUNTER bit 0x0: The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of BYTE_CLK functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x	RW	1
28:16	HS_TX_TO_COUNTER	HS_TX_TIMER counter. It indicates the number of BYTE_CLK function clock for the HS TX timer. The value is from 0 to 8191.	RW	0x1FFF
15	LP_RX_TO	Enables the LP RX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0
14	LP_RX_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x	RW	1
13	LP_RX_TO_X4	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x	RW	1
12:0	LP_RX_TO_COUNTER	LP_RX_TIMER counter. It indicates the number of DSI_FCLK clock for the LP RX timer. The value is from 0 to 8191.	RW	0x1FFF

Table 10-597. DSI_VM_TIMING2

Address Offset	0x0000 0064		
Physical Address	0x5800 4064 0x5800 9064	**Instance**	DSI1_A DSI1_C
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				WINDOW_SYNC				VSA								VFP								VBP							

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27:24	WINDOW_SYNC	Number of BYTE clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchornization on video port is not inside the window. DSI does not change its own timings if the synch is inside the window. The valid values are from 4 to 15.	RW	0x0

Bits	Field Name	Description	Type	Reset
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.(1)	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

(1) In DSI video mode, if the VSA bit field in DSI_VM_TIMING2 is set to 0x0, no vertical synchronization packet will be sent, even if VP_VSYNC_START is set to 0x1 in DSI_CTRL.

Address Offset	0x0000 006C		
Physical Address	0x5800 406C 0x5800 906C	**Instance**	DSI1_A DSI1_C
Description	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register shall not be modified while DSI_CTRL.IF_EN is set to '1'.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DDR_CLK_PRE								DDR_CLK_POST							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:8	DDR_CLK_PRE	Indicates the number of TXBYTECLKHS clock cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.	RW	0x01
7:0	DDR_CLK_POST	Indicates the number of TXBYTECLKHS clock cycles after the de-assertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to '1' since the DDR clock is always present.	RW	0x01

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0000
17	LP_BUSY	Indicates when there are still pending operations for VCs configured for LP mode. Forced to 1 when at least one VC is enabled and configured for LP mode. Read 0x0: LP logic is idle Read 0x1: LP logic is active	R	0
16	HS_BUSY	Indicates when there are still pending operations for VCs configured for HS mode. Forced to 1 when at least one VC is enabled and configured for HS mode. Read 0x0: HS logic is idle Read 0x1: HS logic is active	R	0
15:10	RESERVED		R	0x00

Bits	Field Name	Description	Type	Reset
9	LANE5_ULPS_SIG2	Enables the ULPS for the lane 5. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 5 is a data lane. The state of the signal TxUlpsClk is changed if lane 5 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
8	LANE4_ULPS_SIG2	Enables the ULPS for the lane 4. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 4 is a data lane. The state of the signal TxUlpsClk is changed if lane 4 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
7	LANE3_ULPS_SIG2	Enables the ULPS for the lane 3. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 3 is a data lane. The state of the signal TxUlpsClk is changed if lane 3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0

Bits	Field Name	Description	Type	Reset
6	LANE2_ULPS_SIG2	Enables the ULPS for the lane 2. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 2 is a data lane. The state of the signal TxUlpsClk is changed if lane 2 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
5	LANE1_ULPS_SIG2	Enables the ULPS for the lane 1. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxRequestEsc is changed if lane 1 is a data lane. The state of the signal TxUlpsClk is changed if lane 1 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc.	RW	0
4	LANE5_ULPS_SIG1	Enables the ULPS for the lane 5. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane 5 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc	RW	0

Bits	Field Name	Description	Type	Reset
3	LANE4_ULPS_SIG1	Enables the ULPS for the lane 4. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane 4 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc	RW	0
2	LANE3_ULPS_SIG1	Enables the ULPS for the lane 3. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane 3 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc	RW	0
1	LANE2_ULPS_SIG1	Enables the ULPS for the lane 2. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane 2 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective. WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc	RW	0
0	LANE1_ULPS_SIG1	Enables the ULPS for the lane 1. The hardware shall change the state of the lane to ULPS only when it is in stop state and there is no data pending inside the DSI protocol engine and the DSI protocol engine has control of the bus (BTA has not been sent). The state of the signal TxULPSExit is changed if the lane 1 is a clock lane. There will be a latency depending on the frequency of TxClkExc. This bit should be read back to confirm a write has been effective. 0x0: READ: Inactive state effective. WRITE: Request to change to inactive state 0x1: READ: Active state effective WRITE: Change request to active. If the lane is a data lane, TxRequestEsc is asserted and synchronously TxUlpsEsc is asserted for one period of TxClkEsc	RW	0

Table 10-619. DSI_VM_TIMING7

Address Offset	0x0000 0090		
Physical Address	0x5800 4090 0x5800 9090	**Instance**	DSI1_A DSI1_C
Description	Defines the minimum number of HS bytes clock cycles that are required to allow for the delays in entering and exiting HS mode. The supported values are from 0 to 65535		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENTER_HS_MODE_LATENCY																EXIT_HS_MODE_LATENCY															

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_LATENCY	Defines the number of TXBYTECLKHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000
15:0	EXIT_HS_MODE_LATENCY	Defines the number of TXBYTECLKHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TXBYTECLKHS clock from de-assertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

Address Offset	0x0000 0098		
Physical Address	0x5800 4098 0x5800 9098	**Instance**	DSI1_A DSI1_C
Description	Additional control bits for use with Video Port 2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		LINE_BUFFER		VP_VSYNC_POL		VP_HSYNC_POL		VP_DE_POL		VP_CLK_POL		VP_DATA_BUS_WIDTH			RESERVED		VP_CLK_RATIO		RESERVED				

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x00000
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. The valid values are from 0 to DSI_GNQ[23:22] VP2_NB_LINE_BUFFER. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP shall drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP shall drive the data on the pixel clock falling edge.	RW	1

Bits	Field Name	Description	Type	Reset
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	RESERVED		R	0
4	VP_CLK_RATIO	The field indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0
3:0	RESERVED		R	0x0

Table 10-633. DSI_VC_CTRL_i

Address Offset	0x0000 0100 + (0x20 * i)	**Index**	i = 0 to 3
Physical Address	0x5800 4100 + (0x20 * i) 0x5800 9100 + (0x20 * i)	**Instance**	DSI1_A DSI1_C
Description	CONTROL REGISTER - Virtual channel This register controls the virtual channel.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCS_CMD_CODE	DCS_CMD_ENABLE	DMA_RX_REQ_NB				DMA_RX_THRESHOLD			DMA_TX_REQ_NB		RX_FIFO_NOT_EMPTY	DMA_TX_THRESHOLD			TX_FIFO_FULL	VC_BUSY	PP_BUSY	VP_SOURCE	RGB565_ORDER	OCP_DATA_BUS_WIDTH		MODE_SPEED	ECC_TX_EN	CS_TX_EN	BTA_EN	TX_FIFO_NOT_EMPTY	MODE	BTA_LONG_EN	BTA_SHORT_EN	SOURCE	VC_EN

Bits	Field Name	Description	Type	Reset
31	DCS_CMD_CODE	DCS command code value to insert between header and video port or Interface slave data when enabled by DCS_CMD_ENABLE (only when TE mechanism is not used otherwise the bit field DCS_CMD_CODE is ignored by DSI protocol engine). 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted.	RW	0

Bits	Field Name	Description	Type	Reset
30	DCS_CMD_ENABLE	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is NOT inserted when command mode traffic is coming from the Video Port or Interface slave port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port or Interface slave port.	RW	0
29:27	DMA_RX_REQ_NB	Selection of the use of the DMA request (associated to the RX FIFO) 0x0: DMA_req0 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 0) 0x1: DMA_req1 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 1) 0x2: DMA_req2 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 2) 0x3: DMA_req3 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is equal to 3) 0x4: No DMA req selected	RW	0x0
26:24	DMA_RX_THRESHOLD	Defines the threshold value for the DMA request (associated to the RX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
23:21	DMA_TX_REQ_NB	Selection of the use of the DMA request (associated to the TX FIFO) 0x0: DMA_req0 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 0) 0x1: DMA_req1 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 1) 0x2: DMA_req2 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is greater than 2) 0x3: DMA_req3 is selected (valid only if DSI_GNQ[8:6] NB_DMA_REQUEST is equal to 3) 0x4: No DMA req selected	RW	0x0
20	RX_FIFO_NOT_EMPTY	FIFO status in command mode. Otherwise, this bit can be ignored. Read 0x0: The RX FIFO is empty (the FIFO does not contain any data for the virtual channel) Read 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)	R	0
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0

Bits	Field Name	Description	Type	Reset
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored. Read 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) Read 0x1: The TX FIFO is full	R	0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 if VC is enabled. Software should check this bit is 0 before changing channel configuration. Read 0x0: No pending operations for this VC Read 0x1: Pending operations for this VC	R	0
14	PP_BUSY	Ping-pong buffer busy status. Read 0x0: Software is permitted to write a new header for VP command mode traffic. Read 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0
13	VP_SOURCE	Selection between video port 1 and video port 2. If DSI_GNQ[24] NB_VIDEO_PORTS = 0, the bit field is ignored since only video port 1 is present. 0x0: The video port 1 is selected. 0x1: The video port 2 is selected.	RW	0
12	RGB565_ORDER	Byte order for RBG565 0x0: Byte order as for DBI compliance 0x1: Byte order as for video mode	RW	0
11:10	OCP_DATA_BUS_WIDTH	Defines the size of the Interface data bus 0x0: 16-bits data width (LSB of the 32-bit Interface port data bus) 0x1: 24-bits data width (LSB of the 32-bit Interface port data bus) 0x2: 2x16-bits data width (first pixel on the LSB of the 32-bit Interface port data bus and second pixel on the MSB of the 32-bit Interface port data bus for the same Interface access) 0x3: 32-bits data width	RW	0x0
9	MODE_SPEED	Selection of the mode. The information is used by hardware only if MODE=COMMAND_MODE otherwise it is ignored. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High Speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0
8	ECC_TX_EN	Enables the Error Correction Code generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The checksum value is calculated by HW.	RW	0

Bits	Field Name	Description	Type	Reset
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode is used to allow the user to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: Reads: BTA generation is completed. It is reset by hardware when it is completed. Writes: Cancellation of the BTA generation (not guarantee since it could already on going, shall not be used). 0x1: Reads: BTA generation has been requested by user (it could be on going but not completed). Writes: Request for BTA generation.	RW	0
5	TX_FIFO_NOT_EMPTY	FIFO status Read 0x0: The TX FIFO is empty (the FIFO does not contain any data for the virtual channel) Read 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the virtual channel)	R	0
4	MODE	Selection of the mode 0x0: Command mode. 0x1: Video mode. The bit fields MODE_SPEED and SOURCE are not used by hardware. The bit field VP_SOURCE is used to select between video port 1 and video port 2 when two video ports are present.	RW	0
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled	RW	0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled	RW	0
1	SOURCE	Selection of the source between Interface and the Video port(s) (used by the hardware only if MODE=COMMAND MODE (0x0) otherwise it is ignored). The number of available video ports is defined in DSI_GNQ[24] NB_VIDEO_PORTS bit. 0x0: All the data are provided by the slave port. Any transfer on the video port is ignored for this virtual channel. 0x1: If MODE=VIDEO_MODE. the data received on the video port 1 or video port 2, selected using VP_SOURCE (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END for video port 1 and DSI_CTRL2[] VP_HSYNC_START, DSI_CTRL2[] VP_HSYNC_END, DSI_CTRL2[] VP_VSYNC_START, DSI_CTRL2[] VP_VSYNC_END for video port 2) are sent on the virtual channel (only one virtual channel can be associated with the video port, it is the software responsibility to ensure that no more than one virtual channel is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP.STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the Interface slave port.	RW	0

Bits	Field Name	Description	Type	Reset
0	VC_EN	Enables the virtual channel. 0x0: Disabled. The virtual channel shall be disabled for any register change in the DSI_VC_... registers to the corresponding VC ID (except for setting the DSI_VC_CTRL_i[6] BTA_EN, DSI_VC_TE_i[23:0] TE_SIZE and DSI_VC_TE_i[31] TE_START bit fields, and DSI_VC_LONG_,,, DSI_VC_SHORT_..., DSI_VC_IRQ... registers). 0x1: Enabled. No change is allowed to the virtual channel registers expect resetting the VC_EN.	RW	0

Table 10-635. DSI_VC_TE_i

Address Offset	0x0000 0104 + (0x20 * i)	**Index**	i = 0 to 3
Physical Address	0x5800 4104 + (0x20 * i) 0x5800 9104 + (0x20 * i)	**Instance**	DSI1_A DSI1_C
Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TE_START	TE_EN	TE_LINE	TE_LINE_NB	RESERVED				TE_SIZE																							

Bits	Field Name	Description	Type	Reset
31	TE_START	Manual control of the start of the transfer. The user can use the TE interrupt in order to know that the TE trigger has been received prior to set the TE_START bit field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used by user to cancel the transfer if not already started. The FIFO shall be flushed by software to ensure there is no data remaining in it. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer is completed. It is reset by hardware when the transfer is completed.	RW	0
30	TE_EN	Tearing Effect Control 0x0: Disables the automatic transfer. The user shall use the interruption in order to know when TE PHY trigger is received or when the TE is detected on the input CMOS signals. The hardware reset the bit field when the transfer is completed (TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE PHY trigger or one of the TE input signals as a synchronization event. The bit field TE_LINE defines if the CMOS signal is used or if the PHY trigger is used.	RW	0
29	TE_LINE	0x0: Disabled the TE CMOS signaling for the automatic data transfer. The DSI PHY trigger is used for the automatic data transfer. 0x1: Enables the TE CMOS signaling for the automatic data transfer. The DSI PHY trigger is not used for the automatic data transfer.	RW	0
28	TE_LINE_NB	Selection between TE0 and TE1 CMOS signals. 0x0: TE0 CMOS input line is selected 0x1: TE1 CMOS input line is selected	RW	0
27:24	RESERVED		R	0x0
23:0	TE_SIZE	Defines the number of byte (payload data excluding the check -sum) to be sent. The write into the register DSI_VC_LONG_PACKET_HEADER_i shall be performed by the user before sending data from the register DSI_VC_LONG_PACKET_PAYLOAD_i. The register value is decremented for every byte sent of the DSI link. At the end of the transfer (TE_SIZE=0), the bit field TE_EN is reset by hardware. The DMA request will be asserted when the trigger is received in order to receive data in the TX FIFO. It should not be deasserted until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

RESERVED																							PP_BUSY_CHANGE_IRQ	FIFO_TX_UDF_IRQ	ECC_NO_CORRECTION_IRQ	BTA_IRQ	FIFO_RX_OVF_IRQ	FIFO_TX_OVF_IRQ	PACKET_SENT_IRQ	ECC_CORRECTION_IRQ	CS_IRQ

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x000000
8	PP_BUSY_CHANGE_IRQ	Video port ping-pong buffer busy status. PP_BUSY has changed from 1 to 0. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
7	FIFO_TX_UDF_IRQ	FIFO underflow status. The FIFO used on the L3_MAIN interconnect slave port for buffering the data for the virtual channel has underflowed, which means that the data for the current packet have not been received in time because the transfer of the packets is already started (transfer started because the packet size is bigger than space allocated in the FIFO). 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
6	ECC_NO_CORRECTION_IRQ	ECC error status (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
5	BTA_IRQ	Virtual channel - BTA status. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
4	FIFO_RX_OVF_IRQ	FIFO overflow error status. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the DSI link for the virtual channel has overflowed. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
3	FIFO_TX_OVF_IRQ	FIFO overflow error status. The FIFO used on the L3_MAIN interconnect slave port for buffering the data for the virtual channel has overflowed. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Bits	Field Name	Description	Type	Reset
2	PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
1	ECC_CORRECTION_IRQ	Virtual channel – ECC has been used to correct the only 1-bit error status (short and long packet). 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0
0	CS_IRQ	Virtual channel – Checksum mismatch status 0x0: Reads: Event is false. Writes: Status bit is unchanged. 0x1: Reads: Event is true (pending). Writes: Status bit is reset.	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x000000
8	PP_BUSY_CHANGE_IRQ_EN	Video port ping-pong buffer busy status 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
7	FIFO_TX_UDF_IRQ_EN	FIFO underflow enable. The FIFO used for buffering the data received on the L3_MAIN interface slave port for the virtual channel has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
6	ECC_NO_CORRECTION_IRQ_EN	ECC error (short and long packets). No correction of the header because of more than 1-bit error. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
5	BTA_IRQ_EN	Virtual channel -Bus turn around reception 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
4	FIFO_RX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the DSI link for the virtual channel has overflowed. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
3	FIFO_TX_OVF_IRQ_EN	FIFO overflow enable. The FIFO used on the L3_MAIN interconnect slave port for buffering the data received on the Interface slave port for the virtual channel has overflowed. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
2	PACKET_SENT_IRQ_EN	Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
1	ECC_CORRECTION_IRQ_EN	Virtual channel - ECC has been used to correct the only 1-bit error (short and long packet). 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0
0	CS_IRQ_EN	Virtual channel - checksum of the payload mismatch detection 0x0: Event is masked. 0x1: Event generates an interrupt when it occurs.	RW	0

10.3.6.3.2 DSI PHY Register Description

Table 10-649. DSI_PHY_REGISTER0

Address Offset	0x0000 0000		
Physical Address	0x5800 4200 0x5800 9200	**Instance**	DSI_PHY_DSS_A DSI_PHY_DSS_C
Description	Configuration register for HS mode timings		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_THSPREPARE								REG_THSPRPR_THSZERO								REG_THSTRAIL								REG_THSEXIT							

Bits	Field Name	Description	Type	Reset
31:24	REG_THSPREPARE	REG_THSPREPARE timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: 40 ns + 4 * UI ÷ 85 ns + 6 * UI. UI = Unit Interval, equal to the duration of any HS state on the clock lane. Default value is programmed for 400 MHz.	RW	0x1E
23:16	REG_THSPRPR_THSZERO	REG_THSPREPARE_THSZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: > 145 ns + 10 * UI. Default value is programmed for 400 MHz.	RW	0x48
15:8	REG_THSTRAIL	REG_THSTRAIL timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2. D-PHY specification: > 60 ns + 4 * UI. Default value is programmed for 400 MHz.	RW	0x1D
7:0	REG_THSEXIT	REG_THSEXIT timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2. D-PHY specification: > 100 ns. Default value is programmed for 400 MHz.	RW	0x3A

Table 10-651. DSI_PHY_REGISTER1

Address Offset	0x0000 0004		
Physical Address	0x5800 4204 0x5800 9204	**Instance**	DSI_PHY_DSS_A DSI_PHY_DSS_C
Description	Configuration register for LP mode and HS mode timings		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_TTAGO			REG_TTASURE			REG_TTAGET		REG_CLKINP_SEL	REG_CLKPINP_DIVBY2EN	REG_DCCEN	REG_TLPXBY2					REG_TCLKTRAIL								REG_TCLKZERO							

Bits	Field Name	Description	Type	Reset
31:29	REG_TTAGO	TTA-GO timing in terms of number of TXCLKESC clocks. 0x0: 2 cycles 0x1: 3 cycles 0x2: 4 cycles	RW	0x2

Bits	Field Name	Description	Type	Reset
		0x3: 5 cycles		
		0x4: 6 cycles		
		0x5: 7 cycles		
		0x6: 8 cycles		
		0x7: 9 cycles		
		Default value: 4 cycles		
28:27	REG_TTASURE	TTA-SURE timing in terms of number of TXCLKESC clocks.	RW	0x0
		0x0: 2 cycles		
		0x1: 1 cycles		
		0x2: 3 cycles		
		0x3: 4 cycles		
		Default value: 2 cycles		
26:24	REG_TTAGET	TTA-GET timing in terms of number of TXCLKESC clocks.	RW	0x2
		0x0: 3 cycles		
		0x1: 4 cycles		
		0x2: 5 cycles		
		0x3: 6 cycles		
		0x4: 7 cycles		
		0x5: 8 cycles		
		0x6: 9 cycles		
		0x7: 10 cycles		
		Default value: 5 cycles		
23	REG_CLKINP_SEL	0x0: Default Selects DCC Output	RW	0x0
		0x1: Selects Divby2 Output		
22	REG_CLKPINP_DIVBY2EN	0x0: Default	RW	0x0
		0x1: Enables DivBy2 in Clock Input Path		
21	REG_DCCEN	0x0: Default Enables Duty Cycle Corrector	RW	0x1
		0x1: Disable the DCC clock path		
20:16	REG_TLPXBY2	(TLPX)/2 timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2.	RW	0x0A
		Default value is programmed for 400 MHz. This is the internal timer value. The value seen on line will have variance due to rise/fall mismatch effects.		
		Note: TLPX is used to define the length of LP-01 state in HS start of Transmission sequences on clock and data lanes. For all other purposes TLPX is defined by the period of TXLPESC		
15:8	REG_TCLKTRAIL	REG_TCLKTRAIL timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN2DDR/2.	RW	0x1A
		D-PHY specification: > 60 ns.		
		Default value is programmed for 400 MHz		
7:0	REG_TCLKZERO	REG_TCLKZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN2DDR/2.	RW	0x6A
		D-PHY specification: (REG_TCLKPREPARE + REG_TCLKZERO) > 300 ns.		
		Derived specification for REG_TCLKZERO (Min REG_TCLKPREPARE = 38 ns): REG_TCLKZERO > 262 ns.		
		Default value is programmed for 400 MHz

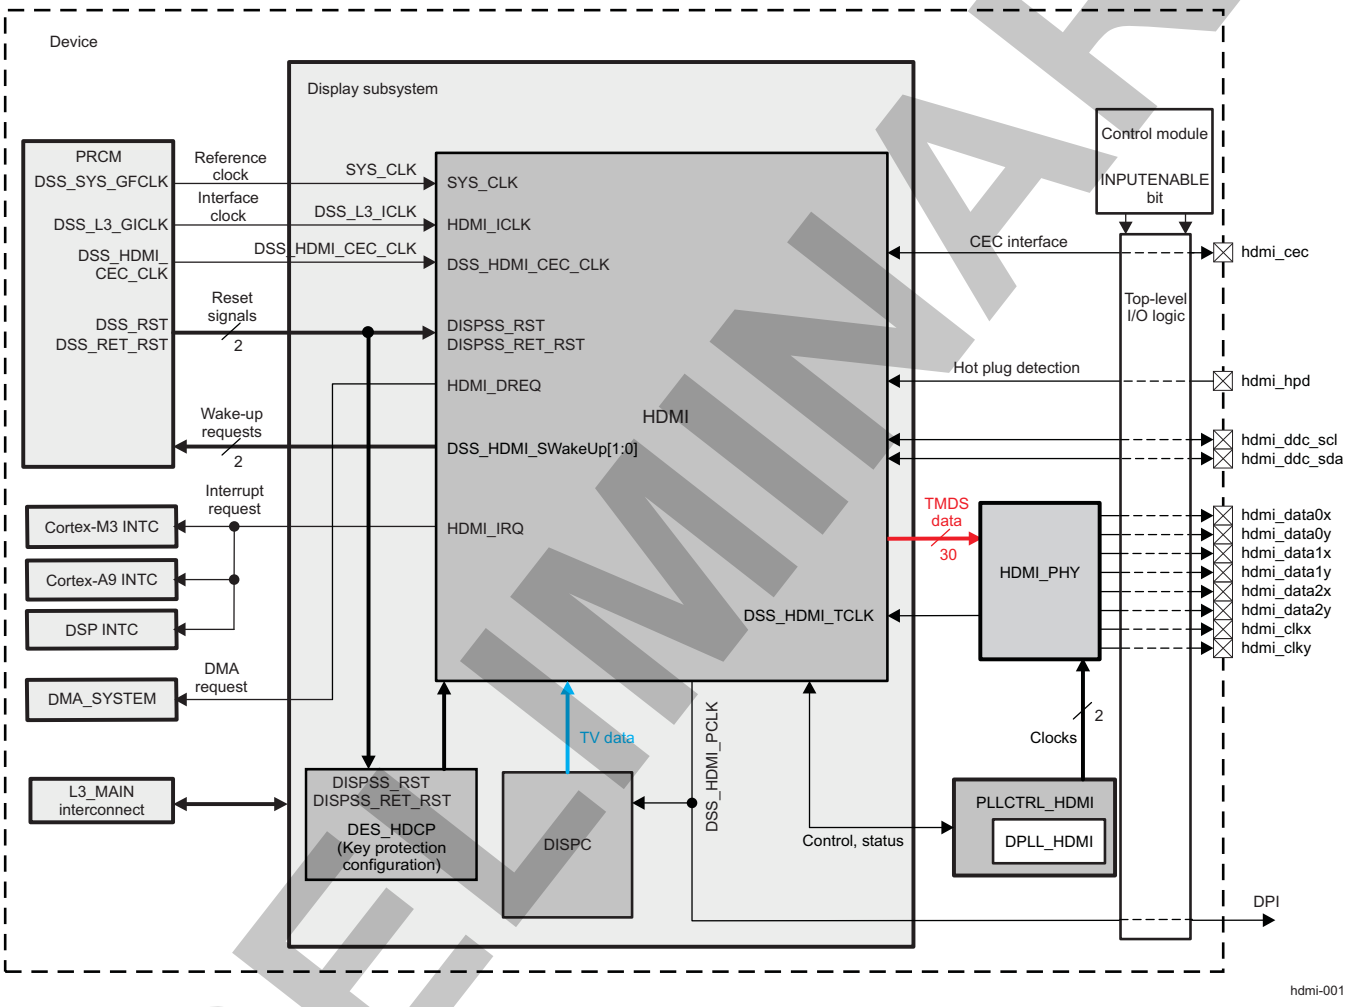
10.4 High-Definition Multimedia Interface

This section introduces the high-definition multimedia interface (HDMI) module and describes its main functions and connections in the device.

10.4.1 HDMI Overview

Figure 10-158 shows an overview of the HDMI module.

Figure 10-158. HDMI Overview



10.4.1.1 HDMI Main Features

The HDMI module provides the following main features:

- HDMI 1.4, HDCP 1.4, and DVI 1.0 compliant
  - Includes support for the 3D stereoscopic frame-packing formats of the HDMI v1.4 standard (1080p24Hz, 720p50Hz, 720p60Hz + side-by-side half structure: 1080p60Hz)
- EIA/CEA-861-D video format support (See Table 10-679 for more information.)
- VESA DMT video format support (See Table 10-680 for more information.)
- Support for deep-color mode:
  - 12-bit and 10 bit per color component deep-color modes up to 1080p @60Hz
- Supports up to 148.5-MHz pixel clock (1920 x 1080p @60Hz)
- Video formats:

- ❑ 24/30/36-bit RGB/YCbCr 4:4:4 (deep color)
- ❑ 16/20/24-bit YCbCr 4:2:2

- Uncompressed multichannel (up to 8 channels) audio (L-PCM) support
- Master I2C interface for display data channel (DDC) connection
- Consumer electronic control (CEC) interface
- Integrated high-bandwidth digital content protection (DES_HDCP) encryption engine to transmit protected audio and video content (authentication performed by software)
- Integrated transition minimized differential signaling (TMDS) and TMDS error reduction coding (TERC4) encoders for data island support
- Integrated TMDS PHY (3 TMDS differential data lanes + TMDS differential clock lane)
  - Up to 2.97 Gbps per lane at (1080p @60Hz at 10 bits/component and 12 bits/component)

10.4.1.2 HDMI Video Formats and Timings

10.4.1.2.1 HDMI CEA-861-D Video Formats and Timings

Table 10-679 presents the video timings supported by the HDMI module, according to the CEA-861-D standard:

Table 10-679. HDMI Video Timings (CEA-861-D)

Refresh Rate	Resolution
24 Hz (Low field rate)	1920 x 1080p
50 Hz	1920 x 1080p 1920 x 1080i 2880 x 576p 2880 x 288p 1440 x 576p 1440 x 288p 1280x720p 720 x 576p
59.94 Hz	1920 x 1080p 1920 x 1080i 1280 x 720p 2880 x 480p 2880 x 240p 1440 x 480p 1440 x 480i 1440 x 240p 720 x 480p 640 x 480p

Table 10-679. HDMI Video Timings (CEA-861-D) (continued)

Refresh Rate	Resolution
60 Hz	1920 x 1080p 1920 x 1080i 2880 x 480p 2880 x 240p 1280 x 720p 1440 x 480p 1440 x 480i 1440 x 240p 1280 x 720p 720 x 576p 720 x 480p 640 x 480p
200 Hz	720 x 576p
239 Hz	720 x 480p
240 Hz	720 x 480p

10.4.1.2.2 HDMI VESA DMT Video Formats and Timings

Table 10-680 presents the video timings supported by the HDMI module, according to the VESA DMT standard. Other various resolutions at 43 up to 120 Hz are also supported not included in Table 10-680.

Table 10-680. HDMI Video timings (VESA DMT)

Refresh Rate	Resolution
60 Hz	640 x 480p 800 x 600p 848 x 480p 1024 x 768p 1280 x 768p 1280 x 800p 1280 x 960p 1280 x 1024p 1360 x 768p 1366 x 768p 1400 x 1050p 1440 x 900p 1680 x 1200p 1680 x 1050p 1792 x 1344p 1856 x 1392p 1920 x 1200p 1920 x 1440p 1920 x 1080p

Table 10-680. HDMI Video timings (VESA DMT) (continued)

Refresh Rate	Resolution
60 Hz (reduced blanking)	1280 x 768p 1280 x 800p 1400 x 1050p 1440 x 900p 1680 x 1050p 1920 x 1200p 2560 x 1600p

10.5 Remote Frame Buffer Interface

This section describes the remote frame buffer interface (RFBI).

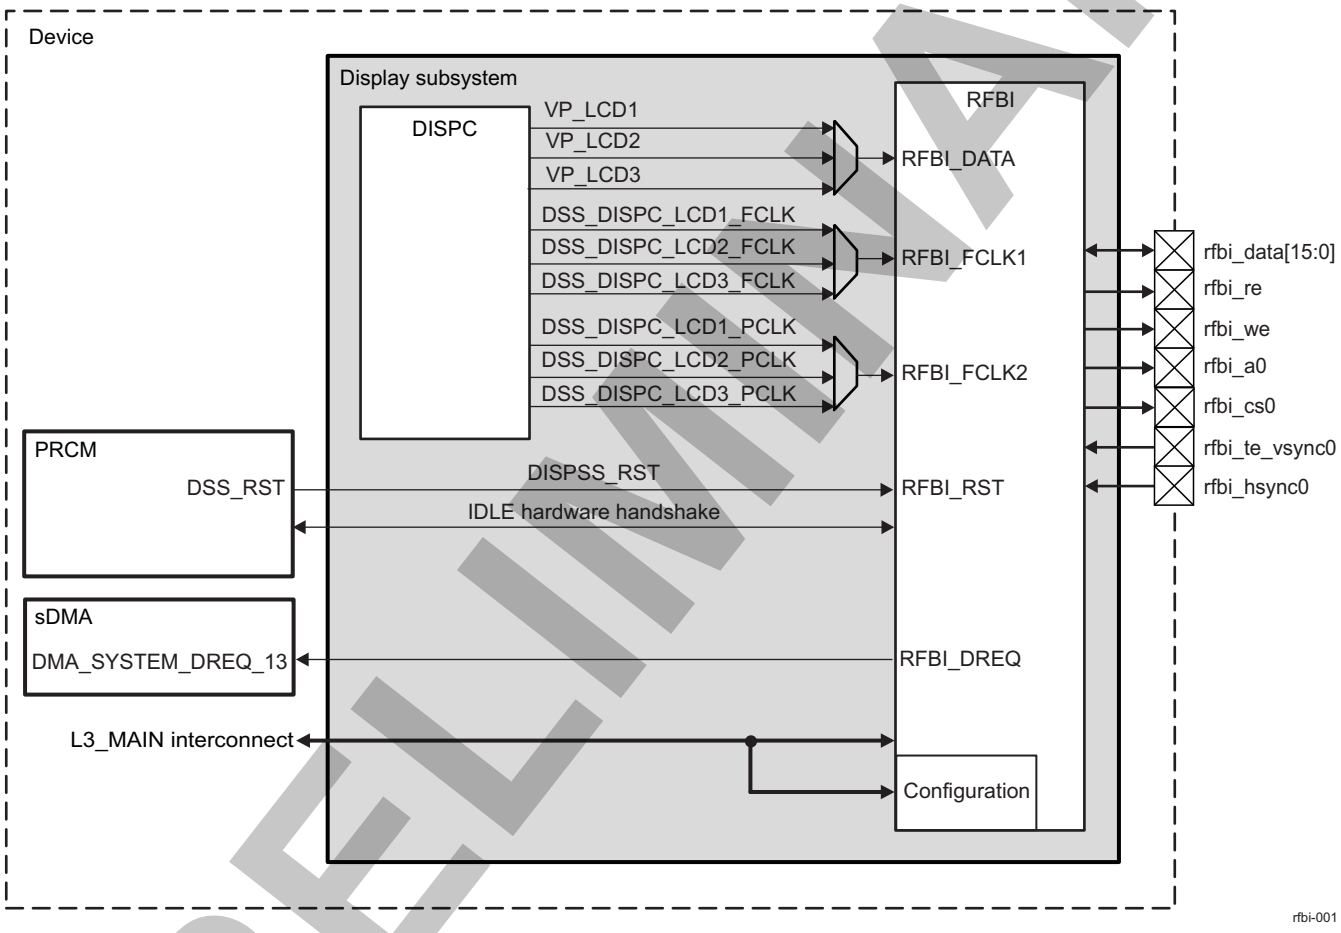
10.5.1 RFBI Overview

The RFBI module is part of the display subsystem that provides the logic to display a picture from the memory frame buffer (SDRAM or SRAM) on an LCD panel.

The RFBI is connected to the L3_MAIN interconnect through the display subsystem local interconnect.

Figure 10-159 shows an overview of the RFBI.

Figure 10-159. RFBI Highlight



The RFBI supports the MIPI DBI protocol with the following features:

- Access to RFB direct MPU interface
  - Sends commands to the RFB panel through the slave port interconnect
  - Sends data, received from the DISPC or from the MPU through the DISPC pixel data bus, to the RFB panel
  - Reads data/status from the RFB to the slave port interconnect
- RFB interface
  - 8-/9-/12-/16-bit parallel interface
  - Three programmable configuration (LCD1, 2, and 3) for an LCD connected to the RFBI
- Data formats
  - Programmable pixel modes (12-/16-/18-/24-bpp modes in RGB format)
  - Programmable output formats on one/multiple cycles per pixel (data from the DISPC and the

L3_MAIN interconnect)

- FIFO
  - One slave port with DMA request and interconnect FIFO of 24 × 32-bit depth (for write access to the RFBI_DATA register only)
  - One video port FIFO of 8 × 24-bit depth receiving data from the DISPC through RFBI_DATA

10.5.2 RFBI Environment

In the display subsystem, data are read by the DISPC from the memory frame buffer (SDRAM, SRAM, IVA-HD SL2, etc.), and sent through the RFBI to the external LCD/RFB.

The DISPC associated with the RFBI implements the MIPI DBI protocol.

The DISPC provides the required control signals to interface the memory frame buffer (SDRAM, SRAM or IVAHD-SL2) directly to the external displays. The RFBI is connected to the memory through the L3_MAIN interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. There is one master port (L3_MAIN interconnect) and one slave port.

The DISPC_CONTROL1[16] GPOUT[1] and DISPC_CONTROL1[15] GPOUT[0] bits control selection of the display subsystem modules (see Table 10-681).

Table 10-681. RFBI I/O Pad Mode Selection

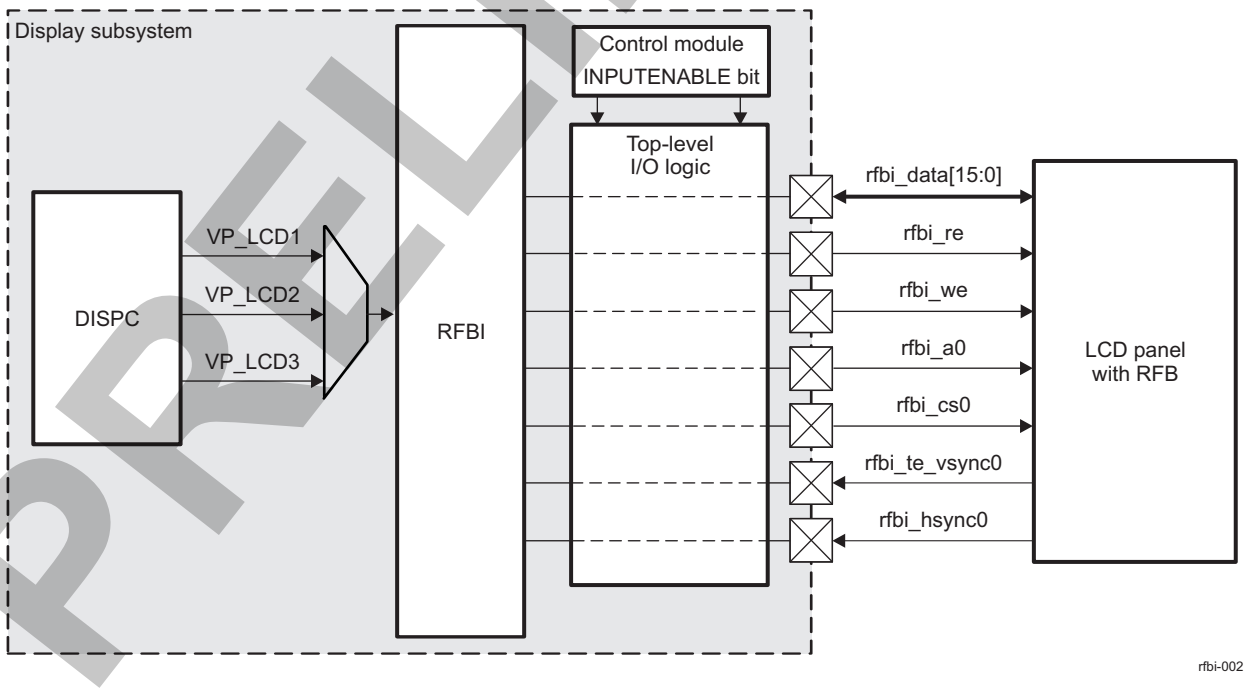
DSS.DISPC_CONTROL[16] GPOUT1	DSS.DISPC_CONTROL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is directly connected to the RFBI of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives data from its slave port or output from the DISPC and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write data from/to the memory in the LCD panel. The RFBI can manage only one LCD panel at a time, although a sequential configuration is also possible.

10.5.2.1 RFBI Parallel Interface (MIPI DBI Protocol)

Figure 10-160 shows the LCD support parallel interface in RFBI mode.

Figure 10-160. RFBI LCD Support Interface



NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers and dedicated IP registers. For more information, see , *Pad Functional Multiplexing and Configuration*, and , *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 10-682 describes the interface signals to/from the LCD panel.

Table 10-682. RFBI LCD Interface Signals

Signal Name	Type[1]	Description
rfbi_data[15:0]	I/O	RFBI I/O data
rfbi_re	O	Read access signal
rfbi_we	O	Write access signal
rfbi_a0	O	Command/data selection signal
rfbi_cs0	O	Chip-select (CS) signal for LCD
rfbi_te_vsync0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
rfbi_hsync0	I	HSYNC from LCD panel

(1) I = Input; O = Output; I/O = Input/Output

- rfbi_data[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

  Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel.
- rfbi_re: The read-enable signal indicates an ongoing read from the embedded memory in the LCD panel. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. The read is used to obtain status/data information from the LCD panel.
- rfbi_we: The write-enable signal indicates an ongoing write. The RFBI registers allow flexible behavior of the write signal (programmable off/on/cycle times and signal polarity).
- rfbi_a0: The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of rfbi_a0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0.
- rfbi_cs0: The signal is the chip-select (CS0) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CS0 must not be changed.

  To select the trigger mode, configure the RFBI_CONFIG[3:2] TRIGGERMODE bit field (0x0: Internal trigger mode with the RFBI_CONTROL[4] ITE bit; 0x1: External trigger mode with the TE signal rfbi_tevsync0; 0x2: External trigger mode with the rfbi_tevsync0 and rfbi_hsync0 signals with the programmable line counter).
- rfbi_te_vsync0 (used by RFBI only if RFBI_CONFIG[3:2] TRIGGERMODE = 0x1 or 0x2; otherwise, this signal is ignored): Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel vertical synchronization (VSYNC) pulse signal. TE logic uses rfbi_te_vsync0 as the synchronization signal to send the pixel to the LCD panel.
- rfbi_hsync0 (used by RFBI only if RFBI_CONFIG[3:2] TRIGGERMODE = 0x2, otherwise, this signal is ignored): The HSYNC pulse signals indicate to the RFBI when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two RFBI_ICLK clock cycles. TE logic uses rfbi_hsync0 as a synchronization signal to send the pixel to the LCD panel.

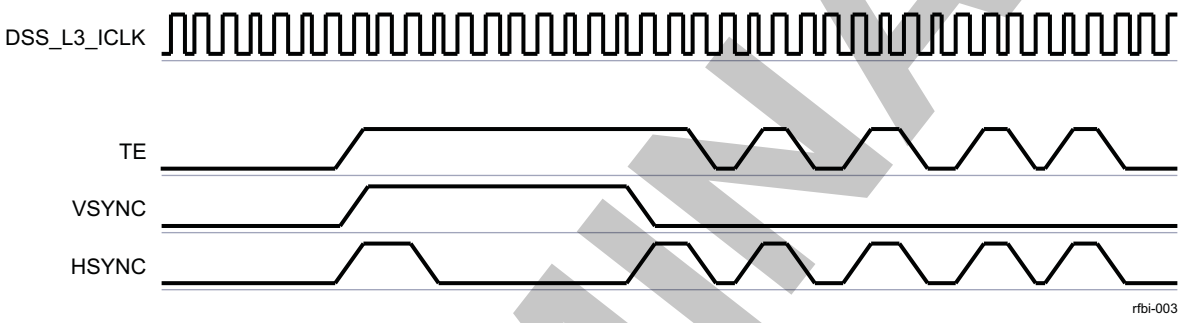
10.5.2.1.1 RFBI Description of the Tearing Effect Pulse Signal

The TE signal can be generated externally by the RFBI depending on the value of the RFBI_CONFIG[3:2] TRIGGERMODE bit field:

- TRIGGERMODE = 0x1: External trigger mode with the TE signal, which corresponds to the rfbi_te_vsync0 pad.
- TRIGGERMODE = 0x2: External trigger mode with the HSYNC/VSYNC signals. The HSYNC signal corresponds to the rfbi_hsync0 pad. The VSYNC signal corresponds to the rfbi_te_vsync0 pad.

The externally generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 10-161). The logical operation (OR or AND) depends on the polarity of the HSYNC and VSYNC signals. The VSYNC signal indicates to the RFBI when vertical synchronization occurs. The HSYNC signal indicates to the RFBI when horizontal synchronization occurs.

Figure 10-161. RFBI External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active High)



- The TE signal is connected to the rfbi_te_vsync0 external pad when the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x1.
- The HSYNC and VSYNC signals are connected to rfbi_hsync0 and rfbi_te_vsync0, respectively, when the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x2.

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the RFBI_VSYNC_WIDTH register. VSYNC is not triggered by an inactive-to-active edge.

HSYNC is detected based on the minimum pulse width defined by the RFBI_HSYNC_WIDTH register. HSYNC is not triggered by an inactive-to-active edge.

The signal is generated from external logic based on VSYNC and HSYNC of the LCD panel. The automatic trigger can be programmed based on the external RFBI_TE signal or use the RFBI_CONTROL[4] ITE bit to start data capture (internal trigger mode).

The polarity of the TE signal is programmable in the RFBI_CONFIG register. HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two RFBI_ICLK clock cycles. Hardware resets the line counter when VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

10.5.2.2 RFBI Transaction Timing Diagrams

Table 10-683 lists the programmable timing fields. Figure 10-162 through Figure 10-164 show timing diagrams of read/write transactions to the LCD panel for the RFBI. In these figures, the polarity 0 (active low) describes the RFBI_A0, RFBI_CSi, RFBI_RE, and RFBI_WE signals.

Table 10-683. RFBI Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	RFBI_ONOFF_TIME[3:0] CSONTIME bit field	CS assertion time from start access time
CSOffTime	RFBI_ONOFF_TIME[9:4] CSOFFTIME bit field	CS deassertion time from start access time

Table 10-683. RFBI Programmable Timing Fields in RFBI Mode (continued)

Timing Name	Register Field	Description
WECycleTime	RFBI_CYCLE_TIME[5:0] WECYCLETIME bit field	The time when A0 becomes valid until write cycle completion
WEOnTime	RFBI_ONOFF_TIME[13:10] WEONTIME bit field	WE assertion delay time from start access time
WEOffTime	RFBI_ONOFF_TIME[19:14] WEOFFTIME bit field	WE deassertion delay time from start access time
RECycleTime	RFBI_CYCLE_TIME[11:6] RECYCLETIME bit field	The time when A0 becomes valid until read cycle completion
REOnTime	RFBI_ONOFF_TIME[23:20] REONTIME bit field	RE assertion delay time from start access time
REOffTime	RFBI_ONOFF_TIME[29:24] REOFFTIME bit field	RE deassertion delay time from start access time
CSPulseWidth	RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH bit field	The time when write cycle time or read cycle time completes

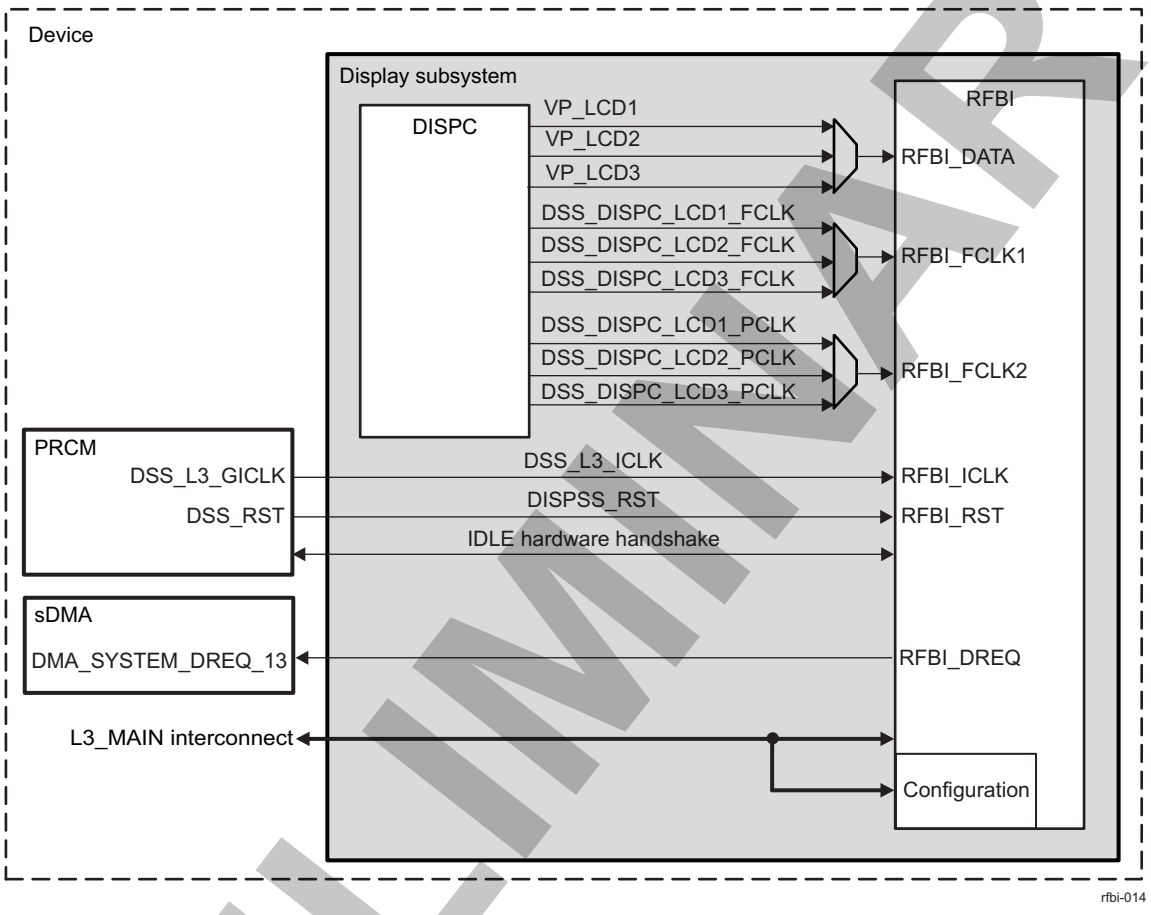
10.5.3 RFBI Integration

This section describes the RFBI integration in the device, including information about clocks, resets, and hardware requests.

Figure 10-165 shows the RFBI module integration.

Figure 10-165. RFBI Integration



NOTE: For more information about the IDLE hardware handshake, see , *Module-Level Clock Management*, in *Chapter 3, Power, Reset, and Clock Management*.

Table 10-684 through Table 10-686 summarize the integration of the module in the device.

Table 10-684. RFBI Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
RFBI	PD_DSS	No	L3_MAIN

Table 10-685. RFBI Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
RFBI	RFBI_FCLK1	DSS_DISPC_LCDx_FCLK	DISPC	Logic clock used by the RFBI when capturing data on the video port and to generate the RFBI_DISPC_STALL signal
	RFBI_FCLK2	DSS_DISPC_LCDx_PCLK	DISPC	Pixel clock used by the RFBI to capture the pixels
	RFBI_ICLK	DSS_L3_MAIN_GICLK	PRCM	L3_MAIN interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

Table 10-686. RFBI Hardware Requests

DMA Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
RFBI	RFBI_DREQ	DSS_SYSTEM_DREQ_13	DMA_SYSTEM	RFBI DMA request. The DMA request can be used to transfer data using the DMA_SYSTEM from memory to the RFBI interconnect slave FIFO. This request is a transition-sensitive (fixed in hardware), active-low request.

10.5.4 RFBI Functional Description

This section describes the functions of the RFBI.

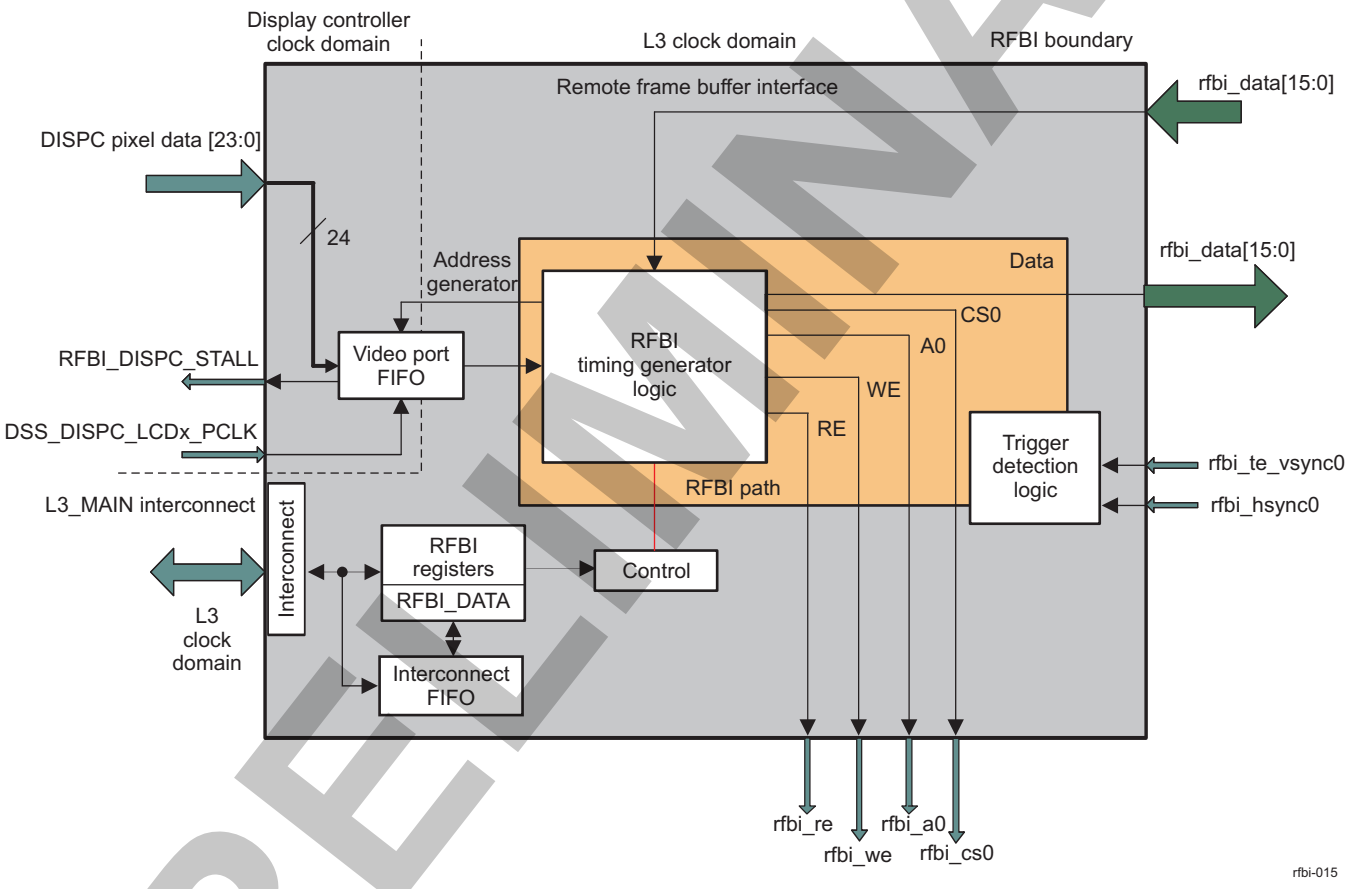
10.5.4.1 RFBI Block Diagram

The RFBI can capture the output pixel from the DISPC and send the data to the RFB in the LCD panel. The application configures the RFBI, sends commands, reads data, and configures the DISPC to send data fetched from the system memory by the DISPC DMA engine. The commands/data are sent using an 8-, 9-, 12- or 16-bit parallel interface.

The DISPC is configured to send the data in 12-, 16-, 18-, or 24-bpp format. In the video port FIFO, the encoded pixel values are in an LSB alignment independent of the endianness in system memory.

Figure 10-166 is an overview of the RFBI architecture.

Figure 10-166. RFBI Architecture Overview



10.5.4.2 RFBI Clock Configuration

The RFBI functional clocks (RFBI_FCLK1 and RFBI_FCLK2) are provided internally to the display subsystem by the DISPC. For more information about the DISPC clocks, see DISPC Clock Configuration, in *Display Controller*.

10.5.4.3 RFBI Software Reset

To perform a software reset, set the RFBI_SYSCONFIG[1] SOFTRESET bit to 1. The RFBI_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the RFBI_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing any RFBI operation.

10.5.4.4 RFBI Power Management

Table 10-687 describes the power-management features available for the RFBI.

NOTE: For information about source clock gating description, see , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 10-687. RFBI Local Power Management Features

Feature	Registers	Description
Clock autogating	RFBI_SYSCONFIG[0] AUTOIDLE bit	This bit allows a local power optimization inside the module by gating functional clocks (RFBI_FCLK1, RFBI_FCLK2) and interface clock (RFBI_ICLK) upon the internal activity.
Slave idle modes	RFBI_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle. For more information, see below.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

As shown in Table 10-687, the RFBI supports the no-idle, force-idle, and smart-idle modes.

The conditions of assertion of the SIdleAck signal are:

- No-idle mode: SIdleAck is never asserted.
- Force-idle mode: SIdleAck is asserted unconditionally after one RFBI_ICLK clock cycle delay with respect to assertion of IdleReq.
- Smart-idle mode: SIdleAck is asserted when the following conditions are satisfied: The RFBI stops using the RFBI_ICLK clock and all data have been sent to the RFB (LCD panel).

Once SIdleAck signal is asserted:

- The RFBI_ICLK (driven from DSS_L3_MAIN_ICLK) clock can shut down at any time.
- Any transaction on the RFBI configuration port is ignored

The conditions of deassertion of the SIdleAck signal are:

- Force-idle mode: SIdleAck is deasserted after one RFBI_ICLK clock cycle delay with respect to deassertion of IdleReq.
- Smart-idle mode: SIdleAck is deasserted after one RFBI_ICLK clock cycle delay with respect to deassertion of IdleReq.

Once SIdleAck is released, the RFBI is fully operational (guaranteed only in the case of the smart-idle mode).

10.5.4.5 RFBI Interrupt Requests

The RFBI does not generate interrupts but the following DISPC interrupts can be enabled depending on which LCD output of DISPC is currently used to connect to the RFBI:

- FRAMEDONE1_IRQ
- PROGRAMMEDLINENUMBER_IRQ
- GFXFIFOUNDERFLOW_IRQ
- GFXENDWINDOW_IRQ
- PALETTEGAMMALOADING_IRQ
- OCPERROR_IRQ
- VID1FIFOUNDERFLOW_IRQ

- VID1ENDWINDOW_IRQ
- VID2FIFOUNDERFLOW_IRQ
- VID2ENDWINDOW_IRQ
- SYNCLOST1_IRQ
- WAKEUP_IRQ
- SYNCLOST2_IRQ
- VID3FIFOUNDERFLOW_IRQ
- VID3ENDWINDOW_IRQ
- FRAMEDONE2_IRQ

NOTE: For more information about DISPC interrupts, see DISPC Overview, in Chapter 10,*Display Controller*.

The other DISPC interrupts are not used in the RFBI.

10.5.4.6 RFBI DMA Requests

Table 10-688 lists event flags and their mask that can cause RFBI DMA requests.

Table 10-688. RFBI DMA Requests Events

DMA Request Name	DMA Request Mask	Map to	Description
RFBI_DREQ	RFBI_CONTROL[7] DISABLE_DMA_REQ	DSS_SYSTEM_DREQ_13	DMA request used to transfer data using the DMA_SYSTEM from memory to the RFBI interconnect FIFO

NOTE: For more information about DMA requests, see Figure 10-173.

10.5.4.7 RFBI Video Port FIFO

10.5.4.7.1 RFBI Video Port Description

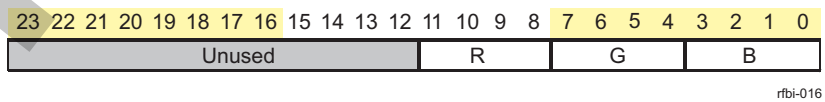
The input video port FIFO receives data from the DISPC at the pixel clock. The data in the video port FIFO are read by the RFBI and sent to the LCD panel. The video port FIFO is 24-bits wide and each pixel in 12-, 16-, 18-, and 24-bpp format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 10.5.4.9, *RFBI Output Parallel Modes*, provides examples of various output configurations based on the interface width (up to 16 bits) and pixel format output (up to 24 bits). Setting the RFBI_CONTROL[1] RFBIMODE bit to 0 directs the MPU to send commands, parameters, and data from the input video port FIFO.

10.5.4.7.2 RFBI Input Formats

The encoded pixel formats supported at the RFBI input interface connected to the DISPC are: RGB12-444, RGB16-565, RGB18-666, and RGB24-888. This input data width is controlled by the RFBI_CONFIG[6:5] DATATYPE bit field.

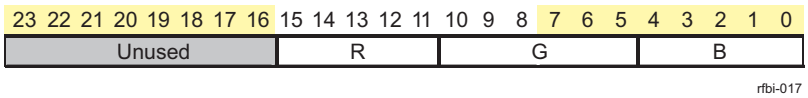
The following graphics describe the bit representation of each format in the video port FIFO. The output of the DISPC is aligned on the LSB of the interface. The pixels are then formatted in accordance with the configuration of the output interfaces (multiple cycles). For more information, see Section 10.5.4.9.1, *Cycle Mode Selection*.

- RGB12-444 format:

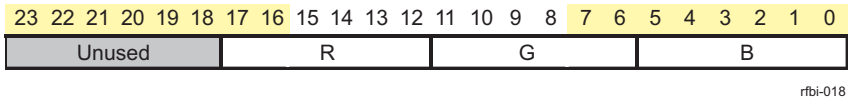


rfbi-016

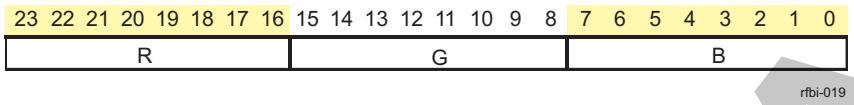
- RGB16-565 format:



- RGB18-666 format:



- RGB24-888 format:



NOTE: These pixel formats are also supported when data are provided from the slave port interconnect (for writing parameters).

10.5.4.7.3 RFBI Stall Mechanism

The stall signal (RFBI_DISPC_STALL) is generated by the video port FIFO to indicate when the DISPC must stop sending data on the corresponding LCD output interface. This stall signal is used for all three LCD outputs only when the DISPC is configured in stall mode. The stall mode is activated by setting the DISPC_CONTROLo[11] STALLMODE for the three LCD outputs.

NOTE: When the DISPC is configured in stall mode, the minimum transfer size is 1 byte.

The RFBI_DISPC_STALL signal allows the RFBI to reformat the data.

RFBI_DISPC_STALL is asserted when at least one of the following cases occurs:

- Default status when there is no data to capture from the DISPC
- High FIFO threshold reached
- End of transfer (number of data to output)
- RFBI reset
- RFBI_CONTROL[0] ENABLE bit reset to 0x0

RFBI_DISPC_STALL is deasserted when the RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occurs:

- Low FIFO threshold reached
- External TE occurs and the RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x1 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- RFBI_CONTROL[4] ITE bit set to 0x1 by users (start of transfer, the FIFO pointers are reset, the FIFO is empty)

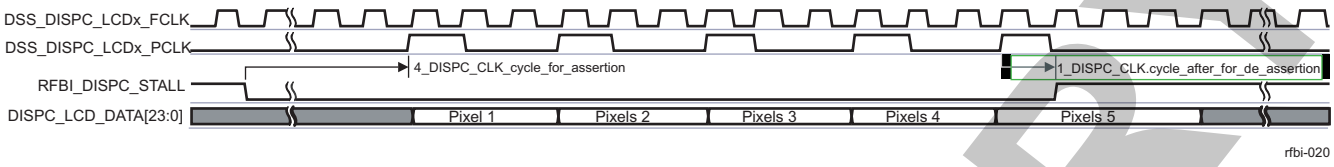
NOTE: This stall mechanism is also used by the DSI protocol engines. When multiple modules are connected to the same LCD output (RFBI and DSI protocol engines), the STALL signals from the modules are merged into a single DSS_DISPC_LCDx_DATA_STALL signal inside the display subsystem. Only one signal for each LCD output is connected to the DISPC (three signals total for the three LCD outputs). In that case, only one module can control the STALL assertion/deassertion. The module that is not using the LCD output interface at that time is not disturbed because the STALL signal is asserted/deasserted by another module. For more information, see Chapter 10, *Display Subsystem* .

The RFBI asserts the STALL signal to stop data output by the DISPC. It is deasserted to indicate when new data must be output by the DISPC.

10.5.4.7.3.1 RFBI Data Stall Diagram Without DMA Buffer Handshake

Figure 10-167 shows the RFBI data stall diagram when the DISPC_DIVISOR[7:0] PCD bit field is set to 3.

Figure 10-167. RFBI Data Stall Signal Diagram With PCD = 3

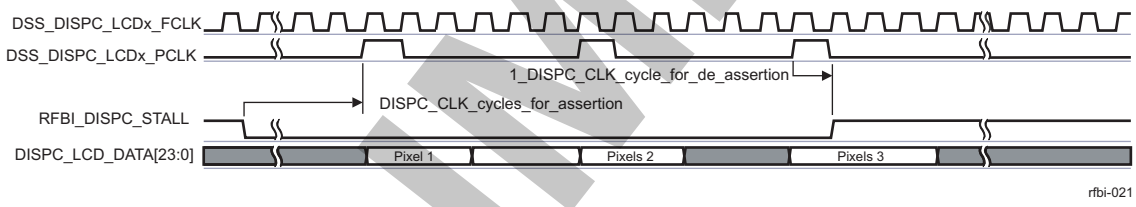


10.5.4.7.3.2 RFBI Data Stall Diagram With DMA Buffer Handshake

To avoid underflow of the DMA buffer, the DMA buffer handshake feature can be enabled by setting the DISPC_CONFIGo[16] BUFFERHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI requests data and there is not enough data in the DISPC DMA buffer. This feature must be enabled only when the stall mode is used (DISPC_CONTROLo[11] STALLMODE bit set to 1).

When the DMA buffer handshake feature is activated, the pixel transfer to the RFBI during STALL inactivity period can be stopped (no DSS_DISPC_LCDx_PCLK pulse) and restarted when there is enough data in the DMA buffer. The DMA buffer handshake ensures that underflow cannot occur for the pipelines associated with the LCD output in stall mode. Figure 10-168 shows the RFBI data stall with the DMA buffer handshake mode activated (PCD = 3).

Figure 10-168. RFBI Data Stall Signal Diagram With Handshake With PCD = 3



10.5.4.8 RFBI Interconnect FIFO

10.5.4.8.1 RFBI Description

The interconnect FIFO receives the data from RFBI_DATA write requests to the slave port interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The interconnect FIFO is 32-bits wide. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA). The address of the RFBI_DATA register is used to access the interconnect FIFO. The RFBI_DREQ DMA request can be used to transfer data using the DMA_SYSTEM from memory to the interconnect FIFO.

10.5.4.8.2 RFBI Using DMA Request With Interconnect FIFO

10.5.4.8.2.1 RFBI Threshold for DMA Request Generation

The RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field defines the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register RFBI_DATA. The DMA_SYSTEM configuration regarding the size of the burst depends on the value of the RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field. The supported values are 4 × 32, 8 × 32, and 16 × 32. For example, when 4 words of 32 bits are set for the threshold, the DMA_SYSTEM sends a burst of 4 × 32 bits only. The DMA_SYSTEM receives the DMA request and is in charge of providing the correct number of bytes.

10.5.4.8.2.2 RFBI Disabling DMA Request

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes slave port requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the slave port request.

If the RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated and the threshold value is ignored.

NOTE: Software users can access the RFBI_DATA location without using the DMA request and without programming the high threshold value (backward compatibility mode).

10.5.4.8.2.3 RFBI Smart DMA Request Mode

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is reset (smart DMA mode disabled), the DMA request is asserted and deasserted depending on the interconnect FIFO space even if MIdlereq is high in smart-idle/no-idle mode and the entire burst gets error responses from the RFBI. The RFBI waits for a free entry in the interconnect FIFO to accept the burst request.

If the RFBI_CONTROL[8] SMART_DMA_REQ bit is set (smart DMA mode enabled), the DMA request is deasserted after two RFBI_ICLK clock cycles, if it has been asserted for more than or equal to two RFBI_ICLK clock cycles and MIdlereq is high in smart-idle or no-idle mode. If asserting time is less than two RFBI_ICLK clock cycles, no more burst requests are accepted even if space is available in the interconnect FIFO.

10.5.4.9 RFBI Output Parallel Modes

10.5.4.9.1 RFBI Cycle Mode Selection

The RFBI_CONFIG[10:9] CYCLEFORMAT bit field defines the number of cycles to output a pixel. The number of cycles determines the number of registers used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface. The data are formatted based on the configuration of the RFBI_DATA_CYCLEi registers.

- One cycle: RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 0x00 and the RFBI_DATA_CYCLE1 register
- Two cycles: RFBI_CONFIG [10:9] CYCLEFORMAT bit field = 0x01 and the RFBI_DATA_CYCLE1 and RFBI_DATA_CYCLE2 registers
- Three cycles: RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 0x10 and the RFBI_DATA_CYCLE1, RFBI_DATA_CYCLE2, and RFBI_DATA_CYCLE3 registers

Figure 10-169 through Figure 10-172 list the bits position of the pixel during the cycles for an 8-, 9-, and 16-bit parallel output, respectively.

Figure 10-171. 12-Bit Interface Settings

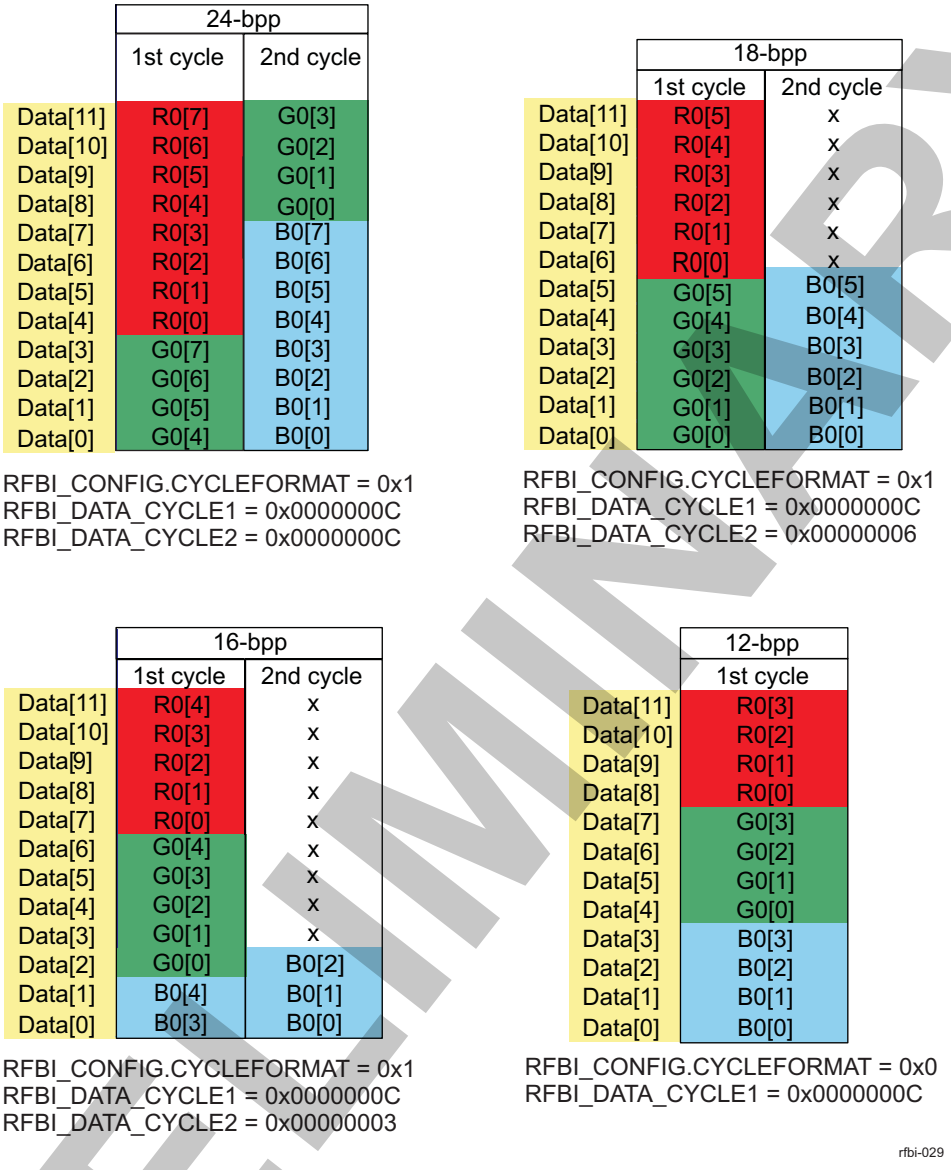

Figure 10-172. 16-Bit Interface Settings

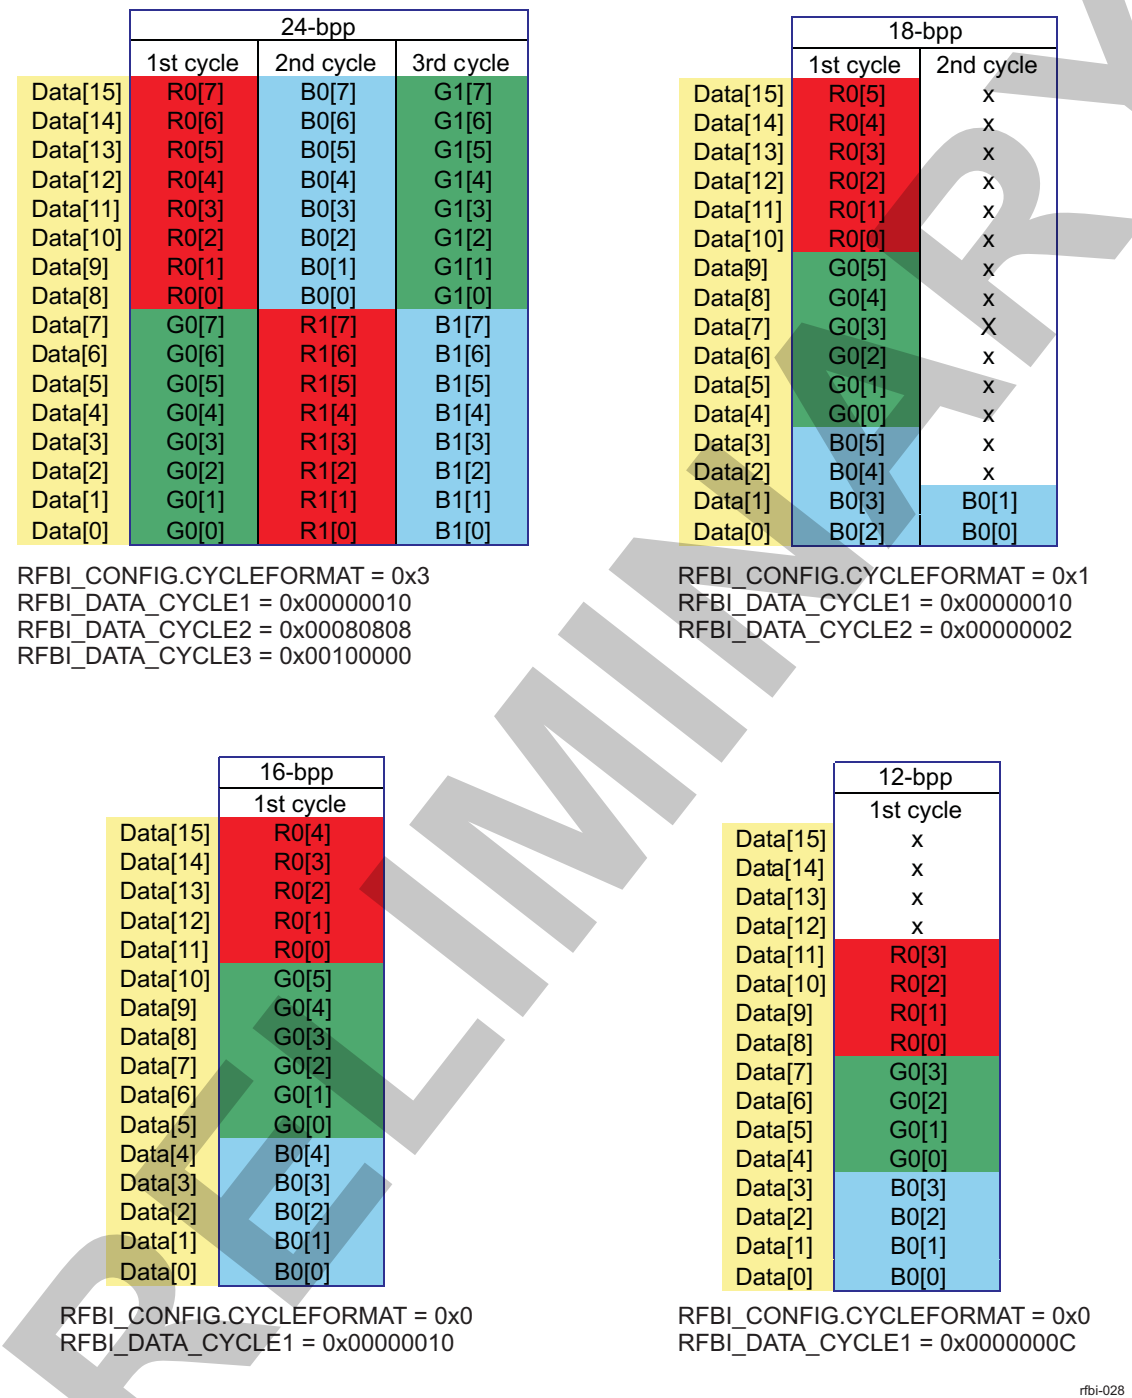

10.5.4.9.2 RFBI Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization). Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The RFBI_CONFIG[12:11] UNUSEDBITS bit field is used.

10.5.4.9.3 RFBI Number of Pixels to Transfer

The RFBI_PIXEL_CNT[31:0] PIXELCNT bit field indicates the number of pixels to be transferred to the LCD panel. The value can be changed only when the RFBI_CONTROL[0] ENABLE bit is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the RFB. When the RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the RFBI_PIXEL_CNT register, and the current value in the register is a not 0 (the remaining number of pixels to transfer), the ongoing transfer is aborted.

10.5.4.10 RFBI Timing Generator

10.5.4.10.1 RFBI Configuration Selection

The RFBI_CONTROL[3:2] CONFIGSELECT bit field selects the chip-select.

10.5.4.10.2 RFBI Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WE signal), RE (RFBI_RE signal), and CS0 (RFBI_CS0 signal) is programmable.

Table 10-689 describes the read/write function.

Table 10-689. RFBI Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WE)	RE (RFBI_RE)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 10-690, is required to keep the RFBI_CS0 signal asserted between write transfers of multiple pixels.

Table 10-690 lists the minimum cycle time for RFBI_CS0, depending on the source of pixels (DISPC or slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, or 1 pixel/3 cycles).

Table 10-690. RFBI Minimum Cycle Time for CS0/WE Always Asserted

RFBI Performance	RFBI_CONFIG[10:9] CYCLEFORMAT	RFBI_CONFIG[8:7] PORTFORMAT	Minimum Cycle Time (in Number of RFBI_ICLK Clock Cycles)
Slave port interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
DISPC	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixel/3 cycles	N/A	6

10.5.4.10.3 RFBI State-Machine

The RFBI_A0, RFBI_RE, and RFBI_WE signals are asserted and deasserted based on the register accessed (RFBI_CMD, RFBI_PARAM, RFBI_DATA, RFBI_READ, or RFBI_STATUS). (See Table 10-689.) When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the RFBI_DATA register only.

- Command register

  Write one command at a time by writing through the slave port interconnect into the RFBI_CMD register. If the previous command is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new command is stalled.

- Parameter register

  Write one parameter at a time by writing in the RFBI_PARAM register.

  If the previous parameter is not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and access to writing a new parameter is stalled.

- Data register

  Write one or two pixels at a time by writing in the RFBI_DATA register.

  The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the RFBI_CONFIG[8:7] PORTFORMAT bit field indicates the number of pixels for each slave port access to the register and the order of the pixels.

  If the previous data are not processed, the RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, access is not stalled.

- Read/status register

  Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the RFBI_READ or RFBI_STATUS registers. In this case, the RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.

  When the RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

10.5.4.10.4 RFBI Timings

The timing registers can be accessed only when there is no transaction in progress (based on the value of the RFBI_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the RFBI_CONFIG[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. See Table 10-691 for the configuration values of the timing bits.

- Chip-select assertion/deassertion time (CSOnTime/CSOffTime)

  RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
  RFBI_ONOFF_TIME[3:0] CSONTIME bit field

  The chip-select deassertion time from the start access time is programmable:
  RFBI_ONOFF_TIME[9:4] CSOFFTIME bit field

CAUTION

Configuring RFBI_ONOFF_TIME[3:0] CSONTIME = RFBI_ONOFF_TIME[9:4] CSOFFTIME = 0 is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width (CSPulseWidth)

The total chip-select pulse width is the time when write cycle time or read cycle time completes and is programmable:
RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH bit field

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

– The RFBI_CYCLE_TIME[19] RRENABLE bit: Read-to-read access
– The RFBI_CYCLE_TIME[20] WWENABLE bit: Write-to-write access
– The RFBI_CYCLE_TIME[18] RWENABLE bit: Read-to-write access
– The RFBI_CYCLE_TIME[21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select CS0 is activated by setting the RFBI_CONTROL[3:2] CONFIGSELECT bit field to 0x1.

- Access time

  Access time is the time delay between A0 assertion to data sampling before RE signal deassertion; access time is programmable:
  RFBI_CYCLE_TIME[27:22] ACCESSTIME bit field

  When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (RFBI_ONOFF_TIME[29:24] REOFFTIME).

- Write-enable cycle time (WECycleTime)

  The total write-enable cycle time is the time when A0 becomes valid until write cycle completion; the write-enable cycle time is programmable:
  The RFBI_CYCLE_TIME[5:0] WECYCLETIME bit field

- Write-enable assertion/deassertion time (WEOnTime/WEOffTime)

  The WE assertion delay time from start access time is programmable:
  RFBI_ONOFF_TIME[13:10] WEONTIME bit field

  The WE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[19:14] WEOFFTIME bit field

- Read-enable cycle time (RECycleTime)

  The total read-enable cycle time is the time when A0 becomes valid until read cycle completion; the read-enable cycle time is programmable:
  The RFBI_CYCLE_TIME[11:6] RECYCLETIME bit field

- Read-enable assertion/deassertion time (REOnTime/REOffTime)

  The RE assertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[23:20] REONTIME bit field

  The RE deassertion delay time from the start access time is programmable:
  RFBI_ONOFF_TIME[29:24] REOFFTIME bit field

At cycle time completion (read access or write access), all control signals (RFBI_CS0, RFBI_WE, and RFBI_RE) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to CS0 is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH bit field = 0), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS0, RFBI_WE, and RFBI_RE) stay asserted. This applies only to write-to-write access combination. In case of read-to-write, read-to-read, or write-to-read sequences, the RFBI_CS0, RFBI_WE, and RFBI_RE signals are always deasserted.

Table 10-691 lists the configuration values for each timing bit.

Table 10-691. RFBI Timings Configuration

Timing Configuration Bits	Granularity[1]	
	One	Two
RFBI_ONOFF_TIME[3:0] CSONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[9:4] CSOFFTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH	0 to 63	0 to 126
RFBI_CYCLE_TIME[27:22] ACCESSTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[5:0] WECYCLETIME	0 to 63	0 to 126
RFBI_ONOFF_TIME[13:10] WEONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[19:14] WEOFFTIME	0 to 63	0 to 126
RFBI_CYCLE_TIME[11:6] RECYCLETIME	0 to 63	0 to 126
RFBI_ONOFF_TIME[23:20] REONTIME	0 to 15	0 to 30
RFBI_ONOFF_TIME[29:24] REOFFTIME	0 to 63	0 to 126

(1) Number of RFBI_ICLK clock cycles. The granularity can be configured using the RFBI_CONFIG[4] TIMEGRANULARITY bit.

10.5.4.11 RFBI Trigger Detection Logic

10.5.4.11.1 RFBI Trigger Mode

Setting the RFBI_CONFIG[3:2] TRIGGERMODE bit field configures the different trigger modes:

- Internal trigger mode with the internal programmable RFBI_CONTROL[4] ITE bit
- External trigger mode with the external TE signal (RFBI_TE_VSYNC)
- External trigger mode with the external VSYNC/HSYNC signals

10.5.4.11.2 RFBI Internal Trigger Mode

10.5.4.11.2.1 RFBI ITE Bit

Set the RFBI_CONTROL[4] ITE bit to start capturing the data from the DISPC. The DISPC must be configured in the RFBI mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (RFBI_CONFIG[3:2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the RFBI_CONTROL[4] ITE bit to be ignored. The chip-select CS0 must be selected (RFBI_CONTROL[3:2] CONFIGSELECT set to 0x1) when this bit is set by users.

10.5.4.11.3 RFBI External Trigger Mode

There are two external trigger modes:

- TE only: VSYNC and HSYNC are merged by logical OR operation and are detected through VSYNC and HSYNC pulse widths.
- HSYNC/VSYNC: This mode uses the two external signals, which are detected through VSYNC and HSYNC pulse widths.

10.5.4.11.3.1 RFBI Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines programmed by the user in the RFBI_LINE_NUMBER[10:0] LINENUMBER bit field (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

10.5.4.11.3.2 RFBI VSYNC Pulse Width (Minimum Value)

The RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of RFBI_ICLK clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in HSYNC/VSYNC mode on the two separate input lines.

- The VSYNC pulse width must be equal to at least two RFBI_ICLK clock cycles when HSYNC is not present (TE trigger mode only).
- The VSYNC pulse width must be equal to at least four RFBI_ICLK clock cycles when HSYNC is present (TE trigger mode only).

10.5.4.11.3.3 RFBI HSYNC Pulse Width (Minimum Value)

The RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of RFBI_ICLK clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in VSYNC/HSYNC mode on the separate two input lines. To be detected, the HSYNC/VSYNC pulse width must always be equal to at least two RFBI_ICLK clock cycles. See Table 10-692.

Table 10-692. RFBI Minimum Pulse Width (HSYNC/VSYNC)

Configuration Bits	TE Mode	HSYNC/VSYNC Mode
RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH field value	2	2
RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH field value	4	2

The pulse received by the RFBI must be at least two RFBI_ICLK clock cycles to be detected. For the TE mode, since the minimum value to differentiate VSYNC and HSYNC is two RFBI_ICLK clock cycles, the VSYNC pulse width must be at least four RFBI_ICLK clock cycles and the HSYNC pulse width must be at least two RFBI_ICLK clock cycles.

10.5.5 RFBI Programming Guide

10.5.5.1 RFBI Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and use of the RFBI.

10.5.5.1.1 RFBI Global Initialization

10.5.5.1.1.1 RFBI Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the RFBI is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration and environment of the RFBI. For more information, see Section 10.5.2, *RFBI Environment*, and Section 10.5.3, *RFBI Integration*.

Table 10-693 describes the global initialization of surrounding modules.

Table 10-693. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	RFBI_ICLK interface clock must be enabled. For more information, see , *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
DISPC	RFBI_FCLK1 and RFBI_FCLK2 functional clocks must be enabled (see Section 10.2.1, DISPC Overview).
Control module	rfbi_re pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_we pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_cs0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_te_vsync0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_data[15:0] pads muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_hsync0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. rfbi_a0 pad muxing must be set in the SYSCTRL_PADCONF_CORE module. For more information, see , *Pad Functional Multiplexing and Configuration*, in *Chapter 18, Control Module*.
MPU INTC	MPU interrupt controller configuration must be done to enable the interrupts from the DISPC module. For more information, see , *Interrupt Controllers Overview*, in *Chapter 17, Interrupt Controllers*.
DMA_SYSTEM	DMA configuration must be done to enable the RFBI module DMA channel requests. For more information, see , *DMA_SYSTEM Module Overview*, in Chapter 16*System DMA*.
Interconnect	For more information about the interconnect configuration, see , *L3 Interconnect*, in *Chapter 14, Interconnects*.

NOTE: The MPU INTC and the DMA_SYSTEM configurations are necessary if the interrupt- and DMA-based communication modes are used.

10.5.5.1.1.2 RFBI Global Initialization

10.5.5.1.1.2.1 RFBI Main Sequence RFBI Global Initialization

This procedure initializes the RFB and DISPC after a power on or software reset (see Table 10-694).

Table 10-694. RFBI Global Initialization

Step	Register/Bit Field Programming Model	Value
DISPC configuration in RFBI mode	See Section 10.5.5.1.1.2.2, *Subsequence: DISPC Configuration*.	
RFBI configuration	See Section 10.5.5.1.1.2.3, *Subsequence: RFBI Configuration.*	
LCD panel configuration	See Section 10.5.5.1.1.2.4, *Subsequence: LCD Panel Configuration*.	

10.5.5.1.1.2.2 RFBI Subsequence: DISPC Configuration

This procedure configures the DISPC registers in RFBI mode (see Table 10-695).

Table 10-695. RFBI DISPC Configuration in RFBI Mode

Step	Register/Bit Field Programming Model	Value
DISPC pipeline configuration	Configuration of the pipeline associated with the LCD output, such as the DMA engine and pipelines associated with the LCD output (see DISPC Overview, in *Display Controller*).	
Enable TFT mode.	DISPC_CONTROLo[3] STNTFT	0x1
Program the DISPC in RFBI mode.	DISPC_CONTROLo[11] STALLMODE	0x1
Reset the DISPC signal configuration to default value.	DISPC_POL_FREQo	0x00
Select the RFBI data path.	DISPC_CONTROL1[16:15] GPOUT	0x1
Enable the hardware handshake to avoid the DISPC FIFO underflow (applies to the pipeline connected to the LCD output).	DISPC_CONFIGo[16] BUFFERHANDCHECK	0x1

NOTE: In RFBI mode, the DISPC_CONTROLo[5] GOLCD bit must not be set to 1. It must be disabled before resetting the DISPC_CONTROLo[11] STALLMODE bit to 0.

The hardware handshake applies to the pipelines connected to the LCD output. It must be disabled before resetting the DISPC_CONTROLo[11] STALLMODE bit to 0.

10.5.5.1.1.2.3 RFBI Subsequence: RFBI Configuration

This procedure configures the RFBI registers. See Table 10-696.

CAUTION

The RFBI configuration registers for CS0 configuration can be accessed only when the configuration is not in use (that is, when the RFBI_CONTROL[3:2] CONFIGSELECT is set to 0x0).

Table 10-696. RFBI Configuration – Main Sequence

Step	Register/Bit Field Programming Model	Value
Enable the RFBI data path.	RFBI_CONTROL[1] RFBIMODE	0x0
DMA mode configuration	See Section 10.5.5.1.1.2.3.1, *Subsequence: DMA Mode Configuration.*	

Table 10-696. RFBI Configuration – Main Sequence (continued)

Step	Register/Bit Field Programming Model	Value
Disable the chip-select and configuration (this step is necessary to configure the timing registers).	RFBI_CONTROL[3:2] CONFIGSELECT	0x0
Timing and polarity signals configuration	See Section 10.5.5.1.1.2.3.2, *Subsequence: Timing and Polarity Signals Configuration*.	
Configure the parallel input data width.	RFBI_CONFIG[6:5] DATATYPE	x(1)
Configure the number of cycles.	RFBI_CONFIG[10:9] CYCLEFORMAT	x(1)
Trigger mode settings	See Section 10.5.5.1.1.2.3.3, *Subsequence: Trigger Mode Settings*.	
Program the data format per cycle.	RFBI_DATA_CYCLE_1	xxx(1)
	RFBI_DATA_CYCLE_2	xxx(1)
	RFBI_DATA_CYCLE_3	xxx(1)
Select the configuration of CS0	RFBI_CONTROL[3:2] CONFIGSELECT	0x1

(1) Values depend on the application

10.5.5.1.1.2.3.1 RFBI Subsequence: DMA Mode Configuration

Figure 10-173 shows DMA mode configuration.

Figure 10-173. RFBI DMA Mode Configuration

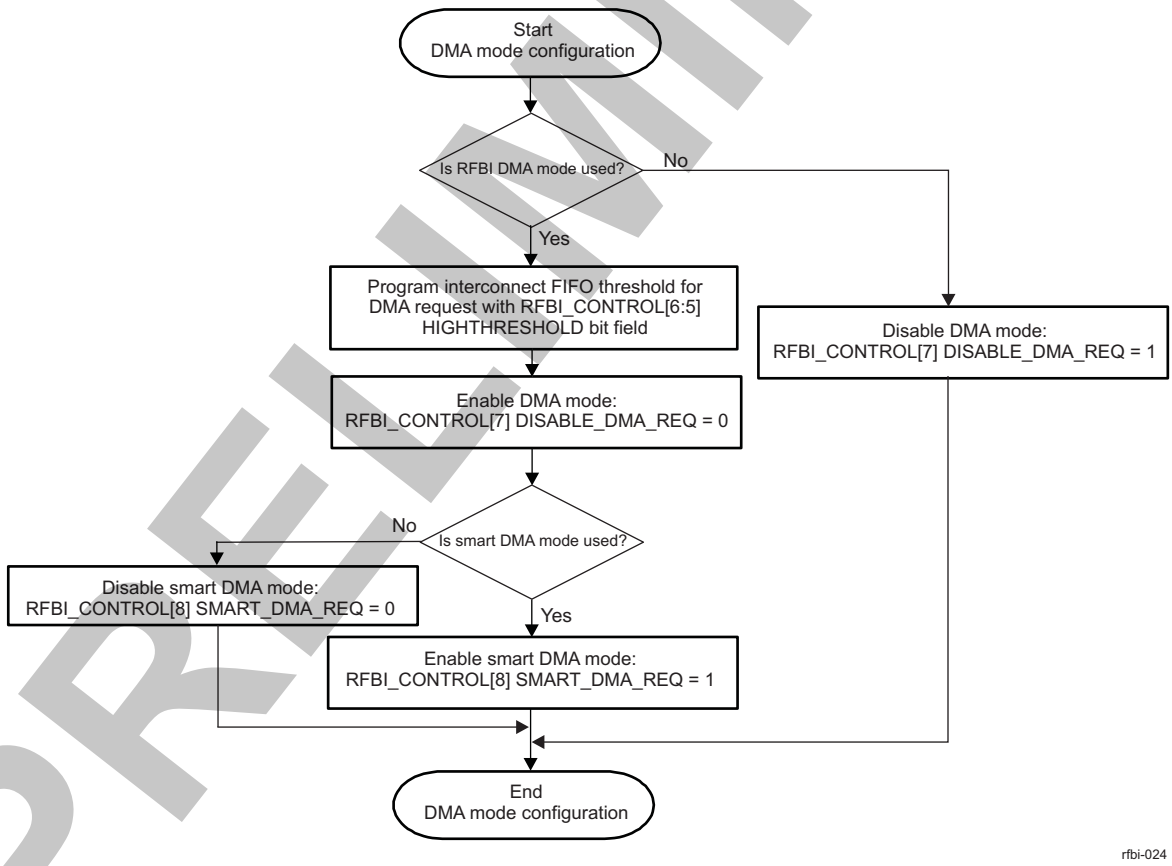

Table 10-697 describes the DMA mode configuration.

Table 10-697. Register Call Summary for Subsequence: DMA Mode Configuration

Register Name
RFBI_CONTROL

10.5.5.1.1.2.3.2 RFBI Subsequence: Timing and Polarity Signals Configuration

Table 10-698 describes timing and polarity signals configuration.

Table 10-698. RFBI Timing and Polarity Signals Configuration

Step	Register/Bit Field Programming Model	Value
Program ON/OFF timings.	RFBI_ONOFF_TIME	xxx(1)
Program cycle timings.	RFBI_CYCLE_TIME	xxx(1)
Program CS polarity.	RFBI_CONFIG[19] CSPOLARITY	x(1)
Program WE polarity.	RFBI_CONFIG[18] WEPOLARITY	x(1)
Program RE polarity.	RFBI_CONFIG[17] REPOLARITY	x(1)
Program A0 polarity.	RFBI_CONFIG[16] A0POLARITY	x(1)
Program unused bits.	RFBI_CONFIG[12:11] UNUSEDBITS	x(1)
Program the factor x2 latency.	RFBI_CONFIG[4] TIMEGRANULARITY	x(1)

(1) Values depend on the application.

10.5.5.1.1.2.3.3 RFBI Subsequence: Trigger Mode Settings

Figure 10-174 shows trigger mode settings.

Figure 10-174. RFBI Trigger Mode Settings

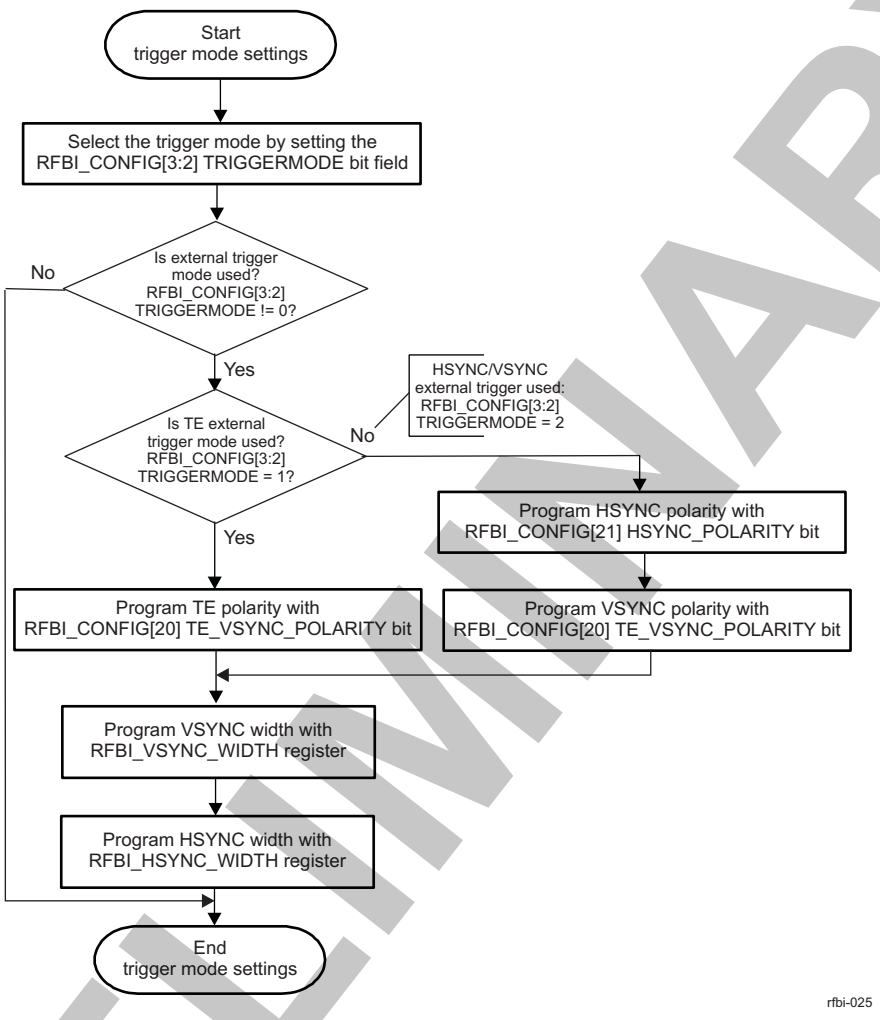

Table 10-699 describes the register call summary for subsequence: trigger mode settings

Table 10-699. Register Call Summary for Subsequence: Trigger Mode Settings

Register Name		
RFBI_CONFIG	RFBI_VSYNC_WIDTH	RFBI_HSYNC_WIDTH

10.5.5.1.1.2.4 RFBI Subsequence: LCD Panel Configuration

This procedure consists of sending and receiving commands. See Table 10-700 and Table 10-701.

Table 10-700. RFBI Command Interface: Writing Command to the LCD Panel

Step	Register/Bit Field Programming Model	Value
Write command to the LCD panel.	RFBI_CMD[8:0] CMD	0x(1)
Wait until BUSY != 1.	RFBI_SYSSTATUS[8] BUSY	

(1) Value depends on the command sent to the LCD panel.

Table 10-701. RFBI Command Interface: Reading Command From the LCD Panel

Step	Register/Bit Field Programming Model	Value
Initialize reading command.	RFBI_STATUS[8:0] STATUS	0x
Initialize reading command.	RFBI_READ [8:0] READ	0x
Wait until BUSY != 1.	RFBI_SYSSTATUS[8] BUSY	
Read command from the LCD panel.	RFBI_STATUS[8:0] STATUS	0x(1)
	RFBI_READ [8:0] READ	0x(1)

(1) Value depends on the command read from the LCD panel.

10.5.5.1.2 RFBI Operational Modes Configuration

10.5.5.1.2.1 RFBI Start Transfer

10.5.5.1.2.1.1 RFBI Main Sequence: RFBI Start Transfer With Polling Method

Table 10-702 describes the RFBI start transfer polling method.

Table 10-702. RFBI Start Transfer With Polling Method

Step	Register/Bit Field Programming Model	Value
Enable DISPC module output.	See Section 10.5.5.1.2.1.4, *Subsequence: DISPC Output Enable.*	
Enable RFBI module output.	See Section 10.5.5.1.2.1.5, *Subsequence: RFBI Interrupts Enable.*	
Detect event.	See Table 10-708.	

10.5.5.1.2.1.2 RFBI Main Sequence: RFBI Start Transfer With Interrupts and DMA Method

Table 10-703 describes the RFBI start transfer interrupts method.

Table 10-703. RFBI Start Transfer With Interrupts Method

Step	Register/Bit Field Programming Model	Value
Enable DISPC interrupts.	See Table 10-704.	
Enable DISPC module output.	See Section 10.5.5.1.2.1.4, *Subsequence: DISPC Output Enable.*	
Enable RFBI module output.	See Section 10.5.5.1.2.1.5, *RFBI Interrupts Enable*.	
Detect Event.	See Table 10-708.	

10.5.5.1.2.1.3 RFBI Subsequence: DISPC Interrupts Enable

This procedure enables the DISPC interrupts used in RFBI mode (see Table 10-704).

Table 10-704. DISPC Interrupts Enable

Step	Register/Bit Field Programming Model	Value
Clear all interrupts.	DISPC_IRQSTATUS	0xFFFF
Enable the FRAMEDONEi IRQ.	DISPC_IRQENABLE FRAMEDONEi_EN	0x1
Enable the BUFFERUNDERFLOW IRQ.	DISPC_IRQENABLE BUFFERUNDERFLOW_EN	0x1
Enable the SYNCLOSTi IRQ.	DISPC_IRQENABLE SYNCLOSTi_EN	0x1

NOTE: The other DISPC interrupts requests can also be enabled, depending on the application.

10.5.5.1.2.1.4 RFBI Subsequence: DISPC Output Enable

This procedure enables the DISPC output. See Table 10-705.

Table 10-705. DISPC Output Enable

Step	Register/Bit Field Programming Model	Value
Enable the video or GFX pipeline.	DISPC_VIDp_ATTRIBUTES[0] ENABLE	0x1
	DISPC_GFX_ATTRIBUTES[0] ENABLE	0x1
Enable the DISPC output.	DISPC_CONTROLo[0] LCDENABLE	0x1

10.5.5.1.2.1.5 RFBI Subsequence: RFBI Output Enable

This procedure enables the RFBI output. Figure 10-175 details the settings for this subsequence.

Figure 10-175. RFBI Output Enable Flow Chart

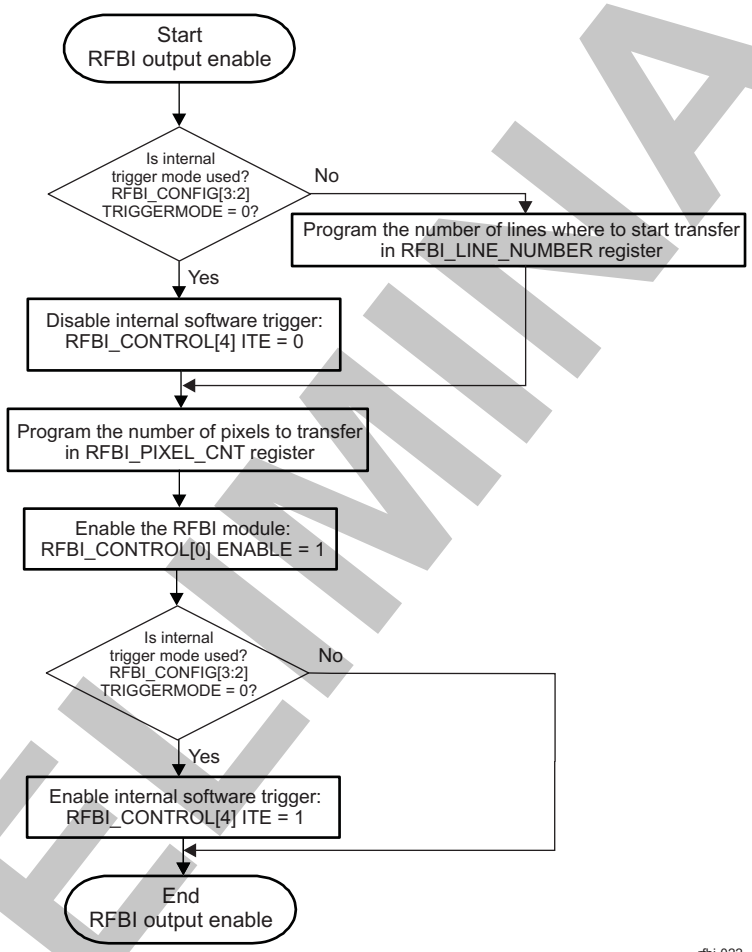

Table 10-706 describes the RFBI output enable.

RFBI_CONFIG	RFBI_CONTROL	RFBI_LINE_NUMBER
RFBI_PIXEL_CNT		

Table 10-707 describes the RFBI behavior depending on the RFBI output enable.

Table 10-707. RFBI Behavior

RFBI_CONTROL[0] ENABLE Bit Value	RFBI Behavior
0	Slave port interconnect can write command/parameter/data and read data/status from the RFB. Slave port interconnect access can only be done to the active CS0.
1	The DISPC sends pixels to the RFB.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DISPC_CONTROLo[0] LCDENABLE bit to 1.

CAUTION

The following registers must not be modified when the module is enabled (the RFBI_CONTROL[0] ENABLE bit is set to 1):

- RFBI_CONTROL
- RFBI_PIXEL_CNT
- RFBI_LINE_NUMBER
- RFBI_STATUS
- RFBI_CONFIG
- RFBI_ONOFF_TIME
- RFBI_CYCLE_TIME
- RFBI_DATA_CYCLEi (i = 1 to 3)
- RFBI_VSYNC_WIDTH
- RFBI_HSYNC_WIDTH

NOTE: The RFBI_DISPC_STALL signal is asserted when the RFBI is disabled. Pixels can be sent to the LCD panel through the slave port only when the pixel count has reached 0x0.

10.5.5.1.2.1.6 RFBI Subsequence: Detect Event

Table 10-708 describes the detect event.

Table 10-708. RFBI Detect Event

Step	Register/Bit Field Programming Model	Value
Wait until DISPC_IRQSTATUS != 0.	DISPC_IRQSTATUS	
Service event	See Section 10.5.5.1.3, *RFBI Events Servicing*.	

10.5.5.1.3 RFBI Events Servicing

10.5.5.1.3.1 RFBI FRAMEDONE Interrupt Servicing

The FRAMEDONE event occurs each time a frame is transferred to the LCD panel. Figure 10-176 details how to serve this event.

Figure 10-176. RFBI FRAMEDONE Event Servicing Flow Chart

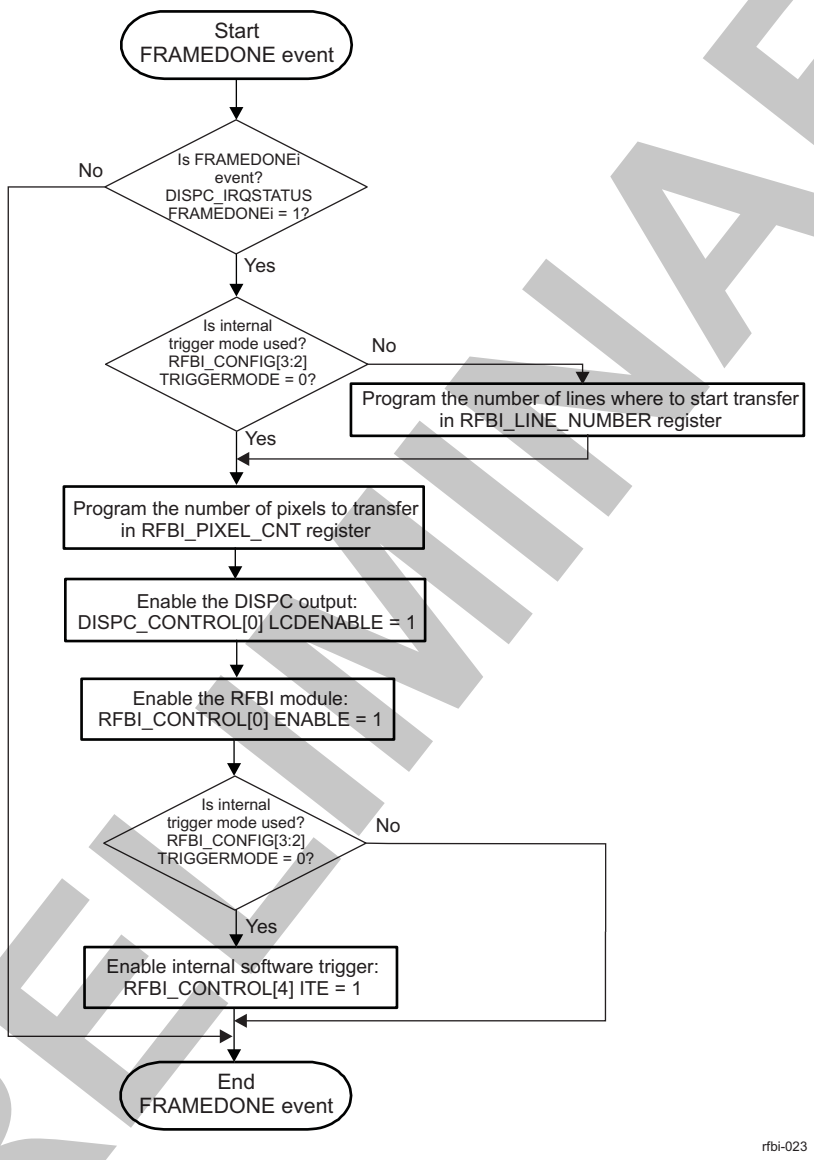

Table 10-709 describes FRAMEDONE interrupt servicing.

Table 10-709. Register Call Summary for RFBI Events Servicing: FRAMEDONE Interrupt Servicing

Register Name		
DISPC_IRQSTATUS	RFBI_CONFIG	RFBI_LINE_NUMBER
RFBI_PIXEL_CNT	DISPC_CONTROL	RFBI_CONTROL

10.5.6 RFBI Hardware Status Features

Table 10-710 lists the RFBI hardware status features.

Table 10-710. RFBI Hardware Status Features

Feature	Type	Register/Bit Field/Observability Control	Description
Data pending	Status	RFBI_SYSTATUS[9] BUSYRFBIDATA	It is set to 1 when some data are pending to be processed from the interconnect FIFO.
Slave port bus busy	Status	RFBI_SYSTATUS[9] BUSY	It is set to 1 when the slave port bus is busy and access to some RFBI registers (RFBI_CMD, RFBI_STATUS, RFBI_PARAM, and RFBI_READ) is stalled.

Table 10-719. RFBI_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x5800 2040	**Instance**	RFBI
Description	The register configures the RFBI module.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							SMART_DMA_REQ	DISABLE_DMA_REQ	HIGHTHRESHOLD		ITE	CONFIGSELECT		RFBIMODE	ENABLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Reads return 0.	RO	0x000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and deasserted depending on FIFO space, even if MIdlereq is high in smart-idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is deasserted after 2 clock cycles, if it has been asserted for more than or equal to 2 clock cycles and MIdlereq is high in smart-idle or no-idle mode. No more burst requests are given, even if the space is available in the FIFO.	RW	0
7	DISABLE_DMA_REQ	Disable DMA request. 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in FIFO. It stays high until the DISABLE DM AREQ is high even if there is space in FIFO to take requests.	RW	0
6:5	HIGHTHRESHOLD	Defines the FIFO high threshold used by hardware to assert DMA request. Used only if data written to RFBI_DATA are sent using sDMA. 0x0: Size of the transfer of 4 words of 32 bits wide 0x1: Size of the transfer of 8 words of 32 bits wide 0x2: Size of the transfer of 16 words of 32 bits wide	RW	0x0
4	ITE	Internal trigger 0x0: Hardware waits for the ITE bit to be set if in internal trigger mode for the configuration in use. 0x1: User sets the ITE bit to start the transfer. When hardware takes into account the bit, the hardware resets it.	RW	0

Bits	Field Name	Description	Type	Reset
3:2	CONFIGSELECT	Select the CS and configuration. 0x0: No CS selected 0x1: CS0 selected 0x2: Reserved 0x3: Reserved	RW	0x0
1	RFBIMODE	RFBI mode 0x0: The RFBI mode is selected. 0x1: The RFBI mode is not selected.	RW	1
0	ENABLE	Enable/disable flag 0x0: Disable the RFBI module. 0x1: Enable the RFBI module.	RW	0

3D Accelerator GPU Subsystem

This chapter is a basic overview and describes the integration of the 3D graphics processing unit (GPU) subsystem in the device.

NOTE: The GPU subsystem is an instantiation by Texas Instruments of the POWERVR™ SGX544 core from Imagination Technologies Ltd.

POWERVR and USSE are trademarks or registered trademarks of Imagination Technologies Ltd.

Topic **Page**

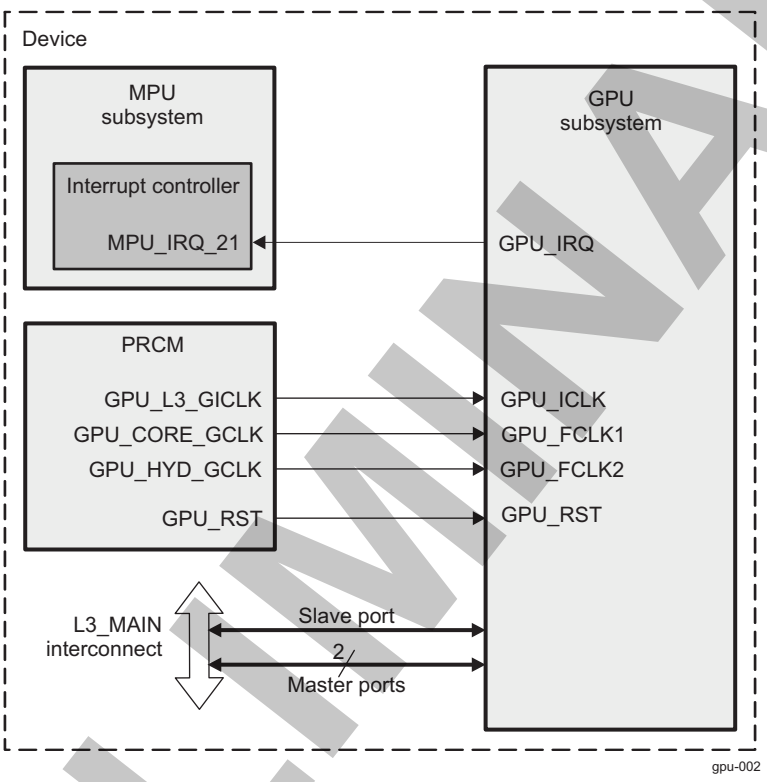
11.1 GPU Overview

The 3D graphics processing unit (GPU) accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics and compute applications. It is based on the POWERVR® SGX544-MP2 core from Imagination Technologies. The SGX544-MP2 core is a multicore evolution of the POWERVR SGX544 GPU.

The multicore GPU splits geometry and pixel rendering among the cores to improve performance proportional to the number of cores.

Figure 11-1 shows the GPU subsystem.

Figure 11-1. GPU Overview



11.1.1 GPU Features Overview

- API support for industry standards:
  - OGL-ES 1.1 and 2.0
  - OpenVG™ 1.1
  - OpenCL™-EP 1.1
  - Direct3D™ Feature Level 9.3
- Multicore GPU architecture:
  - 2 × SGX544 core
  - Shared system level cache of 128 KiB
- Tile-based deferred rendering architecture:
  - Reduces external bandwidth to SDRAM
- Universal Scalable Shader Engine (USSE™):
  - Multithreaded engine incorporating vertex and pixel shader functionality
  - Automatic load balancing of vertex and pixel processing tasks
- Present and texture load accelerator (PTLA):
  - Enables to move, rotate, twiddle, and scale texture surfaces

  - Supports RGB, ARGB, YUV4:2:2, and YUV4:2:0 surface formats
  - Supports bilinear upscale
  - Supports source color key
- Fully virtualized memory addressing for operating system (OS) in a unified memory architecture:
  - Memory management unit (MMU)
  - Up to 4-GiB virtual address space

11.1.2 Graphics Feature Overview

- Texture support:
  - Cube map
  - Projected textures
  - Non-square textures
- Texture formats:
  - RGBA 8888, 565, 1555, and 1565
  - Monochromatic 8, 16, 16f, 32f, and 32int
  - Dual channel, 8:8, 16:16, and 16f:16f
  - Compressed textures:
    - PVRTC-i 2 bpp
    - PVRTC-i 4 bpp
    - PVRTC-ii 2 bpp
    - PVRTC-ii 4 bpp
    - ETC1
    - DXT 1-5 and BC 4-5
  - Programmable support for YUV formats:
    - Programmable matrix in hardware, coefficients on 12 bits
    - YUV4:2;2, YUV4:2:0, two planes (NV12 or NV21); YUV4:2:0, three planes
- Resolution support:
  - Frame buffer maximum = 4096 × 4096
  - Texture maximum size = 4096 × 4096
- Texture filtering:
  - Bilinear, trilinear
  - Independent minimum and mag control
- Anti-aliasing:
  - 4× multisampling
  - Programmable sample positions

NOTE: TI provides the DXT1-5 and BC4-5 texture compression technology for use only with a Microsoft Windows operating system.

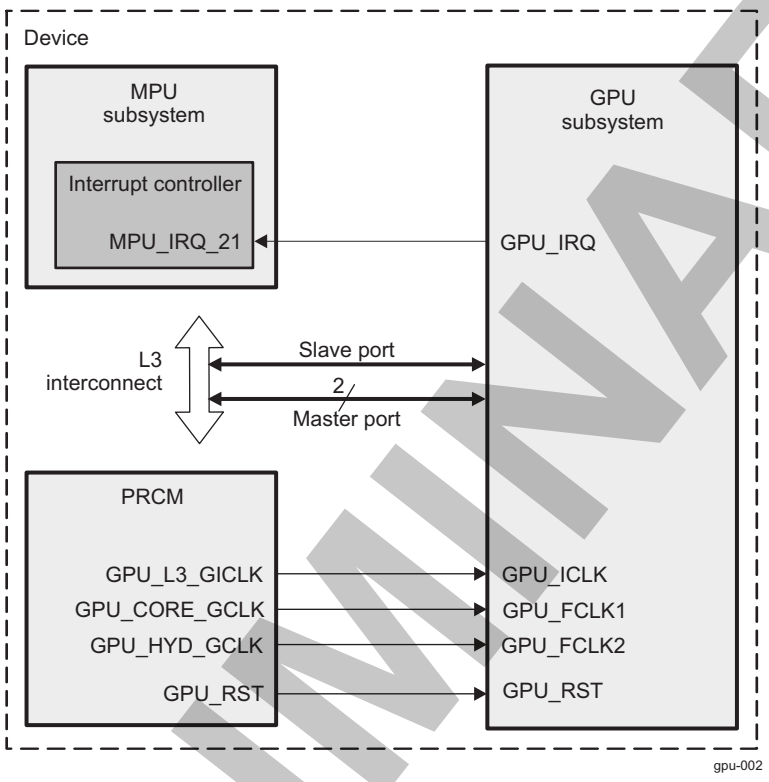
A separate license is required for the use of this technology (also referred to as S3 texture compression technology) with any other operating system.

11.2 GPU Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 11-2 shows the GPU integration.

Figure 11-2. GPU Integration



The GPU subsystem is connected to the level 3 (L3) interconnect by two 128-bit master and a 64-bit slave interfaces.

Table 11-1 through Table 11-3 summarize the integration of the module in the device.

Table 11-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
GPU	PD_GPU	L3_MAIN

Table 11-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**

GPU	GPU_FCLK1	GPU_CORE_GCLK	PRCM	GPU functional clock
GPU	GPU_FCLK2	GPU_HYD_GCLK	PRCM	GPU functional clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPU	GPU_RST	GPU_RST	PRCM	GPU reset signal

Table 11-3. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
GPU	GPU_IRQ	MPU_IRQ_21	Cortex™-A15 INTC	GPU interrupt request to the microprocessor unit (MPU) interrupt controller (INTC)

NOTE: For a description of the interrupt source, see Section 11.3.5, *GPU Interrupt Requests*.

11.3 GPU Functional Description

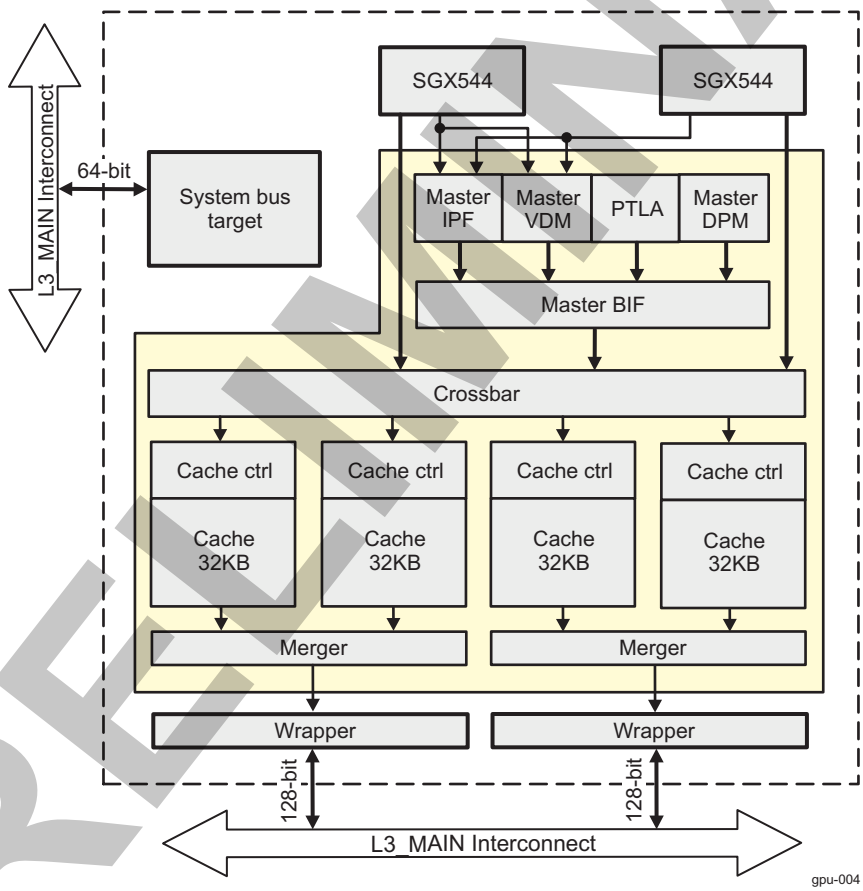
11.3.1 GPU Block Diagram

The GPU subsystem is based on the POWERVR SGX544-MP2 core. Multicore GPU can split geometry and pixel rendering among the cores to improve performance proportional to the number of cores. The graphics software engineer programming the OMAP5430 GPU does not have to deal with the multiple cores, this is done by the graphics drivers. The multiple cores are completely hidden behind the standard high-level graphics APIs that are supported by the graphics core. The GPU architecture comprises the following elements:

- SGX544 cores
- PTLA
- Cross bar
- System-level cache (SLC)

Figure 11-3 shows the GPU top-level block diagram.

Figure 11-3. GPU Block Diagram



The SGX544-MP2 has 2 × SGX544 cores. Graphics rendering is automatically load-balanced between the 2 × SGX544 cores. It is possible to disable one or two of the cores if required. The glue logic is used to enable the multicore architecture. The crossbar enables any SGX544 core to access the SLC. The SLC is a 128-KiB unified multibanked cache with four banks of 32 KiB. The cache line size is 64 bytes. The SGX544 core accesses are interleaved in the different banks.

11.3.2 GPU Clock Configuration

The GPU subsystem operates from three clocks: an interface clock (GPU_ICLK) and two functional clocks (GPU_FCLK1 and GPU_FCLK2). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The GPU_ICLK manages the data transfer on the L3 master and slave ports.

  The GPU_ICLK frequency is selected based on the L3 interconnect clock frequency of the whole device. For more information about the interface clock, see Section 3.6.12, *CD_GPU Clock Domains*.

  When no longer required by the GPU subsystem, GPU_ICLK can be disabled by software at the PRCM level. For more information, see PD_GPU Description, in *Power, Reset, and Clock Management*.

  NOTE: GPU_ICLK is cut only if the GPU is ready to go into IDLE state.

- GPU_FCLK1 and GPU_FCLK2 are the functional clocks and are used inside the GPU subsystem to generate clock signals to multiple GPU clock domains.

  Using the clock source selection and the digital phase-locked loop (DPLL) settings, GPU_FCLK1 and GPU_FCLK2 frequencies can be adjusted.

  The GPU_FCLK1 and GPU_FCLK2 clocks are provided by the peripheral DPLL and the core DPLL, as described in CD_GPU Clock Domain, in *Power, Reset, and Clock Management*. Selection is made at the PRCM level.

  When no longer needed by the GPU subsystem, GPU_FCLK1 and GPU_FCLK2 can be cut by software at the PRCM level if the module is ready to enter IDLE state. For more information, see PD_GPU Description, in *Power, Reset, and Clock Management*.

11.3.3 GPU Software Reset

The GPU subsystem has its own reset domain. Global reset of the GPU is performed by activating the GPU_RST signal in the GPU_RST domain.

NOTE: The APIs delivered with the GPU provide a software reset functionally equivalent to a hardware reset.

11.3.4 GPU Power Management

The GPU subsystem has its own power domain (GPU power domain). For additional information about the GPU power domain, see PD_GPU Description, in *Power, Reset, and Clock Management*.

NOTE: The GPU handles automatic clock gating performed on the multiple internal module clock domains.

In addition, software-controlled clock gating is managed inside the GPU and handled by the related API delivered with the module.

11.3.5 GPU Interrupt Requests

The GPU subsystem can generate one interrupt signal to the MPU INTC mapped to GPU_IRQ.

11.4 GPU Register Manual

CAUTION

All GPU registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

11.4.1 GPU Instance Summary

Table 11-4. GPU Instance Summary

Module Name	Base Address	Size
GPU_WRAPPER	0x5600 FE00	512 bytes

The GPU domain's base address is at 0x5600 0000. GPU address space is 32MiB wide.

2D Graphics Accelerator

This chapter describes the advanced bit blitter 2-dimensional (2D) graphics accelerator (BB2D) for the device.

NOTE: The BB2D subsystem is an instantiation by Texas Instruments of the GC320™ core from Vivante Corp.

GC320 is a trademark or registered trademark of Vivante Corp.

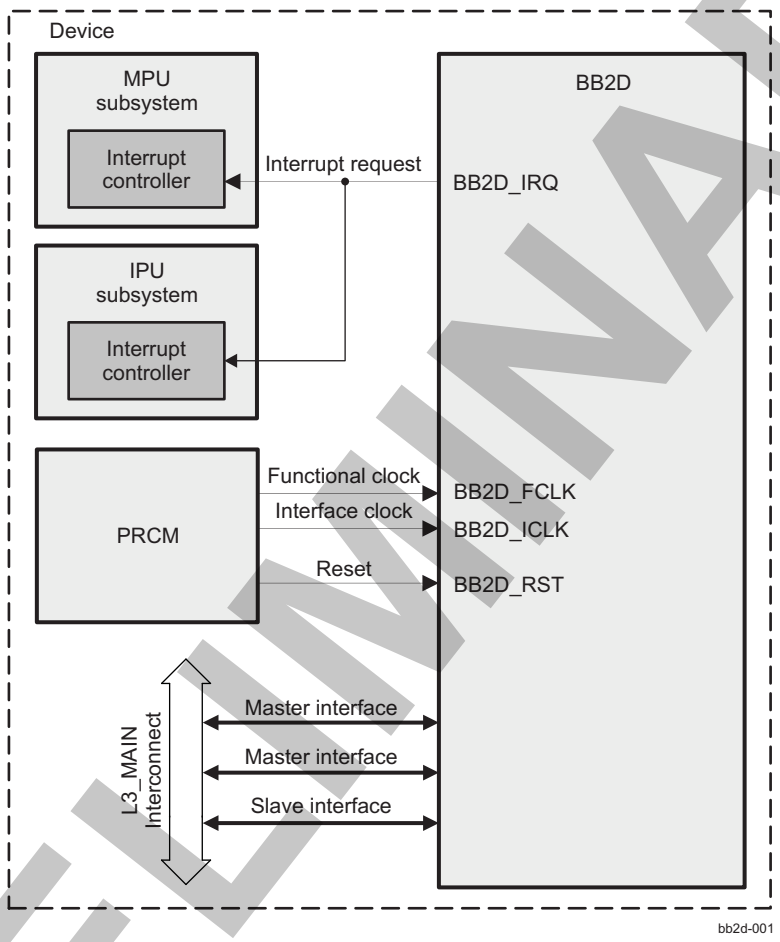
Topic **Page**

12.1 BB2D Overview

The 2D graphics accelerator subsystem accelerates 2D graphics applications. The 2D graphics accelerator subsystem is based on the GC320 2D GPU core from Vivante Corporation. The hardware acceleration is brought to numerous 2D applications, including on-screen display and touch screen user interfaces, graphical user interfaces (GUIs) and menu displays, flash animation, and gaming.

Figure 12-1 shows the BB2D subsystem.

Figure 12-1. BB2D Overview



12.1.1 BB2D Features Overview

- API support:
  - OpenWF™, DirectFB
  - GDI/DirectDraw™
  - Flash
- BB2D architecture:
  - BitBlt and StretchBlt
  - DirectFB hardware acceleration
  - ROP2, ROP3, ROP4 full alpha blending and transparency
  - Clipping rectangle support
  - Alpha blending includes Java® 2 Porter-Duff compositing rules
  - 90-, 180-, 270-degree rotation on every primitive
  - YUV-to-RGB color space conversion

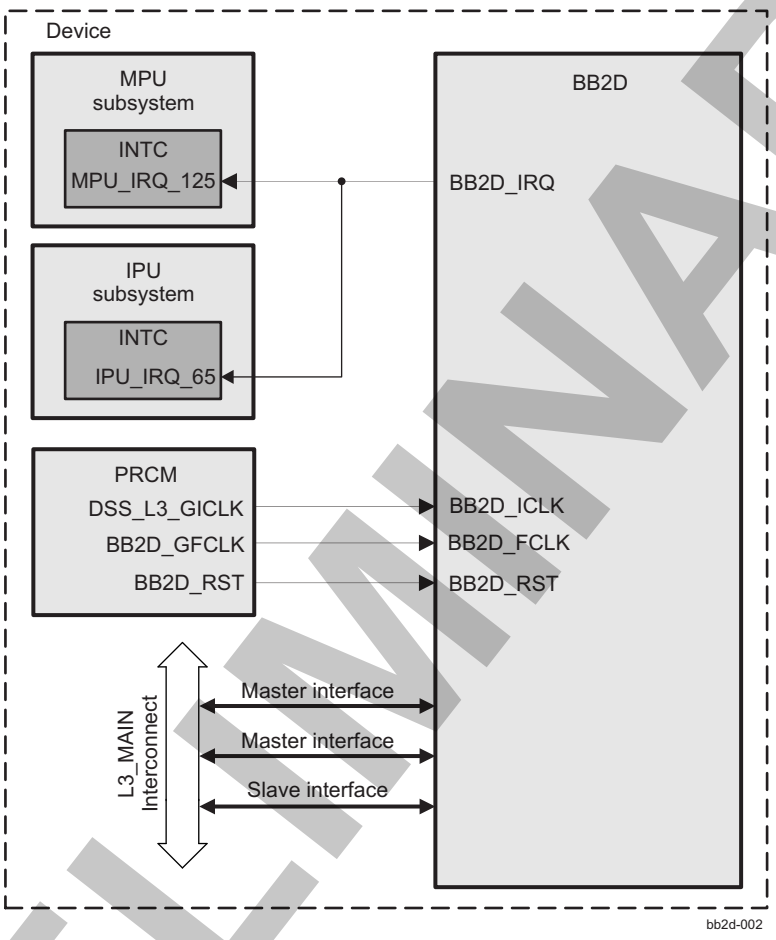
  - Programmable display format conversion with 14 source and 7 destination formats
  - High-quality 9-tap, 32-phase filter for image and video scaling at 1080p
  - Monochrome expansion for text rendering
  - 32 K × 32 K coordinate system
- Hardware acceleration for DirectFB:
  - High-speed video scaler
  - ROP2/3/4
  - Rectangle filling and drawing
  - Line drawing
  - Simple blitting
  - Stretch blitting
  - Blending with alpha channel (per-pixel alpha)
  - Blending with alpha factor (alpha modulation)
  - Nine source and destination blending functions
  - Porter-Duff rules support
  - Premultiplied alpha support
  - Colorized blitting (color modulation)
  - Source color keying
  - Destination color keying

12.2 BB2D Integration

This section describes subsystem integration in the device, including information about clocks, resets, and hardware requests.

Figure 12-2 shows BB2D integration.

Figure 12-2. BB2D Integration



The BB2D subsystem is connected to the level 3 (L3_MAIN) interconnect by two 128-bit master interfaces and one 32-bit slave interface.

Table 12-1 through Table 12-3 summarize the integration of the subsystem in the device.

Table 12-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
BB2D	PD_DSS	L3_MAIN

Table 12-2. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
BB2D	BB2D_ICLK	DSS_L3_GICLK	PRCM	BB2D interfaces clock
	BB2D_FCLK	BB2D_GFCLK	PRCM	BB2D functional clock.
Resets				

Table 12-2. Clocks and Resets (continued)

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
BB2D	BB2D_RST	BB2D_RST	PRCM	BB2D reset signal

Table 12-3. Hardware Requests

	Interrupt Requests			
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
BB2D	BB2D_IRQ	MPU_IRQ_125	MPU INTC	BB2D interrupt request to the MPU interrupt controller (INTC)
	BB2D_IRQ	IPU_IRQ_65	IPU INTC	BB2D interrupt request to the IPU INTC

12.3 BB2D Functional Description

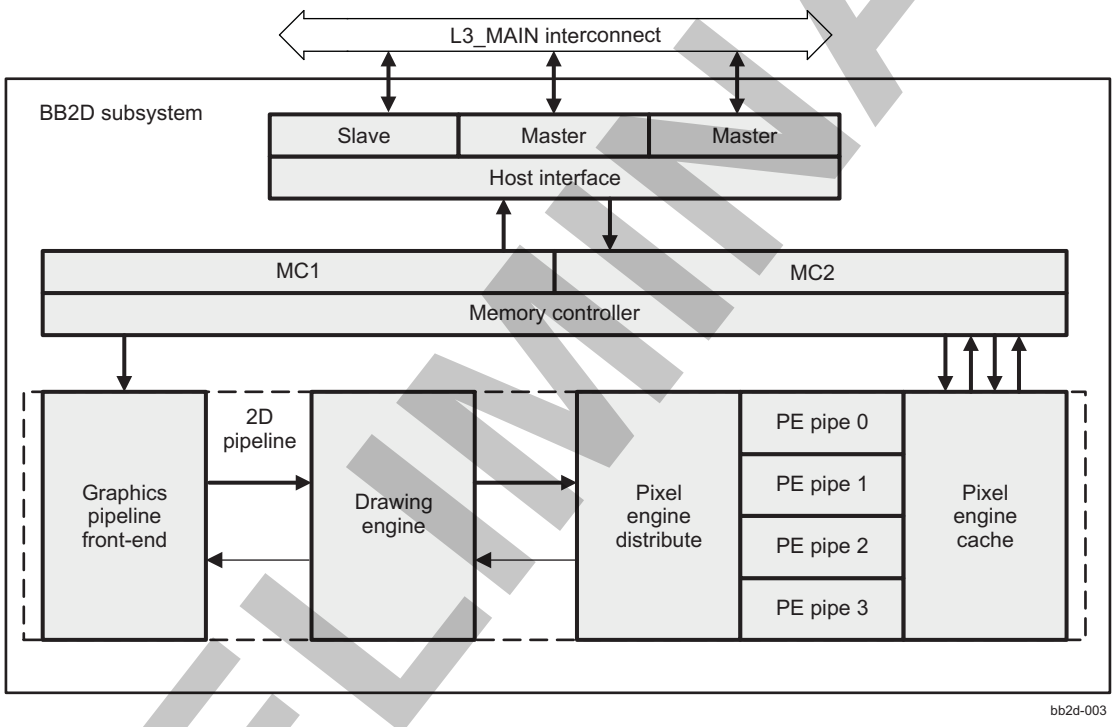
12.3.1 BB2D Block Diagram

The BB2D subsystem is based on the following main blocks:

- Host interface: Allows the BB2D core to communicate with external memory and the MPU through the L3_MAIN interconnect. In this block, data crosses clock domain boundaries.
- Memory controller: Internal memory unit that is the block-to-host interface for memory requests
- Graphics pipeline front-end: Inserts high-level primitives and commands into the graphics pipeline.
- 2D drawing and scaling engine: Draws 2D graphics primitives and rasterizes 2D images.
- Pixel engine: manipulates and filters pixels in rendered images. BB2D has four pixel pipes.

Figure 12-3 shows the BB2D top-level block diagram.

Figure 12-3. BB2D Block Diagram



12.3.2 BB2D Clock Configuration

The BB2D subsystem operates from two clocks: an interface clock (BB2D_ICLK) and functional clock (BB2D_FCLK). The power, reset, and clock management (PRCM) module generates and distributes the clocks inside the device.

- The BB2D_ICLK interface clock manages the data transfer on the L3_MAIN master and slave ports.

  The BB2D_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see *CD_DSS Clock Domain* in Section 3.6, *Clock Management Functional Description*.

  When BB2D_ICLK is no longer required by the BB2D subsystem, it can be disabled by software at the PRCM level.

  NOTE: BB2D_ICLK is cut only if the BB2D is ready to go into IDLE state.

- The BB2D_FCLK functional clock is used inside the BB2D subsystem to generate clock signals to multiple BB2D clock domains. The BB2D automatically gates clocks to domains, that are not currently in use.

Using the clock source selection and the DPLL settings, the frequency of BB2D_FCLK can be adjusted.

When BB2D_FCLK is no longer needed by the BB2D subsystem, it can be cut by software at the PRCM level, if the module is ready to enter IDLE state.

12.3.3 BB2D Software Reset

The BB2D subsystem is part of the DSS reset domain. A global reset of the BB2D is performed by activating the BB2D_RST signal in the DSS_RST domain.

NOTE: The APIs delivered with the BB2D provide a software reset functionally equivalent to a hardware reset.

12.3.4 BB2D Power Management

The BB2D subsystem is part of the DSS power domain (PD_DSS). For additional information about PD_DSS, see *PD_DSS Description* in Section 3.1.2.3, *Power Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The BB2D handles automatic clock gating performed on the multiple internal clock domains.

When 2D operations are complete, software may set the GCGPOUT0[0] GCHOLD bit to 1 to enter a low-power state. Setting GCHOLD to 1 moves the BB2D operational state into IDLE. Once in IDLE state, the system standby hardware signal (mstandby) is asserted.

12.3.5 BB2D Interrupt Requests

The BB2D subsystem can generate one interrupt signal to the MPU INTC and to the IPU INTC mapped to BB2D_IRQ.

12.4 BB2D Register Manual

CAUTION

All BB2D registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Bits	Field Name	Description	Type	Reset
31	FE20_BIT_INDEX	Supports 20 bit index.	R	1
30	RS_YUV_TARGET	Supports resolveing into YUV target.	R	1
29	BYTE_WRITE_3D	3D PE has byte write capability.	R	1
28	FE20	FE 2.0 is present.	R	0
27	VGTS	VG tesselator is present.	R	0
26	PIPE_VG	VG pipe is present.	R	0
25	MEM32_BIT_SUPPORT	32 bit memory address support.	R	0
24	YUY2_RENDER_TARGET	YUY2 support in PE and YUY2 to RGB conversion in resolve.	R	0
23	HALF_TX_CACHE	TX cache is half.	R	0
22	HALF_PE_CACHE	PE cache is half.	R	0
21	YUY2_AVERAGING	YUY2 averaging support in resolve.	R	1
20	NO_SCALER	No 2D scaler.	R	0
19	BYTE_WRITE_2D	Supports byte write in 2D.	R	1
18	BUFFER_INTERLEAVING	Supports interleaving depth and color buffers.	R	1
17	NO422_TEXTURE	No 422 texture input format.	R	0
16	NO_EZ	No early-Z.	R	0
15	MIN_AREA	Configured to have minimum area.	R	1
14	MODULE_CG	Second level clock gating is available.	R	1
13	YUV420_TILER	YUV 4:2:0 tiler is available.	R	1
12	HIGH_DYNAMIC_RANGE	Shows if there is HDR support.	R	1
11	FAST_SCALER	Shows if there is HD scaler.	R	1
10	ETC1_TEXTURE_COMPRESSION	ETC1 texture compression.	R	1
9	PIPE_2D	Shows if there is 2D engine.	R	1
8	DC	Shows if there is a display controller.	R	0
7	MSAA	MSAA support.	R	1
6	YUV420_FILTER	YUV 4:2:0 support in filter blit.	R	1
5	ZCOMPRESSION	Depth and color compression.	R	0

Bits	Field Name	Description	Type	Reset
4	DEBUG_MODE	Debug registers.	R	0
3	DXT_TEXTURE_COMPRESSION	DXT texture compression.	R	1
2	PIPE_3D	3D pipe.	R	0
1	SPECIAL_ANTI_ALIASING	Full-screen anti-aliasing.	R	1
0	FAST_CLEAR	Fast clear.	R	0

Bits	Field Name	Description	Type	Reset
31	ENHANCE_VR	Enhance VR and add a mode to walk 16 pixels in 16-bit mode in vertical pass to improve cache hit rate when rotating 90/270.	R	1
30	CORRECT_STENCIL	Correct stencil behavior in depth only.	R	1
29	A8_TARGET_SUPPORT	2D engine supports A8 target.	R	0
28	NEW_TEXTURE	New texture unit is available.	R	0
27	HIERARCHICAL_Z	Hierarchiccal Z is supported.	R	1
26	BYPASS_IN_MSAA	Shader supports bypass mode when MSAA is enabled.	R	0
25	VAA	VAA is available or not.	R	0
24	BUG_FIXES0		R	1
23	SHADER_MSAA_SIDEBAND	Put the MSAA data into sideband fifo.	R	0
22	MC_20	New style MC with separate paths for color and depth.	R	0
21	DEFAULT_REG0	Unavailable registers will return 0.	R	1
20	EXTRA_SHADER_INSTRUCTIONS1	Sqrt, sin, cos instructions are available.	R	1
19	SHADER_GETS_W	W is sent to SH from RA.	R	1
18	VG_21	Minor updates to VG pipe (Event generation from VG, TS, PE). Tiled image support.	R	0
17	VG_FILTER	VG filter is available.	R	0
16	EXTRA_SHADER_INSTRUCTIONS0	Floor, ceil, and sign instructions are available.	R	1

Bits	Field Name	Description	Type	Reset
15	COMPRESSION_FIFO_FIXED	If this bit is not set, the FIFO counter should be set to 50. Else, the default should remain.	R	1
14	TS_EXTENDED_COMMANDS	New commands added to the tessellator.	R	0
13	VG_20	Major updates to VG pipe (TS buffer tiling. State masking.).	R	0
12	SUPER_TILED_32X32	32 × 32 super tile is available.	R	1
11	SEPARATE_TILE_STATUS_WHEN_INTERLEAVED	Use 2 separate tile status buffers in interleaved mode.	R	1
10	TILE_STATUS_2BITS	2 bits are used instead of 4 bits for tile status.	R	1
9	RENDER_8K	Supports 8K render target.	R	1
8	CORRECT_AUTO_DISABLE	Reserved.	R	0
7	PE20_2D	2D PE 2.0 is present.	R	1
6	FAST_CLEAR_FLUSH	Proper flush is done in fast clear cache.	R	1
5	SPECIAL_MSAA_LOD	Special LOD calculation when MSAA is on.	R	1
4	CORRECT_TEXTURE_CONVERTER	Driver hack is not needed.	R	1
3	TEXTURE8_K	Supports 8K × 8K textures.	R	1
2	ENDIANNESS_CONFIG	Configurable endianness support.	R	1
1	DUAL_RETURN_BUS	Dual Return Bus from HI to clients.	R	1
0	FLIP_Y	Y flipping capability is added to resolve.	R	1

Table 12-90. GCDISPLAYPRIORITY

Address Offset	0x0000 0434		
Physical Address	0x5900 0434	**Instance**	BB2D
Description	Controls the priority of the display controller requests. This works like a PWM. One register gives the period, and the other gives the ON time. When PWM is ON, display requests are accepted if both display and the other request is valid. If it is OFF, the other request will be accepted. If only one request is valid, it takes the bus regardless of the PWM bit.		
Type	RW

Audio Back End

This chapter describes the audio back end (ABE) module.

Topic **Page**

13.1 ABE Overview

The audio back end (ABE) module is a subsystem that manages various audio and voice uplink and downlink streams between the initiator (the Cortex™-A15 microprocessor unit [MPU], digital signal processor [DSP], or direct memory access [DMA] controller) and the peripheral physical interfaces (multichannel buffered serial port [MCBSP], digital microcontroller [DMIC], multichannel pulse density modulation [MCPDM], and multichannel audio serial port [MCASP]).

The ABE module handles the audio processing for the applications. It receives voice or audio samples from the initiator or the external audio chip (TWL6041 or other) and sends them to the peripheral interfaces or memories after processing. The ABE can perform buffering of audio samples, mix audio with a voice downstream and/or a microphone upstream (sidetone), and can apply some post-processing.

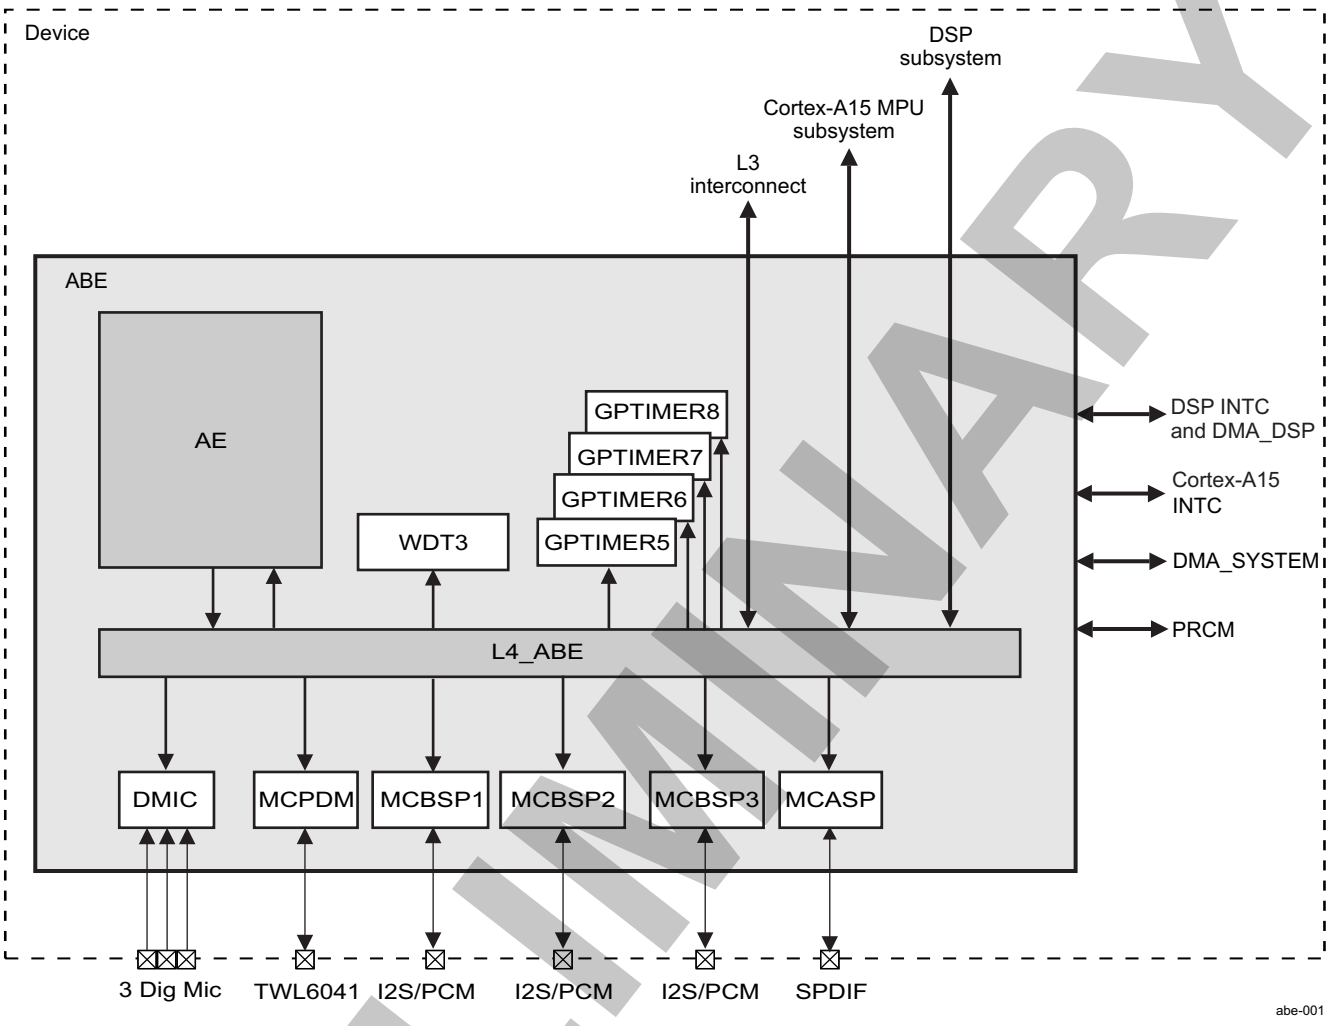
The ABE integrates the following modules:

- Peripheral physical interfaces:
  - Three MCBSP modules
  - One MCASP module
  - One DMIC module to support up to six mono and three stereo digital microphones
  - One MCPDM module to support interconnect with an external audio chip
- Audio engine (AE):
  - Performs real-time signal processing, such as sample rate conversion, filtering, equalizing, and side-tone
  - Audio traffic controller (ATC):
    - Performs data move in the ABE
    - Generates interrupt requests to the DSP and Cortex-A15 interrupt controllers (INTCs)
  - On-chip memory:
    - 64KiB of RAM; 32-bit data memory (DMEM)
    - 6KiB for coefficient memory RAM (CMEM)
    - 18KiB for sample memory RAM (SMEM)
- Local level 4 (L4) interconnect (L4_ABE) to:
  - Level 3 (L3) interconnect
  - Cortex-A15 MPU
  - DSP

  The Cortex-A15 MPU and the DSP have private access to the L4_ABE interconnect. All other initiators (DMA_SYSTEM) can access the L4_ABE interconnect only through the L3 interconnect.
- Timers:
  - Four general-purpose (GP) timers
  - One watchdog timer
- Clock and reset management: Receives clock and reset signals from the device power, reset, and clock management (PRCM) module. The audio engine operates from the DPLL_ABE, which is in the PRCM module. Clock signals from the DPLL_ABE or the DPLL_PER can supply the ABE modules. The ABE has its own hardware reset domain (AUDIO_RST).
- Power management: The ABE module is power-independent. It has its own dedicated power domain (PD_ABE) and can execute audio processing with the rest of the device in retention or off mode.
- The initiator can directly access each peripheral in the ABE when the AE is bypassed (legacy mode, for old software compatability).

Figure 13-1 is a high-level overview of the ABE.

Figure 13-1. Audio Back End



13.1.1 AE Subsystem

The AE is the core of the ABE subsystem. It performs the real-time audio processing within the ABE:

- Mixing
- Muxing
- Volume control
- Smooth muting
- Sampling rate conversion
- Side-tone equalization

The AE subsystem also processes and executes all data transfers. To optimize the global processing, the ATC moves the data. An interrupt request (IRQ)/DMA controller controls system IRQs and DMA requests. Input DMA requests come from the ABE peripherals, and output DMA requests and IRQs are generated and sent to the system (Cortex-A15 MPU INTC, DSP INTC, system DMA [DMA_SYSTEM], and the DSP enhanced DMA controller [DMA_DSP]).

The AE subsystem contains:

- AE: Processes the sample in SMEM with the help of CMEM:
  - SMEM
  - CMEM

- DMEM: Contains the audio buffer and communication circular buffer
- ATC: Transfers data between all modules in the ABE
- IRQ DMA controller

For more information about the audio engine, see the *Hardware Abstraction Layer (HAL) Addendum*.

13.1.2 Local Audio Interconnect

The ABE has its own audio local interconnect (L4_ABE), which interconnects and manages the data flow among all ABE modules.

The main features of the L4_ABE are:

- Initiator ports:
  - Cortex-A15 MPU
  - DSP
  - L3 interconnect
  - AE subsystem

  The sDMA operates with the L4_ABE interconnect through the L3 interconnect initiator port. The DMA_DSP operates with the L4_ABE interconnect through the DSP initiator port.
- Target ports:
  - AE subsystem
  - MCBSP1, MCBSP2, and MCBSP3
  - DMIC
  - MCPDM
  - MCASP
  - GPTIMER5 through GPTIMER8
  - WDT3
- 8-, 16-, or 32-bit data, single access
- 4-bit × 32-bit initiator ports for each interconnect instance
- Auto clock-gating feature
- Little-endian transaction assumed for all packing or unpacking operations
- Nonblocking architecture with fair arbitration between threads
- Target interconnect interfaces support fully synchronous and divided synchronous accesses.

For more information, see Chapter 14, *Interconnect*.

13.1.3 GP Timers

The ABE embeds four GP timers: GPTIMER5 through GPTIMER8. All GP timers have interrupts connected to the Cortex-A15 MPU, DSP, and AE subsystems.

GP timer controllers have the following functions:

- Interconnect slave interface (L4) supports:
  - 32-bit data bus width
  - 16- and 32-bit access
  - 10-bit address bus width
  - Write-Non-Posted (WNP)

  Burst is not supported.
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Supported modes:

  - Compare and capture modes
  - Auto-reload mode
  - Start-stop mode
- Programmable divider clock source
- Dedicated input trigger for capture mode and dedicated OUT trigger/pulse width modulation (PWM) signal
- On-the-fly read/write register
- The disconnect protocol

For more information, see Section 22.2, *General-Purpose Timers*.

13.1.4 Watchdog Timer

The ABE embeds one watchdog timer, WDT3, that generates an interrupt condition to the Cortex-A15 MPU on overflow. Application software can use an overflow to indirectly trigger a global warm reset through the PRCM module.

The main features of the WDT3 are:

- Interconnect slave interface (L4) supports:
  - 32-bit data bus width
  - 16- and 32-bit access
  - 11-bit address bus width
  - WNP

  Burst is not supported.
- Free-running 32-bit upward counter
- Programmable divider clock source
- Watchdog is reset on power up or after a warm reset and then starts counting.
- Reset or interrupt actions on a timer overflow condition and according to the watchdog timer source
- The disconnect protocol

For more information, see Section 22.3, *Watchdog Timers*.

13.1.5 Digital Microphone Controller

The DMIC allows support of up to three digital stereo microphones, which send it a pulse-density modulated stream of bits that are transferred on one period or one half-period of the clock (over-sampling clock) provided to the DMIC. Each microphone is connected directly to the TX filter decimator to extract the audio samples with a maximum of 96 db SNR with a frequency sampling set to 96 kHz.

The DMIC has the following features:

- Has six external pin connections (three data lines and three clock lines)
- Delivers one common clock (on the three clock lines) for all digital microphones
- Supports idle request and idle acknowledge protocol
- Supports stereo and mono digital microphones (up to three)
- Supoorts rising or falling edge configuration for the clock signal sampling
- Is DMIC-clock-programmable
- Has an interconnect slave interface (internal interconnect) that supports 32-bit data bus width.
- Has one DMA request capability on a programmable first in first out (FIFO) threshold
- Supports one RX FIFO (16-bit × 24-bit word depth) per microphone
- Complies with PRCM interrupts to the Cortex-A15 MPU and DSP subsystems
- Supports interconnect sample format: 32 bits (only 24 are significant)
- Supports idle request and idle acknowledge PRCM protocol

For more information, see Section 23.7, *Digital Microphone Module*.

13.1.6 Multichannel Audio Serial Port

The MCASP is a GP audio serial port. It is useful for intercomponent (DIT) transmission. The MCASP is intended to be flexible enough so that it can connect gluelessly to audio A/D, D/A, CODEC, SPDIF transmit and recieve physical layer components and clocked frame-oriented protocols (inter-IC sound [I2S] and time division multiplexing [TDM]).

The MCASP has the following features:

- 2-interconnect slave interface supports:
  - One interconnect configuration slave interface
  - One interconnect DMA slave interface
  - 32-bit data bus width
  - 16- and 32-bit access
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Supports idle request/acknowledge protocol
- Buffers for transmit/receive operations
- DMA requests (one per direction) link with the 32-bit register
- Up to four transmit and receive channels
- Four serializers implemented
- Support of disconnect protocol

For more information, see Section 23.8, *MCASP*.

13.1.7 Multichannel Buffered Serial Port

There are three MCBSP instantiations: MCBSP1 through MCBSP3. They provide a full-duplex direct serial interface between the ABE and external devices, such as Bluetooth chips, or codecs. Because of its versatility, a MCBSP can accommodate a wide range of peripherals and clocked frame-oriented protocols (I2S, PCM, and TDM).

The recommended use per MCBSP is:

- MCBSP1: Bluetooth voice/audio data
- MCBSP2: Digital baseband (DBB) voice data
- MCBSP3: MIDI FM data

The MCBSP has the following features:

- Interconnect slave interface (internal interconnect) supports:
  - 32-bit data bus width
  - 8-, 16-, and 32- bit access
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Buffers for transmit/receive operations: 128/128 32-bit words (MCBSP1, 2, 3)
- Interrupts configurable in legacy mode (two requests) or PRCM module-compliant (one request)
- DMA requests (one per direction) triggered with programmable FIFO thresholds
- Multidrop support
- Serial interface description
- Four-pin configuration (MCBSP1, 2, 3)

- Full-duplex communication
- Multichannel selection modes
- Support to enable or block transfers in each channel
- Up to 128 channels for transmission and for reception
- Supported protocols
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
  - I2S-compliant devices
  - TDM bus devices
  - PCM devices
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Supports idle request/acknowledge protocol
- Clock generation support:
  - Independent clocking and framing for reception and transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
- Support of disconnect protocol

For a complete description, see Section 23.5, *Multichannel Buffered Serial Port (MCBSP)*.

13.1.8 Multichannel Pulse Density Modulation Module

The MCPDM is a proprietary interface based on multichannel pulse density modulation. The module consists of five downlinks and three uplinks. Two other uplink channels are reserved for status communication.

The MCPDM has the following features:

- Interconnect slave interface (L4_ABE internal interconnect) supports:
  - 32-bit data bus width
  - 10-bit address bus width
  - WNP

  Burst is not supported.
- Full-duplex communication:
  - Five audio downstream channels
  - Three audio upstream channels
- RX/TX FIFO operations: 32-bit words per channel
- Complies with PRCM module interrupts:
  - One to the MPU subsystem
  - One to the DSP subsystem
- DMA requests (one per direction) triggered with programmable FIFO thresholds; depending on the FIFO implementation, one request per channel or one per direction
- Decimation filter for embedded uplink paths (five paths if two status paths)
- Oversampling for embedded uplinks (five paths)
- Sigma-delta for embedded downlinks (three paths)
- Deserializers for the two status upstream channels
- Support of disconnect protocol

For more information, see Section 23.6, *Multichannel PDM Controller*.

Interconnect

This chapter describes the device interconnect.

NOTE: The level 3 (L3) interconnect is an instantiation of the NoC interconnect from Arteris, Inc. Arteris is a registered trademark of Arteris, Inc.

Topic **Page**

14.1 Interconnect Overview

14.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- Initiator: Module able to initiate read and write requests to the chip interconnect (typically: processors, direct memory access (DMA), and so forth).
- Target: Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals and memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be an initiator and a target.

- Agent: Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- Interconnect: The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it
- Register target (RT): Special TA used to access the interconnect internal configuration registers
- Data-flow signal: Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, and so forth). Signal behavior is defined by the protocol semantics.
- Sideband signal: Any signal whose behavior is not associated to a precise transaction or data flow
- Out-of-band error: Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- Firewall: A programmable feature integrated in a TA or level 4 (L4) interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
  - Initiator requesting access
  - Address space access
  - Type of access
- ConnID: Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. Table 14-1 lists the commands encoded. For information specific to L3_MAIN interconnect error logging, see Table 14-27.

Table 14-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Read link
1 0 1	Write nonposted
1 1 0	Write conditional
1 1 1	Write broadcast

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in Table 14-2.

Table 14-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- Register that configures the combination of the MReqInfo, allowing access permission to the target module (TM) based on the MReqInfo in-band qualifier values
- SError: Target that indicates an error condition to the initiator
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in Table 14-3

Table 14-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

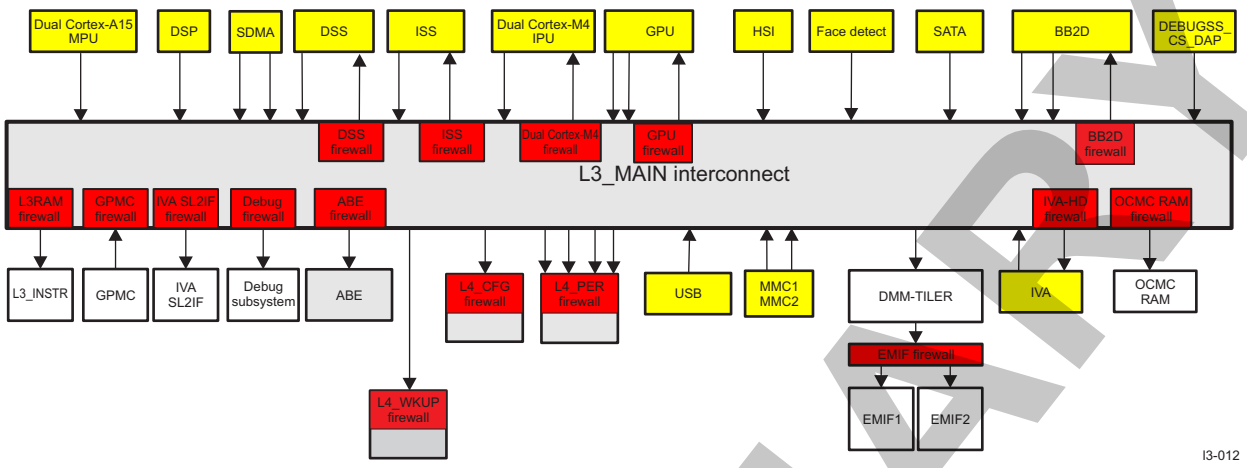
14.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- Level 1 (L1) is internal to the CPUs. The L1 interconnect concerns data exchange with the internal L1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA core.
- Level 2 (L2) is included in the IPU subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and three L4 interconnects. The chip-level interconnect enables communication among the modules and subsystems in the device.

Figure 14-1 shows an overview of the L3 and L4 interconnect architecture.

Figure 14-1. Interconnect Overview



- L3_MAIN handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 128 bits from the initiator to the target. The L3_MAIN interconnect is a little-endian platform
- The L4 is composed of the following:
  - L4_CFG: Includes the majority of the configuration interface for L3 system modules and peripheral interconnect
  - L4_PER: Includes the main peripherals that require system direct memory access (sDMA) access
  - L4_WKUP: Includes peripherals attached to the WKUP power domain

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module or subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. Software usually configures the firewalls.

The default settings of the L3_MAIN and L4 interconnect are fully functional; they enable all possible functional data paths and a minimal default protection setting. However, the interconnect parameters can be modified to fit user expectations. Interconnect parameters can also be modified by the ROM code for HS/EMU devices.

14.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

Table 14-4 through Table 14-11 list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3_MAIN initiator (master network interface units (NIU) - MN) and target (slave NIUs - SN) agents
- L4_PER initiator and target agents
- L4_CFG initiator and target agents
- L4_WKUP initiator and target agents

14.1.3.1 L3_MAIN Interconnect Module Distribution

Table 14-4 and Table 14-5 list the IAs and TAs, respectively, of the L3_MAIN interconnect.

Table 14-4. Master NIUs

Master NIU	Description
MPU_INIT	Cortex™ A15 MPU subsystem
DSP_INIT	DSP subsystem
IPU_INIT	IPU subsystem
IVA_INIT	Video accelerator subsystem
MMC1_INIT, MMC2_INIT	Multimedia controller
GPU_P1_INIT	3D graphics accelerator port 1
GPU_P2_INIT	3D graphics accelerator port 2
DSS_INIT	Display subsystem
ISS_INIT	Imaging accelerator subsystem
FDIF_INIT	Face detection module
DEBUG_CS_DAP_INIT	JTAG®/emulation access to system resources
SDMA_RD_INIT	System DMA read
SDMA_WR_INIT	System DMA write
HSI_INIT	HSI module
BB2D_P1_INIT	2D graphics accelerator port 1
BB2D_P2_INIT	2D graphics accelerator port 2
USB_HOST_HS_INIT	Multiport USB host controller
USB_OTG_SS_INIT	USB on-the-go controller
SATA_INIT	SATA initiator port

Table 14-5. Slave NIUs

Slave NIU	Description
OCMC_RAM_TARG	On-chip memory controller target port
GPMC_TARG	General-purpose memory controller target port
DMM_P1_TARG	Dynamic memory management target port 1
DMM_P2_TARG	Dynamic memory management target port 2
GPU_TARG	3D graphics accelerator target port
BB2D_TARG	2D graphics accelerator target port
ISS_TARG	Imaging accelerator target port
IVA_CONFIG_TARG	Video accelerator subsystem configuration
IVA_SL2IF_TARG	Video accelerator subsystem shared memory
IPU_TARG	Dual Cortex-M4 subsystem
DSS_TARG	Display subsystem
ABE_TARG	Audio back end (ABE) target port
L3_INSTR_TARG	L3 instrumentation target port
L4_CFG_TARG	L4 interconnect configuration
L4_PER0/1/2/3_TARG	L4 interconnect peripherals
L4_WKUP_TARG	L4 interconnec wakeup
DEBUGSS_CT_TBR_TARG	Debug subsystem target port

14.1.3.2 L4 Interconnect Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 14-6 through Table 14-11 list all modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

14.1.3.2.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 14-6 lists the PER TAs.

Table 14-6. L4_PER TAs

Module Target Name	Description
UART1_TARG	UART port 1 module
UART2_TARG	UART port 2 module
UART3_TARG	UARTport 3 module
UART4_TARG	UART port 4 module
UART5_TARG	UART port 5 module
UART6_TARG	UART port 6 module
TIMER2_TARG	General-purpose TIMER2 module
TIMER3_TARG	General-purpose TIMER3 module
TIMER4_TARG	General-purpose TIMER4 module
TIMER9_TARG	Genera-purposel TIMER9 module
TIMER10_TARG	General-purpose TIMER10 module
TIMER11_TARG	General-purpose TIMER11 module
GPIO2_TARG	General-purpose input/output 2 (GPIO2) module
GPIO3_TARG	GPIO3 module
GPIO4_TARG	GPIO4 module
GPIO5_TARG	GPIO5 module
GPIO6_TARG	GPIO6 module
GPIO7_TARG	GPIO7 module
GPIO8_TARG	GPIO8 module
I2C1_TARG	Multimaster I2C1 module
I2C2_TARG	Multimaster I2C2 module
I2C3_TARG	Multimaster I2C3 module
I2C4_TARG	Multimaster I2C4 module
I2C5_TARG	Multimaster I2C5 module
MCSPI1_TARG	Multichannel serial port interface controller 1 module
MCSPI2_TARG	Multichannel serial port interface controller 2 module
MCSPI3_TARG	Multichannel serial port interface controller 3 module
MCSPI4_TARG	Multichannel serial port interface controller 4 module
MMC1_TARG	MMC1 module
MMC2_TARG	MMC2 module
MMC3_TARG	MMC3 module
MMC4_TARG	MMC4 module
MMC5_TARG	MMC5 module
ELM_TARG	Error location module
HDQ1W_TARG	HDQ 1-Wire® serial interface controller

Four ports communicate between the L3_MAIN interconnect and the L4_PER interconnect to allow the L3_MAIN initiators to access the L4_PER targets. Table 14-7 lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4_PER peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-7. L4_PER IAs

Module Initiator Name	Description
L3_MAIN_P0_INIT	L3 sDMA RD interconnect port
L3_MAIN_P1_INIT	L3 sDMA WR interconnect port
L3_MAIN_P2_INIT	L3 MPU susbystem interconnect port
L3_MAIN_P3_INIT	L3 others interconnect port

14.1.3.2.2 L4_CFG Interconnect Agents

The L4 CFG interconnect handles only transfers to peripherals in the CORE power domain. Table 14-8 lists the TAs.

Table 14-8. L4_CFG TAs

Module Target Name	Description
CTRL_MODULE_CORE_TARG	Control module core
CM_CORE_AON_TARG	CORE_AON module
DMA_SYSTEM_TARG	System DMA module
HSI_TARG	High-speed synchronous serial interface module
USB_TLL_HS_TARG	High-speed USB_TLL module
USB_OTG_SS_TARG	USB_OTG module
USB_HOST_HS_TARG	High-Speed Multi-port USB host controller module
SMARTREFLEX_CORE_TARG	SmartReflex core module
SMARTREFLEX_MM_TARG	SmartReflex MM module
SMARTREFLEX_MPU_TARG	SmartReflex MPU module
OCP2SCP1_TARG	OCP to SCP1 module
CM_CORE_TARG	CM_CORE module
DSP_TARG	DSP module
MAILBOX_TARG	MAILBOX module
SPINLOCK_TARG	SPINLOCK module
IVA_FW_TARG	IVA firewall
MPU_NTTP_FW_TARG	MPU NTTP firewall
OCMC_RAM_FW_TARG	OCMC_RAM firewall
EMIF_OCP_FW_TARG	EMIF L3 firewall
GPMC_FW_TARG	GPMC firewall
ISS_FW_TARG	ISS firewall
GPU_FW_TARG	GPU firewall
IPU_FW_TARG	IPU firewall
IVA_SL2IF_FW_TARG	IVA SL2 interface firewall
DEBUGSS_CT_TBR_FW_TARG	Debug subsystem CT TBR firewall
L3_INSTR_FW_TARG	L3 instruction firewall
ABE_FW_TARG	ABE firewall
OCP_WP_NOC_TARG	OCP_WP firewall
DSS_FW_TARG	Display subsystem firewall
FDIF_TARG	Face detection interface module
SATA_TARG	SATA module
BB2D_TARG	2D graphics accelerator module
OCP2SCP3_TARG	OCP-to-SCP3 module

L3_MAIN_INIT communicates between the L3_MAIN interconnect and the L4_CFG interconnect to allow the L3_MAIN initiators to access the L4_CFG targets (see Table 14-9).

For the list of initiators authorized to access the L4_CFG peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-9. L4_CFG IAs

Module Initiator Name	Description
L3_MAIN_INIT	L3_MAIN interconnect port

14.1.3.2.3 L4_WKUP Interconnect Agents

The L4_WKUP interconnect handles transfers only to peripherals in the WKUP power domain. Table 14-10 lists the TAs. Table 14-11 lists the L4_WKUP IAs.

Table 14-10. L4_WKUP TAs

Module Target Name	Description
GPIO1_TARG	GPIO1 module
32KTIMER_TARG	32-kHz timer module
SAR_RAM_TARG	Save-and-restore RAM
KEYBOARD_TARG	Keyboard module
CTRL_MODULE_WKUP_TARG	Control module WKUP module
PRM_TARG	Power reset management module
SCRM_TARG	System clock and reset management module
WD_TIMER2_TARG	Watchdog TIMER2 module
TIMER1_TARG	General-purpose TIMER1 module
SCRM_TARG	System clock and reset manager module

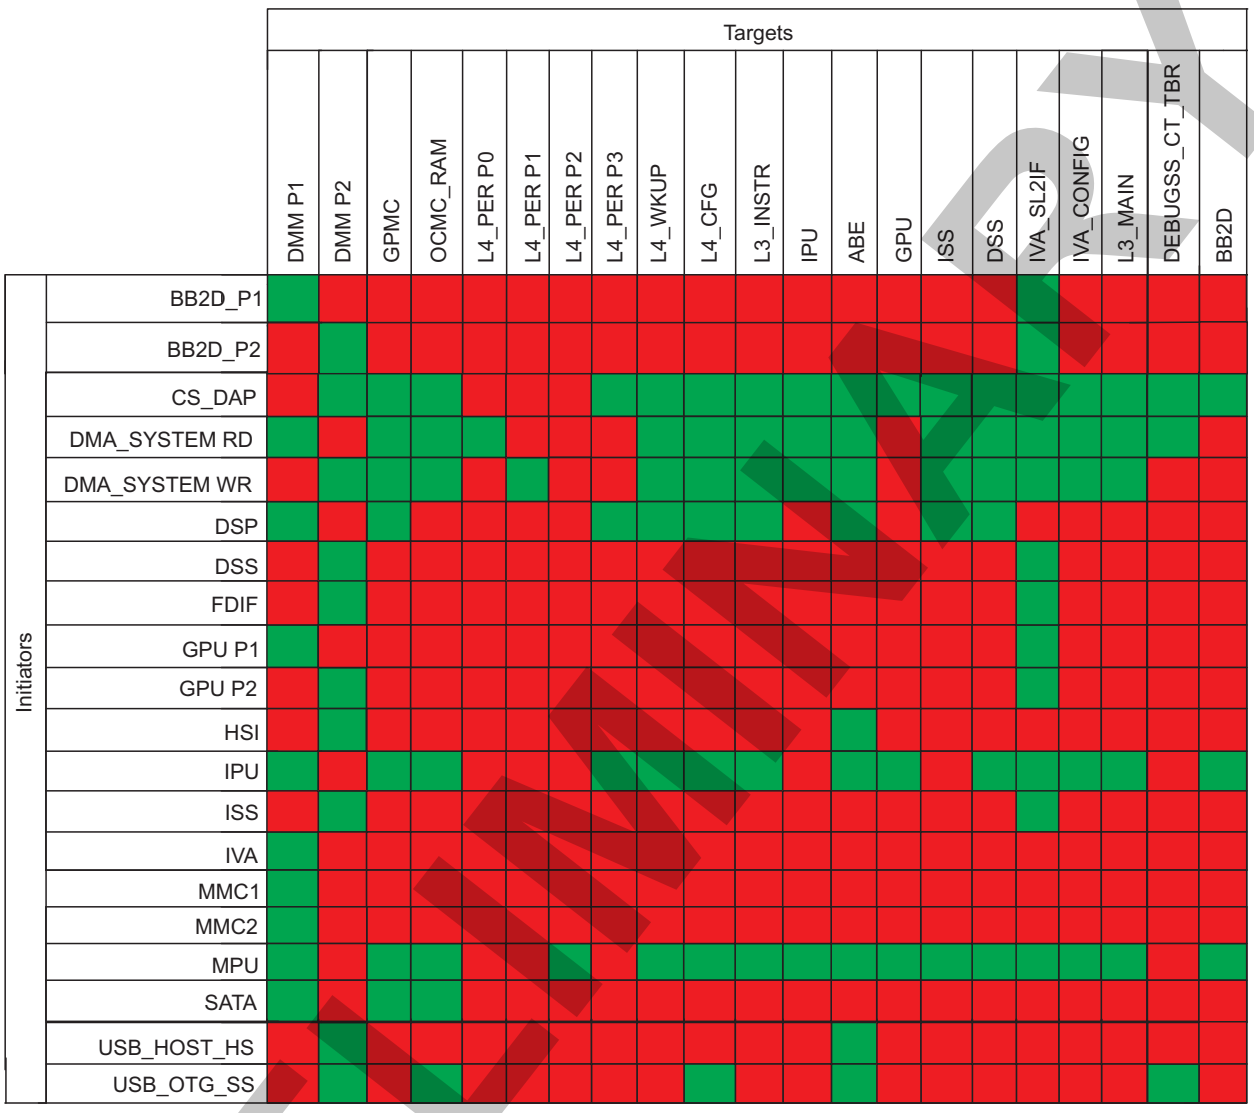
14.1.4 Connectivity Matrix

Figure 14-2 lists the functional paths between the L3_MAIN interconnect initiator modules and the L3_MAIN and L4 TAs. In this matrix:

- a cell is green when a functional path exists.
- a cell is red when a functional path does not exist.

Figure 14-2. Connectivity Matrix



I3-001

14.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

14.2.1 L3_MAIN Interconnect Overview

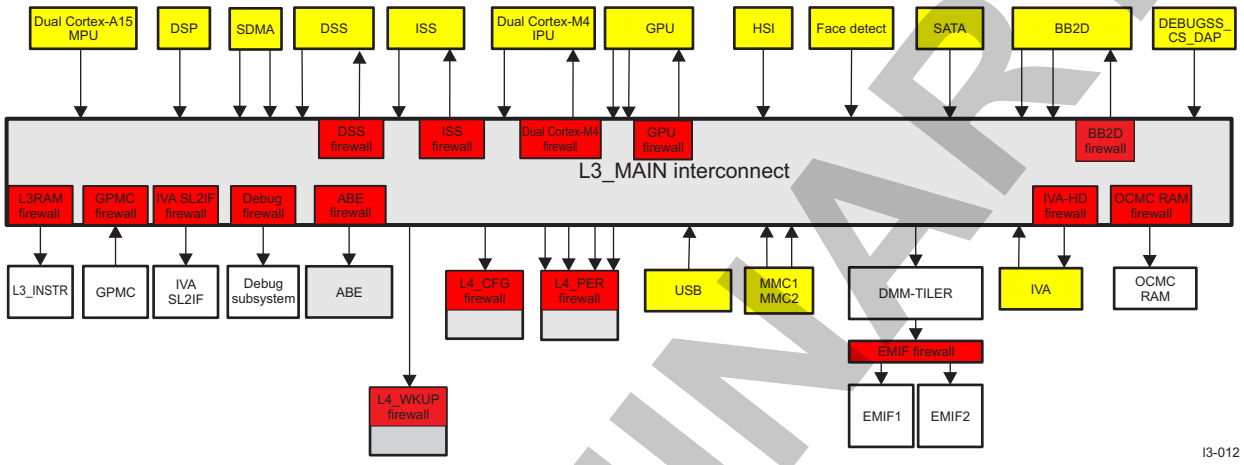
The L3_MAIN interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3_MAIN interconnects are:

- NIUs: Master NIUs for the IAs and slave NIUs for the TAs
- A partially depleted cross-bar exchange network
- A special internal slave NIU for accessing L3_MAIN interconnect configuration registers
- QoS management for real-time hardware operators, while maintaining optimal memory latency for CPU access to memory resources
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure
- One interrupt line signaling transaction error
- One interrupt line for reporting satistical events on the L3_MAIN interconnect

Figure 14-3 shows an overview of the L3 interconnect and the peripherals attached to it.

Figure 14-3. L3_MAIN Interconnect Overview



14.2.2 L3_MAIN Interconnect Integration

Table 14-12 through Table 14-14 summarize the integration of the module in the device.

Table 14-12. Integration Attributes

Module Instance	Attributes
	Power Domain
L3_MAIN	PD_CORE

Table 14-13. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L3_MAIN	L3_CLK2	L3MAIN2_L3_GICLK	PRCM	Functional and interface clock
	L3_CLK1	L3MAIN1_L3_GICLK	PRCM	Functional and interface clock
	L3_CLK3	L3INSTR_L3_GICLK	PRCM	Functional and interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L3_MAIN	L3_CORE_RET_RST	CORE_PWRON_RET_RST	PRCM	Reset of L3_PER interconnect retention registers
	L3_CORE_RST	CORE_RST	PRCM	Reset of L3_PER interconnect

Table 14-14. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
L3_MAIN	L3_MAIN_IRQ_DBG_ERR	MPU_IRQ_9	Cortex-A15 INTC	Interrupt to the Cortex-A15
	L3_MAIN_IRQ_APP_ERR	DSP_IRQ_84	DSP INTC	Interrupt to the digital signal processor (DSP)
	L3_MAIN_IRQ_APP_ERR	MPU_IRQ_10	Cortex-A15 INTC	Interrupt to the Cortex-A15
	L3_MAIN_IRQ_START_ALARM	MPU_IRQ_16	Cortex-A15 INTC	Interrupt to the Cortex-A15
	L3_MAIN_IRQ_APP_ERR	IPU_IRQ_46	IPU INTC	Interrupt to the IPU

14.2.3 L3_MAIN Interconnect Functional Description

14.2.3.1 Module Use in L3_MAIN Interconnect

The L3_MAIN interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUX to mask interrupts: Three, one for each clock domain
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration
- Some rate adapters for configuration of throughput ratio

14.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

Table 14-15 and Table 14-16 list all the modules and subsystems with their associated agents. The agents are listed for each L3_MAIN interconnect domain.

14.2.3.2.1 L3_MAIN Interconnect Agents

Any initiator or target core is connected to the L3_MAIN interconnect through an NIU. NIUs act as entry points to the L3_MAIN interconnect, and also include various programming registers. Table 14-15 lists the supported master NIU ports.

Table 14-15. Master NIUs

Master NIU	Description
MPU_INIT	Cortex-A15 microprocessor subsystem unit
DSP_INIT	DSP subsystem unit
IPU_INIT	IPU subsystem
IVA_INIT	Video accelerator subsystem
MMC1/2_INIT	Multimedia controller
GPU_P1_INIT	3D graphics accelerator port 1
GPU_P2_INIT	3D graphics accelerator port 2
DSS_INIT	Display subsystem
ISS_INIT	Imaging accelerator subsystem
FDIF_INIT	Face detection module
DEBUG_CS_DAP_INIT	JTAG or emulation access to system resources
SDMA_RD_INIT	System DMA read
SDMA_WR_INIT	System DMA write
HSI_INIT	HSI module
BB2D_P1_INIT	2D graphics accelerator port 1
BB2D_P2_INIT	2D graphics accelerator port 2
USB_HOST_HS_INIT	Multiport USB host controller
USB_OTG_SS_INIT	USB on-the-go controller
SATA_INIT	SATA initiator port

Table 14-16 lists the supported slave NIU ports.

Table 14-16. Slave NIUs

Slave NIU	Description
OCMC_RAM_TARG	On-chip memory controller target port
GPMC_TARG	General-purpose memory controller target port
DMM_P1_TARG	Dynamic memory management target port 1
DMM_P2_TARG	Dynamic memory management target port 2
GPU_TARG	3D graphics accelerator target port
BB2D_TARG	2D graphics accelerator target port
ISS_TARG	Imaging accelerator target port
IVA_CONFIG_TARG	Video accelerator subsystem configuration

DEBUGSS_CT_TBR_TARG	Debug subsystem target port

14.2.3.2.2 L3_MAIN Connectivity Matrix

The L3 interconnect is divided into three clock domains:

- L3_CLK1: Low-power domain
- L3_CLK2: Peripherals and multimedia
- L3_CLK3: Instrumentation (debug)

Each clock element is implemented in a different clock domain.

14.2.3.2.2.1 Clock Domain Mapping of the L3_MAIN Interconnect Modules

Each clock domain (CLK1, CLK2, and CLK3) has it own host, flag mux, slave NIUs, and bandwidth regulators. Table 14-17 lists the relationships between these domains and these elements.

Table 14-17. L3_MAIN Clock Domains and Elements

Clock Domain	Elements
L3_CLK1	HOST_CLK1
	DMM1/2_TARG

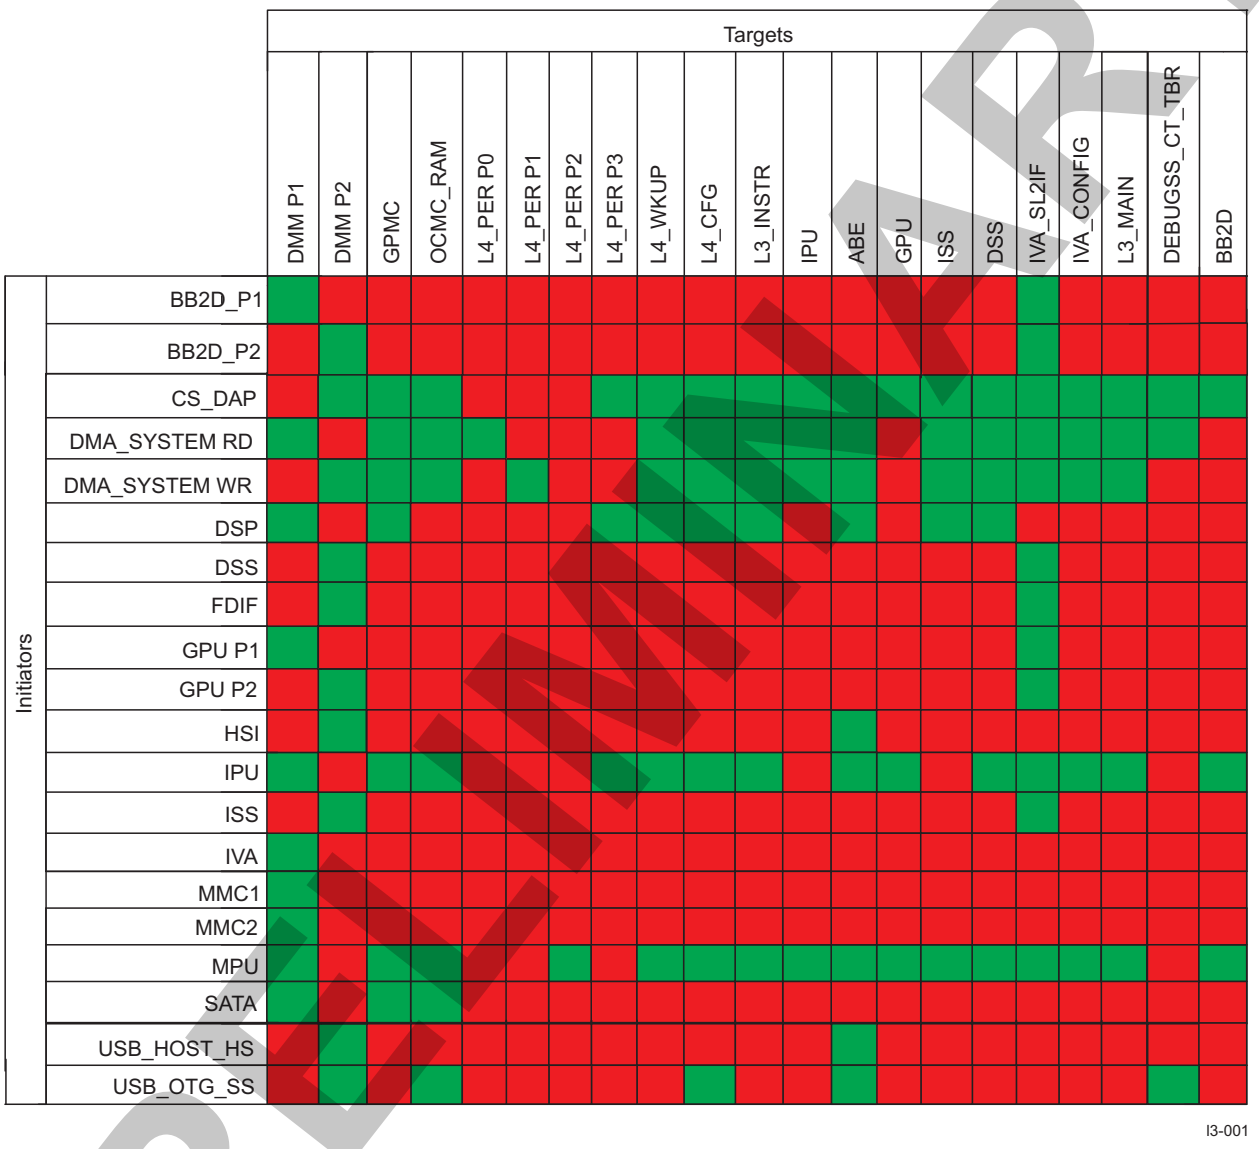
Figure 14-4 lists the functional paths between the L3_MAIN master NIUs and the L3_MAIN and L4 slave NIU agents. In this matrix:

- a cell is green when a functional path exists.
- a cell is red when a functional path does not exist.

Figure 14-4. L3_MAIN Connectivity Matrix



14.2.3.2.3 Master NIU Identification

A master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 14-18). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3_MAIN interconnect error logging

Table 14-18. ConnID Values

ConnID	Master NIU
0x0	Cortex-A15 MPU
0x4	DAP
0x8	DSP
0xC	IVA
0x10	ISS
0x11	IPU subsytem
0x12	Face detect
0x14	sDMA_rd
0x15	sDMA_wr
0x18	GPU_P1
0x19	GPU_P2

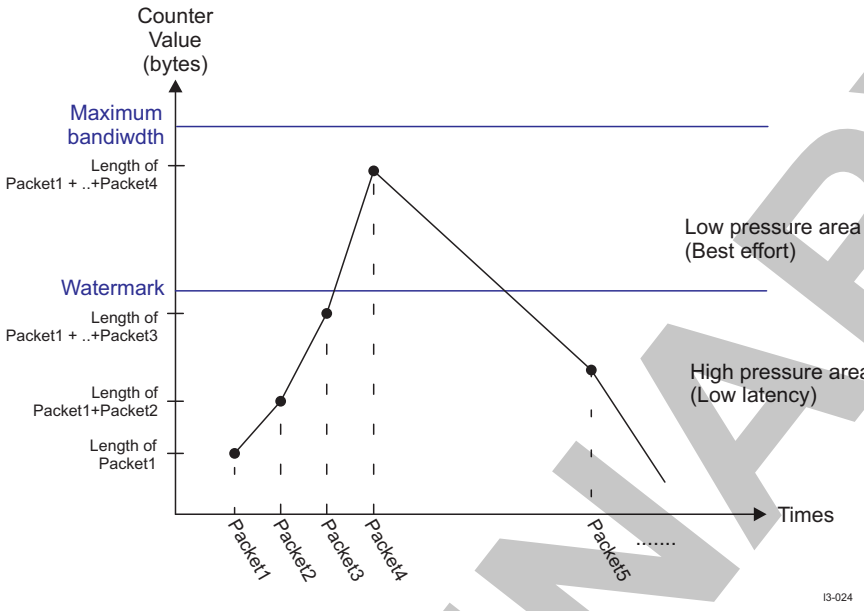
14.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

A counter is used to store the sum of data lengths (in bytes) of each packet passing through the bandwidth regulator, and a value equal to the expected bandwidth is subtracted from the counter at each clock cycle. The value of the counter is compared to a programmable threshold (called Watermark), and this comparison determines whether the packet is processed with high pressure for minimum latency or low pressure for best effort processing.

The bandwidth regulator monitors the traffic using open connections between the initiators and the targets. If there is insufficient bandwidth allocated to the connection, the bandwidth regulator can increase the pressure on connections. Generally, the connection is a dataflow between master and slave NIUs. In some cases, the bandwidth regulator is attached to the master and monitors single dataflow to a target (single connection).

Figure 14-5. Bandwidth Regulator Pressure Settings



When Counter Value (bytes) falls below Watermark, the pressure bit is assigned to 1

The bandwidth regulator effective resolution is set to 16.6 MBps. The maximum average bandwidth (max watermark value) computed in a moving window is set to up to 4096 bytes of payload. These settings are implemented by hardware.

The following is an example of bandwidth regulator settings:

The bandwidth regulator is set to run at 200 MHz and the application requires an expected bandwidth of 165.888 MBps (±5 MBps), computed through a moving window of 5 µs (1000 cycles). To attribute high pressure on all packets requests, the watermark could be set to the maximum bandwidth needed in the 5-µs window.

Considering the example, the settings of the bandwidth regulator are:

- L3_BW_R_WATERMARK[11:0] WATERMARK = moving window × expected bandwidth = 829.44 bytes = 0x33D
- L3_BW_R_BANDWIDTH[15:0] BANDWIDTH = 165.888 MBps / effective resolution = 13,271 = 0xD

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- L3_BW_REGULATOR_WATERMARK: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- L3_BW_REGULATOR_PRESS: Describes the pressure applied to outgoing packets
- L3_BW_REGULATOR_CLEARHISTORY: Resets the traffic counter when set to 1. This register is used after an update in the L3_BW_REGULATOR_BANDWIDTH and L3_BW_REGULATOR_WATERMARK registers (see Section 14.2.5.1.6, *L3 BW Regulator Register Summary and Description*).

Bandwidth regulators are mainly used to give priority to the following masters: IVA, GPU_P1/P2 and BB2D_P1/P2.

As far as DSS and ISS real-time traffic is concerned, its priority is given by internal signal (outputted by the corresponding module). The L3_MAIN interconnect uses this signal to control its internal arbitration.

14.2.3.4 Bandwidth Limiters

The bandwidth limiter is added to control the bandwidth of the BB2D module. This prevents a large number of RD requests being processed together, thus avoiding a large number of RD responses.

The bandwidth limiter regulates the packet flow in the L3_MAIN interconnect by applying flow control when a user-defined bandwidth limit is reached. The next packet is served only after an internal timer expires, thus ensuring that traffic does not exceed the allocated bandwidth.

The registers in this group are:

- L3_BW_LIMITER_WATERMARK_0: Gives the amount of data allowed to exceed the average bandwidth during a short time period. To set the actual watermark to n bytes, the register must be set to n + 1.
- L3_BW_LIMITER_CLEARHISTORY: Resets the traffic counter when set to 1.
- L3_BW_LIMITER_BANDWIDTH_FRACTIONAL and L3_BW_LIMITER_BANDWIDTH_INTEGER: These two registers are used to set the average payload bandwidth.

NOTE: The bandidth limiter is configured to be transparent at reset.

14.2.3.5 Flag Muxing

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU interrupt controller (INTC) without interfering with the interconnect traffic. Using the L3_FLAGMUX_MASK registers can prevent the flag mux from seeing certain events.

The unit has a standard COREREG register for identification of the attached core type. The L3_FLAGMUX_STDHOSTHDR_VERSIONREG register identifies the characteristics of the attached core. Use unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number; for example, L3_FLAGMUX_REGERR0 reports on bit 0, and L3_FLAGMUX_REGERR1 reports on bit 1. Any given L3_FLAGMUX_REGERR register reports the same bit for all flag source inputs (see Table 14-164).

14.2.3.5.1 Flag Mux Time-out

If a target does not respond after a fixed number of clock cycles, an error time-out flag is generated, in case it is enabled. The value of the flag is always 3 if a time-out error is present.

To enable time-out for each target, set the L3_FLAGMUX_TIMEOUT_MASK0 register to 1. See Table 14-19.

Table 14-19. L3 Time-out Flag Mapping

	Flag Mux Input	Source
CLK1 Time-out FlagMux	0	L4_WKUP_TARG
	1	L4_CFG_TARG
	2	ABE_TARG
	3	DMM_P2_TARG
	4	DMM_P1_TARG

Table 14-19. L3 Time-out Flag Mapping (continued)

	Flag Mux Input	Source
CLK2 Time-out FlagMux	0	IVA_SL2IF
	1	Reserved
	2	GPU
	3	OCMC_RAM
	5	L4_PER_P3
	6	Reserved
	7	Reserved
	8	L4_PER_P2
	9	L4_PER_P1
	10	L4_PER_P0
	11	IVA_CONFIG
	12	ISS
	13	GPMC
	14	Reserved
	15	Reserved
	16	IPU
	17	BB2D
	18	DSS
CLK3 Time-out FlagMux	0	03_INSTR
	1	DEBUGSS_CT_TBR

For example, to enable all targets in CLK1, write 0x1F in L3_FLAGMUX_TIMEOUT_MASK0. To enable only OCMC_RAM, write 0x8 in L3_FLAGMUX_TIMEOUT_MASK0 (for instance, CLK2_FLAGMUX_CLK2).

If an error time-out occurs, read the L3_FLAGMUX_TIMEOUT_REGERR0 register to check which target does not respond according to Table 14-19.

14.2.3.6 Rate Adapter Generators

The rate adapter generators give the option to configure the L3 interconnect to work in auto-adaptive mode or pipeline mode for sending the packets by using the CNF register. The rate adapter can be configured in store-and-forward mode when the throughput ratio is not well defined, or in auto-adaptive mode when the throughput ratio is predictable. Because the ratios are predictable in the L3_MAIN interconnect, the rate adapters are always used in auto-adaptive mode, except for the rate adapter on the L4_CFG and L4_ ABE responses path. L4_CFG and L4_ABE are configured in store-and-forward mode. The main rate adapt registers are:

- CLK1_RATE_ADAPT_RESP_32TO128_CLK1: Removes WAIT cycles on responses coming from ABE, L4_CFG, and power disconnect to host
- CLK2_RATE_ADAPT_RESP_32TO128_CLK2: Removes WAIT cycles on responses coming from CLK2 32-bit slaves (see Table 14-217)

14.2.3.7 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Event detectors are programmed through the L3_STCOL_REQEVT and L3_STCOL_RSPEVT configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the L3_STCOL_EN register. The L3_STCOL_SOFTEN register enables software to monitor the performance. Event muxes are programmed through the L3_STCOL_EVTMUX_SEL0 configuration register, which determines which port will be monitored by a filter configured by the filter registers (see Table 14-318).

Filters are programmed through the Table 14-318 configuration register, along with additional selection criteria programmed through the mask/match registers (see Table 14-227). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see Table 14-227).

14.2.3.8 L3_MAIN Protection and Firewalls

Device protection relies on L3 firewalls and their configuration.

14.2.3.8.1 L3_MAIN Firewall Reset

The values of L3_MAIN firewall registers on reset are tied in hardware or exported from the control module registers.

Values exported from the control module are intended to give defined rights to the firewalls at reset and thus ensure the content after going out of reset. Because the control module consists of retention flip-flops (RFFs), which immunize it against register content loss during retention power state, the registers of the control module storing the exported values are not subject to a soft reset.

The L3_MAIN firewall registers are also retention-capable and are immune against content loss during CORE RETENTION power state. The control module registers are reset by a cold reset only, whereas the L3_MAIN firewall registers are reset by clearing the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit. When the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit comes back automatically to 1, the exported values are loaded.

CAUTION

Before reprogramming the firewall registers and/or before using the FW_LOAD_REQ mechanism, the request must be asserted by configuring the REGUPDATE_CONTROL[0] BUSY_REQ bit.

To load the exported values at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Clear the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit by writing 0x1 to it.
3. Wait until the REGUPDATE_CONTROL[1] FW_LOAD_REQ bit is reset to 0x1 by hardware.
4. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

To reprogram the firewall registers at run time:

1. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Upload the new values to all firewall registers.
3. Set the REGUPDATE_CONTROL[0] BUSY_REQ bit to 0x0 to allow transactions to reach the slave NIU (resume).

NOTE: At reset, exported values from the control module can modify hardware reset values.

14.2.3.8.1.1 L3_MAIN Firewall – Exported Reset Values

Table 14-20 and Table 14-21 list the exported reset values and mapping, respectively.

Table 14-20. L3_MAIN Firewall Exported Reset Values

MRM_PERMISSION_REGION_LOW_j [15:12]	MRM_PERMISSION_REGION_LOW_j [11:0]
0x0	0xFFF
0xF	0xFFF
0x0	0x038
0x2	0x038

Table 14-21. L3_MAIN Firewall Exported Values Mapping

[5]	ISS and IPU subsystem
[6]	GPU
[7]	IVA_SL2
[8]	IVA_CFG
[10]	ABE
[11]	EMIF
[12]	DEBUG Subsystem
[13]	L4_ABE
[16]	BB2D

For more information, see Chapter 18, *Control Module*.

14.2.3.8.2 Power Management

As part of the system-wide power-management scheme, the L3_MAIN interconnect goes into IDLE state after receiving a request from the power, reset, and clock management (PRCM) module after all commands are serviced. This function is handled by hardware.

To reduce power consumption, the L3_MAIN interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers:

- Statistic collectors
- Internal rate adapters
- Bandwidth regulators

- Target agents
- Firewalls

This process prevents reconfiguration after a clock domain switches off.

14.2.3.8.3 L3_MAIN Firewall Functionality

The access to the slave NIUs is granted only to master NIUs according to in-band attributes sent in each transaction crossing the L3_MAIN interconnect, such as:

- MCMD: Specifies the type of access (read or write) required by the master NIU
- ConnID: Used to determine the permission of the master NIU
- MReqInfo: Transaction attribute adding information about the access type

Table 14-22 lists the MReqInfo values.

Table 14-22. MReqInfo Values

Qualifier	Access Definition	Access Description
MReqType	00: Processor data access 01: Processor instruction access 10: DMA access 11: Other	Indicates whether the request is for processor instruction fetch, processor data access or DMA access
MReqDebug	0: Functional 1: Debug	When set, indicates that the request has been issued by a master NIU in DEBUG state
MReqSupervisor	0: User 1: Privilege	When set, indicates that the request is qualified with the supervisor attribute. It can be provided by a processor running in supervisor mode or by a module that inherited this attribute from the processor (DMA channel with a supervisor attribute).

The firewall comparison mechanism enables access to a protected slave NIU only when a correct combination of three MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor. See Table 14-23.

Table 14-23. L3_MAIN ReqInfo Mapping

ReqInfo Name		MReqDebug	MReqType	MReqSupervisor
Master NIUs	MPU_INIT	x	x	x

	DSS			

14.2.3.8.3.1 Protection Regions

Each slave NIU address space is subdivided into protection regions (maximum of 10). The regions are configurable with a size of 4-KiB granularity. The firewalls can also be multiport while using the description of the same regions for dual access memories or to support interleaving mechanisms on several memories.

Table 14-24 lists the number of protected regions and ports for each slave NIU.

Table 14-24. Slave NIU Firewall and Region Configuration

Domain	Slave NIU	Firewall	Number of Regions	Number of Ports
CLK1	ABE	ABE_FW	1	1
CLK2	OCMC_RAM	OCMC_RAM_FW	16	1
	GPMC	GPMC_FW	8	1
	IVA_SL2IF	IVA_SL2_IF_FW	4	1
	IVA_CONFIG	IVA_CONFIG_FW	1	1
	DSS	DSS_FW	8	1
	ISS	ISS_FW	1	1
	IPU	IPU_FW	4	1
	GPU	GPU_FW	1	1
	BB2D	BB2D_FW	1	1
CLK3	L3_INSTR	L3_INSTR_FW	2	1
	DEBUGSS_CT_TBR	DEBUGSS_CT_TBR_FW	1	1

Two types of regions are distinguished in a slave NIU firewall:

- Default region: Available in all slave NIUs. The default region covers the entire slave NIU address range. Other firewall-configured regions must reset or overlay the default region, because it always has the lowest priority.
- Normal region: The number of normal regions varies in a slave NIU; they have identical capabilities (see Table 14-24).

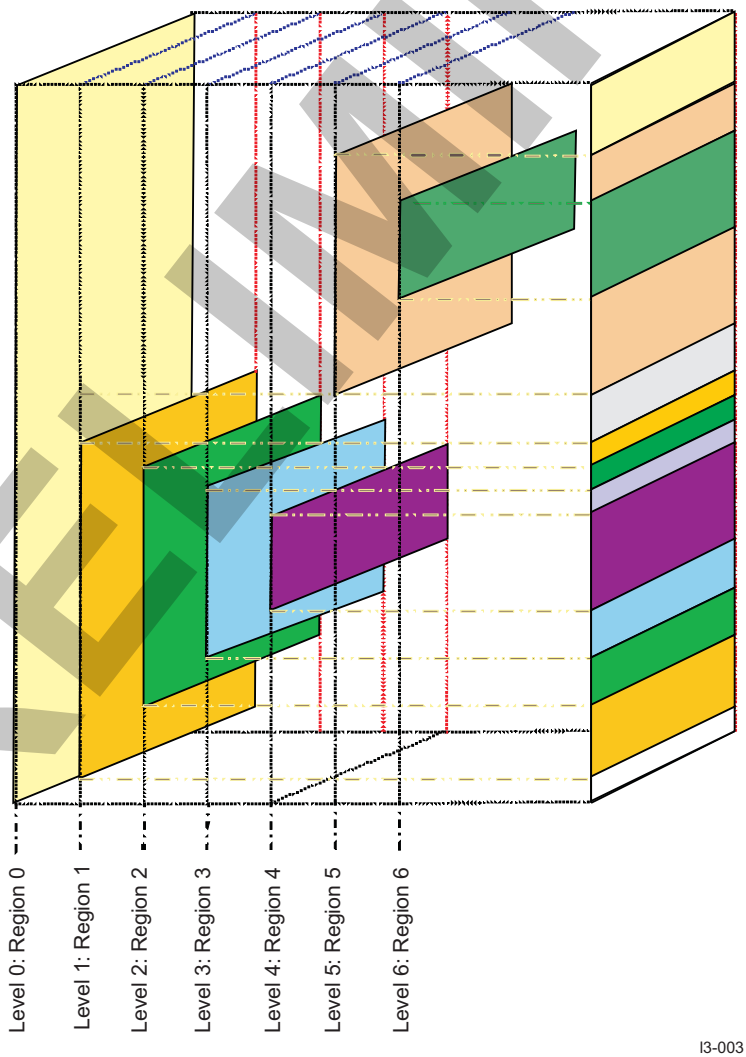
Each region has the following characteristics:

- Start address: Physical slave NIU start address
- End address: Physical slave NIU end address
- Specific access rights (see Section 14.2.3.8.3.3, *Protection Mechanism per Region Examples*)
- Priority level from 0 (lowest) to 10 (highest)

Depending on its priority level, a region can override the settings of another region; the access rights of the region with the highest priority apply. All regions have a fixed (not configurable) priority level that corresponds to their number: Region 1 has priority level 1, region 2 has priority level 2, and so on.

Figure 14-6 shows the priority level with associated regions. This priority level scheme allows multiplying the flexibility and capability of the firewall. Figure 14-6 shows a 7-region firewall setting that creates 13 regions (twice the number of regions created than originally available).

Figure 14-6. L3 Interconnect Region Overlay and Priority Level Overview



The address range covered by the regions is defined in the START_REGION_i and END_REGION_i registers. The boundary checks are done on a minimum size of 4-KiB pages; thus, bits [11:0] of those 32-bit registers are not checked.

The address space size of the slave NIUs ([bits [31:12]) depends on the size of the slave NIU to protect (that is, if a memory is only 48KiB, then the size is defined through bits [16:12] of the slave NIU start and end address registers of the firewall region (START_REGION_i[16:12] and END_REGION_i[16:12]).

On multiport firewalls (EMIF), the checking of each REGION {0, n} can activate on one or several ports at the same time. However, if interleaving is not desired on some parts of the protected memory space, it is possible to apply or not apply region checking on selected ports using the region enable/disable on port instance capability of the END_REGION_i register.

Most slave NIUs support only one input port (port 0) except:

- The EMIF module protected by the EMIF firewall has three ports:
  - Port 0 for MPU accesses
  - Port 1 for the first L3_MAIN interconnect accesses
  - Port 2 for the second L3_MAIN interconnect accesses

A region can be applied or not to each port independently. To enable and disable the regions:

- For port 0: Set/clear the END_REGION_i[0] END_REGION_i_ENABLE_CORE0 bit (for all L3_MAIN firewalls).
- For port 1: Set/clear the END_REGION_i[1] END_REGION_i_ENABLE_CORE1 bit (EMIF firewalls).

14.2.3.8.3.2 L3_MAIN Firewall Registers Overview

Table 14-25 and Table 14-26 list the L3_MAIN firewall permission-setting registers.

Table 14-25. L3_MAIN Firewall Read/Write Permission-Setting Register

Register Name	Bits	Field Name	Description (see Table 14-18)	Field Modifiability
MRM_PERMISSION_REGION_HIGH_j	31	W	ConnID = 15 write permission	RW
	30	R	ConnID = 15 read permission	RW
	29	W	ConnID = 14 write permission	RW
	28	R	ConnID = 14 read permission	RW
	27	W	ConnID = 13 write permission	RW
	26	R	ConnID = 13 read permission	RW
	25	W	ConnID = 12 write permission	RW
	24	R	ConnID = 12 read permission	RW
	23	W	ConnID = 11 write permission	RW
	22	R	ConnID = 11 read permission	RW
	21	W	ConnID = 10 write permission	RW
	20	R	ConnID = 10 read permission	RW
	19	W	ConnID = 9 write permission	RW
	18	R	ConnID = 9 read permission	RW
	17	W	ConnID = 8 write permission	RW
	16	R	ConnID = 8 read permission	RW
	15	W	ConnID = 7 write permission	RW
	14	R	ConnID = 7 read permission	RW
	13	W	ConnID = 6 write permission	RW
	12	R	ConnID = 6 read permission	RW
	11	W	ConnID = 5 write permission	RW
	10	R	ConnID = 5 read permission	RW
	9	W	ConnID = 4 write permission	RW
	8	R	ConnID = 4 read permission	RW
	7	W	ConnID = 3 write permission	RW
	6	R	ConnID = 3 read permission	RW
	5	W	ConnID = 2 write permission	RW
	4	R	ConnID = 2 read permission	RW
	3	W	ConnID = 1 write permission	RW
	2	R	ConnID = 1 read permission	RW
	1	W	ConnID = 0 write permission	RW
	0	R	ConnID = 0 read permission	RW

Table 14-26. L3_MAIN Firewall Permission-Setting Register

Register name	Type of Permission	Bits	Field Name	Description	Field Modifiability
MRM_PERMISSION_REGION_LOW_j	Reserved	31:16		Reserved	
	Debug	15	DEBUG	PUBLIC PRIVILEGE DOMAIN DEBUG ALLOWED	RW
		14	DEBUG	PUBLIC USER DOMAIN DEBUG ALLOWED	RW
	Reserved	13:12		Reserved	
	Access	11	READ	PUBLIC PRIVILEGE READ ACCESS ALLOWED	RW
		10	WRITE	PUBLIC PRIVILEGE WRITE ACCESS ALLOWED	RW
		9	EXE	PUBLIC PRIVILEGE EXE ACCESS ALLOWED	RW
		8	READ	PUBLIC USER READ ACCESS ALLOWED	RW
		7	WRITE	PUBLIC USER WRITE ACCESS ALLOWED	RW
		6	EXE	PUBLIC USER ECXE ACCESS ALLOWED	RW

14.2.3.8.3.3 Protection Mechanism per Region Examples

The access permission of each region is configurable and defined through the MRM_PERMISSION_REGION_HIGH_j and MRM_PERMISSION_REGION_LOW_j registers (see Section 14.2.3.8.3.2, *L3_MAIN Firewall Registers Overview*).

Master NIU permissions:

1. To give read access to the master NIU with ConnID = n, set the MRM_PERMISSION_REGION_HIGH_j[n × 2] R bit.
2. To give write access to the master NIU with ConnID = n, set the MRM_PERMISSION_REGION_HIGH_j[n × 2 + 1] W bit.

Debug permissions:

1. To give privilege debug access, set the MRM_PERMISSION_REGION_LOW_j[15] DEBUG bit.
2. To give user debug access, set the MRM_PERMISSION_REGION_LOW_j[14] DEBUG bit.

User, read, write, and executable permissions:

1. To give privileged write access, set the MRM_PERMISSION_REGION_LOW_j[11] READ bit.
2. To give privileged read access, set the MRM_PERMISSION_REGION_LOW_j[10] WRITE bit.
3. To give privileged executable access, set the MRM_PERMISSION_REGION_LOW_j[9] EXE bit.
4. To give user write access, set the MRM_PERMISSION_REGION_LOW_j[8] READ bit.
5. To give user read access, set the MRM_PERMISSION_REGION_LOW_j[7] WRITE bit.
6. To give user executable access, set the MRM_PERMISSION_REGION_LOW_j[6] EXE bit.

Example: To provide debug write privilege access to the master NIU ConnID = 7, set the following bits:

- MRM_PERMISSION_REGION_HIGH_j[15] W
- MRM_PERMISSION_REGION_LOW_j[15] DEBUG

14.2.3.8.3.4 L3_MAIN Firewall Error Logging

If a protection violation error is detected, the following signals are generated:

- An in-band error is generated to the master NIU of the access.
- An interrupt is generated to the Cortex-A15 and DSP INTCs.

The L3_MAIN interconnect does not differentiate errors generated by firewalls from all other supported types of errors.

An in-band error is generated by modules each time an access is not allowed. When an in-band error is sent back into the transaction it is seen as an external prefetch or data abort by the initiator, depending on whether the transaction was an instruction fetch or a data access.

Information about in-band errors is logged into two registers:

- ERROR_LOG_k: Logs the information about the start/end address of the hit region and the qualifiers of the transaction
- LOGICAL_PHYSICAL_ADDRESS_ERRLOG_k[31:12]: Logs the address of the failed access

NOTE: When a multiport firewall is implemented, these registers are duplicated for each port.

Table 14-27 lists the L3_MAIN firewall error-logging registers.

Table 14-27. L3 Firewall Error-Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
ERROR_LOG (When multiport firewall is implemented the error log register is duplicated for each port.)	RESERVED[31:24]	Read only	Reads return 0s.
	BLK_BURST_VIOLATION[23]	Read/write	Read 0x1: 2D burst not allowed or exceeds allowed size. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	SLVOFST_TRANSLATION_VIOLATION[22]	Read/write	START and END address of translated region cross two regions Marked as reserved when translation mechanism is not generated
	REGION_START_ERRLOG[21:17]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REGION_END_ERRLOG[16:12]	Read/write	Read: Wrong access hit this region number. Write to clear the ERROR_LOG and LOGICAL_PHYSICAL_ADDRESS_ERRLOG registers.
	REQINFO_ERRLOG[11:0]	Read/write	Mapping of the error according to the reqinfo vector: ConnID [3:0] MCMD [0] [3] MReqDebug [1] MReqSupervisor [0] MReqType

L3 firewall errors can be cleared by writing to the ERROR_LOG_k register in the firewall that recorded the error. Clearing the ERROR_LOG_k register deasserts the corresponding error if it exists.

The L3 firewall register ERROR_LOG_k must be cleared before clearing the CONTROL_CORE_SEC_ERR_STATUS_FUNC and CONTROL_CORE_SEC_ERR_STATUS_DEBUG registers in the control module.

When a protection violation occurs, an interrupt is sent to the MPU and DSP INTC (if enabled). An in-band error is sent back, and an error is logged in the CONTROL_SEC_ERR_STATUS_FUNC and CONTROL_SEC_ERR_STATUS_DEBUG registers, depending on the functional mode:

- In application mode:
  - CONTROL_SEC_ERR_STATUS_FUNC[1] – L3 RAM protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[2] – GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[3] – EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[4] – IVA protection violation

- CONTROL_SEC_ERR_STATUS_FUNC[5] – IPU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[6] – IVA SL2 protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[8] – SYSTEM DMA protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[13] – GPU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[14] – DSS protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[15] – ISS protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[16] – L4_PER protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[17] – L4_CFG protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[18] – DEBUG subsystem protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[19] – AUDIO slave NIU protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[22] – L4_WKUP protection violation
- CONTROL_SEC_ERR_STATUS_FUNC[23] – BB2D protection violation

• In debug mode:

- CONTROL_SEC_ERR_STATUS_DEBUG[1] – L3 RAM protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[2] – GPMC protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[3] – EMIF protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[4] – IVA protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[5] – IPU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[6] – IVA SL2 protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[13] – GPU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[14] – DSS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[15] – ISS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[16] – L4_PER protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[17] – L4_CFG protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[18] – DEBUG subsystem protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[19] – AUDIO slave NIU protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[22] – L4_WKUP protection violation
- CONTROL_SEC_ERR_STATUS_BEGUG[23] – BB2D protection violation

For more information, see Chapter 18, *Control Module*.

14.2.3.8.3.5 L3_MAIN Firewall Default Configuration

Table 14-28 summarizes the configuration of the L3_MAIN firewalls.

Table 14-28. L3_MAIN Firewalls Default Configurations

Device/Region: 0						
Permission Type	**Reset Value**	**Reset Value**	**Reset Type**	**Run Time**	**Firewall Register (where j = 0)**	**Control Module Register**
ACCESS_ PERMISSION	All	0xFFF	Exported	Configurable	MRM_PERMISSION_REGION_LOW_j[11:0]	CONTROL_CORE_L3_HW_FW_ EXPORTED_VALUES_LOCK[k]
DEBUG_ PERMISSION	All	0xF	Exported	Configurable	MRM_PERMISSION_REGION_LOW_j[15:12]	CONTROL_CORE_L3_HW_FW_ EXPORTED_VALUES_LOCK[k]
INITIATOR_ PERMISSION	All	0xFFF FFFFF	Tied	Configurable	MRM_PERMISSION_REGION_HIGH_j[31:0]	N/A

NOTE: For the values of k see Table 14-29.

Table 14-29. Control Module Register – Factorization

Variable Value k	Module Name	Regions
3	L3 RAM firewall	Regions 1 to 7
0	GPMC firewall	Regions 1 to 7
7	IVA_SL2IF firewall	Regions 1 to 7
6	GPU firewall	Regions 1 to 7
5	ISS firewall	Regions 1 to 7
4	DSS firewall	Regions 1 to 7
8	IVA firewall	Regions 1 to 7
12	DEBUG firewall	Region 1
13	DEBUGSS_CT_TBR firewall	Region 1
11	EMIF firewall	Regions 1 to 7

14.2.3.9 L3_MAIN Interconnect Error Handling

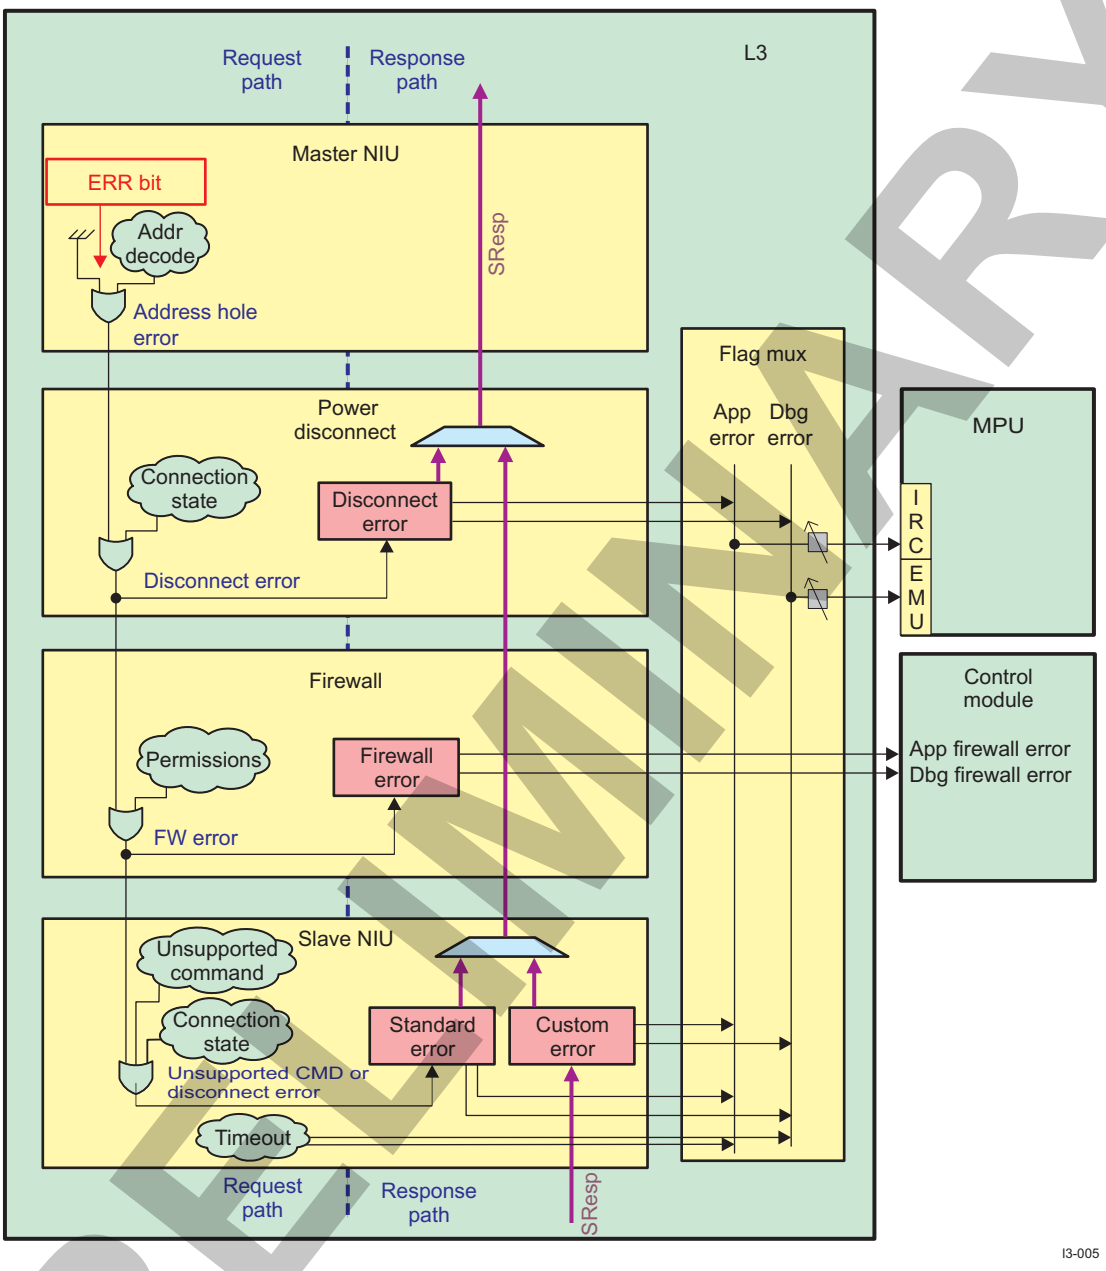
Error logging is enabled in the L3_MAIN interconnect. The three major types of errors are:

- Slave NIU errors
- Firewall errors (see Section 14.2.3.8.3.4, *L3_MAIN Firewall Error Logging*)
- Flag mux errors

14.2.3.9.1 Global Error-Routing Scheme

Figure 14-7 shows the L3_MAIN global error-routing scheme.

Figure 14-7. L3_MAIN Global Error-Routing Scheme



14.2.3.9.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 14-30).

Table 14-30. L3_MAIN Connectivity and Holes Error Routing

Master	Connectivity and Holes Errors Logged Into Slave NIUs
DEBUGSS_CS_DAP	GPMC
IPU	
MPU	
DMA_SYSTEM_RD	
DMA_SYSTEM_WR	
SATA	
DSP	
IVA	DMM1
MMC1	
MMC2	
BB2D_P1	
GPU_P1	
DSS	
	ISS
	FACE DETECT
	BB2D_P2
	GPU_P2
USB_OTG_SS	OCMC_RAM
HSI	ABE
USB_HOST_HS	

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module. For more information, see Section 14.2.3.8.3.4, *L3_MAIN Firewall Error Logging*.
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3_MAIN address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
  - None: Error logging for this type of error is disabled.
  - Error: Error is logged for this type of error.
  - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
  - Application error - FAULT[0]
  - Debug error - FAULT[1]

  By default, all slave NIUs are configured with standard and custom error levels set to FAULT. The errors are reported on the two flag muxes (see Figure 14-7), depending on the access type, application or debug. For more information, see Section 14.2.3.9.3, *Flag Mux Error Logging*.

  The slave NIU power-disconnect component also has error logging enabled, because in this case the slave NIU is in a clock domain that is switched off and therefore cannot catch the error. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

  Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the

slave is awake. Although this is inefficient, it simplifies NIU implementation and should not be a problem because errors are supposed to occur only during software debug.

14.2.3.9.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- L3_FLAGMUX_MASK0: Masks application error sources
- L3_FLAGMUX_MASK1: Masks debug error sources
- L3_FLAGMUX_REGERR0: Checks which application error sources are active
- L3_FLAGMUX_REGERR1: Checks which debug error sources are active

The two L3_FLAGMUX_MASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

Table 14-31 describes the mapping of the flags to the corresponding sources.

Table 14-31. Interconnect Flag Mapping

	Flag Mux Input	Source
CLK1 Flag Mux	0	DMM_P1
	1	DMM_P2
	2	ABE
	3	L4_CFG
	4	CLK1_PWR_DISC_TARG_CLK2
	5	HOST_CLK1
	6	L4_WKUP
CLK2 Flag Mux	0	IPU
	1	DSS
	2	GPMC
	3	ISS
	4	IVA_CONFIG
	6	L4_PER_P0
	7	OCMC_RAM
	8	GPMC SERROR
	9	GPU
	10	IVA_SL2IF
	12	CLK2_PWR_DISC_TARG_CLK1
	15	L4_PER_P3
	16	L4_PER_P1
	17	L4_PER_P2
	18	HOST_CLK2
	22	BB2D
CLK3 Flag Mux	0	L3_INSTR
	1	DEBUGSS_CT_TBR
	2	HOST_CLK3

14.2.3.9.4 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The L3_TARG_STDERRLOG_SVRTSTDLVL register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The L3_TARG_STDERRLOG_SVRTCUSTOMLVL register shows the severity level for custom errors

(see Table 14-69).

- The L3_TARG_STDERRLOG_MAIN register (the main register for error-logging management) shows the validity of the logged information, standard or custom.
- The L3_TARG_STDERRLOG_HDR register stores packets in case of a standard error.
- The L3_TARG_STDERRLOG_MSTADDR register returns the MSTADDR field of the logged packet.
- The L3_TARG_STDERRLOG_SLVADDR register returns the SLVADDR field of the stored packet.
- The L3_TARG_STDERRLOG_INFO register saves the information field of the logged packet.

14.2.4 L3_MAIN Interconnect Programming Guide

14.2.4.1 L3 _MAIN Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3_MAIN interconnect module.

14.2.4.1.1 Global Initialization

14.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3_MAIN interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3_MAIN interconnect. For more information, see Section 14.2.2, *L3_MAIN Interconnect Integration* .

Table 14-32. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For information about the configuration of the PRCM module, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	For information about the configuration of the control module, see Chapter 18, *Control Module*.
MPU INTC	The MPU INTC must be configured to enable interrupts from the L3 interconnect module. See Chapter 17, *Interrupt Controllers*.
sDMA	For information about the configuration of the sDMA, see Chapter 16, *sDMA*.
L3 interconnect	For information about the configuration of the interconnect, see Chapter 14, *Interconnect*.

14.2.4.2 Operational Modes Configuration

14.2.4.2.1 L3_MAIN Interconnect Error Analysis Mode

14.2.4.2.1.1 Main Sequence: L3_MAIN Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-8 shows the software sequence required in most cases.

Figure 14-8. Typical Error Analysis Sequence

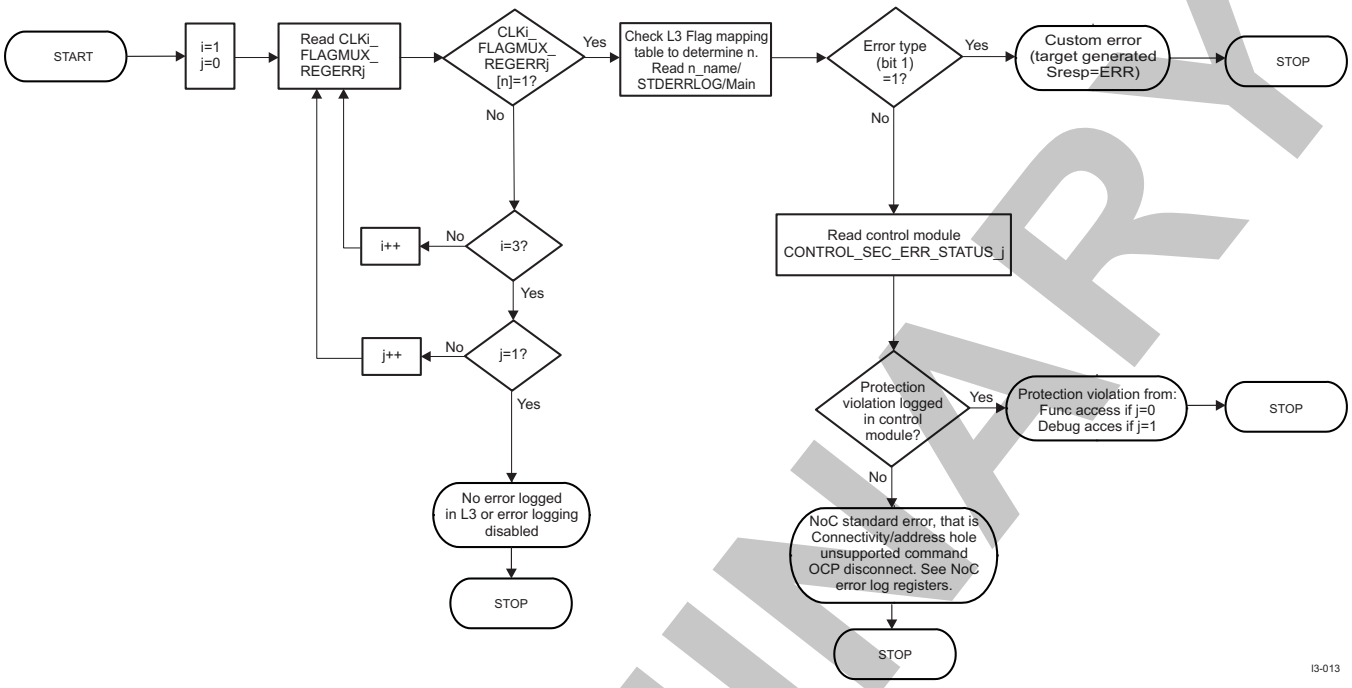


Table 14-33 lists the subprocess call summary for error analysis mode in the main sequence.

Table 14-33. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	See Section 14.2.4.2.1, *L3_MAIN Interconnect Error Analysis Mode.*
L3_MAIN interconnect protection violation error identification	See Section 14.2.4.2.1.1.2, *Subsequence: L3_MAIN Interconnect Protection Violation Error Identification.*
L3_MAIN interconnect unsupported command/address hole error identification	See Section 14.2.4.2.1.1.3, *Subsequence: L3_MAIN Interconnect Standard Error Identification.*
L3_MAIN interconnect reset FLAGMUX and module	See Section 14.2.4.2.1.1.4, *Subsequence: L3_MAIN Interconnect FLAGMUX Configuration.*

14.2.4.2.1.1.1 Subsequence: L3_MAIN Custom Error Identification

The procedure listed in Table 14-34 describes custom error identification.

Table 14-34. Custom Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is custom error detected?	L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE	=0x1
Read information field of the response packet.	L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO	xxx
Read the address of the initiator that caused error.	L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[10:0] STDERRLOG_CUSTOMINFO_MSTADDR	xxx
Read the type of operation (read/write).	L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE	xxx
ENDIF		

14.2.4.2.1.1.2 Subsequence: L3_MAIN Interconnect Protection Violation Error Identification

The procedure listed in Table 14-35 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 14-35. L3_MAIN Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	xxx
Read the initiator ID.	ERROR_LOG_k[3:0] ConnID	xxx
Read the command that caused the error.	ERROR_LOG_k[7] MCMD	xxx
Read the address of the request that caused the error.	ERROR_LOG_k[31:12] SLVOFS_LOGICAL	xxx
IF: Is it an application error?	L3_FLAGMUX_REGERR0 [7:0] REGERROR0	0x0
Read the status bits to see which module firewall has worked.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0]	xxx
Clear the status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN [31] STDERRLOG_MAIN_CLRLOG	0x0
ELSE IF	L3_FLAGMUX_REGERR1[7:0] REGERROR1	= 0x1
Read the status bits to see the module.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0]	xxx
Clear the status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0]	xxx
Clear the status bit.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
ENDIF		
Clear the burst violation.	ERROR_LOG_k[23] 2D_BURST_VIOLATION	0x0
Clear the error status.	ERROR_LOG_k[21:17] REGION_START_ERRLOG	0x00

14.2.4.2.1.1.3 Subsequence: L3_MAIN Interconnect Standard Error Identification

The procedure listed in Table 14-36 describes the identification of standard errors inside the L3_MAIN interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Table 14-36. L3_MAIN Standard Error Identification

Step	Register/Bit Field/Programming Model	Value
IF: Is an error detected?	L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT	= 0x1
Read the corresponding flag.	L3_FLAGMUX_REGERR0[7:0] REGERROR0	xxx
Read the corresponding flag.	L3_FLAGMUX_REGERR1[7:0] REGERROR1	xxx
Localize the slave NIU that generated the error.	See Table 14-31.	
ELSE		
Clear the error log.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG	0x0
Clear the severity error status.	L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0	0x2
ENDIF		

14.2.4.2.1.1.4 Subsequence: L3_MAIN Interconnect FLAGMUX Configuration

The procedures listed in Table 14-37 and Table 14-38 give information about the configuration of FLAGMUX masks.

Table 14-37. FLAGMUX Configuration

Step	Register/Bit Field/Programming Model	Value
Set the FLAGMUX masks to mask an event.	L3_FLAGMUX_MASK0[7:0] MASK0 L3_FLAGMUX_MASK1[7:0] MASK1	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_REGERR0[7:0] REGERR0 L3_FLAGMUX_REGERR1[7:0] REGERR1	xxx
Clear the slave NIU error log and the FLAGMUX error.	L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0	0x1

Table 14-38. FLAGMUX Time-out Configuration

Step	Register/Bit Field/Programming Model	Value
Enable time-out for target.	L3_FLAGMUX_TIMEOUT_MASK0[4:0] MASK0 (1)	xxx
Read the REGERR bits to see if an error is recorded.	L3_FLAGMUX_TIMEOUT_REGERR0[4:0] REGERR0 (1)	xxx

(1) Bit fields are [4:0] for CLK1_FLAGMUX_CLK1, [18:0] for CLK2_FLAGMUX_CLK2, and [1:0] for CLK3_FLAGMUX_CLK3.

14.2.5 L3_MAIN Interconnect Register Manual

14.2.5.1 L3_MAIN Register Group Summary

The registers in the L3 interconnect are divided into eight groups:

- Firewall registers (see Table 14-40)
- HOST registers (see Table 14-62)
- TARG registers (see Table 14-98)
- PWR_DISC registers (see Table 14-141)
- FLAGMUX registers (see Table 14-165)
- BW registers (see Table 14-188)
- RA registers (see Table 14-218)
- STATCOLL registers (see Table 14-227)

14.2.5.1.1 L3_MAIN Firewall Registers Summary and Description

Table 14-39. L3_MAIN Firewall Instance Summary

Module Name	Base Address	Size
EMIF Firewall	0x4A20 C000	256B
GPMC Firewall	0x4A21 0000	256B
OCMC_RAM Firewall	0x4A21 2000	384B

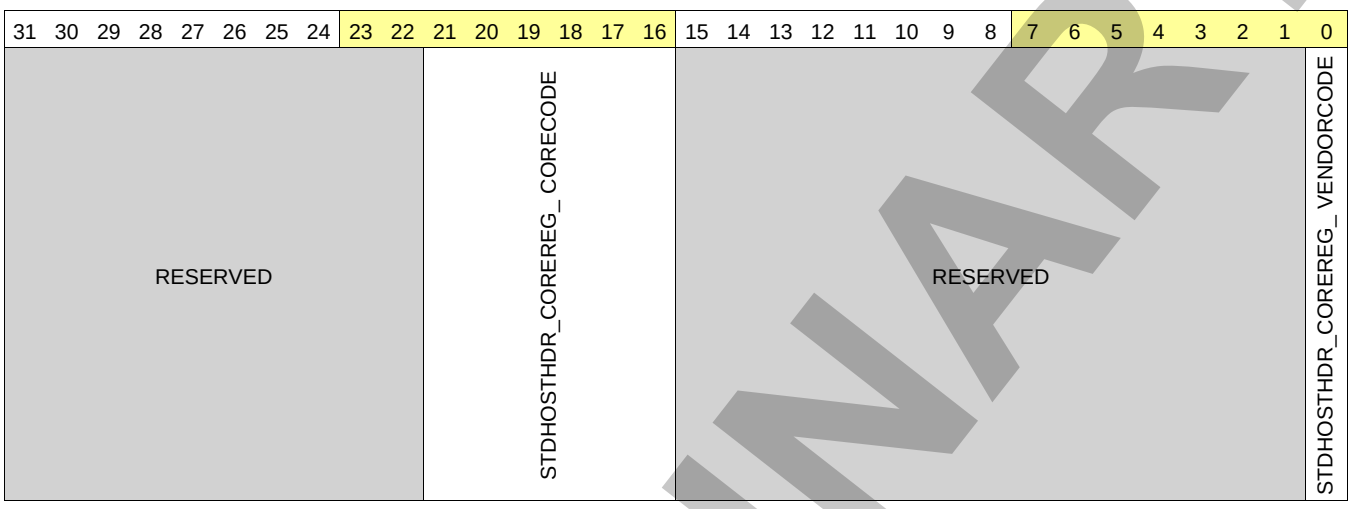
14.2.5.1.3.2 L3_MAIN TARG Registers Description

Table 14-106. L3_TARG_STDHOSTHDR_COREREG

Address Offset	See Table 14-98.	**Index**	
Physical Address	See Table 14-98 to Table 14-105	**Instance**	See Table 14-98 to Table 14-105
Description			
Type	R		



Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21:16	STDHOSTHDR_COREREG_ CORECODE	The Core Code field is a constant reporting a vendor-specific core generator code. Type: Constant. Reset value: 0x13.	R	0x13
15:1	RESERVED		R	0x0000
0	STDHOSTHDR_COREREG_ VENDORCODE	The Vendor Code field is a constant reporting the core generator vendor code. Type: Constant. Reset value: 0x1. Read 0x0: Third-party vendor. Read 0x1:	R	1

Table 14-108. L3_TARG_STDHOSTHDR_VERSIONREG

Address Offset	See Table 14-98.	**Index**	
Physical Address	See Table 14-98 to Table 14-105	**Instance**	See Table 14-98 to Table 14-105
Description			
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STDHOSTHDR_VERSIONREG_REVISIONID								STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM																									

Bits	Field Name	Description	Type	Reset
31:24	STDHOSTHDR_VERSIONREG_REVISIONID	The Revision Identifier field is a constant reporting the core generator revision number. Type: Constant. Reset value: 0x0.	R	0x00
23:0	STDHOSTHDR_VERSIONREG_COREPARAMSCHECKSUM	Reserved. Type: Reserved. Reset value: Reserved.	R	0x000000

Table 14-109. Register Call Summary for Register L3_TARG_STDHOSTHDR_VERSIONREG

L3 Interconnect

- L3_MAIN TARG Registers Summary: [0] [1] [2] [3] [4] [5] [7] [8]

Table 14-110. L3_TARG_STDHOSTHDR_MAINCTLREG

Address Offset	See Table 14-98.	**Index**	
Physical Address	See Table 14-98 to Table 14-105	**Instance**	See Table 14-98 to Table 14-105
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												STDHOSTHDR_MAINCTLREG_CM	STDHOSTHDR_MAINCTLREG_FLT	RESERVED	STDHOSTHDR_MAINCTLREG_EN

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3	STDHOSTHDR_MAINCTLREG_CM	Reserved for internal testing. Must be set to 0. Type: Control. Reset value: 0x0.	R	0

Bits	Field Name	Description	Type	Reset
2	STDHOSTHDR_MAINCTLREG_FLT	Asserted when a Fault condition is detected: if the unit includes Error Logging, Flt is asserted when the FltCnt register field indicates a Fault, and deasserted when FltCnt is reset. If no Error Logging is implemented, this bit becomes unit-dependent. In all cases, Flt bit and Flt pin (service network) have the same logical level. Type: Status. Reset value: X.	R	0
1	RESERVED	Reserved	R	0
0	STDHOSTHDR_MAINCTLREG_EN	Sets the global core enable. Note: A disabled master does not generate any NTTP requests, and a disabled slave replies with an error packet to any request it receives. Type: Control. Reset value: 0x1.	RW	1

Address Offset	See Table 14-98.	**Index**	
Physical Address	See Table 14-98 to Table 14-105	**Instance**	See Table 14-98 to Table 14-105
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
STDERRLOG_MAIN_CLRLOG	RESERVED											STDERRLOG_MAIN_FLTCNT	STDERRLOG_MAIN_ERRCNT	RESERVED																	STDERRLOG_MAIN_ERRTYPE	STDERRLOG_MAIN_ERRLOGVLD

Bits	Field Name	Description	Type	Reset
31	STDERRLOG_MAIN_CLRLOG	Clears "Error Logging Valid" bit when written to 1. Type: Give_AutoCleared. Reset value: 0x0.	RW	0
30:20	RESERVED	Reserved	R	0x000
19	STDERRLOG_MAIN_FLTCNT	Asserted when at least one error with severity level FAULT is detected. Reset when written to 1. Type: Take. Reset value: 0x0.	RW	0
18	STDERRLOG_MAIN_ERRCNT	Asserted when at least one error with severity level ERROR is detected. Reset when written to 1. Type: Take. Reset value: 0x0.	RW	0
17:2	RESERVED	Reserved	R	0x0000
1	STDERRLOG_MAIN_ERRTYPE	Indicates logging type. Type: Status. Reset value: X. Read 0x0: Logged Error format is standard (header and necker recorded). Read 0x1: Logged Error format is module dependent. CustomInfo register(s) may be implemented to store additional information.	R	0
0	STDERRLOG_MAIN_ERRLOGVLD	Error Logging Valid. Asserted when logging information is valid(indicates that an error has been logged). Type: Status. Reset value: X.	R	0

14.3 L4 Interconnects

This section details the device L4 interconnects.

14.3.1 L4 Interconnect Overview

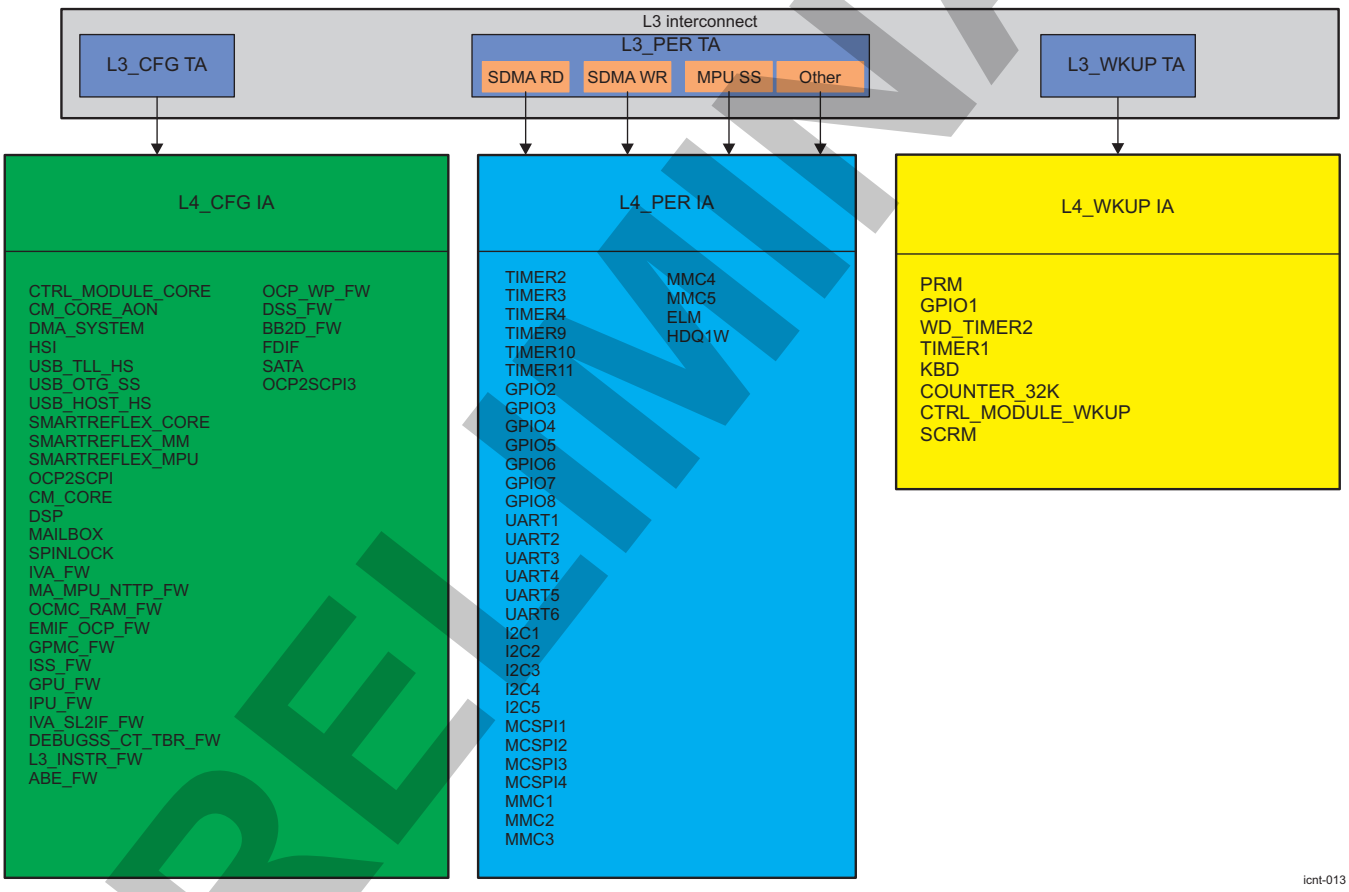
The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 14-9 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3_MAIN system modules and peripheral interconnect
- L4_PER: Includes the main peripherals that require sDMA access
- L4_WKUP: Includes peripherals attached to the WKUP power domain

Figure 14-9. L4 Interconnect Overview



The main features of the L4 interconnects are:

- Six ports from L3 interconnect onto three parallel L4 interconnects
- From one to four 32-bit initiator ports for each L4 interconnect instance
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian platform
- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- L4_CFG and L4_PER frequency equal half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator

14.3.2 L4 Interconnect Integration

Table 14-368 and Table 14-369 summarize the integration of the module in the device.

Table 14-368. Integration Attributes

Module Instance	Attributes
	Power Domain
L4_PER	PD_L4_PER
L4_CFG	PD_CORE
L4_WKUP	PD_WKUPAON

Table 14-369. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L4_PER	L4_PER_CLK	L4PER_L4_GICLK	PRCM module	Functional and interface clock
L4_CFG	L4_CFG_CLK	L4CFG_L4_GICLK	PRCM module	Functional and interface clock
L4_WKUP	L4_WKUP_CLK	WKUPAON_GICLK	PRCM module	Functional and interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
L4_PER	L4_PER_RST	L4_PER_RST	PRCM module	Reset of L4_PER interconnect
	L4_PER_RET_RST	L4_PER_PWRON_RET_RST	PRCM module	Reset of L4_PER interconnect retention registers. For information about retention reset, see Section 3.1.1, *Power, Reset, and Clock Management*.
L4_CFG	L4_CFG_RST	CORE_RST	PRCM module	Reset of L4_CFG interconnect
	L4_CFG_RET_RST	CORE_PWRON_RET_RST	PRCM module	Reset of L4_CFG interconnect retention registers. For information about retention reset, see Section 3.1.1, *Power, Reset, and Clock Management*.
L4_WKUP	L4_WKUP_RST	WKUPAON_RST	PRCM module	Reset of L4_WKUP interconnect

14.3.3 L4 Interconnect Functional Description

14.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 14-370 through Table 14-375 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

14.3.3.1.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 14-370 lists the L4_PER TAs.

Table 14-370. L4_PER TAs

Module Target Name	Description
UART1_TARG	UART port 1 module
UART2_TARG	UART port 2 module
UART3_TARG	UART port 3 module
UART4_TARG	UART port 4 module
UART5_TARG	UART port 5 module
UART6_TARG	UART port 6 module
TIMER2_TARG	General-purpose TIMER2 module
TIMER3_TARG	General-purpose TIMER3 module
TIMER4_TARG	General-purpose TIMER4 module
TIMER9_TARG	General-purpose TIMER9 module
TIMER10_TARG	General-purpose TIMER10 module
TIMER11_TARG	General-purpose TIMER11 module
GPIO2_TARG	General-purpose input/output 2 (GPIO2) module
GPIO3_TARG	GPIO3 module
GPIO4_TARG	GPIO4 module
GPIO5_TARG	GPIO5 module
GPIO6_TARG	GPIO6 module
GPIO7_TARG	GPIO7 module
GPIO8_TARG	GPIO8 module
I2C1_TARG	Multimaster I2C1 module
I2C2_TARG	Multimaster I2C2 module
I2C3_TARG	Multimaster I2C3 module
I2C4_TARG	Multimaster I2C4 module
I2C5_TARG	Multimaster I2C5 module
MCSPI1_TARG	Multichannel serial port interface controller 1 module
MCSPI2_TARG	Multichannel serial port interface controller 2 module
MCSPI3_TARG	Multichannel serial port interface controller 3 module
MCSPI4_TARG	Multichannel serial port interface controller 4 module
MMC1_TARG	MMC1 module
MMC2_TARG	MMC2 module
MMC3_TARG	MMC3 module
MMC4_TARG	MMC4 module
MMC5_TARG	MMC5 module
ELM_TARG	Error location module
HDQ1W_TARG	HDQ 1-Wire serial interface controller

Four ports communicate between the L3 interconnect and the L4_PER interconnect to allow the L3_MAIN initiators to access the L4_PER targets. Table 14-371 lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4_PER peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-371. L4_PER IAs

Module Iniator Name	Description
L3_MAIN_P0_INIT	L3 sDMA RD interconnect port
L3_MAIN_P1_INIT	L3 sDMA WR interconnect port
L3_MAIN_P2_INIT	L3 MPU susbystem interconnect port
L3_MAIN_P3_INIT	L3 others interconnect port

14.3.3.1.2 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the CORE power domain. Table 14-372 lists the TAs.

Table 14-372. L4_CFG TAs

Module Target Name	Description
CTRL_MODULE_CORE_TARG	Control module core
CM_CORE_AON_TARG	CORE_AON module
DMA_SYSTEM_TARG	System DMA module
HSI_TARG	High-speed synchronous serial interface module
USB_TLL_HS_TARG	High-speed USB_TLL module
USB_OTG_SS_TARG	USB_OTG module
USB_HOST_HS_TARG	High-speed multiport USB host controller module
SMARTREFLEX_CORE_TARG	SmartReflex core module
SMARTREFLEX_MM_TARG	SmartReflex MM module
SMARTREFLEX_MPU_TARG	SmartReflex MPU module
OCP2SCP1_TARG	OCP to SCP1 module
CM_CORE_TARG	CM_CORE module
DSP_TARG	DSP module
MAILBOX_TARG	MAILBOX module
SPINLOCK_TARG	SPINLOCK module
IVA_FW_TARG	IVA firewall
MPU_NTTP_FW_TARG	MPU NTTP firewall
OCMC_RAM_FW_TARG	OCMC_RAM firewall
EMIF_OCP_FW_TARG	EMIF L3 firewall
GPMC_FW_TARG	GPMC firewall
ISS_FW_TARG	ISS firewall
GPU_FW_TARG	GPU firewall
IPU_FW_TARG	IPU firewall
IVA_SL2IF_FW_TARG	IVA SL2 interface firewall
DEBUGSS_CT_TBR_FW_TARG	Debug subsystem CT TBR firewall
L3_INSTR_FW_TARG	L3 instruction firewall
ABE_FW_TARG	ABE firewall
OCP_WP_NOC_TARG	OCP_WP firewall
DSS_FW_TARG	Display subsystem firewall
FDIF_TARG	Face detection interface module
SATA_TARG	SATA module

Table 14-372. L4_CFG TAs (continued)

Module Target Name	Description
BB2D_TARG	2D graphics accelerator module
OCP2SCP3_TARG	OCP-to-SCP3 module

A unique port, L3_MAIN_INIT, communicates between the L3 interconnect and the L4_CFG interconnect to allow the L3 initiators to access the L4_CFG targets (see Table 14-373).

For the list of initiators authorized to access the L4_CFG peripherals, see Section 14.2.3.2.2, *Connectivity Matrix*.

Table 14-373. L4_CFG IAs

Module Iniator Name	Description
L3_MAIN_INIT	L3 interconnect port

14.3.3.1.3 L4_WKUP Interconnect Agents

The L4-WKUP interconnect handles transfers only to peripherals in the WKUP power domain. Table 14-374 lists the TAs. Table 14-375 lists the L4 WKUP IAs.

Table 14-374. L4_WKUP TAs

Module Target Name	Description
GPIO1_TARG	GPIO1 module
32KTIMER_TARG	32-kHz timer module
SAR_RAM_TARG	Save-and-restore RAM
KEYBOARD_TARG	Keyboard module
CTRL_MODULE_WKUP_TARG	Control module WKUP module
PRM_TARG	Power reset management module
SCRM_TARG	System clock and reset management module
WD_TIMER2_TARG	Watchdog TIMER2 module
TIMER1_TARG	General-purpose TIMER1 module

Table 14-375. L4_WKUP IAs

Module Iniator Name	Description
L3_MAIN_INIT	L3 interconnect port

14.3.3.2 Power Management

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see Section 3.1.1, *Power, Reset, and Clock Management*.

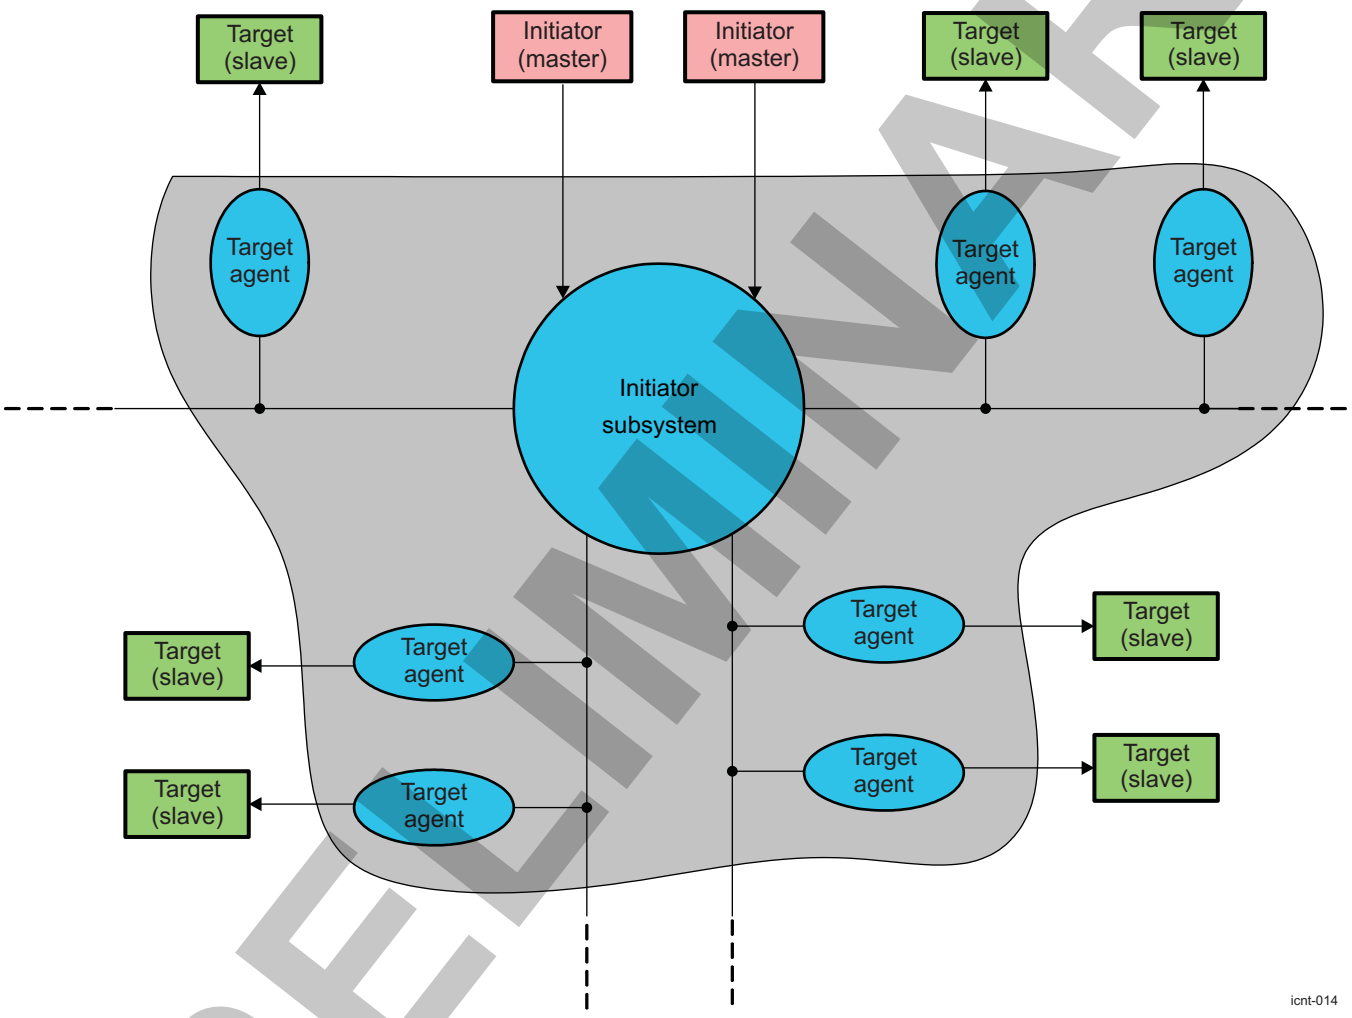
To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers at IAs, TAs, and firewalls. This process prevents reconfiguration after a clock domain switches off. For more information, see Section 3.1.1.2, *Power Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.

14.3.3.3 L4 Firewalls

Figure 14-10 is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 14-10. L4 Initiator-Target Connectivity



NOTE: As Figure 14-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators:
  - Eight protection groups for the L4 interconnect
- Segments divided into regions
  - 85 regions for the L4_PER interconnect
  - 112 regions for the L4_CFG interconnect
  - 30 regions for the L4_WKUP interconnect

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

14.3.3.3.1 Protection Group

A protection group is defined by its initiators (or members) and MReqInfo is allowed. Two registers define these two settings:

- The 64-bit CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k_L and L4_AP_PROT_GROUP_MEMBERS_k_H registers define which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. Table 14-376 lists all the ConnIDs available at the L4 levels.
- The ENABLE field L4_AP_PROT_GROUP_ROLES_k_L register lists all possible MReqInfo combinations associated with the L4_AP_PROT_GROUP_MEMBERS register. Setting a Req bit in this register determines the initiators type of access. For more information, see Section 14.2.3.8, *L3 Firewall Functionality*. Two MReqInfos are used in L4 interconnects: MReqDebug and MReqSupervisor.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

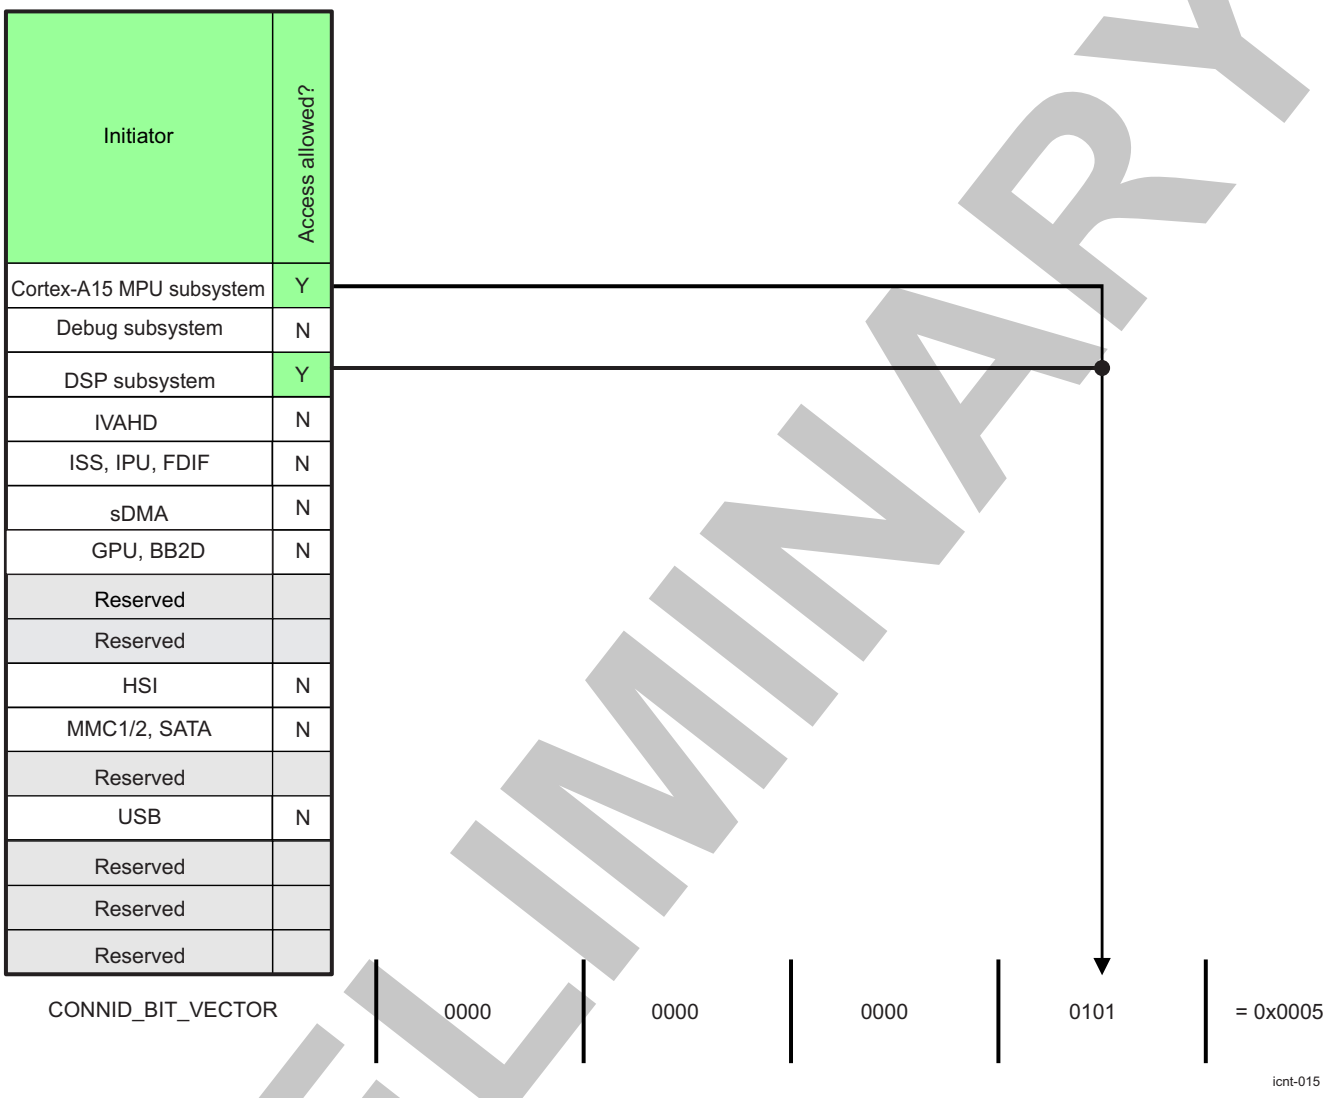
L indicates the region number.

Table 14-376. L4 ConnID Definition

ConnID	Initiator
0	Cortex-A15 MPU subsystem
1	Debug subsystem
2	DSP subsystem
3	IVAHD
4	ISS, IPU, Face Detect
5	sDMA
6	GPU, BB2D
7	Reserved
8	Reserved
9	HSI
A	MMC1, MMC2, SATA
B	Reserved
C	USB
D	Reserved
E	Reserved
F	Resered

Figure 14-11 is an example of CONNID_BIT_VECTOR.

Figure 14-11. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k



Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A15 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_i_H PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of some CONNID_BIT_VECTOR and ENABLE fields are exported by the system control module (SCM) at reset or are user writable (see Figure 14-11 for more information).

Table 14-377 and Table 14-378 list the default configuration of the various groups for each L4 interconnect. For each group, some modules or regions are associated with it using default initiator members.

Table 14-377. L4_PER Firewall Default Configuration

Group	Default Modules Associated With Group	Register	Modifiability	Default Value
Group 0 AP registers	L4_PER_AP registers	L4_AP_PROT_GROUP_ROLES_0_L	No	0xFFFF FFFF FFFF FFFF (all)
		L4_AP_PROT_GROUP_ROLES_0_H	No	0xFFFF FFFF FFFF FFFF (all)

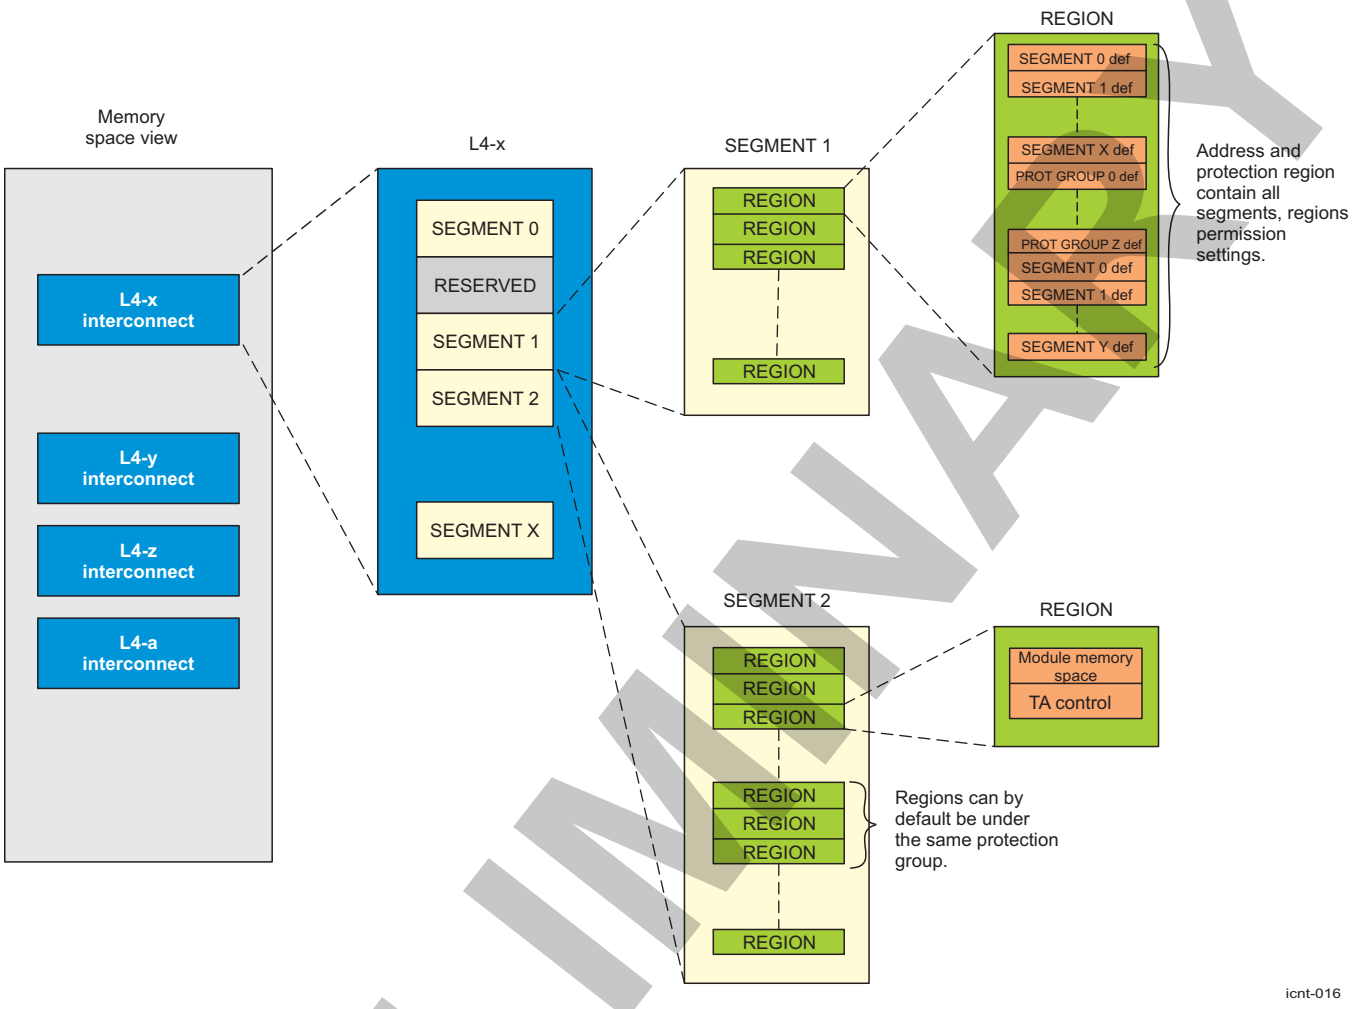
14.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in Figure 14-12. By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Figure 14-12. L4 Segmentation



All interconnect address spaces are covered by regions. Table 14-380 through Table 14-382 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

NOTE: Module refers to the configuration registers of the module.

TA refers to the interconnect configuration registers of the TA associated with the module.

14.3.3.3.3 L4 Firewall Address and Protection Register Settings

Table 14-383 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 14-383. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L (1)	31:0	BASE	Segment base address
	L4_AP_SEGMENT_i_H (1)	5:0	SIZE	Segment size equals to 2^{SIZE}
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L (2)	15:0	CONNID_BIT_VECTOR	For L4ConnID, see Table 14-376.
	L4_AP_PROT_GROUP_ROLES_k_L (2) L4_AP_PROT_GROUP_ROLES_k_H	31:0	ENABLE	See Section 14.2.3.8.3 for REQ_INFO description. (3)
Region setting	L4_AP_REGION_l_L (4)	20:0	BASE	Defines the base address of region with respect to its segment base address
	L4_AP_REGION_l_H (4)	31:28	MADDRSPACE	Target interconnect MAddrSpace
		26:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	Protection group member attached to the region
		18:17	BYTE_DATA_WIDTH_EXP	Determines the number of bytes in an access
		14:8	PHY_TARGET_ID	Physical target ID
		6:1	SIZE	Size of the region equals to 2^{SIZE}
		0	ENABLE	Enables the region protection

(1) i = 0 to 1 for PER_AP
i = 0 to 6 for CFG_AP
i = 0 to 1 for WKUP_AP

(2) k = 0 to 7 for PER_AP
k = 0 to 7 for CFG_AP
k = 0 to 7 for WKUP_AP

(3) For L interconnects, only MReqDebug and MReqSupervisor are available.

(4) l = 0 to 84 for PER_AP
l = 0 to 111 for CFG_AP
l = 0 to 29 for WKUP_AP

14.3.3.4 L4 Error Detection and Reporting

14.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see Section 14.3.3.3, *L4 Firewalls*)
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see Section 14.3.3.4.2, *Time-Out*).

Table 14-384 lists the value of the L4_IA_ERROR_LOG_L[25:24] CODE bit field stored when an error occurs.

Table 14-384. L4 CODE Bit Field Definition

CODE (bits 1:0)	Error Type	REQ_INFO	Secondary	ConnID	CMD
0	No error				
1	Unsupported command	x	x	x	x
2	Address hole	x	x	x	x
3	Protection violation	x		x	x

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. Additionally, an address hole error code is logged to the L4_IA_ERROR_LOG_L[25:24] CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by the accessed target register. The error is logged into the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. An unsupported command error code is written to the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the initiator interface.
- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the L4_IA_AGENT_STATUS_L[27] INBAND_ERROR bit. A protection violation error code is saved into the L4_IA_ERROR_LOG_L[25:24] CODE bit field for the same initiator interface. A protection violation is also logged in the L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

  The L4_IA_ERROR_LOG_L[30] SECONDARY bit indicates whether the error occurred in application or debug.

  The L4_IA_ERROR_LOG_H[15:0] REQ_INFO bit field returns the type of access (REQ_INFO qualifier) that caused the error.

  The L4_IA_ERROR_LOG_L[13:8] CONNID bit field returns the ID of the initiator that caused the error.

  The L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR register logs the address for error conditions.

14.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

NOTE: The time-out mechanism is not available on the L4_WKUP interconnect, but L4_WKUP time-outs are detected in CFG_TA_L4WKUP of the L4_CFG interconnect.

The error is logged in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, system software must reset the TA. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. The time-base signals are selected by programming the L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 14-385 lists all values in number of L4 clock cycles.

Table 14-385. L4 Time-out Link and TA Programming

	L4_TA_AGENT_CONTROL_L [2:0] REQ_TIMEOUT				
L4_LA_NETWORK_CONTROL_L[2:0] TIMEOUT_BASE	**0**	**1**	**2**	**3**	**4**
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16,384
3		1024	4096	16,384	65,536
4		4096	16,384	65,536	262,144

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65-MHz, 15.3-µs period
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for TA A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 µs to 756 µs.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

When a time-out condition is detected, the TA logs the error in the L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT bit, and it also reports the error to the IA, which forwards it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit.

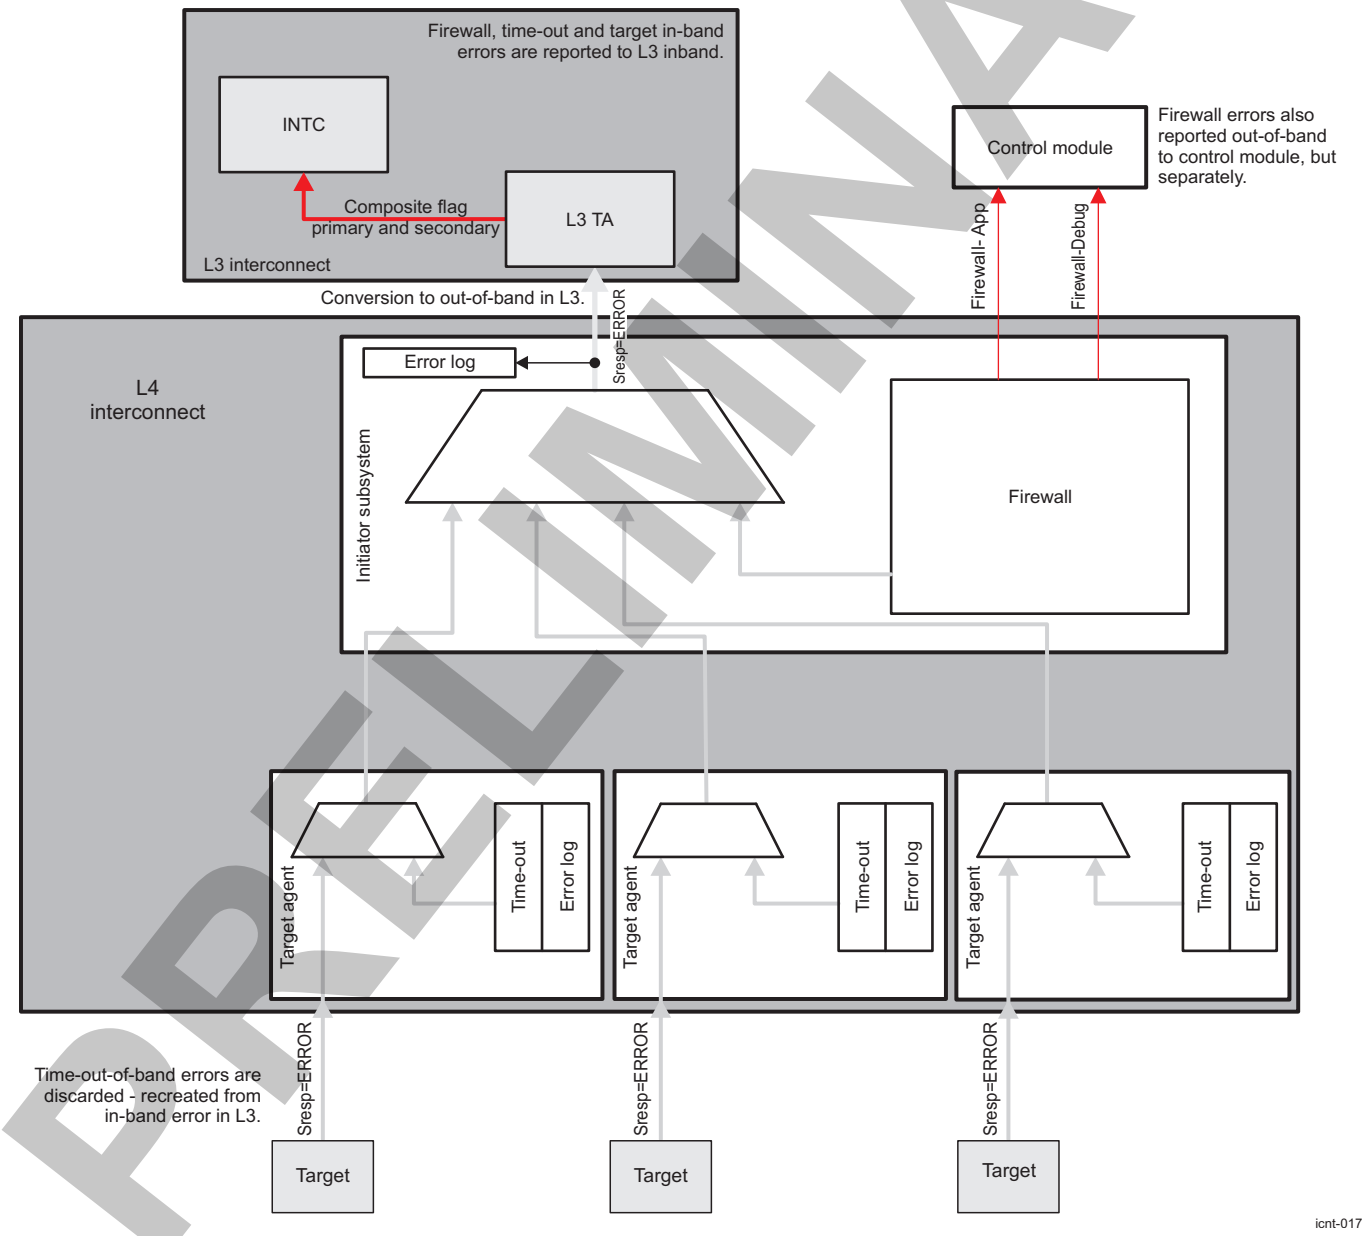
14.3.3.4.3 Error Reporting

Figure 14-13 shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signal (the L3 applicative and debug composite flags) going to the L3 INTCs.

Two levels of mask are present to report the error at INTC level:

- At the applicative and debug composite flag, to enable interrupt reporting, the following bits must be set:
  - L4_CFG in L3_CLK1_FLAG_MASK_0[3] and L3_CLK1_FLAG_STATUS_1[3]
  - L4_PER in L3_CLK2_FLAG_MASK_0[17][16][15][6] and L3_CLK2_FLAG_STATUS_1[17][16][15][6]
- At the L3 TA level, see Section 14.2.1, *L3 Interconnect*.

Figure 14-13. L4 Error Reporting



14.3.3.4.4 Error Recovery

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 1 initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Setting the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit to 0 terminates the software reset period.

Reset the attached module to complete the recovery.

14.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is send to the INTCs (if enabled). An in-band error is sent back to L3 IA and an out-of-band error can also be logged in the CONTROL.CONTROL_SEC_ERR_STATUS register in the SCM. These out-of-band errors are enabled and disabled at the L4 IA level by setting the L4_IA_AGENT_CONTROL_L[31][30] PROT_ERROR_SECONDARY_REP or PROT_ERROR_PRIMARY_REP bit to 1 for debug and application mode, respectively.

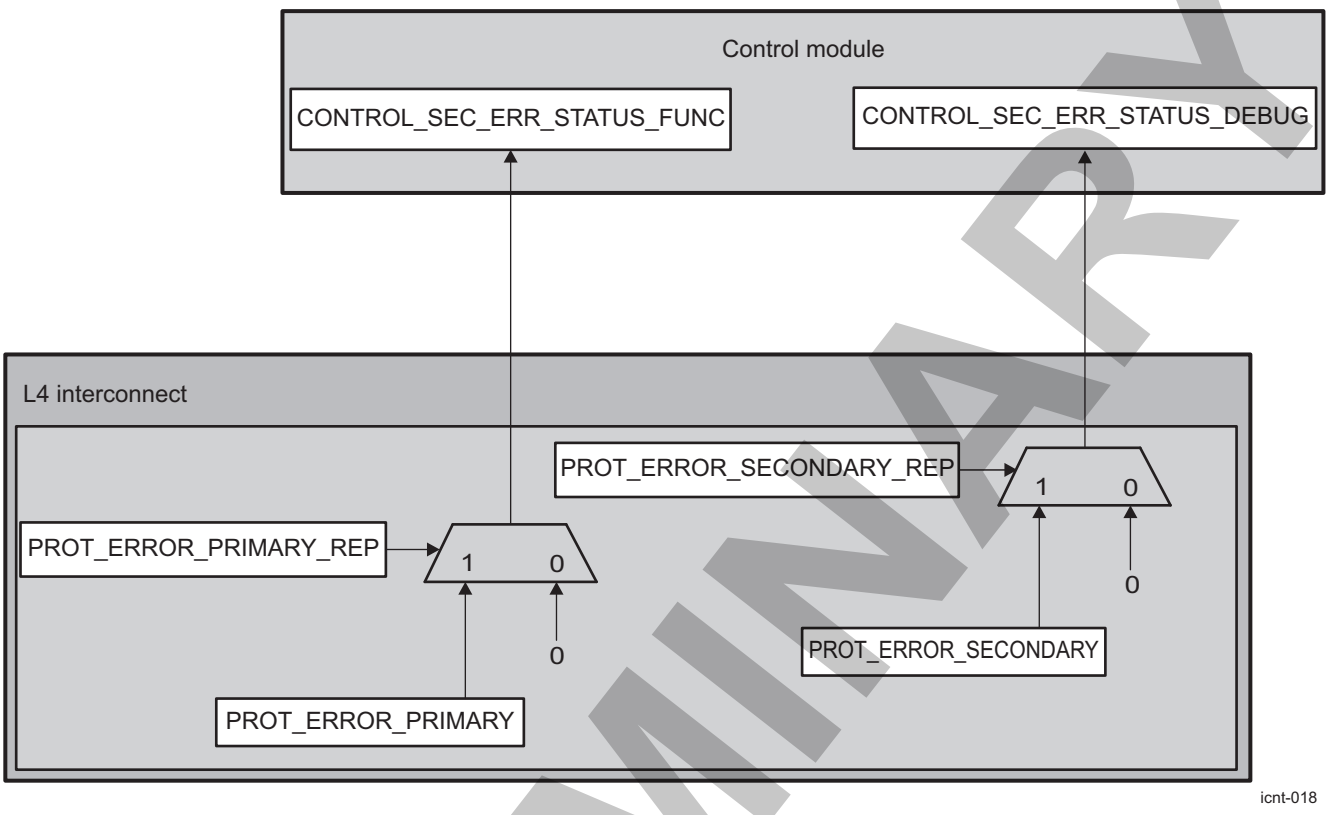
At the control module level, two logging registers are used, depending on the mode:

- In application mode or primary error reporting:
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[16] = L4_CFG protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[17] = L4_PER protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_FUNC[22] = L4_WKUP protection violation
- In debug mode or secondary error reporting:
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[16] = L4_CFG protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[17] = L4_PER protection violation
  - CONTROL_CORE_SEC_ERR_STATUS_DEBUG[22] = L4_WKUP protection violation

NOTE: The CONTROL_CORE_SEC_ERR_STATUS_xxx registers are only readable.

Figure 14-14 shows the global protection error reporting to the control module.

Figure 14-14. Protection Violation Out-of-Band Error Reporting



14.3.4 L4 Interconnect Programming Guide

14.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

14.3.4.1.1 Global Initialization

14.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see Section 14.3.2, *L4 Interconnect Integration*.

Table 14-386 lists the surrounding modules.

Table 14-386. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Section 3.1.1, *Power, Reset, and Clock Management*.
Control module	For more information about the configuration of the module, see Figure 18-1, *Control Module*.
MPU INTC	Configure the MPU INTC to enable the interrupts from L4 interconnect module. SeeSection 17.1 *Interrupt Controllers*.
sDMA	For more information about the configuration of the sDMA, see Section 16.1, *sDMA*.
L3 interconnect	For more information about the interconnect configuration, see Section 14.2.1, *L3 Interconnect*.

14.3.4.1.2 Operational Modes Configuration

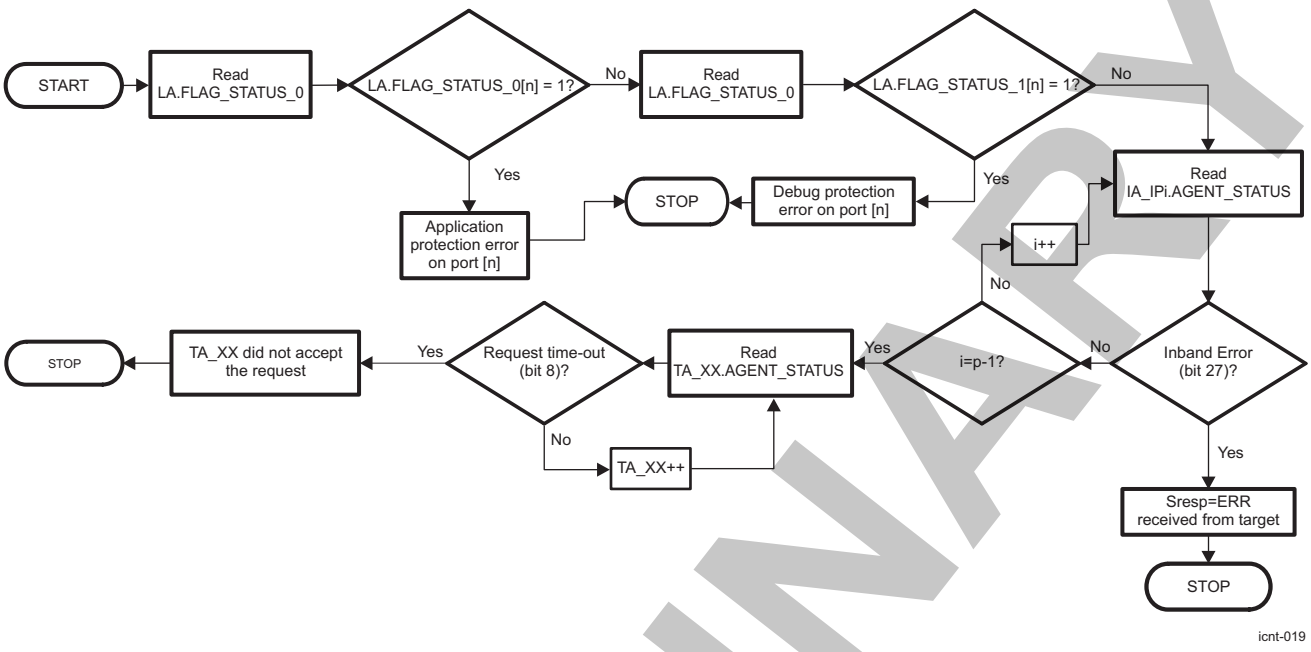
14.3.4.1.2.1 L4 Interconnect Error Analysis Mode

14.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

Figure 14-15 shows the software sequence required in most cases.

Figure 14-15. Typical Error Analysis Sequence



NOTE: L4 interconnects don't log any address or other specific information for a custom error returned from any target IP. They rather pass an error response ut to the master supposed to analyze it.

In case of posted writes, the master access completes before it actually completed at the end slave level, this way no error response is sent back to the master, making it impossible to have a direct way of uderstanding the origin of L4 error during posted writes. However, even though no address is logged, an error flag is generated and needs to be processed.

14.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see Table 14-387).

Table 14-387. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	
Read command that cause the error.	L4_IA_ERROR_LOG_L[2:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
IF: Is it a primary error?	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17:16]	0x3
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17:16]	0x3

Table 14-387. Protection Violation Error Identification (continued)

Step	Register/Bit Field/Programming Model	Value
Write 1 to clear IA status bit	L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY	0x1
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear in-band error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

14.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see Table 14-388).

Table 14-388. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator ID.	L4_IA_ERROR_LOG_L[11:8] CONNID	
Read command that caused the error.	L4_IA_ERROR_LOG_L[2:0] CMD	
Read address of request that caused the error.	L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR	
Read secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	
Write 1 to clear secondary status.	L4_IA_ERROR_LOG_L[30] SECONDARY	0x1
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[24] INBAND_ERROR	0x1

14.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure describes the reset TA and module (see Table 14-389).

Table 14-389. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time-out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module.(1)		

(1) For more information, see the respective module chapter.

14.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

14.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see Table 14-390).

Table 14-390. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status.(1)	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level.(1)	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx

(1) Required for each TA.

Table 14-390. Time-Out Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

14.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

14.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see Table 14-391).

Table 14-391. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k.(1)	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k.(1)	L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE	xx
Set region affiliation to protection group.(2)	L4_AP_REGION_l_L[22:20] PROT_GROUP_ID	xxx

(1) Required for each protection group.
(2) Required for each region.

14.3.5 L4 Interconnects Register Manual

Table 14-392 through Table 14-394 list all L4 register blocks for IA, TA, AP, and LA. Each module instance is shown with the module register mapping and bit and bit field definitions.

14.3.5.1 L4 Interconnects Instance Summary

Table 14-458. L4_TA_AGENT_CONTROL_L

Address Offset	0x0000 0020
Physical Address	See Table 14-420 to Table 14-433.
Description	Enable error reporting
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							SERROR_REP	RESERVED													REQ_TIMEOUT			RESERVED							OCP_RESET

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	SERROR_REP	Enable logging of error	R	0x0
23:11	RESERVED	Read returns 0.	UNDEFINED_TYPE_STRING	

Bits	Field Name	Description	Type	Reset
10:8	REQ_TIMEOUT	Time-out Bound. Values are: 0 - No time-out 1 - 1x base cycles. 2 - 4x base cycles. 3 - 16x base cycles. 4 - 64x base cycles.	RW	0x2
7:1	RESERVED	Read returns 0.	R	0x00
0	OCP_RESET	The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to deassert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core.	RW	0

Table 14-483. L4_LA_NETWORK_CONTROL_H

Address Offset	0x0000 0024		
Physical Address	0x4800 0824 0x4A00 0824 0x4AE0 0824	**Instance**	PER_LA CFG_LA WKUP_LA
Description	Control interconnect global power control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							CLOCK_GATE_DISABLE	RESERVED			THREAD0_PRI	RESERVED											EXT_CLOCK	RESERVED							

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	RESERVED	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	RESERVED	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	RESERVED	Read returns 0.	R	0x00

Memory Subsystem

This chapter introduces the memory subsystem of the device.

NOTE: Some of the memory subsystem features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

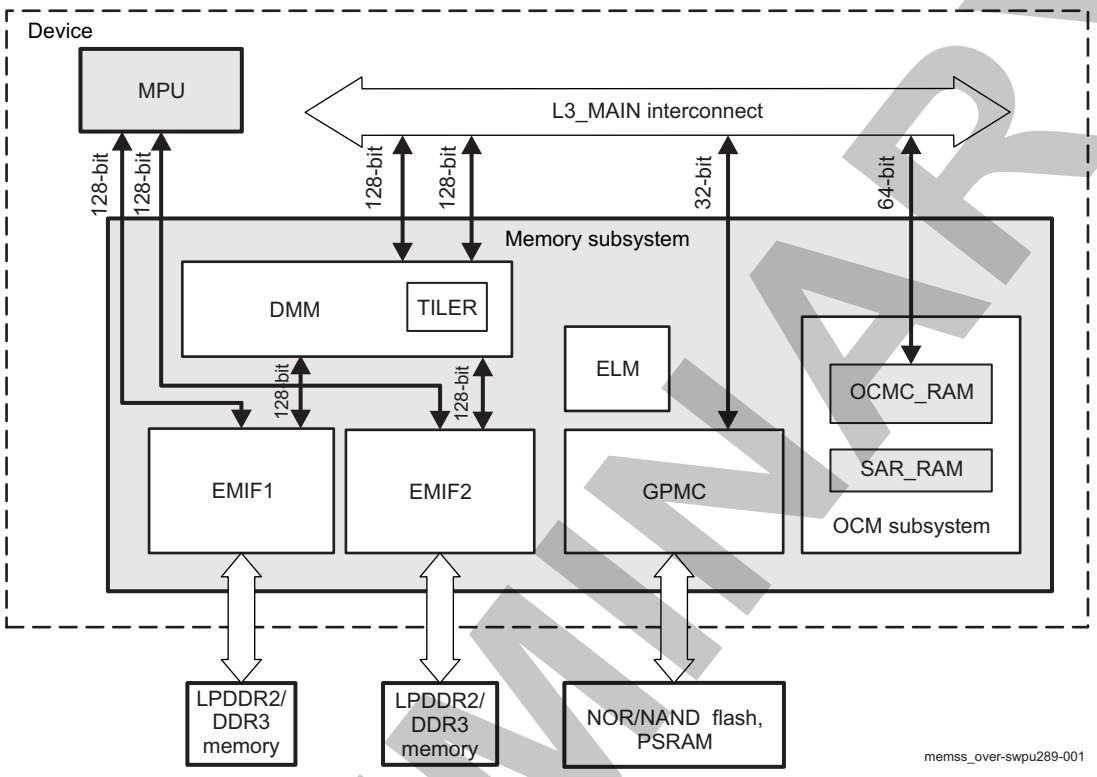
For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

15.1 Memory Subsystem Overview

Figure 15-1 shows a functional diagram of all memory subsystems in the device.

Figure 15-1. Memory Subsystem Functional Diagram



15.1.1 DMM Overview

The dynamic memory manager (DMM) module is typically located immediately in front of the synchronous dynamic random access memory (SDRAM) controllers (EMIF), as shown in Figure 15-1, *Memory Subsystem Functional Diagram*.

In a broad sense, the DMM manages various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM interleaving configuration
- Block object transfer optimization – tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability, and hence the runtime nature, of the four aspects of memory management handled by the DMM.

15.1.1.1 DMM Features

From a functional perspective, the role of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to/from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally, provide a low-latency page-based translation to handle memory fragmentation – MMU
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The main features of the DMM are:

- Programmable multizone DRAM mapping and interleaving configuration

- Programmable initiator-based request priority extension
- Multichannel memory transfer optimization
- Single SDRAM page request generation
- Low-latency interconnect port
- Page-grained address translation to manage memory fragmentation
- Automatic synchronized reloading of the address translation table

15.1.2 TILER Overview

The tiling and isometric lightweight engine for rotation (TILER) is a submodule of the DMM (see Figure 15-1) and is therefore described in Section 15.2.1, *Dynamic Memory Manager*.

The TILER is intended to improve bidimensional (tiled) block transfer efficiency. It is, therefore, a module aimed at:

- Primarily, efficient handling of 2-dimension (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally, managing the memory fragmentation and zero-copy physical frame-buffer swapping through a page-grained translation
- Making isometric (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection

The lightweight qualifier of this engine highlights its limited support of isometric transforms, as:

- Rotation performs only basic quadrant rotations by some multiple of 90 degrees.
- Reflection is limited to horizontal and vertical flip.
- Translation is restricted to a 4-KiB page granularity.

Written differently, the functionality of the TILER is to map a 2D virtually addressed interconnect request into one or more physically addressed interconnect requests by:

- Transforming the virtual address, data, and byte-enable to match the requested 0-, 90-, 180-, or 270-degree orientation in a tiled 2D addressing space
- Optionally, translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing

15.1.2.1 TILER Features

The main features of the TILER are:

- Efficiency improvement of 2D block access on SDRAMs
- Optimized interlaced access on tiled frames
- 2D virtual-to-physical address translation of SDRAM bidimensional objects to handle rotation
- Page-grained address translation to manage memory fragmentation and physical buffer aliasing
- Unlimited number of 2D tiled objects supported in any (0, 90, 180, or 270 degrees) orientation
- Full bandwidth use by minimizing the size of raster-based initiator buffers
- Optimization of multichannel memory transfers
- Interconnect request granularity balance (in X and Y directions)

15.1.3 EMIF Overview

The two external memory interface (EMIF) modules are typically located near the DMM module, as shown in Figure 15-1 , *Memory Subsystem Functional Diagram*.

The EMIF module provides connectivity between the device and LPDDR2-type or DDR3-type of memories and manages data bus read/write accesses between external memories and device subsystems having master access to the L3_MAIN interconnect and DMA capability.

15.1.3.1 Main Features

Each EMIF module has the following capabilities:

- Supports JEDEC standard-compliant DDR3-SDRAM, DDR3L-SDRAM, and LPDDR2-SDRAM (S2 and S4) devices
- 4-GiB SDRAM address range over two chip-selects (2 GiB per chip-select) (configurable with the dynamic memory manager (DMM) module; see Section 15.2.1, *Dynamic Memory Manager*, for more information)

NOTE: Even though the two EMIF modules work independently and can have connected different (LPDDR2 and DDR3) memories at a time, the device package restricts the physical connections to only one memory type (LPDDR2 or DDR3) per device. See more details about device family in , *Introduction*

- Supports SDRAM devices with one, two, four, or eight internal banks
- Data bus widths:
  - 128-bit L3_MAIN (system) interconnect data bus width
  - 128-bit port for direct connection with MPU subsystem
  - 32-bit SDRAM data bus width
- Supports CAS latencies:
  - DDR3: 5, 6, 7, 8, 9, 10, and 11
  - LPDDR2: 3, 4, 5, 6, 7, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supported burst length: 8
- Supports sequential burst type
  - For LPDDR2, burst read can be interrupted by another read, burst write can be interrupted by another write.
  - DDR3 does not support the burst interrupt of a BL8 command
- SDRAM auto initialization from reset or configuration change for DDR3 (LPDDR2 needs to have initalization started via software)
- Supports bank interleaving across both chip-selects
- Supports self refresh and power-down modes for low power
- Supports deep power-down mode for LPDDR2 for low power
- Partial array self-refresh and temperature-controlled self-refresh modes for low power. Temperature-controlled self-refresh is supported only for mobile SDRAM having on-chip temperature sensor.
- Supports temperature monitoring for LPDDR2
- Output impedance (ZQ) calibration
- Supports on-die termination (ODT) on DDR3
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Write/read leveling/calibration and data eye training for DDR3.

The EMIF modules do not support:

- Burst chop for DDR3.
- Auto precharge
- Per-bank refreshes for LPDDR2-SDRAM

15.1.4 GPMC Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmuxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

15.1.4.1 GPMC Features

The GPMC is the external memory controller of the device. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, and 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (nonburst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 KiB)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 512 MiB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-ChaudhurI-Hocquenghem (BCH) (t = 4, 8, or 16) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- External device clock provided from L3_MAIN clock (GPMC_FCLK) divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one GPMC_FCLK clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with system DMA (sDMA) to achieve full performance from the AND device with minimum effect on NOR/SRAM concurrent access

NOTE: Page mode is available only in nonmultiplexed mode.

15.1.5 ELM Overview

In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process can be delegated to the error location module (ELM) used in conjunction with the GPMC.

15.1.5.1 ELM Features

The ELM features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

15.1.6 OCM Overview

The on-chip memory (OCM) subsystem consists of the following OCM controllers.

- One connected to an on-chip RAM (SAR RAM)
- One connected to an on-chip SRAM (L3 SRAM)

Each memory controller has its own dedicated interface to the L3_MAIN interconnect.

15.2 Dynamic Memory Manager

15.2.1 DMM Overview

This section describes the dynamic memory manager (DMM) and its tiling and isometric lightweight engine for rotation (TILER) submodule.

The DMM is introduced in Section 15.1, *Memory Subsytem Overview*.

The function of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to-and-from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally provide a low-latency page-based translation to handle memory fragmentation – memory management unit (MMU)
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

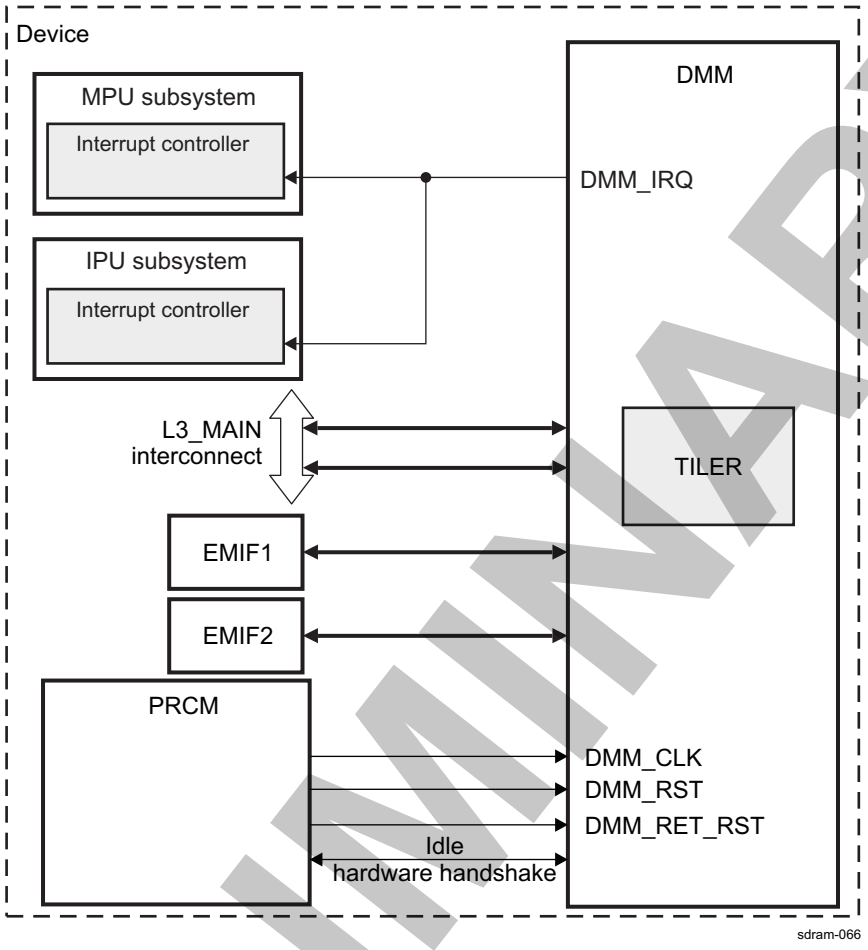
The TILER is also introduced in Section 15.1, *Memory Subsystem Overview*.

The functions of the TILER are:

- Primary handling efficiently 2-dimensional (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- Allowing optimized interlaced accesses on tiled frames
- Making (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection
- Interleaving the memory accesses among the two memory controllers (also called EMIF). For more information, see Section 15.3.1, *EMIF Controller*.

Figure 15-2 is an overview of the DMM and TILER in the device.

Figure 15-2. DMM and Tiler Overview



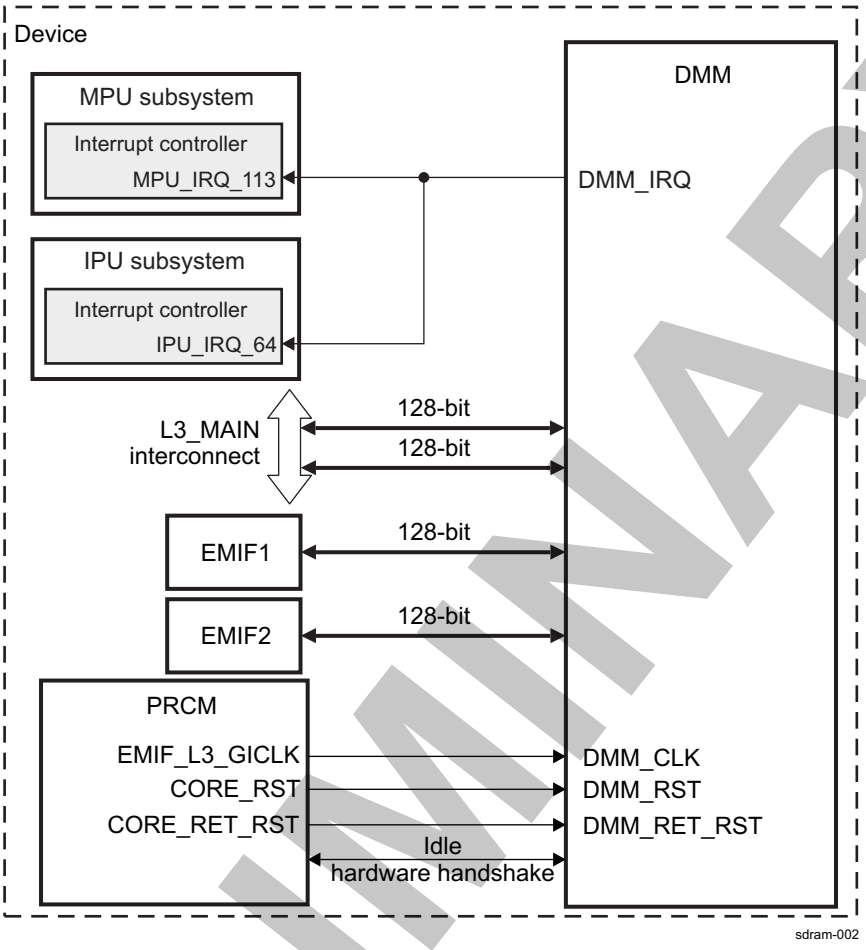
15.2.2 DMM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- IDLE hardware handshake (the DMM supports only smart-idle mode)
- No STANDBY hardware handshake
- No wake-up request
- No system direct memory access (sDMA) requests
- One interrupt line for interrupt request (IRQ)
- One functional clock

Figure 15-3 shows the integration of DMM in the device.

Figure 15-3. DMM Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 15-1 through Table 15-3 summarize the integration of DMM in the device.

Table 15-1. DMM Integration Attributes

Module Instance	Attributes

15.2.3 DMM Functional Description

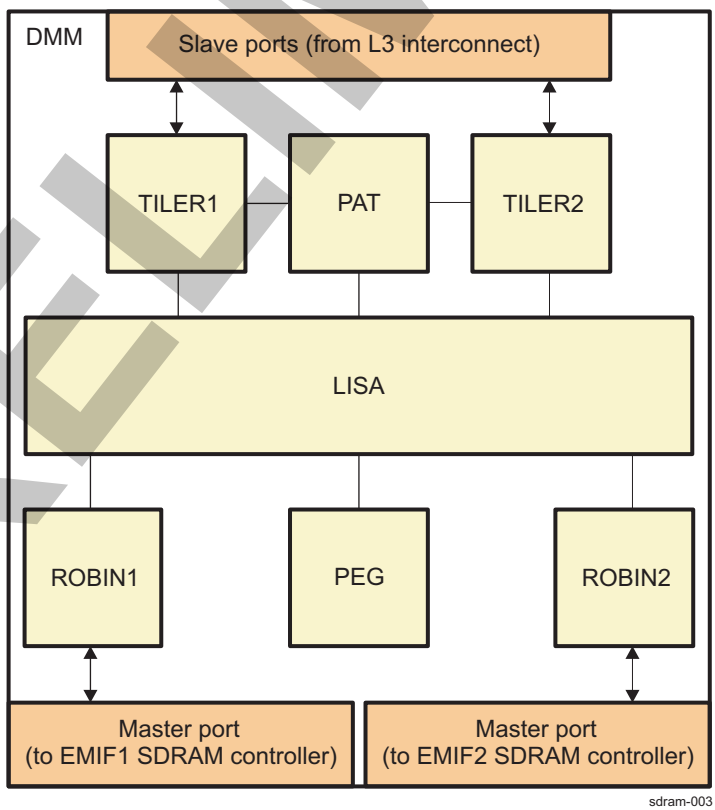
15.2.3.1 DMM Block Diagram

Figure 15-4 shows the DMM macro architecture. The DMM consists of six blocks:

- Two TILERs, each with its own interconnect slave port for converting requests back and forth between the input virtual addressing mode and the output physical tiledaddressing mode. The tiling conversions of requests, write data, and responses is performed entirely in the TILER blocks.
- Two reordering buffer and initiator nodes (ROBINs), each with its own interconnect master port to initiate requests to the SDRC and allow tiled data, tiled response, and split response reconstruction. The ROBIN block manages only the reordering buffer and performs data reordering due to the orientation.
- A physical address translator (PAT) for managing the memory fragmentation
- A priority extension generator (PEG) to generate priorities required by the SDRC; these priorities are not used in the DMM.
- A local interconnect and synchronization agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers

Figure 15-4 is a block diagram of the DMM.

Figure 15-4. DMM Block Diagram



CAUTION

The interconnect must ensure that virtually addressed requests target only a TILER port.

15.2.3.2 DMM Clock Configuration

Table 15-5 describes the DMM clocks.

Table 15-5. DMM Clocks

Signal	I/O[1]	Description
DMM_CLK	I	Functional and interface clock

(1) I = Input; O = Output

The DMM is concerned with SDRC management and is in the MEMIF clock domain among the SDRCs. The DMM is a fully synchronous module, which uses the clock and clock-enable signals provided in the MEMIF clock domain to generate its interface and functional clocks.

To configure DMM_CLK control and settings, see Table 15-2.

15.2.3.3 DMM Power Management

DMM power is supplied by the CORE power domain, and DMM power management complies with system power-management guidelines.

Table 15-6 describes the power-management features available for the DMM module.

Table 15-6. DMM Local Power-Management Features

Feature	Registers	Description
Slave idle modes	DMM_SYSCONFIG[3:2] SIDLEMODE bit field	Only smart-idle wake-up mode is available.

15.2.3.4 DMM Interrupt Requests

Errors in PAT area refill registers are reported through the DMM_PAT_STATUS_i[15:10] ERROR bit field (see Table 15-7).

Table 15-7. DMM Hardware Status Features

Feature	Type	Register	Description
PAT error flags	Read-only	DMM_PAT_STATUS_i[15:10] ERROR (where i = 0 to 3)	Unexpected update of the PAT area refill registers

Table 15-8 lists the event flags, and their masks, that can cause module interrupts.

Table 15-8. Events

Interrupt	Event Flag	Event Mask
ERR_LUT_MISS3	DMM_PAT_IRQSTATUS[31] ERR_LUT_MISS3 DMM_PAT_IRQSTATUS_RAW[31] ERR_LUT_MISS3	DMM_PAT_IRQENABLE_SET[31] ERR_LUT_MISS3 DMM_PAT_IRQENABLE_CLR[31] ERR_LUT_MISS3

15.2.3.5 DMM

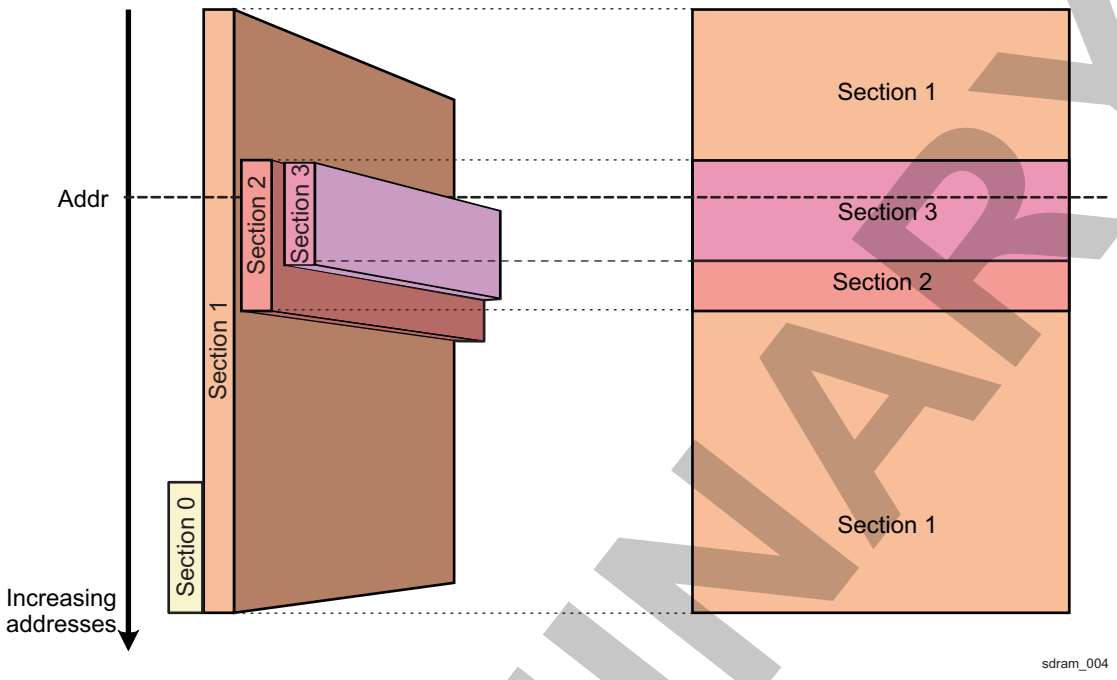
15.2.3.5.1 DMM Concepts

The DMM introduces the concepts of dynamic mapping and DMM atomic units.

15.2.3.5.1.1 Dynamic Mapping

The DMM manages its internal memory space as an ordered set of up to four sections. Figure 15-5 shows the DMM sections and memory mapping.

Figure 15-5. DMM Sections and Memory Mapping



In the DMM, a section is:

- A segment of 16MiB to 2GiB, which is power-of-two in size and aligned to that size in the system map
- An area with a constant interleaving scheme: constant interleaving granularity on a constant set of SDRC (EMIF) targets
- Given a priority equal to its index: the higher the index, the higher the priority

NOTE: Whenever a request hits more than one DMM section, it follows the interleaving scheme of the section having the highest index.

The interleaving configuration of the DMM, its section-based dynamic memory mapping, is shown on the right in Figure 15-5. In this example, a request at the system address Addr follows the interleaving scheme of section 3, although it hits sections 1, 2, and 3. Similarly, the DMM configuration given in this example prevents any request from using the interleaving scheme of section 0, because section 0 is fully masked by section 1, which has a higher priority.

Each of the four sections is configured through a DMM_LISA_MAP_i register, where i = 0 to 3.

NOTE: The DMM and SDRC registers (and EMIF registers; see Section 15.3.1, *EMIF Controller*) are declared in two extra static DMM sections of the highest priority so that they cannot be masked by any standard programmable DMM section.

NOTE: The DMM atomic size is:

- 1KiB in noninterleaved sections
- Equal to the interleaving granularity (128, 256, or 512 bytes) in interleaved sections

15.2.3.5.1.2 Address Mapping

The address mapping inside the DMM is configurable through up to four sections. A DMM section description fits in a single register (DMM_LISA_MAP_i). Each section is defined based on:

- Its system address: The base address of the decoding range for the section
- Its size: The encoding is the number of bits used in the upper 8 bits of the incoming system address
- Its physical address: The base address of the memory range access in the external memory controller
- Its address space: The address space used on the external memory controller (for the DMM) when hitting this section. For details, see , *Local Interface*.
- The target memory controller. A section may hit a single or pair of controllers.
- Its interleaving definition

The address decoding is priority-based. In case of overlapping sections, only the highest-order one is hit. Register memory spaces have priority over regular memory sections. In case of four sections, the priority order is therefore:

1. Registers
2. DMM_LISA_MAP_3
3. DMM_LISA_MAP_2
4. DMM_LISA_MAP_1
5. DMM_LISA_MAP_0

All register-related addresses are reserved and fixed in the overall address mapping:

- DMM registers: 0x4E00_0000 to 0x4FFF_FFFF
- EMIF1 registers: 0x4C00_0000 to 0x4CFF_FFFF
- EMIF2 registers: 0x4D00_0000 to 0x4DFF_FFFF

There is no overlapping between register sections.

NOTE: Section decoding happens after PAT address translation in the case of TILER. In non-bypass mode, the system address considered for TILER accesses is the virtual address computed based on the PAT translation tables.

The DMM_LISA_LOCK register is used to lock the configuration once set. If written to 1, the LOCK bit prevents further writes to all DMM_LISA_MAP_i registers. The LOCK bit cannot be written back to 0. A reset is required to reprogram the sections.

15.2.3.5.1.3 Address Translation

The PAT engine of the DMM is composed of a 32-k entry physical address translation vector table and one or two refill engines. The refill engine is a specialized DMA for refilling the content of the PAT table.

The address translation mechanism is available only when the incoming request hits a page mode or tiled mode container; that is, when the incoming address targets the TILER or its aliased view in the system addressing space. Otherwise, the PAT logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT engine supports multiple address translation schemes, called views, which can be bound to one or more initiators through a view mapping mechanism.

15.2.3.5.1.3.1 PAT View Mappings

The PAT engine can have up to 16 groups of initiators that share a set of four PAT views. The connection from an initiator to a PAT view is made through the DMM_PAT_VIEW register. Given that each PAT view index is coded on 4 bits, the DMM_PAT_VIEW register is a 64-bit register split into two 32-bit registers (DMM_PAT_VIEW0 for the first eight PAT view indexes and DMM_PAT_VIEW1 for the last eight PAT view indexes.

The PAT view index that corresponds to the initiator having the value i as the 4 most-significant bits (MSBs) of its L3 ConnID uses the view referenced in entry i of the DMM_PAT_VIEW. For example, the initiator 0xC7 uses the thirteenth view index of the DMM_PAT_VIEW register, the fifth view index in the DMM_PAT_VIEW1 register.

The PAT view index of the initiator i is found in the Vi field. The Wi field is aimed at writing the corresponding Vi. When writing to the DMM_PAT_VIEW registers, the only Vi view indexes that are updated are those having their corresponding Wi bit, and byte enable, set. The Wi bits are always read as 0. For instance, to set the PAT view indexes V3 and V7 to 2 and 1, respectively, the DMM_PAT_VIEW0 register must be written with 5000 6000h.

15.2.3.5.1.3.2 PAT View Map Base Address

The PAT view map base address defines the base address of all PAT translated addresses.

Bit [31] of all PAT translated addresses is set to BASE_ADDR. For example, if the DMM_PAT_VIEW_MAP_BASE register is set to 8000 0000h, all PAT translated addresses will have bit [31] set to 1 so that the translated addresses range from 8000 0000h to FFFF FFFFh. All reserved bits of this DMM PAT base address register are read to 0.

15.2.3.5.1.3.3 PAT Views

A PAT view defines the kind of physical address translation to perform for each mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to use a container-grained translation or page-mode translation.

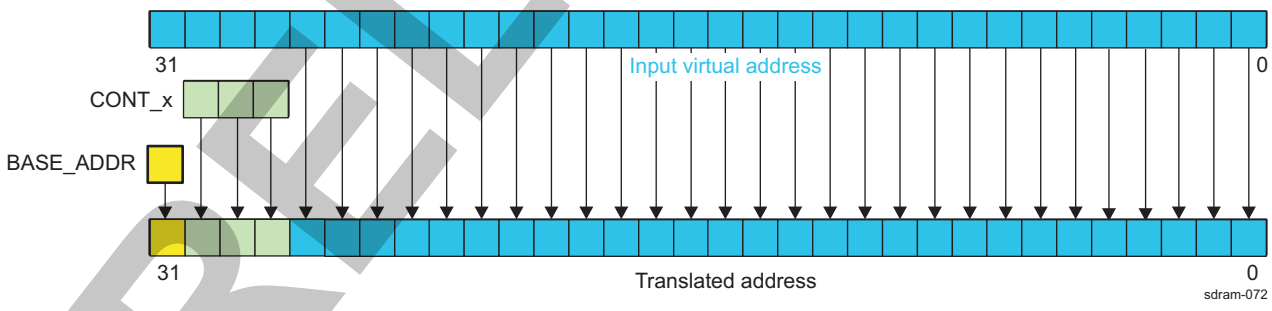
15.2.3.5.1.3.3.1 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is given directly by the CONT_x bit field that corresponds to the accessed mode.

- A page mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[26:24] CONT_PAGE bit field concatenated with 1 (bit 27 of translated address).
- A 32-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[18:16] CONT_32 bit field concatenated with 0 (bit 27 of translated address).
- A 16-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[10:8] CONT_16 bit field concatenated with 0 (bit 27 of translated address).
- An 8-bit mode access uses the vector contained in the DMM_PAT_VIEW_MAP_i[2:0] CONT_8 bit field concatenated with 0 (bit 27 of translated address).

Figure 15-6, *PAT Direct Access Translation* describes PAT direct access translation .

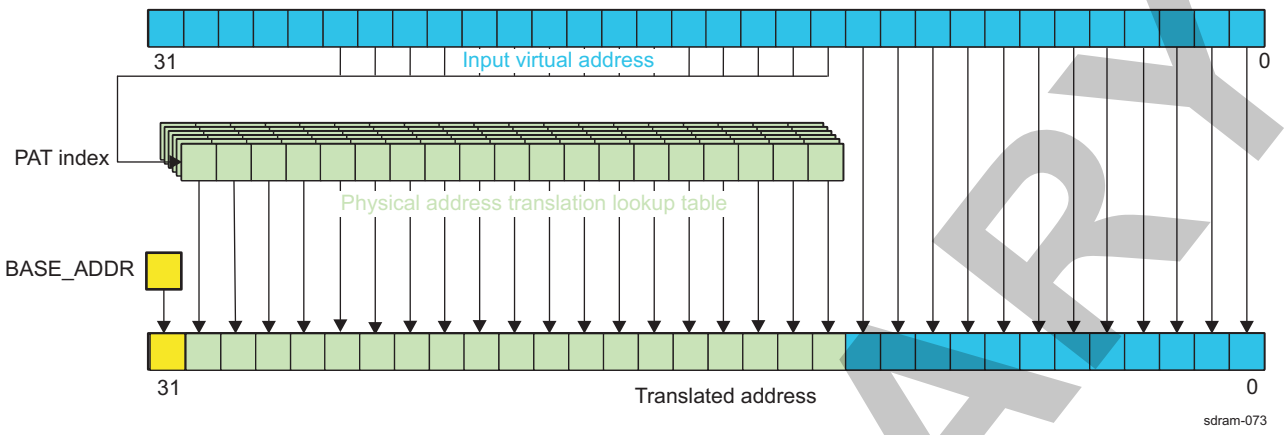
Figure 15-6. PAT Direct Access Translation



15.2.3.5.1.3.3.2 PAT Indirect Access Translation

The page-grained translation is named the indirect access. In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits [26:12] of the input virtual address, and the DMM_PAT_VIEW_MAP_i CONT_x bit field references the internal physical address translation table to use. Because the DMM uses only one such table, in this mode the CONT_x bit field must be written as 0. See Figure 15-7.

Figure 15-7. PAT Indirect Access Translation



Each entry of the PAT lookup table (LUT) is a 19-bit vector that replaces bits [30:12] of the input virtual address. The PAT index aimed at selecting the vector in the table consists of bits [26:12] of the input virtual address.

The mode associated to the transaction is used to define if the upper or lower half of the LUT is effectively used:

- If the mode is 8-, 16- or 32-bit, the lower part of the LUT (indexes 0x0000 to 0x7FFF; that is, lines 0 to 127) is used.
- If the mode is page, the upper part of the LUT (indexes 0x8000 to 0xFFFF; that is, ines 128 to 256) is used.

This means the PAT index used is the concatenation of 0 and address bits 12 to 26 in 8-, 16- or 32-bit mode, and the concatenation of 1 and address bits 12 to 26 in page mode.

Using different LUT indexes depending on the mode enables the user to define a larger tiled space, with the constraint that half of the space can be used only in 8-, 16- or 32-bit mode and the other half only in page mode. If the user wishes to preserve software compatibility with the case CONT_HGHT = 128, it is required to mirror the configuration for the lower half of the LUT on the upper half of the LUT. In that way, all views see the same address decoding through PAT.

15.2.3.5.1.3.3.3 PAT View Configuration

There are four different views in a DMM, each with its own DMM_PAT_VIEW_MAP_i register for defining the kind of address translation to perform.

The PAT view type of each mode is selected by the ACCESS_x bit field in the DMM_PAT_VIEW_MAP_i register, i being the index of the considered view. When this field is set to 1, the indirect access scheme is used; otherwise, the PAT performs the address translation in a direct way with the corresponding CONT_x vector.

When configuring a mode in a view to use the indirect access, the corresponding CONT_x bit field must be filled with 0.

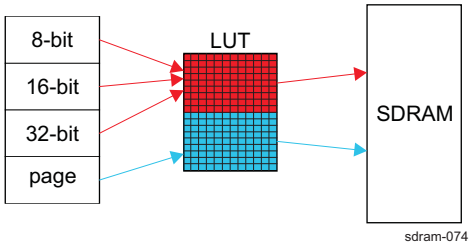
15.2.3.5.1.3.3.4 PAT Address Translation LUT

The PAT LUT does not have the same geometry as the DMM container. The PAT LUT has 256 lines of 256 entries of 19 bits each. The geometry of the DMM container is 256 × 128 entries.

- The lower 128MiB are restricted for use with 8-, 16-, and 32-bit modes.
- The upper 128MiB are restricted for use with page mode.

See Figure 15-8.

Figure 15-8. Physical Address Translation Table



15.2.3.5.1.3.3.5 Direct Access to the PAT Table Vectors

The PAT table is typically refilled with specialized DMA called refill engines. Some direct read and write access to the content of this table is granted when disabling the use of one or the other refill engine by writing 1 in the MODEi field of the DMM_PAT_CONFIG register that corresponds to the refill engine i to disable.

In this mode, often called the debug mode, the data read in or written to the DMM_PAT_DATA_i register corresponds to the vector in the PAT table, whose index is in the X0 and Y0 fields of the DMM_PAT_AREA_i register.

15.2.3.5.1.3.3.6 Automatic Refill Through the Refill Engines

See Section 15.2.4.1, *PAT Use Cases*.

15.2.3.5.2 DMM Transaction Flows

15.2.3.5.2.1 Nontiled Transaction Flow

Each nontiled interconnect transaction that reaches the DMM on a TILER port is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the flow consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting 2D requests in a collection of 1D requests – TILER ports
- Splitting requests at DMM unit boundaries; the split granularity is provided by the LISA mapping registers
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the write data path, the flow consists of forwarding incoming data to the relevant reordering buffer in accordance with the corresponding TILER write context.

On the response path, responses are returned when:

- At least one response has entered each related buffer, in case of read requests.
- All related responses have returned from the SDRC, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.2.2 Tiled Transaction Flow

Similarly, each tiled interconnect transaction that reaches the DMM is subject to the same processing.

The TILER blocks consider separated request, data, and response paths. An overview of each path follows, and more detailed information is in Section 15.2.3.5.3, *DMM Internal Macro-Architecture*.

On the request path, the processing phase consists of:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Transforming TILER-specific requests to their natural representation; the address, width, and height are modified accordingly

On the request path, the generation phase consists of:

- Allocating a TILER response context for the timely generation of the appropriate responses
- Splitting malformed: The request stride differs from the container stride and from the double of this container stride – tiled 2D requests in a collection of 1D requests
- Splitting tiled requests at tile boundaries
- Performing the page-based address translation by use of the PAT block
- Allocating an available buffer in the appropriate ROBIN, for read and write requests
- In case of a write request, allocating and updating a TILER write context to direct the incoming write data into the relevant reordering buffer
- Generating the initiator-indexed priority extension by use of the PEG block

On the data path, any incoming data is transformed in accordance with the corresponding TILER write context and sent to the appropriate reordering buffer.

On the response path, responses are returned when:

- A minimal number of responses have entered the corresponding buffers, in case of read requests.
- All related responses have returned from the SDRCs, in case of write requests.
- No other previous pending response with the same tag exists.

15.2.3.5.3 DMM Internal Macro-Architecture

This section describes the DMM internal macro-architecture, specifically:

- Input request decoding
- PAT and synchronized translation table reloading
- Output request and response generation
- Memory mapping in the system addressing space, including interleaving
- Tag management
- Priority handling
- Contexts
- Maximum allowed burst size
- Reconstruction buffer dimensioning

15.2.3.5.3.1 LISA Description

The LISA is a full crossbar aimed at setting priorities, managing tags, and mapping memory.

The interconnect routes are:

- TILER requests on the ROBIN initiator nodes
- TILER write data on the ROBIN write buffers
- ROBIN read data to the relevant TILER initiators

The LISA block registers are DMM_LISA_MAP_i (where i = 0 to 3) and DMM_LISA_LOCK.

When two ROBINs are in use, the two ports are interleaved at a programmable boundary from 128 bytes or more (configurable with the DMM_LISA_MAP_i[19:18] SDRC_INTL bit field).

15.2.3.5.3.2 PAT Description

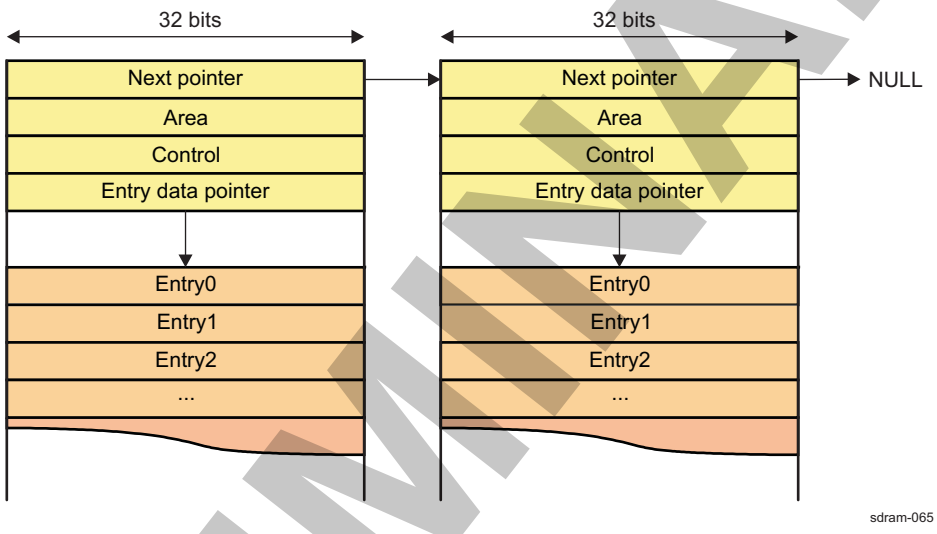
The PAT block maps physical pages to each TILER container page. The internal address translation memories used in the PAT block are designed with RFFs. It consists of:

- A memory-based LUT which has the same geometry as the container pages
- A refill engine for modifying entries in a given area of the internal LUT

A PAT descriptor is a singly-linked list node (see Figure 15-9) that contains:

- A description of the LUT area to reload
- A description of how to reload the defined LUT area
- A pointer to the location where the corresponding LUT entries are stored

Figure 15-9. PAT Descriptors



PAT descriptors are chained and processed until a NULL pointer is encountered. The PAT bank allocation scheme allows the updating of four consecutive entries of a line in a single cycle regardless of the refilling orientation.

The PAT descriptor structure directly maps the following registers (where i = 0 to 3):

- DMM_PAT_DESCR_i
- DMM_PAT_AREA_i
- DMM_PAT_CTRL_i
- DMM_PAT_DATA_i

The PAT refill engine can be started either of the following:

- Filling manually all the necessary registers:
  - DMM_PAT_AREA_i with the (x0, y0) (x1, y1) area definition
  - DMM_PAT_DATA_i with the physical address of the corresponding area entry table
  - DMM_PAT_CTRL_i[6:4] DIRECTION bit field with the relevant (S, Y, X) direction of the area refill
  - DMM_PAT_CTRL_i[0] START bit with 1
- Writing the physical address of a memory-mapped PAT descriptor in DMM_PAT_DESCR_i register, which updates:
  - DMM_PAT_AREA_i with the area value of the descriptor
  - DMM_PAT_DATA_i with the data value of the descriptor
  - DMM_PAT_CTRL_i with the control value of the descriptor
  - DMM_PAT_DESCR_i with the next value of the descriptor

The data part of the PAT refill starts only when the DMM_PAT_CTRL_i[0] START bit is asserted.

The DMM_PAT_STATUS_i register can be used to determine whether the process has completed without errors.

15.2.3.5.3.3 PEG Description

The PEG is a dynamic software-programmable, initiator-indexed table of priorities. Its unique role is to bind a priority to an initiator on the fly. The mapping of each initiator to the table (split into eight registers) is based on its 6-MSB group ConnID (see Section 14.2.3.2.3, *Master NIU Identification*, in Chapter 14, *Interconnect*).

When an interconnect request enters the DMM, its priority is extracted from the PEG LUT.

The 64 priority entries are software-programmable with the DMM_PEG_PRIO_k register. A priority of 0 defines the highest priority and a priority of 7 defines the lowest priority. At reset, all priorities are set to 4.

These registers are each split into eight 4-bit fields, each field mapping an entry of the LUT with:

- The 3-bit priority coded on the 3 least-significant bits (LSBs): P field
- A $\overline{W}$ field-specific active-low local write enable bit, always read as 0, on the MSB. The role of the $\overline{W}$ bit is to allow the modification of a single entry without requiring a read-modify-write sequence. Because its $\overline{W}$ bits are always read as 0, writing back the modified register updates all priority fields of the register.

Table 15-9 lists the initiator ConnIDs that are mapped to PEG priority register fields (P/W).

Table 15-9. ConnIDs vs PEG Priority Register Fields

Registers	P0/W0	P1/W1	P2/W2	P3/W3	P4/W4	P5/W5	P6/W6	P7/W7
DMM_PEG_PRIO_0	0	1	2	3	4	5	6	7
DMM_PEG_PRIO_1	8	9	10(0xA)	11(0xB)	12(0xC)	13(0xD)	14(0xE)	15(0xF)
DMM_PEG_PRIO_2	16(0x10)	17(0x11)	18(0x12)	19(0x13)	20(0x14)	21(0x15)	22(0x16)	23(0x17)
DMM_PEG_PRIO_3	24(0x18)	25(0x19)	26(0x1A)	27(0x1B)	28(0x1C)	29(0x1D)	30(0x1E)	31(0x1F)
DMM_PEG_PRIO_4	32(0x20)	33(0x21)	34(0x22)	35(0x23)	36(0x24)	37(0x25)	38(0x26)	39(0x27)
DMM_PEG_PRIO_5	40(0x28)	41(0x29)	42(0x2A)	43(0x2B)	44(0x2C)	45(0x2D)	46(0x2E)	47(0x2F)
DMM_PEG_PRIO_6	48(0x30)	49(0x31)	50(0x32)	51(0x33)	52(0x34)	53(0x35)	54(0x36)	55(0x37)
DMM_PEG_PRIO_7	56(0x38)	57(0x39)	58(0x3A)	59(0x3B)	60(0x3C)	61(0x3D)	62(0x3E)	63(0x3F)

Although this priority information is generated before entering the LISA block, it is not used internally in the local interconnect arbitration but is forwarded to the EMIF as MReqInfo, where it indicates the command priority.

It is also possible to give a priority for the internal PAT engine through the DMM_PEG_PRIO_PAT register.

15.2.3.5.3.4 LISA Interconnect Arbitration

When Mflag[i][63:0] ≠ 0 is signaled at TILERi or both TILERs, the transactions of TILERi or both TILERs form an additional new group called the high priority group. Within this group, reads and writes are sorted and arbitrated the same way as in the normal priority group. Arbitration between transactions out of the high priority group and out of the normal priority group is based on a weighted round-robin algorithm. Weight is software selectable using the DMM_EMERGENCY[20:16] WEIGHT bit field. Weight selection is considered static (that is, behavior is undefined when software changes the weight, and DMM is not empty of transaction).

The counter that is implemented to support the weighted round-robin is enabled as long as emergency signaling is present. The counter increments by one each time a command (from the normal or the high priority group) is pushed to ROBIN. The counter wraps on DMM_EMERGENCY[20:16] WEIGHT value. One command from the normal priority group is serviced in any of the following scenarios:

- The counter is enabled and wraps.
- The counter is enabled, has not reached its wrap value, and no command is queued in the high priority group (a case where one device module is signaling emergency but its requests have not yet reached

the TILERs).

- The counter is disabled.

Setting the DMM_EMERGENCY[0] ENABLE bit to 1 enables the emergency arbitration scheme.

NOTE: It is recommended to set the DMM_EMERGENCY[0] ENABLE bit to 1, and the DMM_EMERGENCY[20:16] WEIGHT bit to 0x8. This provides better and faster recovery behavior, and benefits system performance.

15.2.3.5.3.5 ROBIN Description

The ROBIN is a block that provides some working buffering for converting data and responses to-and-from between raster and tiled organizations, and a master port to connect to the EMIF.

The ROBIN block:

- Forwards requests
- Writes data and buffers responses
- Keeps write data ordering
- Performs intraword tiling and orientation transforms
- Handles tags

15.2.3.5.3.6 TILER Description

The main function of the TILER is request conversion caused by tiling.

The TILER block:

- Decodes the address to qualify whether the request targets the TILER or the memory directly
- Converts TILER-specific requests to their natural representation; address, width, and height are modified accordingly
- Allocates an internal response context for the timely generation of appropriate responses
- Splits tiled requests at tile boundaries and not-tiled requests at DMM atomic section boundaries
- Requests the page-based address translation
- Requests buffer allocation in the appropriate ROBIN
- In case of a write request, allocates and updates an internal write context to direct the incoming write data into the relevant reordering buffer

The interdependent tilingand isometric transform concepts introduced in the TILER are described in the following section.

15.2.3.6 TILER

15.2.3.6.1 TILER Concepts

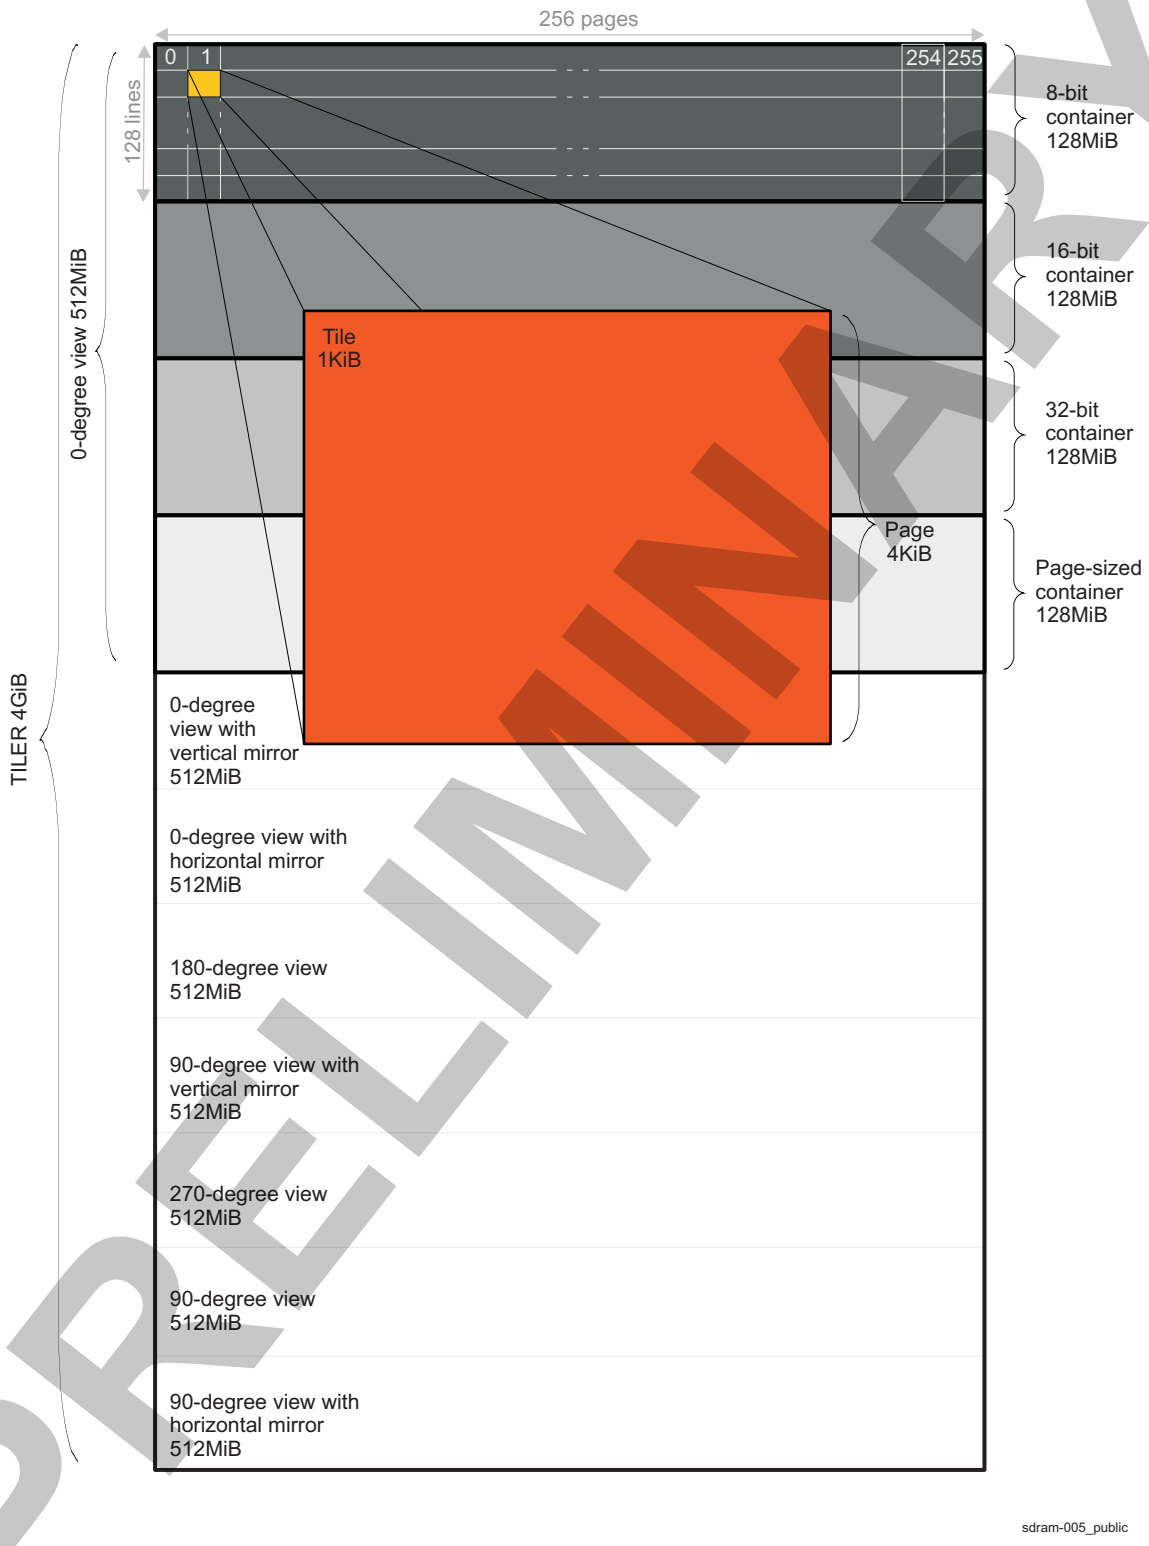
This section describes the concepts behind the TILER transforms, through a top-down approach starting from the main object container.

15.2.3.6.1.1 TILER Rationale

This section is a synthesis of all TILER concepts, giving one rule per TILER structure level.

Figure 15-10 shows the TILER address space structure for tiled modes.

Figure 15-10. TILER Address Space Structure for Tiled Modes



15.2.3.6.1.1.1 The TILER is a 4-GiB Virtual Address Space Composed of Eight Views

There is one view for each of the eight possible ways of scanning a frame-buffer:

- From left to right and then from top to bottom

- From right to left and then from top to bottom
- From left to right and then from bottom to top
- From right to left and then from bottom to top
- From top to bottom and then from left to right
- From top to bottom and then from right to left
- From bottom to top and then from left to right
- From bottom to top and then from right to left

15.2.3.6.1.1.2 A View is a 512-MiB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated.

The element is the entity of maximum size (8, 16, 32 bits, or page-sized), which is invariant in any orientation.

15.2.3.6.1.1.3 A Container is a 128-MiB Virtual Address Space

A container is composed of an array of 128 lines of 256 pages of 4kiB each.

The page defines the granularity of physical memory allocation through a PAT unit – MMU.

15.2.3.6.1.1.4 A Page is a 4-kiB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles.

15.2.3.6.1.1.5 A Tile is a 1-kiB Address Space

The tile is designed to offer bidimensional data locality in a single SDRAM page. In this respect, it is sized to 1kiB; that is, to the size of the smallest SDRAM page.

15.2.3.6.1.2 TILER Modes

The TILER supports three major modes, bypass, page, and tiled. Each mode has a specific output request generation.

15.2.3.6.1.2.1 Bypass Mode

This mode is transparent from the TILER perspective. However, from the DMM perspective:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at the DMM atomic unit of the section hit by the burst at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.2 Page Mode

This mode uses the DMM address translation mechanism for nontiled accesses. In this respect it is similar to bypass mode:

- 2D block bursts are broken down on a line basis in a set of incremental bursts.
- Incremental bursts, including those issued by a 2D block burst breakdown, are split at:
  - The interleaving granularity of the section (128, 256, or 512 bytes) in interleaved sections
  - 1-kiB boundary in noninterleaved sections

15.2.3.6.1.2.3 Tiled Mode

Tiled mode has two major breakdown algorithms:

- One for well-formed 2D block requests that conform to the orientation, mode, and stride listed in Table 15-10
- One for 1D incremental requests and ill-formed 2D block requests

Table 15-10. Well-Formed Tiled Mode 2D Block Requests

Orientation			Mode		Stride	Description
S	$\overline{Y}$	$\overline{X}$	M1	M0	(bytes)	
0	x	x	0	0	16,384	Plain access to an 8-bit progressive frame in 0 or 180 degrees
					32,768	Field access to an 8-bit interlaced frame 0 or 180 degrees
			0	1	32,768	Plain access to a 16-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 16-bit interlaced frame 0 or 180 degrees
			1	0	32,768	Plain access to a 32-bit progressive frame in 0 or 180 degrees
					65,536	Field access to a 32-bit interlaced frame 0 or 180 degrees
1	x	x	0	0	8192	Plain access to an 8-bit progressive frame in 90 or 270 degrees
					16,384	Field access to an 8-bit interlaced frame 90 or 270 degrees
			0	1	8192	Plain access to a 16-bit progressive frame in 90 or 270 degrees
					16,384	Field access to a 16-bit interlaced frame 90 or 270 degrees
			1	0	16,384	Plain access to a 32-bit progressive frame in 90 or 270 degrees
					32,768	Field access to a 32-bit interlaced frame 90 or 270 degrees

Similar to the bypass and page modes, ill-formed 2D block requests are broken down on a line basis in a set of incremental bursts. In tiled mode, however, these incremental virtual bursts do not translate to 1D physical burst requests.

15.2.3.6.1.3 Object Container Definition

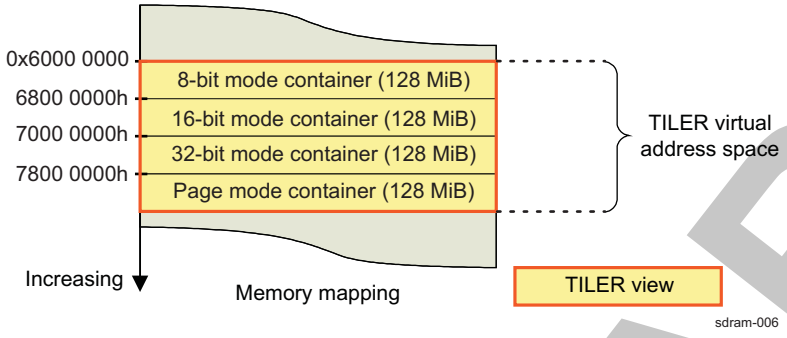
The object container is the unique addressable entry point of the TILER. It is a 128-MiB virtual address space, where all objects of a same kind and orientation are allocated.

Four main types of containers are present in the TILER, each referred by a mode:

- 8-bit element mode, for efficiently accessing bidimensional arrays of 8-bit data
- 16-bit element mode, for efficiently accessing bidimensional arrays of 16-bit data
- 32-bit element mode, for efficiently accessing bidimensional arrays of 32-bit data
- Page mode, for efficient 1D accesses

Figure 15-11 shows the TILER object containers and views.

Figure 15-11. TILER Object Containers and Views

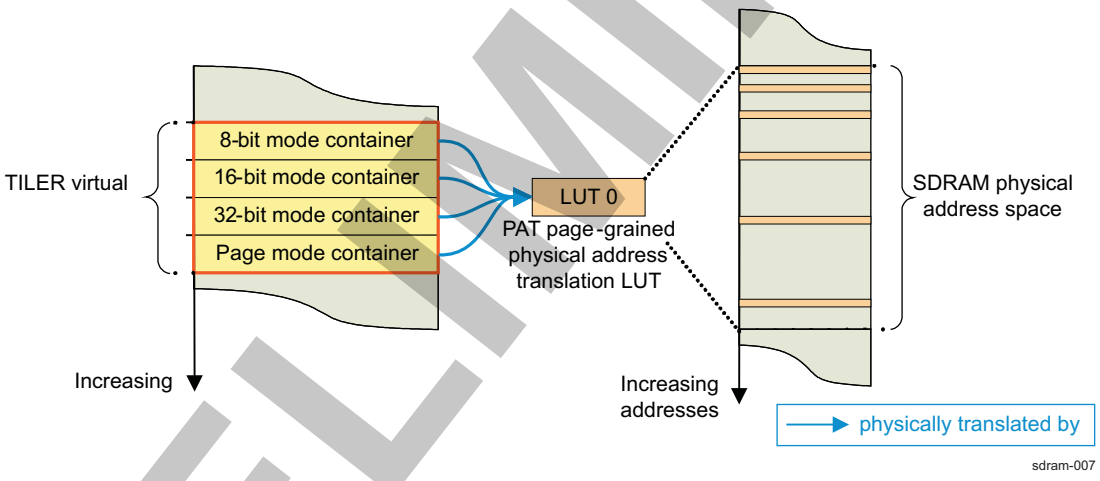


The 512-MiB virtual address space composed of four 128-MiB object containers of different modes is called a view. Because eight orientations are available per mode, the TILER actually manages 32 kinds of containers.

The physical memory footprint of a 512-MiB TILER view is directly subject to the nature of the PAT unit.

A unique PAT LUT is instantiated in the DMM. This table is shared by all TILER modes. Hence, each of the four modes cannot be given its own private page-grained PAT LUT. A maximum of 128MiB of objects among all TILER modes can be managed as shown in Figure 15-12.

Figure 15-12. TILER Memory Footprint With PAT and Shared Physical Address Translation LUT



Although each of the four modes has its own separate virtual 128-MiB object container, these containers are all mapped to the same piecewise 128-MiB physical address space, and are then not physically separated. Consequently, a memory-related system constraint is that no more than 128-MiB of objects can be available simultaneously in a TILER view.

NOTE: Software must ensure that any object allocated in a mode does not physically overlap with any other object, even in another mode.

15.2.3.6.1.4 Page Definition

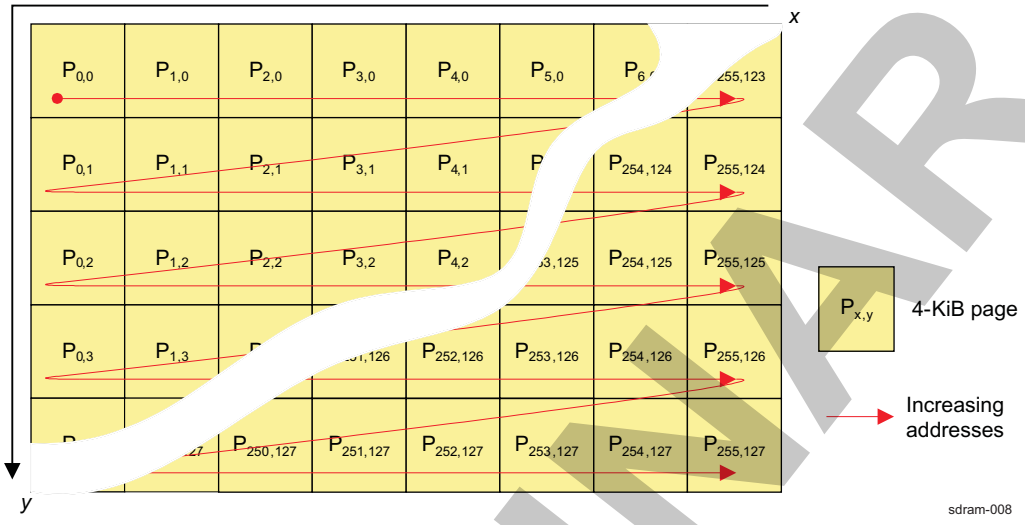
A TILER page defines the granularity of object allocation in virtual TILER containers.

Because the subpage structure is mode-specific, the page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

15.2.3.6.1.4.1 Container Geometry With 4-kiB Pages

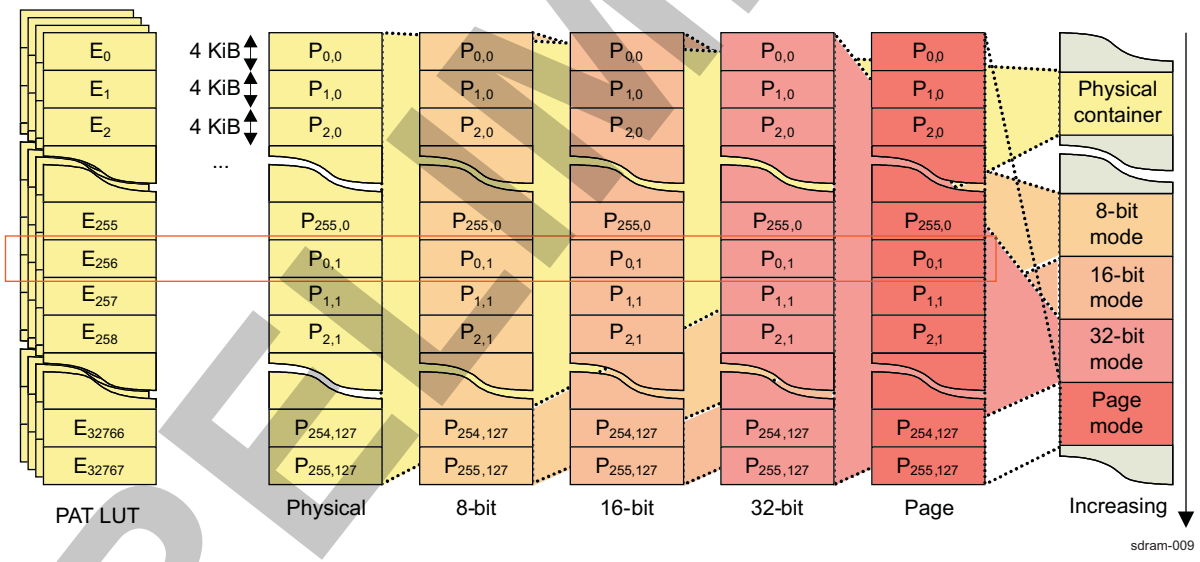
Because the size of the page is 4kiB, any 128-MiB object container is a set of 32,768 pages, organized in an array of 256 columns and 128 rows, as shown in Figure 15-13.

Figure 15-13. Object Container Geometry With 4-kiB Pages



This array of pages is mapped to the system address space, as shown in Figure 15-14.

Figure 15-14. TILER Page Mapping When Using 4-kiB Pages



In any 128-MiB object container, the 4-kiB page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is found at an offset of 4096.(x+256.y) bytes from the base address of the related object container.

Similarly, the page Px,y at column x (where 0 =< x < 256) and row y (where 0 =< y < 128), is translated by the LUT entry Ex+256.y found at the index x+256.y.

15.2.3.6.1.4.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page $P_{x,y}$:

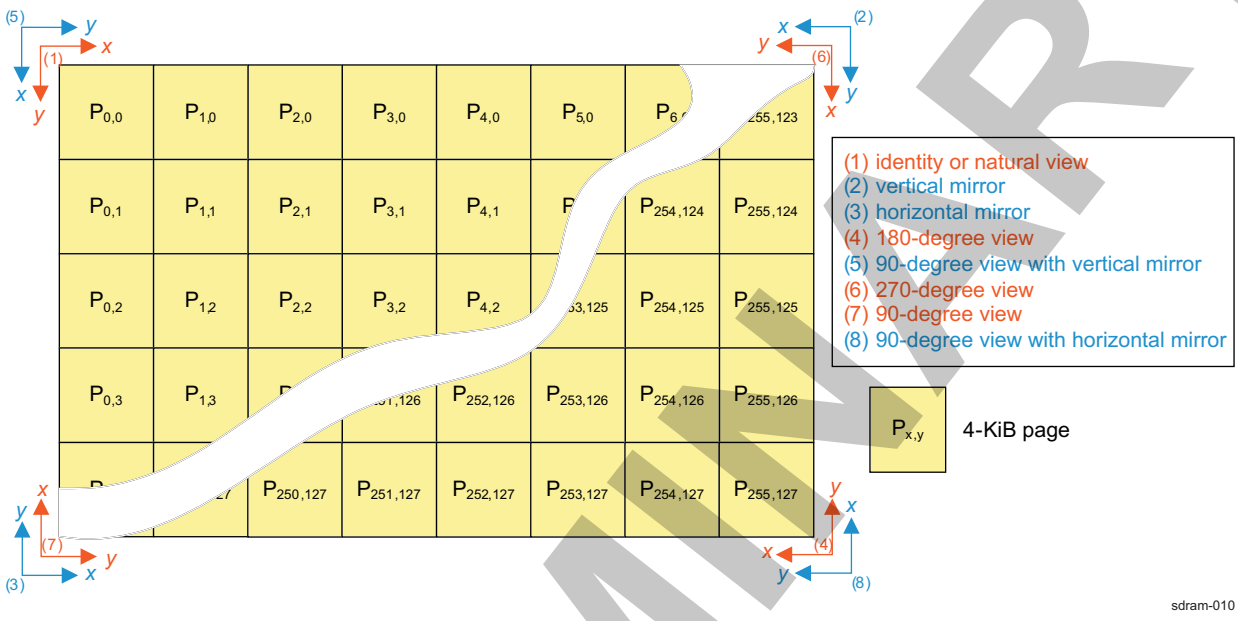
- Has max_x = 256 and max_y = 128
- Is found at an offset of 4096.(x + max_x.y) bytes from the base address of the related object container
- Is translated by the entry at the index (x + max_x.y) of the LUT

15.2.3.6.1.5 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, which correspond to all available changes of orthonormal basis in the bidimensional space of the TILER container.

Figure 15-15 shows isometric transforms in the TILER container

Figure 15-15. Isometric Transforms in the TILER Container



Mathematically speaking, all these transforms correspond to the composition of a 0-, 90-, 180-, or 270-degree rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- *X* to change the direction of the $_{x}$ axis of the TILER container
- *Y* to change the direction of the $_{y}$ axis of the TILER container
- *S* to swap the modified $_{x}$ and $_{y}$ axis

Hereafter in this document the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal (flip-flop) or vertical mirroring.

15.2.3.6.1.6 Tile Definition

A tile is a subdivision of a page that is aimed at:

- Representing a 2D block to better balance accesses in both directions
- Ensuring that any tiled access that fits within a tile is made atomic in the SDRC and fits in a single SDRAM memory page
- Minimizing the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1-kiB 2D block, and a 4-kiB page as an array of two lines of two tiles each.

When the considered page is in an interleaved DMM section, it is necessary that:

- The DMM memory interleaving size of tiled accesses is set to 1kiB (a tile size) so that any tiled request that fits within a tile, fits in a single SDRAM memory page.
- Any request that spans two or four tiles is distributed on a maximum number of SDRCs.

15.2.3.6.1.7 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 15-11.

Table 15-11. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

For instance, making a vertical mirror of a 16-byte horizontal line that contains the word 000102030405060708090A0B0C0D0E0Fh, leads to:

- 0F0E0D0C0B0A09080706050403020100h in 8-bit tiled mode
- 0E0F0C0D0A0B08090607040502030001h in 16-bit tiled mode
- 0C0D0E0F08090A0B0405060700010203h in 32-bit tiled mode
- 000102030405060708090A0B0C0D0E0Fh in page mode – unchanged because the element granularity is 4 KiB

Besides, because each of the eight orientations is available for any of the four modes, the TILER has 32 addressing possibilities (see Table 15-12).

Table 15-12. Coding and Description of TILER Orientations

S	$\overline{Y}$	$\overline{X}$	Description	Alternate description
0	0	0	0-degree view	Natural view
0	0	1	0-degree view with vertical mirror	180-degree view with horizontal mirror
0	1	0	0-degree view with horizontal mirror	180-degree view with vertical mirror
0	1	1	180-degree view	
1	0	0	90-degree view with vertical mirror	270-degree view with horizontal mirror
1	0	1	270-degree view	
1	1	0	90-degree view	
1	1	1	90-degree view with horizontal mirror	270-degree view with vertical mirror

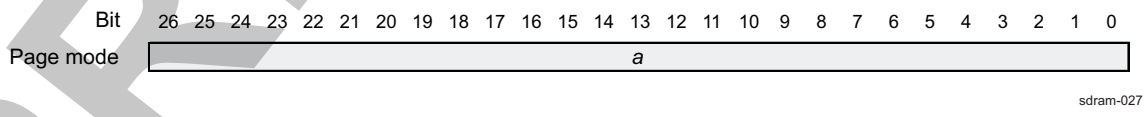
15.2.3.6.1.7.1 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32,768 pages of 4kiB each. The access sequence inside a page is left unchanged.

Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

NOTE: From here forward, the address is noted as *a* (see Figure 15-16).

Figure 15-16. Page Mode Virtual Addressing



15.2.3.6.1.7.2 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer, the container. The addressing and characteristics of this giant frame-buffer depend on:

- The tiled mode, which defines the considered atomic element size
- The orientation, which potentially swaps its x and y axis, and hence the container geometry

Table 15-13 summarizes the container characteristics in tiled mode.

Table 15-13. Tiled Mode Container Characteristics

Orientation			Element Size (Bits)	Width (Elements)	Height (Elements)	Stride (Bytes)	
S	$\bar{Y}$	$\bar{X}$				Progressive	Interlaced
0	x	x	8	16,384	8192	16,384	32,768
			16	16,384	4096	32,768	65,536
			32	8192	4096	32,768	65,536
1	x	x	8	8192	16,384	8192	16,384
			16	4096	16,384	8192	16,384
			32	4096	8192	16,384	32,768

As a result, the coordinate (x_0, y_0) of a pixel in an oriented view is translated in a virtual address, as shown in Figure 15-17 and Figure 15-18.

Figure 15-17. Tiled Mode Addressing in 0- or 180-Degree Orientation (S = 0)

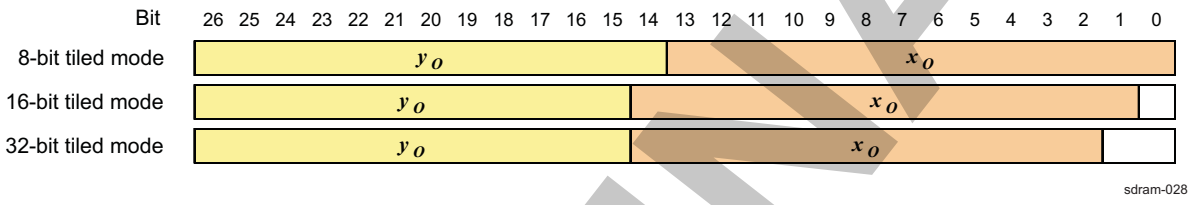


Figure 15-18. Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)

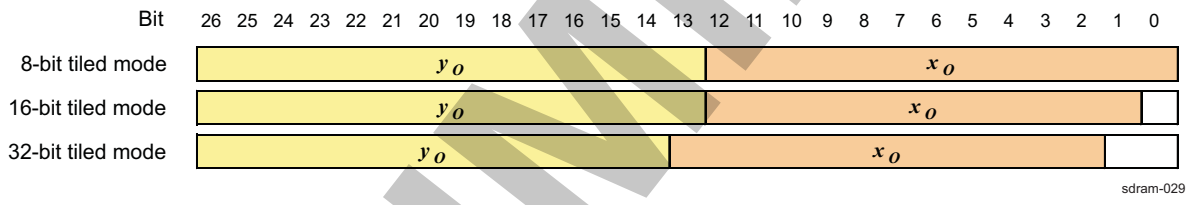


15.2.3.6.1.7.3 Element Ordering in the TILER Container

This section describes how elements (8-, 16-, or 32-bit data or a 4-kiB page) are ordered in the container. In other words, this section describes how the path of incrementing virtual addresses is mapped in the container.

Regardless of the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and depends only on the related orientation. In other words:

- Mode is concerned with element granularity.
- Orientation is concerned with change of orthornormal basis for ordering the elements in the mode-specific container.

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged regardless of the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the following sections, the natural container orthonormal basis is referenced as:

$$(\vec{x}_N, \vec{y}_N)$$

sdram-030

and the oriented orthonormal basis is referenced as:

$$(\vec{x}_O, \vec{y}_O)$$

sdram-031

15.2.3.6.1.7.3.1 Natural View or 0-Degree View (Orientation 0)

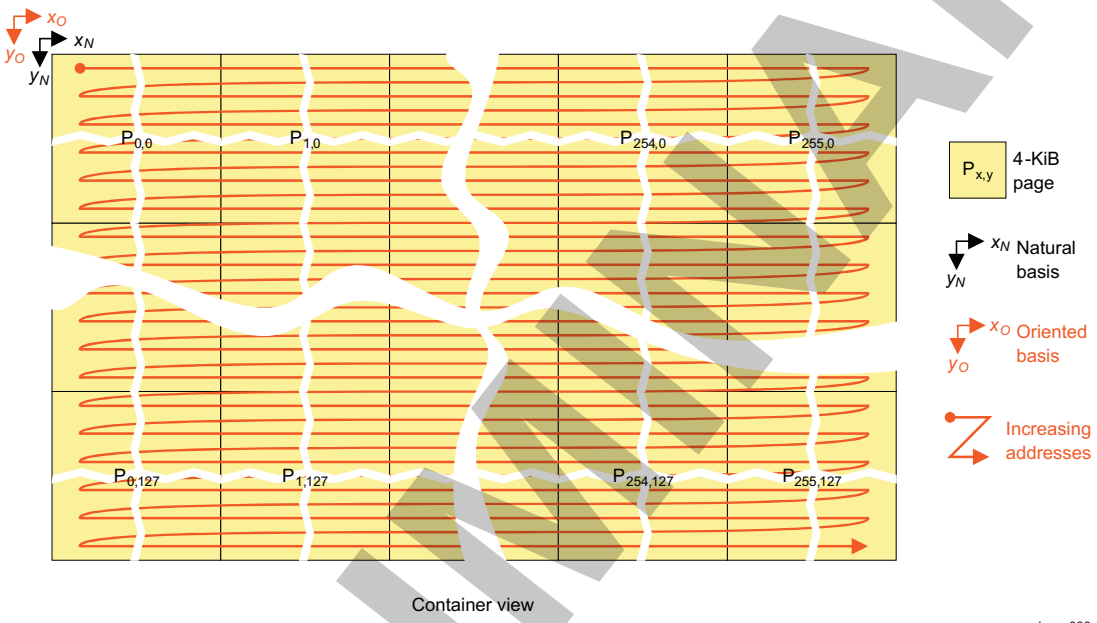
This orientation defined by S = 0, $\overline{Y}$ = 0, and $\overline{X}$ = 0 means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{x}_N \\ \vec{y}_O = \vec{y}_N \end{cases}$$

sdram-032

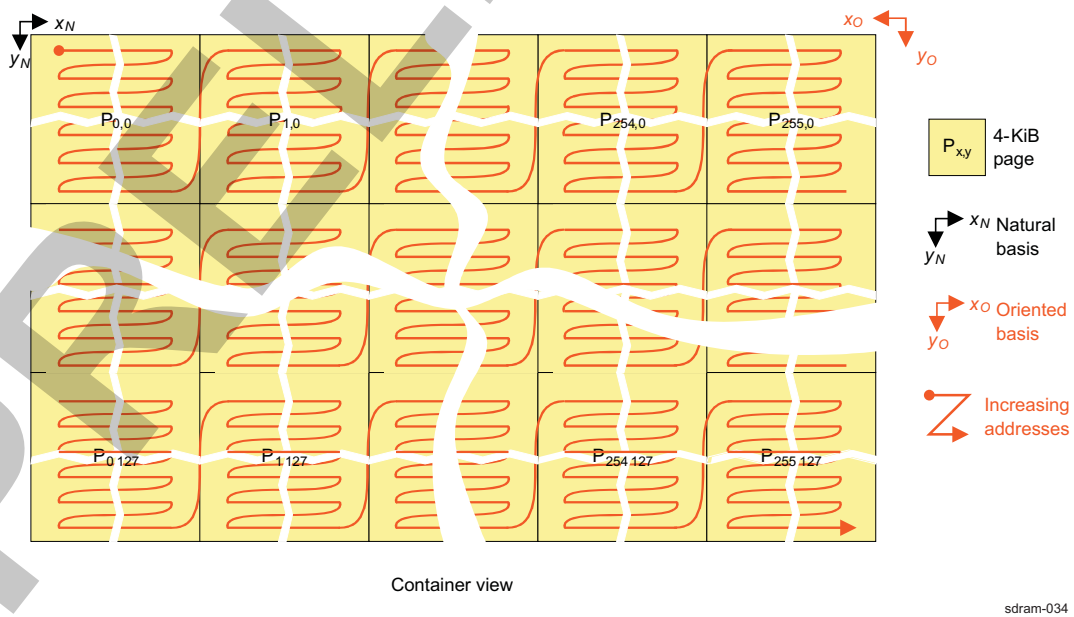
In any TILER mode, the elements are ordered from left to right and then from top to bottom in their container, as shown in Figure 15-19 and Figure 15-20.

Figure 15-19. Tiled Mode Ordering of Elements in Natural View



sdram-033

Figure 15-20. Page Mode Ordering of Elements in Natural View



sdram-034

15.2.3.6.1.7.3.2 0-Degree View With Vertical Mirror or 180-Degree View With Horizontal Mirror

(Orientation 1)

This orientation defined by S = 0, $\overline{Y}$ = 0, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{x}_N \\ \vec{y}_O = \vec{y}_N \end{cases}$$

sdram-035

In any TILER mode, the elements are then ordered from right to left and then from top to bottom in their container, as shown in Figure 15-21 and Figure 15-22.

Figure 15-21. Tiled Mode Ordering of Elements in 0-Degree View With Vertical Mirror

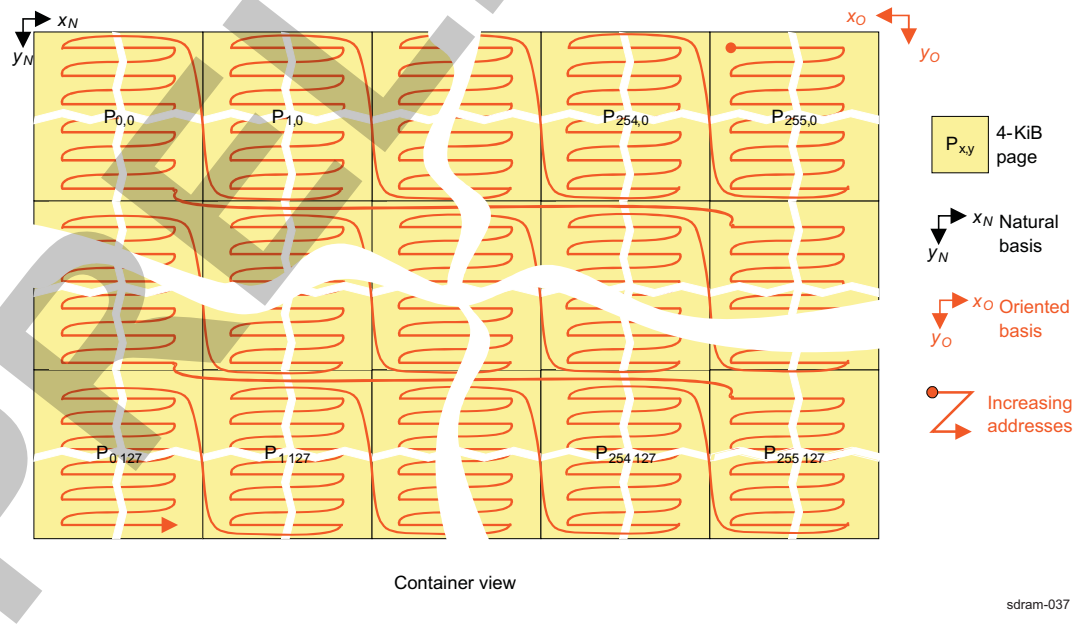
Figure 15-22. Page Mode Ordering of Elements in 0-Degree View With Vertical Mirror



sdram-037

15.2.3.6.1.7.3.3 0-Degree View With Horizontal Mirror or 180-Degree View With Vertical Mirror

(Orientation 2)

This orientation defined by S = 0, $\overline{Y}$ = 1, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{x}_N \\ \vec{y}_O = -\vec{y}_N \end{cases}$$

sdram-038

In any TILER mode, the elements are ordered from left to right and then from bottom to top in their container, as shown in Figure 15-23 and Figure 15-24.

Figure 15-23. Tiled Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

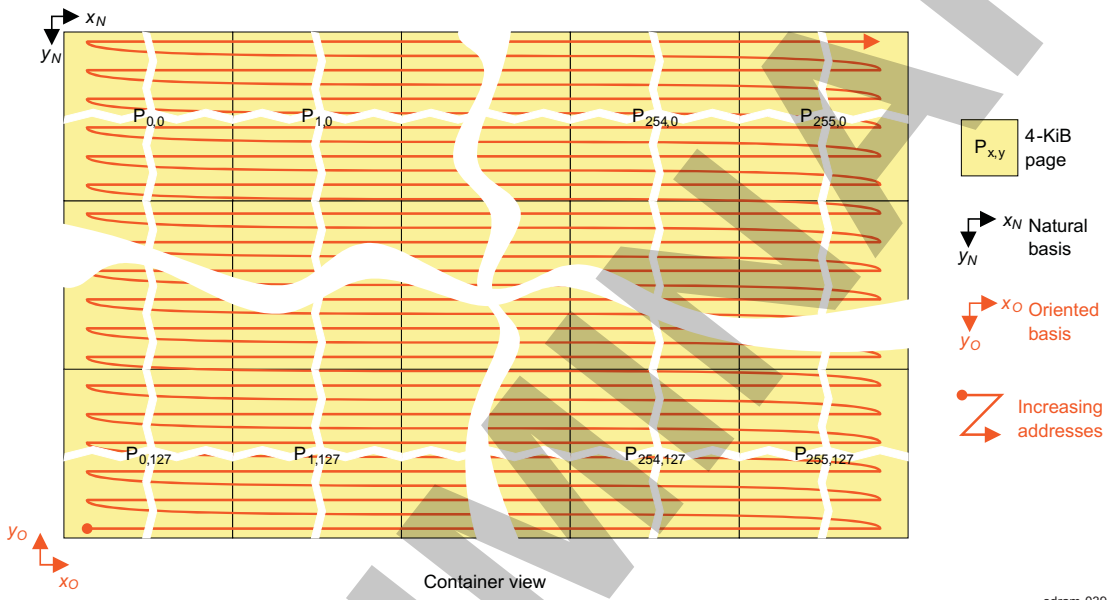


Figure 15-24. Page Mode Ordering of Elements in 0-Degree View With Horizontal Mirror

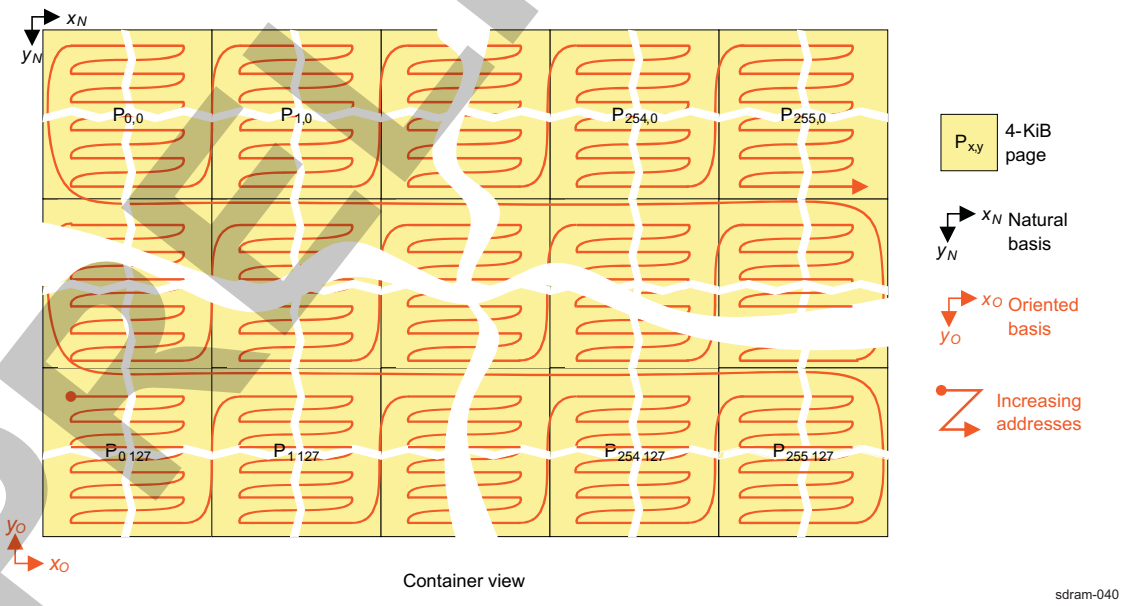


15.2.3.6.1.7.3.4 180-Degree View (Orientation 3)

This orientation defined by S = 0, $\overline{Y}$ = 1, and $\overline{X}$ = 1 and means that the operated change of basis is:

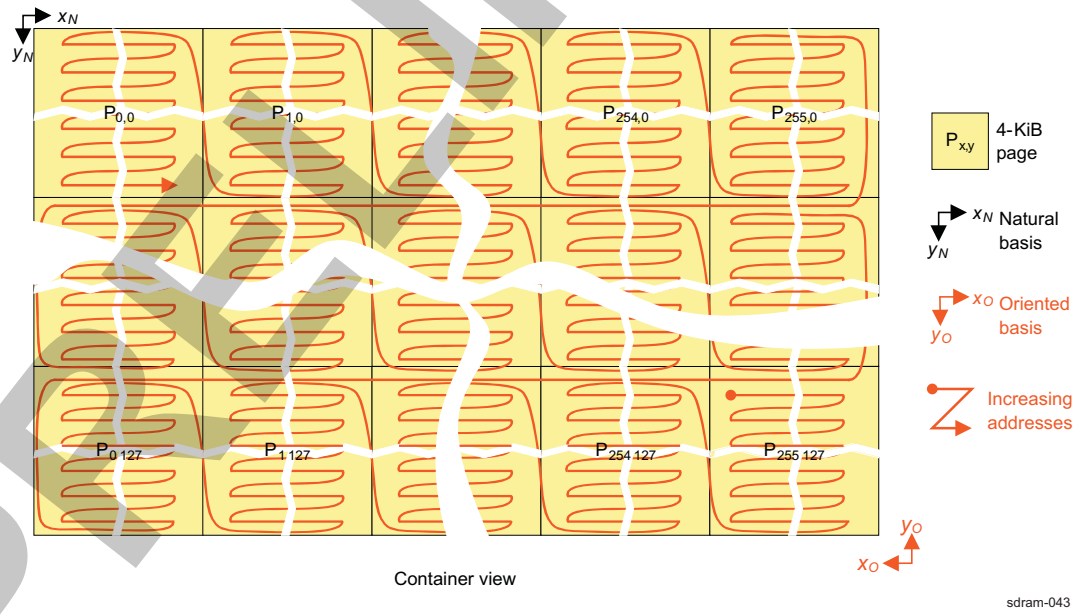
$$\begin{cases} \vec{x}_O = -\vec{x}_N \\ \vec{y}_O = -\vec{y}_N \end{cases}$$

sdram-041

In any TILER mode, the elements are ordered from right to left and then from bottom to top in their container, as shown in Figure 15-25 and Figure 15-26.

Figure 15-25. Tiled Mode Ordering of Elements in 180-Degree View

Figure 15-26. Page Mode Ordering of Elements in 180-Degree View



15.2.3.6.1.7.3.5 90-Degree View With Vertical Mirror or 270-Degree View With Horizontal Mirror (Orientation 4)

This orientation defined by S = 1, $\overline{Y}$ = 0, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{y}_N \\ \vec{y}_O = \vec{x}_N \end{cases}$$

sdram-044

In any TILER mode, the elements are ordered from top to bottom and then from left to right in their container, as shown in Figure 15-27 and Figure 15-28.

Figure 15-27. Tiled Mode Ordering of Elements in 90-Degree View With Vertical Mirror

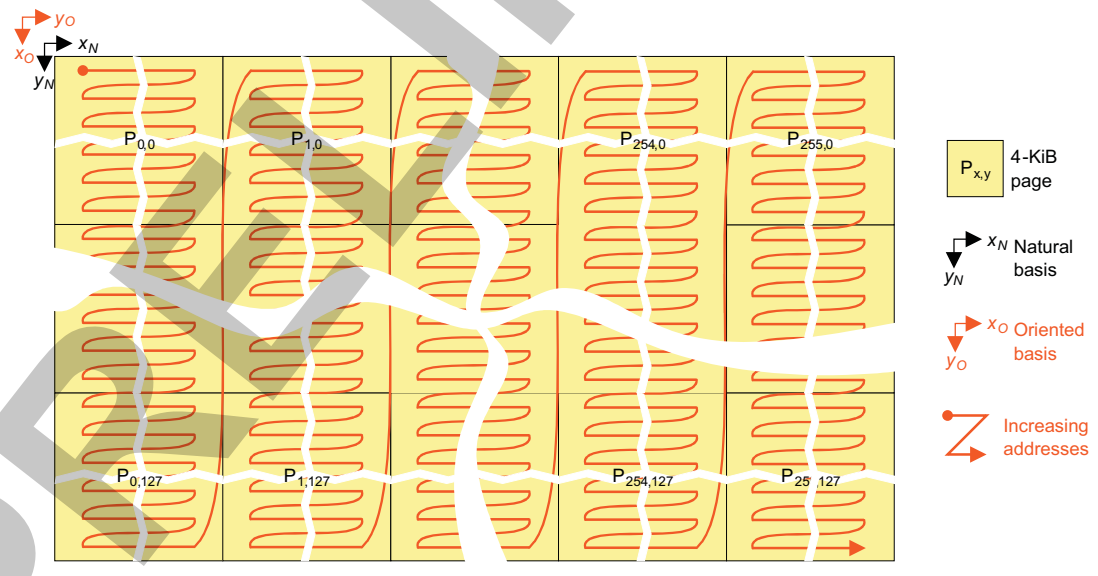
Figure 15-28. Page Mode Ordering of Elements in 90-Degree View With Vertical Mirror



sdram-046

15.2.3.6.1.7.3.6 270-Degree View (Orientation 5)

This orientation defined by S = 1, $\overline{Y}$ = 0, and $\overline{X}$ = 1 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = \vec{y}_N \\ \vec{y}_O = -\vec{x}_N \end{cases}$$

sdram-047

In any TILER mode, the elements are ordered from top to bottom and then from right to left in their container, as shown in Figure 15-29 and Figure 15-30.

Figure 15-29. Tiled Mode Ordering of Elements in 270-Degree View

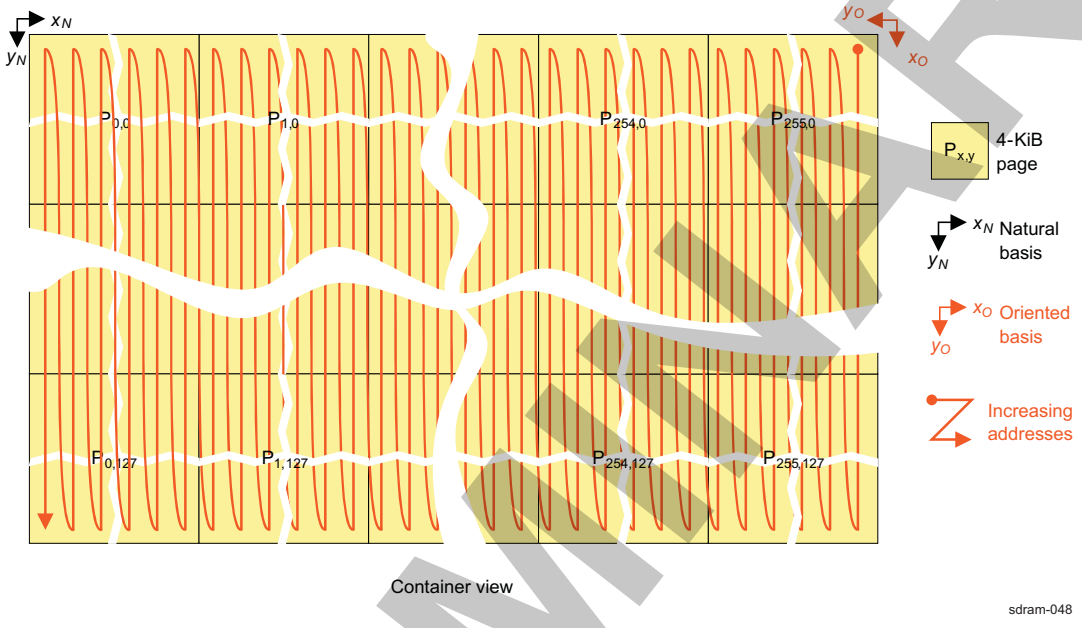


Figure 15-30. Page Mode Ordering of Elements in 270-Degree View

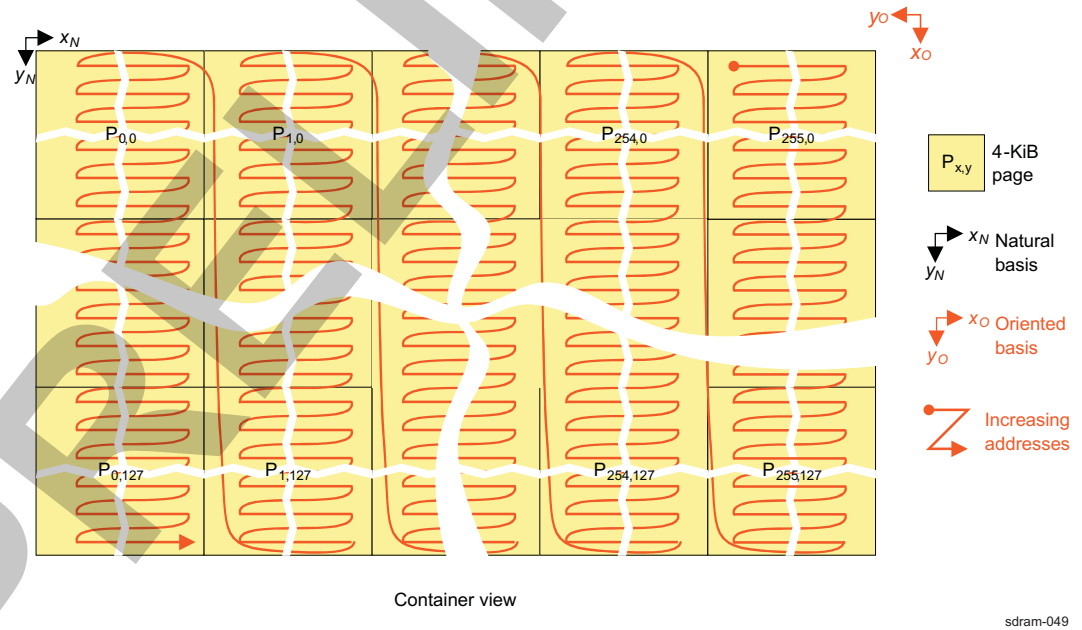

15.2.3.6.1.7.3.7 90-Degree View (Orientation 6)

This orientation defined by S = 1, $\overline{Y}$ = 1, and $\overline{X}$ = 0 and means that the operated change of basis is:

$$\begin{cases} \vec{x}_O = -\vec{y}_N \\ \vec{y}_O = \vec{x}_N \end{cases}$$

sdram-050

In any TILER mode, the elements are ordered from bottom to top and then from left to right in their container, as shown in Figure 15-31 and Figure 15-32.

Figure 15-31. Tiled Mode Ordering of Elements in 90-Degree View

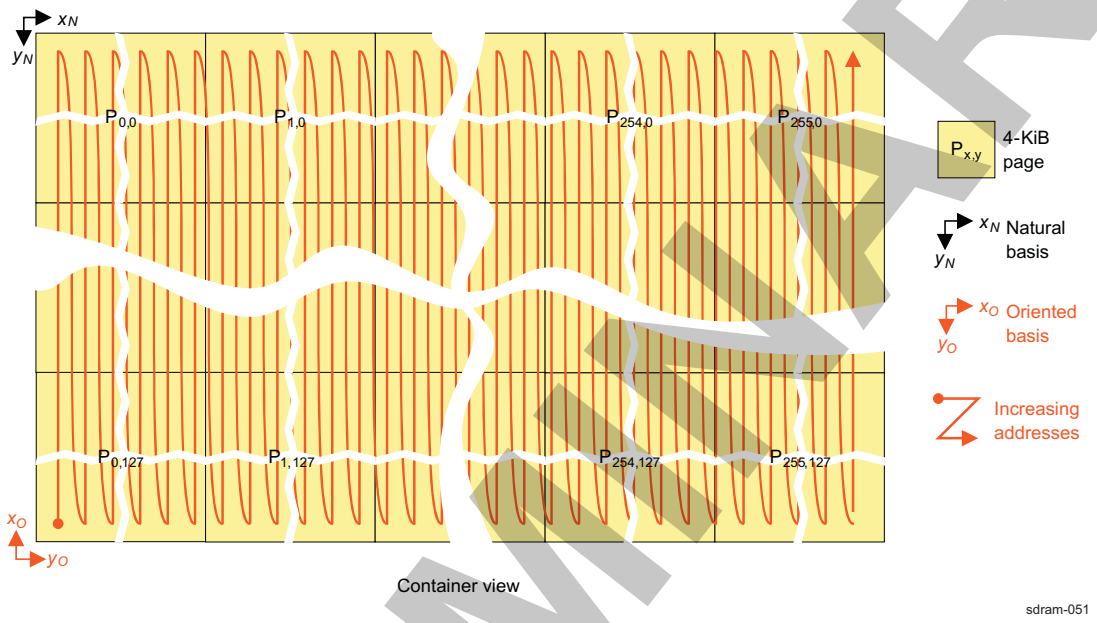

Figure 15-32. Page Mode Ordering of Elements in 90-Degree View

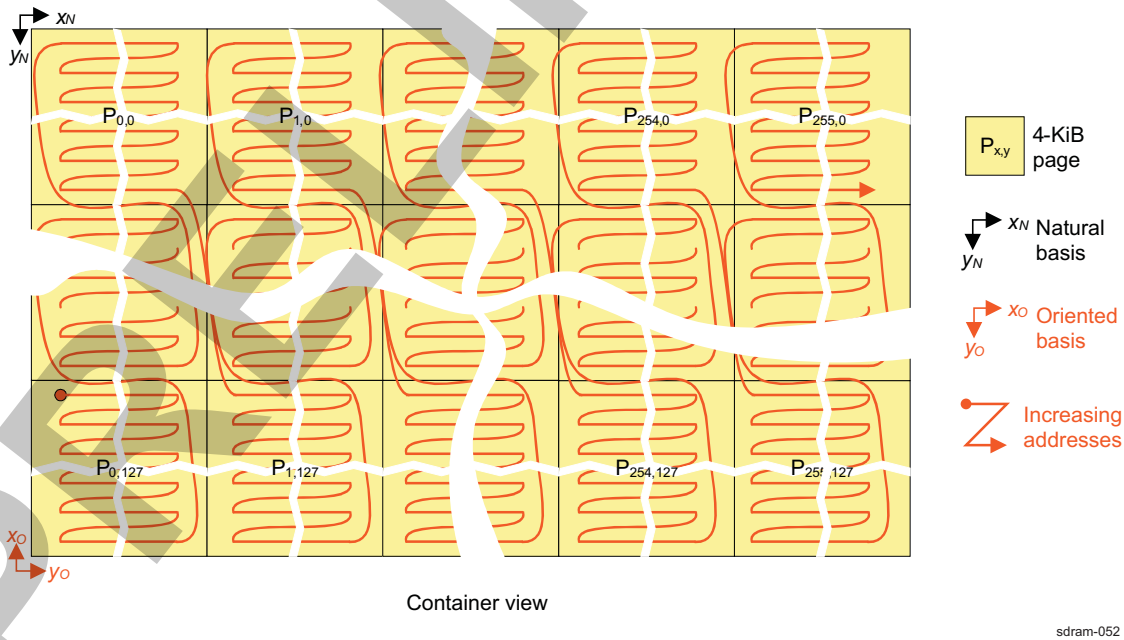


15.2.3.6.1.7.3.8 90-Degree View With Horizontal Mirror or 270-Degree View With Vertical Mirror (Orientation 7)

This orientation defined by S = 1, $\overline{Y}$ = 1, and $\overline{X}$ = 1 and means that the operated change of basis is:

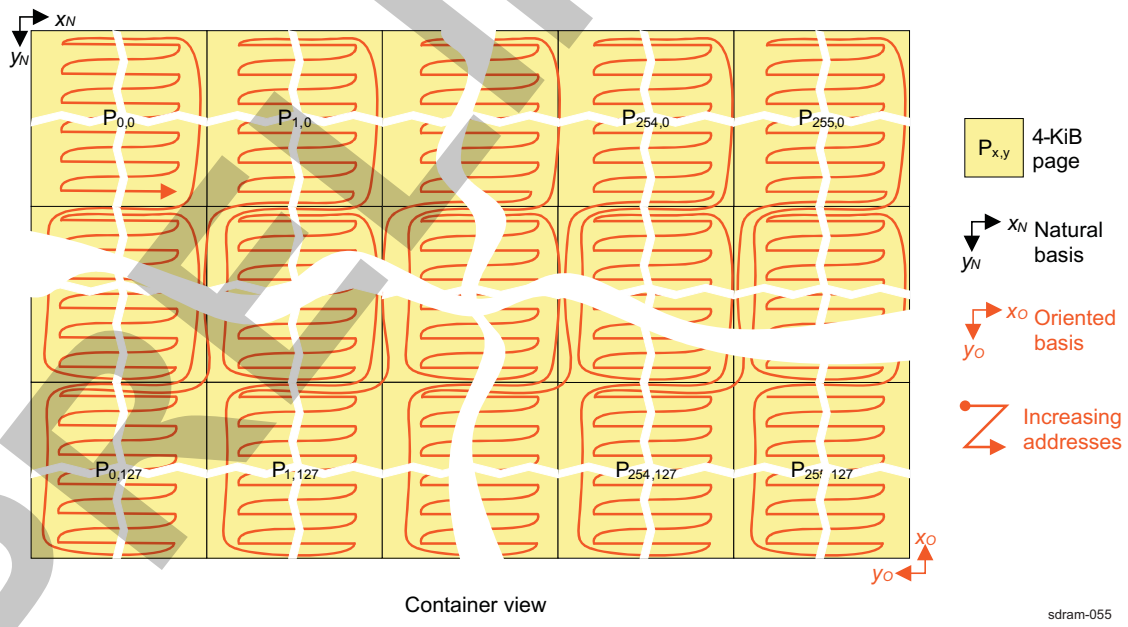
$$\begin{cases} \vec{x}_O = -\vec{y}_N \\ \vec{y}_O = -\vec{x}_N \end{cases}$$

sdram-053

In any TILER mode, the elements are ordered from bottom to top and then from right to left in their container, as shown in Figure 15-33 and Figure 15-34.

Figure 15-33. Tiled Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

Figure 15-34. Page Mode Ordering of Elements in 90-Degree View With Horizontal Mirror

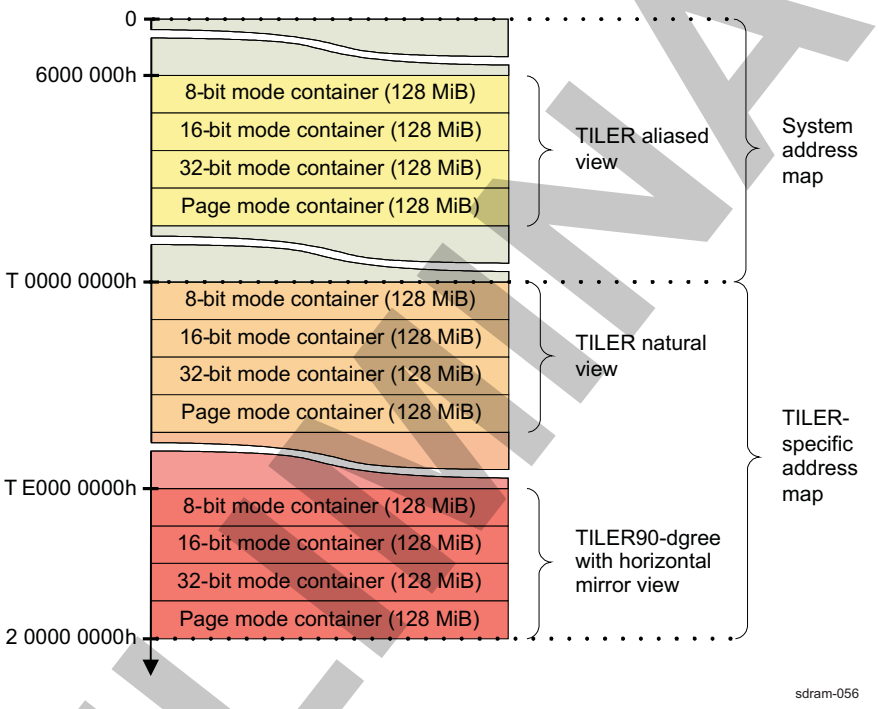


15.2.3.6.2 TILER Macro-Architecture

The TILER requires a 4-GiB addressing space to map its 128-MiB physical container in four modes and eight orientations. Because its addressing space alone fills the 4-GiB global system address map, the TILER addressing space cannot enter as-is into the system address map. Besides, putting in place a register-based mechanism per initiator to specify the orientation of the following accesses and then reducing the TILER addressing space to a single 512-MiB view is not an option; this is because most of the bandwidth-hungry initiators require simultaneous accesses to the TILER container in different views.

As a result, 32 bits are not enough to address all these requests, because the TILER port must convey not only virtually addressed requests to the "oriented" TILER containers but also physically addressed requests to the attached SDRCs. A thirty-third address bit is necessary to distinguish the two separated address maps, as shown in Figure 15-35.

Figure 15-35. TILER Port Address Map



Still, having separated systems and TILER-specific address maps is not sufficient. In a system many existing and external IP blocks still rely on a 32-bit address and would then be limited to one or the other 4-GiB addressing space. To overcome this limitation, one 512-MiB view is aliased in the system address map as (see Table 15-14 and Figure 15-36).

Table 15-14. TILER Aliased View in the L3 Interconnect Mapping

Start Address (hex)	End Address (hex)	Size
0x6000_0000	0x7FFF_FFFF	512 MiB

From all incoming requests, TILER requests are filtered as having an address that fits one of the following:

- The address format in the TILER-specific address map given in Table 15-15
- The address format of the aliased view in the system address map given in Table 15-16

Other requests are forwarded directly to the SDRC in TILER bypass mode.

Table 15-15. Address Format in the TILER-Specific Address Map

32	31	30	29	28	27	26 ... 4	3 ... 0
T	Orientation			Mode		Virtual address	
1	S	$\overline{Y}$	$\overline{X}$	M1	M0	A26 ... A4	0

Table 15-16. Address Format of the TILER Aliased View in the System Address Map

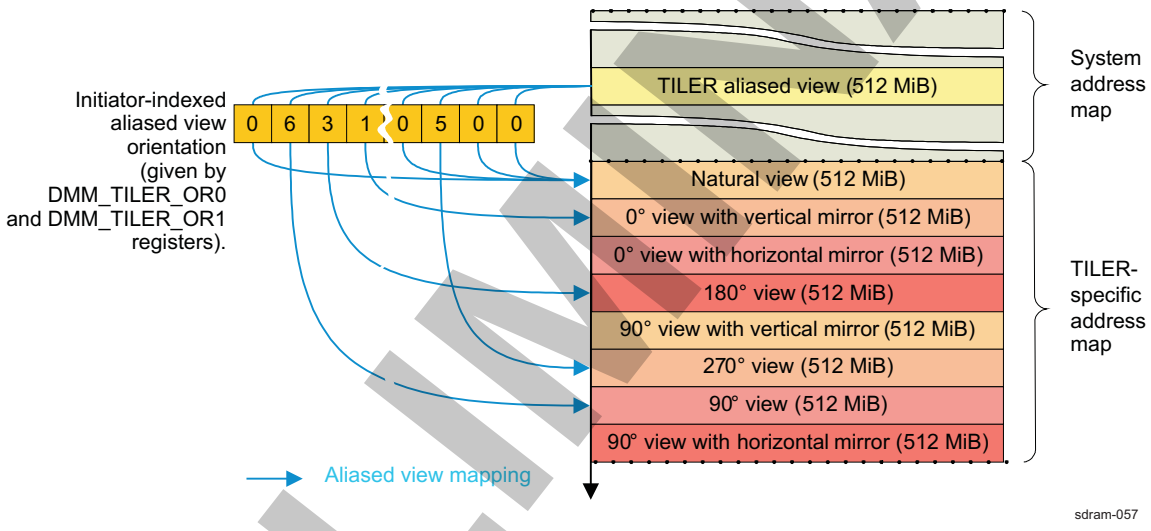
32	31	30	29	28	27	26 ... 4	3 ... 0
T	TILER aliasing			Mode		Virtual address	
0	0	1	1	M1	M0	A26 ... A4	0

In these address formats:

- The thirty-third bit, noted T, is aimed at distinguishing the standard 4-GiB system address map from the 4-GiB TILER-specific address map.
- The orientation bits, noted S, $\overline{Y}$, and $\overline{X}$, define the request orientation, as specified in Table 15-12.
- The mode bits, noted M1 and M0, define the request mode, as specified in Table 15-11.
- The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address, as defined in Figure 15-16, Figure 15-17, and Figure 15-18.

The orientation of the aliased TILER view is extracted from an initiator-indexed LUT, as shown in Figure 15-36.

Figure 15-36. TILER Aliased View Orientation



As shown in Figure 15-36, an internal initiator-indexed LUT stores the current orientation of the aliased view for each initiator.

When an interconnect request hits the TILER aliased view in the system address map, the request initiator orientation is extracted from the LUT and the request address is translated according to this orientation: the T bit is set and bits [31:29] are replaced with the orientation.

Regarding the dimensioning of this LUT, given that initiators simultaneously accessing multiple views use the TILER-specific address map, and many initiators do not need to access any view or can be restricted to accessing only the natural view, only a limited number of initiators are likely to dynamically modify the orientation of its aliased TILER view.

The orientation LUT is limited to 16 entries. These 16 orientation entries are mapped on the two 32-bit DMM_TILER_OR0 and DMM_TILER_OR1 registers.

The first eight entries of the LUT are mapped in the DMM_TILER_OR0 register, and the last eight entries are mapped in the DMM_TILER_OR1 register. Therefore, given an index x, the orientation related to this index is given in the ORx field.

Each of these registers is split into eight 4-bit fields, each field mapping an entry of the LUT with:

- An S, $\overline{Y}$, $\overline{X}$ orientation code on the 3 LSBs
- An $\overline{W}$ field-specific active-low local write-enable bit, always read as 0, on the MSB.

The registers fields that correspond to initiators that do not need any dynamic configuration of their aliased view orientation must be specified as reserved fields, and only written with zeros.

The $\overline{W}$ bit allows the modification of a single entry without requiring a read-modify-write sequence. This approach is then more accommodating:

- In a system where multiple initiators can modify their own fields in the registers
- With initiators unable to make the read-modify-write sequence, such as DMA

Still, the $\overline{W}$ bit is active-low to keep the compatibility with the usual read-modify-write sequence. When reading an aliased view orientation register, because all its $\overline{W}$ bits are read as 0, if these bits are untouched by the modification—as they should be—writing back the modified register updates all orientation fields of the register.

15.2.3.6.3 TILER Guidelines for Initiators

15.2.3.6.3.1 Buffered Raster-Based Initiators

15.2.3.6.3.1.1 Buffer Size

The necessary minimum buffer size depends on the SDRAM prefetch size and on initiator support in terms of the following:

- Element size
- Orientation
- Maximum number of elements per line in all supported element sizes and orientations

Let N be the maximum number of elements per line for a given mode (element size) and orientation, P be the SDRAM memory prefetch size in bytes, and *max* be the function returning the maximum of the two parameters. The minimum necessary line buffer size to handle all resolutions in a given mode and orientation is listed in Table 15-17.

Table 15-17. Minimum Buffer Size to Efficiently Handle Lines of up to N Elements

	0- or 180- Degree Orientation (S = 0)	90- or 270-Degree Orientation (S = 1)
8-bit mode	4 × N bytes	*max* (4,P/4) × N bytes
16-bit mode	None	*max* (8,P/2) × N bytes
32-bit mode	None	*max* (8,P/2) × N bytes

This minimal buffer size can be reached only with an advanced FIFO management scheme. The standard ping-pong buffer requires twice this buffer size.

NOTE: Given their nature, field accesses to an interlaced frame-buffer require buffers twice as small as in the standard progressive case.

For instance, an initiator that must handle only a single progressive frame-buffer in any orientation of:

- Up to 1920 × 1080 in YUV4:2:0
- Up to 1600 × 1200 in 16-bit RGB565
- Up to 800 × 600 in 32-bit ARGB

requires a line buffer of at least 15,360 bytes because:

- 4 × 1920 + 4 × 2960 = 15,360 bytes required for a 3-plane YUV4:2:0 frame of 1920 × 1080
- 4 × 1920 + 8 × 960 = 15,360 bytes required for a 2-plane YUV4:2:0 frame of 1920 × 1080
- 8 × 1600 = 12,800 bytes required for a 16-bit RGB565 frame of 1600 × 1200
- 8 × 800 = 6400 bytes required for a 32-bit ARGB frame of 800 × 600

and a line buffer of at least 30,720 bytes when using a simple ping-pong buffer scheme.

15.2.3.6.3.1.2 Performance

Table 15-18 gives the ratio of effective data to transferred data at the external memory interface for buffered raster-based initiators in each mode and orientation, when using an up-to-32-bit DDR, lpDDR, or lpDDR2 SDRAM, or an up-to-16-bit DDR2 memory.

Table 15-18. Memory Data Payload for Buffered Raster-Based Initiators on Up-to-32-Bit DDR, lpDDR, or lpDDR2

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	100%	100%	50%
16-bit mode	100%	100%	100%	50%
32-bit mode	100%	100%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR, lpDDR, or lpDDR2 SDRAMs, or 16-bit DDR, DDR2, lpDDR, or lpDDR2 memories, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in 90- or 270-degree orientation where the memory bandwidth is twice the requested bandwidth.

When using up-to-32-bit DDR, lpDDR, lpDDR2, or up-to-16-bit DDR2 SDRAMs, all accesses, except interlaced accesses in a 90- or 270-degree orientation, are equally efficient and offer the full possible memory bandwidth.

Because of its progressive nature, page mode does not introduce any performance hit.

Table 15-19 lists the ratio of effective data-to-transferred data at the external memory interface for the buffered raster-based initiators in each mode and orientation when using a 32-bit DDR2 or DDR3 memory.

Table 15-19. Memory Data Payload for Buffered Raster-Based Initiators on 32-Bit DDR2 or DDR3

	0- or 180-Degree Orientation (S = 0)		90- or 270-Degree Orientation (S = 1)	
	Progressive	Interlaced	Progressive	Interlaced
8-bit mode	100%	50%	100%	50%
16-bit mode	100%	50%	100%	50%
32-bit mode	100%	50%	100%	50%
Page mode	100%	N/A	100%	100%

When using 32-bit DDR2 or DDR3 SDRAMs, whenever all previous guidelines are fulfilled, there is no penalty for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in any orientation where the memory bandwidth is twice the requested bandwidth.

When using DDR2 or DDR3 SDRAMs, all accesses, except interlaced accesses, are equally efficient and offer the full possible memory bandwidth.

Similarly, page mode does not introduce any performance hit.

15.2.4 DMM Use Cases and Tips

15.2.4.1 PAT Use Cases

Five ways to use PAT are:

- Simple manual area refill: Section 15.2.4.1.1
- Single auto-configured area refill: Section 15.2.4.1.2
- Chained auto-configured area refill: Section 15.2.4.1.3
- Synchronized auto-configured area refill: Section 15.2.4.1.4
- Cyclic synchronized auto-configured area refill: Section 15.2.4.1.5

NOTE: PAT refill area must be fully contained within either the LUT lower half or the LUT upper half. It must not span over both areas. That is, y0 MS

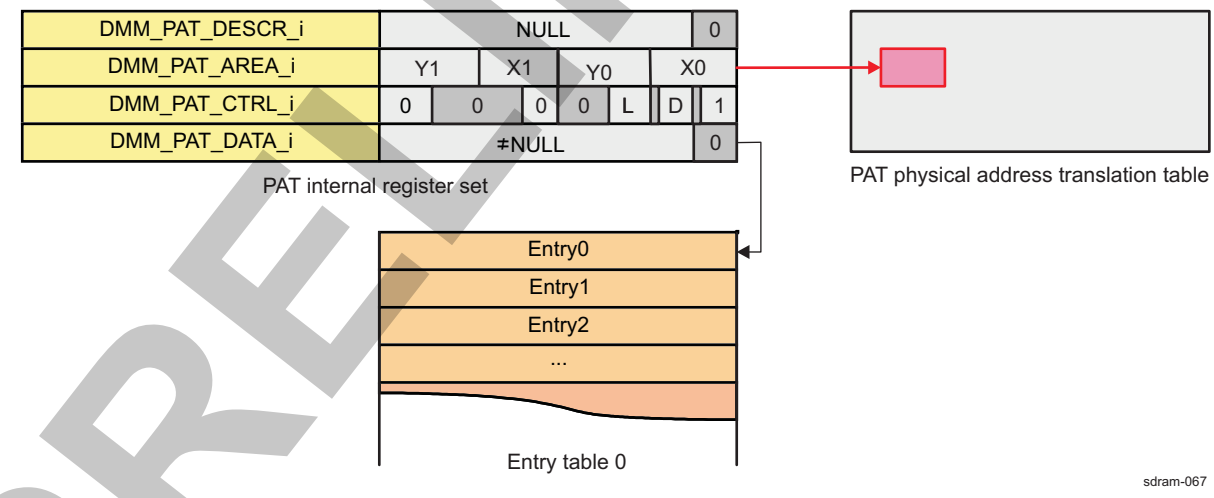
bit y0[7] must be equal to y1 MSbit y1[7] when defining the area descriptor.

15.2.4.1.1 Simple Manual Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-37):

1. Write the DMM_PAT_AREA_i register with the relevant (x0, y0) (x1, y1) area definition.
2. Write the DMM_PAT_DATA_i register with the physical address of the created entry table.
3. Write the DMM_PAT_CTRL_i register with the requested refill direction and assert the DMM_PAT_CTRL_i[0] START bit with the requested refill direction D and with the LUT ID L if multiple LUTs are present in the system.
4. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-37. Simple Manual Area Refill Scheme



15.2.4.1.2 Single Auto-Configured Area Refill

The following must be performed to create a 16-byte aligned memory-mapped entry table containing all entries of the defined area (see Figure 15-38):

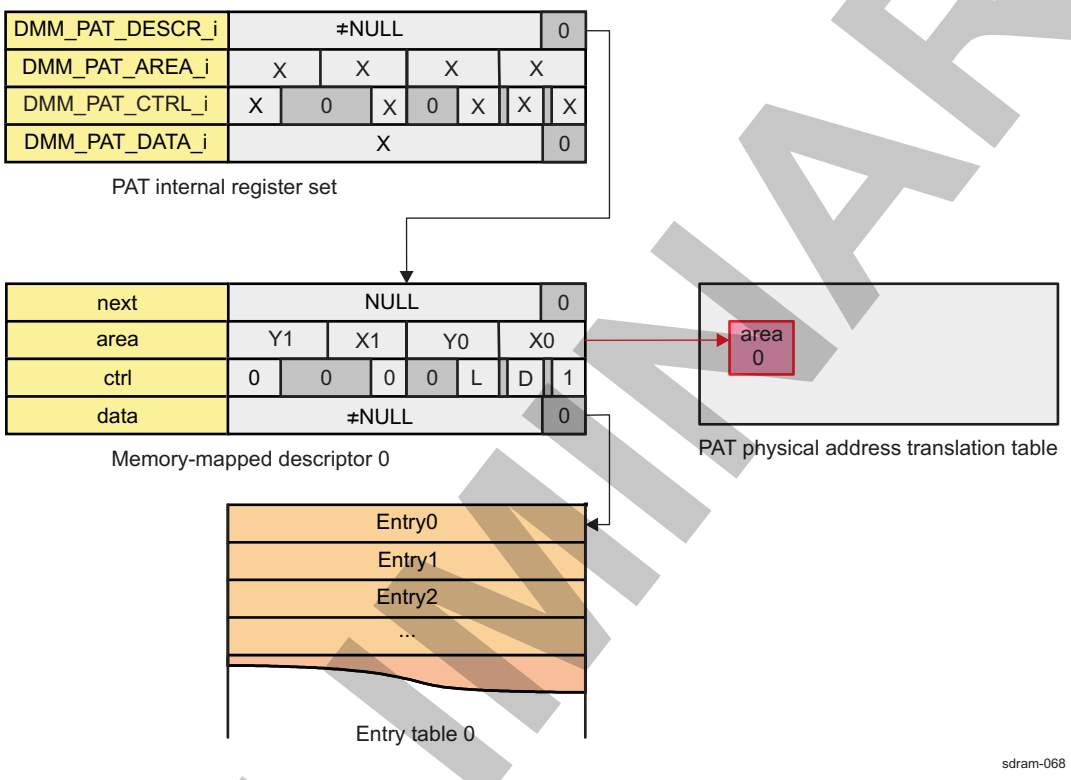
1. Create a 16-byte aligned memory-mapped descriptor structure where:
   - The next field is set to NULL.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are

present in the system, and the START bit is asserted to start refilling as soon as this descriptor enters the PAT refill engine.

- The data field is set to the physical address of the created entry table.

2. Write the DMM_PAT_DESCR_i register with the physical address of the created descriptor.
3. The refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-38. Single Auto-Configured Area Refill Scheme

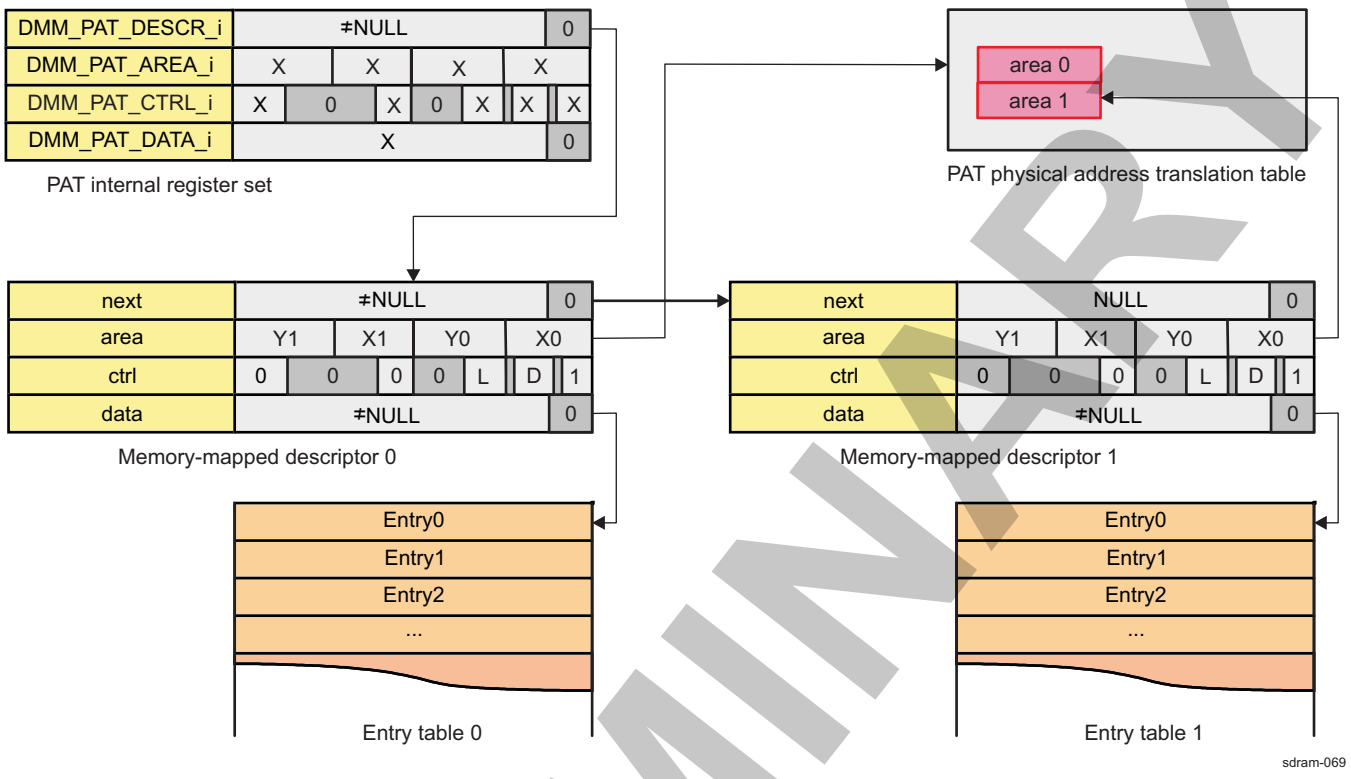


15.2.4.1.3 Chained Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-39):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the requested direction D, with the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-39. Chained Auto-Configured Area Refill Scheme

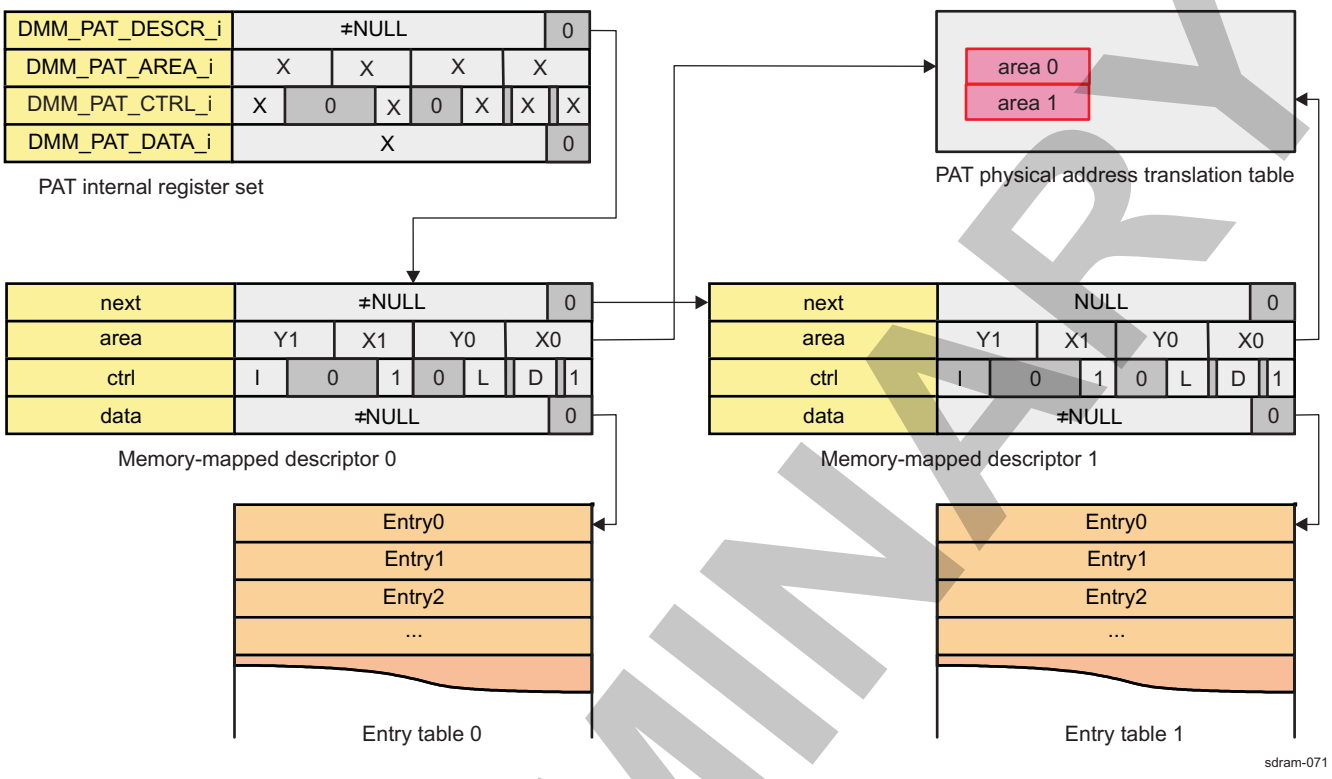


15.2.4.1.4 Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-40):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor or NULL for the last one.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit is asserted, the requested direction D and the requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the first created descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. All area refills are done when the DMM_PAT_STATUS_i[0] READY bit is set.
5. A new refill can be initiated when the DMM_PAT_STATUS_i[0] READY bit is set.

Figure 15-40. Synchronized Auto-Configured Area Refill Scheme

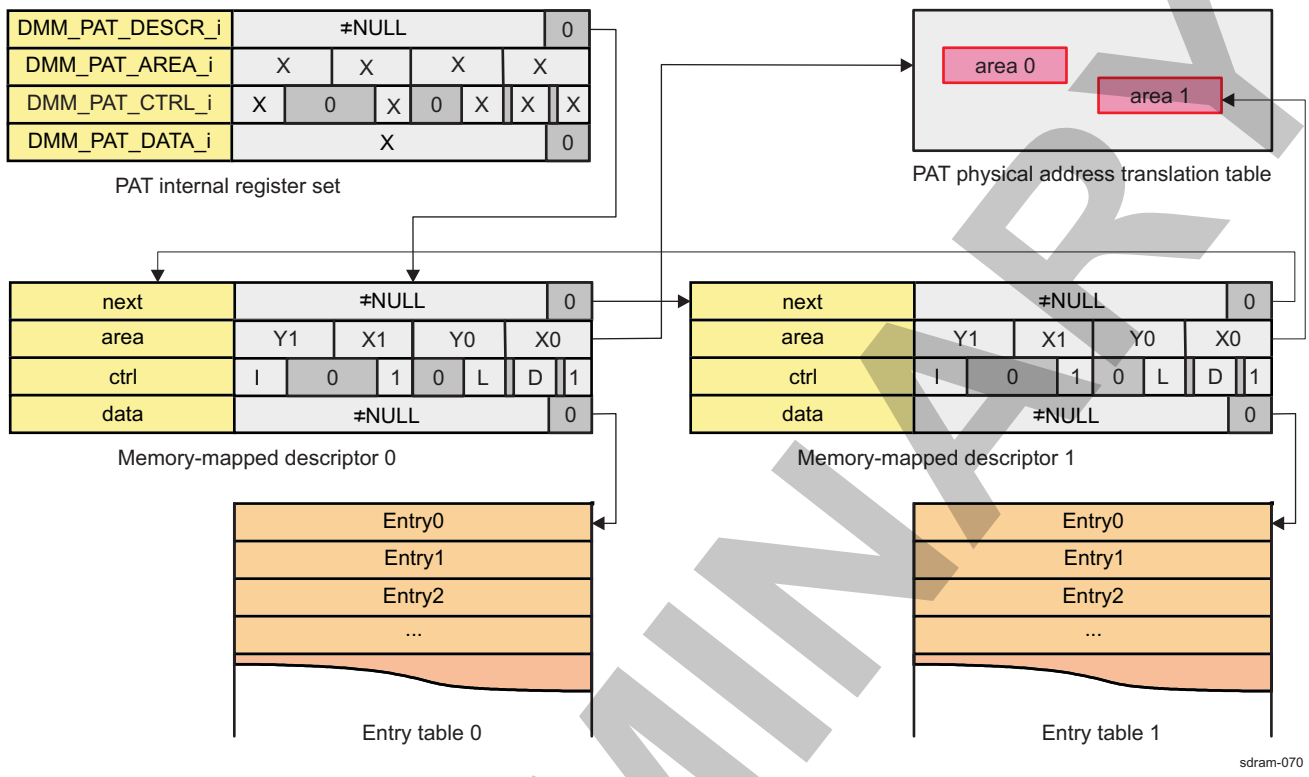


15.2.4.1.5 Cyclic Synchronized Auto-Configured Area Refill

The following must be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-41):

1. Create one 16-byte aligned memory-mapped descriptor structure per area where:
   - The next field is set to the physical address of the next descriptor in the circular list.
   - The area field is set with the relevant (x0, y0) (x1, y1) area definition.
   - The ctrl field is set with the synchronizing initiator identifier I, the SYNC bit asserted, the requested direction D and requested LUT ID L if multiple LUTs are present in the system, and the START bit is asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area.
   - The data field is set to the physical address of the corresponding entry table.
2. Write the DMM_PAT_DESCR_i register with the physical address of the initial descriptor.
3. Each area refill is done when the DMM_PAT_STATUS_i[3] DONE bit is set.
4. A new refill can be initiated by writing any value to the DMM_PAT_DESCR_i register to abort the current one.

Figure 15-41. Cyclic Synchronized Auto-Configured Area Refill Scheme



NOTE: Never use circular lists of descriptors where all descriptors have the DMM_PAT_CTRL_i[0] START bit set and there is no synchronization. This leads to an endless continuous refill.

15.2.4.2 Addressing Management with LISA

15.2.4.2.1 Case 1: Use of One Memory Controller

In this example, assume there is 1 GiB of external memory evenly spread onto two address spaces. The address range for address space 0 must start at offset 0x2000_0000 (see Table 15-20).

Table 15-20. Address Definition

Address Range	Memory Controller	Memory Controller Address Space[(1)]	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1	0x1	0x0000_0000 to 0x1FFF_FFFF
0xA000_0000 to 0xBFFF_FFFF	EMIF1	0x0	0x2000_0000 to 0x3FFF_FFFF

(1) For memory controller address spaces, see , *Local Interface*.

This configuration requires two nonoverlapping sections to be set. They can be defined in any order because there is no concern with priority in this case (see Table 15-21):

Table 15-21. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x5
[19:18] SDRC_INTL	0x0 (not applicable)	0x0 (not applicable)

Table 15-21. Configuration (continued)

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[17:16] SDRC_ADDRSPC	0x1	0x0
[9:8] SDRC_MAP	0x1 (only EMIF1)	0x1 (only EMIF1)
[7:0] SDRC_ADDR	0x00	0x20

To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: 2^8–2^{SYS_SIZE}. If the result is equal to SYS_ADDR, the section is hit.

To define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: 2^{SYS_SIZE}–1, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: 2^8–2^5 = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: 2^5–1 = 0x1F
- Masked upper address bits: 0x19
- OR with SDRC_ADDR: 0x19
- Physical address: 0x19AE_37F0

This request is forwarded to address 0x19AE_37F0, address space 1 of the memory controller.

Request to address 0xB7FF_0340:

- Upper address bits: 0xB7
- Hit mask: 2^8–2^5 = 0xE0
- Masked upper address bits: 0xA0, that is, hits section 1
- Address mask: 2^5–1 = 0x1F
- Masked upper address bits: 0x17
- OR with SDRC_ADDR: 0x37
- Physical address: 0x37FF_0340

This request is forwarded to address 0x37FF_0340, address space 0 of the memory controller.

15.2.4.2.2 Case 2: Use of Two Memory Controllers

In the case of 512 MiB interleaved at 128-byte boundaries and 256 MiB noninterleaved on the second memory controller, one address space per memory controller, we have the following results (see Table 15-22).

Table 15-22. Address Definition

Address Range	Memory Controller	Memory Controller Address Space[(1)]	Memory Controller Address Range
0x8000_0000 to 0x9FFF_FFFF	EMIF1 and EMIF2, interleaved at 128-byte boundaries	0x0 on both controllers	0x0000_0000 to 0x0FFF_FFFF on both controllers
0xA000_0000 to 0xAFFF_FFFF	EMIF2 only	0x0	0x1000_0000 to 0x1FFF_FFFF

(1) For memory controller address spaces, see , *Local Interface*.

Two sections are used to map such a configuration (see Table 15-23).

Table 15-23. Configuration

Bit Field	Section 0 (DMM_LISA_MAP_0)	Section 1 (DMM_LISA_MAP_1)
[31:24] SYS_ADDR	0x80	0xA0
[22:20] SYS_SIZE	0x5	0x4
[19:18] SDRC_INTL	0x1	0x0 (not applicable)
[17:16] SDRC_ADDRSPC	0x0	0x0
[9:8] SDRC_MAP	0x3	0x2
[7:0] SDRC_ADDR	0x00	0x10

Detecting a section hit is the same for the interleaved case as for the single controller case: To check whether an address hits a section, use the 8 upper address bits of the address and mask them with the hit mask: $28–2^{SYS\_SIZE}$. If the result is equal to SYS_ADDR, the section is hit.

The physical address generation is modified for the interleaved case. In case of 256-byte interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the controller indicator, 0 for the first controller, and 1 for the second controller (system address bit 7 is used for interleaving at the 128-byte boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits [31:9] are shifted to bits [30:8] when generating the physical address.

The rest of the address generation is handled the same as for the single controller case: to define the physical address to be issued to the memory controller, use the 8 upper address bits of the system address, mask them with the address mask: $2^{SYS\_SIZE}–1$, and OR them with SDRC_ADDR. This gives the resulting 8 upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8–2^5$ = 0xE0
- Masked upper address bits: 0x80, that is, hits section 0
- Address mask: $2^5–1$ = 0x1F
- Masked upper address bits: 0x19
- Full masked address: 0x19AE_37F0
- Bit 7 is 1, that is, targets the second memory controller
- Full masked shifted address (suppressing bit 7): 0x0CD7_1BF0 (see Section 15.2.4.2.2.1)
- OR upper physical address bits with SDRC_ADDR: 0x0CD7_1BF0
- Physical address: 0x0CD7_1BF0

This request is forwarded to address 0x0CD7_1BF0, address space 0, of the second memory controller.

15.2.4.2.2.1 Address Upper Bits Shifting

Table 15-24 describes shifting the address upper bits.

Table 15-24. Address Upper Bits Shifting

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Address Before Interleaving																															
0	0	0	1	1	0	0	1	1	0	1	0	1	1	1	0	0	0	1	1	0	1	1	1	1	1	1	1	0	0	0	0
Address After Interleaving																															
0	0	0	0	1	1	0	0	1	1	0	1	0	1	1	1	0	0	0	1	1	0	1	1	1	1	1	1	0	0	0	0

15.2.5 DMM Basic Programming Model

The programming model section:

- Describes how objects can be addressed in all TILER modes and orientations
- Explains how the physical containers and PAT LUT can be shared between different modes
- Does not give an exhaustive description of the TILER and DMM registers, because these are described in Section 15.2.3.5, *DMM*, and Section 15.2.3.6, *TILER*.

15.2.5.1 Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMM is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMM (see Table 15-25).

Table 15-25. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Section 3.1.1, *Power, Reset, and Clock Management.*
Image processing unit (IPU)	IPU interrupt controller (INTC) configuration must be done to enable the interrupts from the DMM. See Section 17.1, *Interrupt Controllers.*
Main processing unit (MPU)	MPU INTC configuration must be done to enable interrupts from the DMM. See Section 17.1, *Interrupt Controllers.*
L3_MAIN interconnect	Data interface

15.2.5.2 DMM Module Global Initialization

Theprocedure in Table 15-26 initializes the DMM after a power-on reset (POR).

Table 15-26. DMM Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the DMM for smart-idle power management mode.	DMM_SYSCONFIG[3:2] IDLE_MODE	0x2

15.2.5.3 DMM Operational Modes Configuration

15.2.5.3.1 Different Operational Modes

The TILER can be virtually accessed in four different modes: 8-, 16-, 32-bit, and page modes. Each mode defines the element granularity to apply isometric transforms (see Table 15-27).

Table 15-27. Coding and Description of TILER Modes

Mode	Name	Granularity (Element Size)
0	8-bit tiled mode	8 bits
1	16-bit tiled mode	16 bits
2	32-bit tiled mode	32 bits
3	Page mode	4096 bytes

15.2.5.3.2 Configuration Settings and LUT Refill

The procedure in Table 15-28 provides the configuration settings and LUT refill.

Table 15-28. Configuration Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
PAT configuration refill Engine 0	DMM_PAT_CONFIG[0] MODE0	xxx
PAT configuration refill Engine 1	DMM_PAT_CONFIG[1] MODE1	xxx
Set DMM PAT view register value for each initiator.	DMM_PAT_VIEW0 Vx DMM_PAT_VIEW1 Vx	xxx
Set DMM PAT write enable for the initiators.	DMM_PAT_VIEW0 Wx DMM_PAT_VIEW1 Wx	xxx
Choosing container type and access method	DMM_PAT_VIEW_MAP_i	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
Set area definition for DMM physical address translator.	DMM_PAT_AREA_i	xxx
Set the physical address of the current table refill entry data or entry data when in manual mode.	DMM_PAT_DATA_i[31:4] ADDR	xxx
Define the direction of this PAT table refill (S Y X), different from 0x011.	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.3 Interleaving Settings

The procedure in Table 15-29 provides the interleaving settings.

Table 15-29. Interleaving Settings

Step	Register/Bit Field/Programming Model	Value
Set DMM system section address MSB.	DMM_LISA_MAP_i[31:24] SYS_ADDR	xxx
Set DMM system section size.	DMM_LISA_MAP_i[22:20] SYS_SIZE	xxx
Set SDRC interleaving mode.	DMM_LISA_MAP_i[19:18] SDRC_INTL	xxx
Set SDRC address space.	DMM_LISA_MAP_i[17:16] SDRC_ADDRSPC	xxx
Set SDRC mapping.	DMM_LISA_MAP_i[9:8] SDRC_MAP	xxx
Set SDRC address MSB.	DMM_LISA_MAP_i[7:0] SDRC_ADDR	xxx
Enable/disable DMM memory mapping lock.	DMM_LISA_LOCK[0] LOCK	xxx

15.2.5.3.4 Aliased Tiled View Orientation Settings and LUT Refill

The procedure in Table 15-30 provides the settings for aliased tiled view and LUT refill.

Table 15-30. Aliased Tiled View Orientation Settings and LUT Refill

Step	Register/Bit Field/Programming Model	Value
Set DMM TILER orientation for each initiator.	DMM_TILER_OR0 ORx DMM_TILER_OR1 ORx	xxx
Set DMM TILER write enable for the initiators.	DMM_TILER_OR0 Wx DMM_TILER_OR1 Wx	xxx
Define the base address of all view mappings.	DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR	xxx
DMM PAT initiator for synchronization	DMM_PAT_CTRL_i[31:28] INITIATOR	xxx
Set DMM PAT table reload synchronization.	DMM_PAT_CTRL_i[16] SYNC	xxx
Set DMM PAT LUT index (when more than one LUTs).	DMM_PAT_CTRL_i[9:8] LUT_ID	xxx
Define the direction of this PAT table refill (S Y X).	DMM_PAT_CTRL_i[6:4] DIRECTION	xxx
Start a PAT table refill.	DMM_PAT_CTRL_i[0] START	0x1

15.2.5.3.5 Priority Settings

The procedure in Table 15-31 provides the sequence to set priorities.

Table 15-31. Priority Settings

Step	Register/Bit Field/Programming Model	Value
Set priority for each initiator.	DMM_PEG_PRIO_k Px	xxx
Set write enable for P_PAT field.	DMM_PEG_PRIO_PAT[4] W_PAT	xxx
Set priority for PAT engine.	DMM_PEG_PRIO_PAT[2:0] W_PAT	xxx

15.2.5.3.6 Error Handling

The procedure in Table 15-32 provides the sequence for error handling.

Table 15-32. Error Handling

Step	Register/Bit Field/Programming Model	Value
Enable interrupt for selected type of error.	DMM_PAT_IRQENABLE_SET[15:9] DMM_PAT_IRQENABLE_SET[7:0]	xxx
When interrupt occurs		
Disable type of error to handle.	DMM_PAT_IRQENABLE_CLR[15:9] DMM_PAT_IRQENABLE_CLR[7:0]	xxx
Check error status.	DMM_PAT_IRQSTATUS[15:9] DMM_PAT_IRQSTATUS[7:0]	xxx

15.2.5.3.7 PAT Programming Model

The PAT maps the tiled data anywhere in the 4-GiB physical address range, with a PAGE granularity. (The TILER page is the granularity of physical memory allocation in the TILER container. Each page is 4kiB).

A PAT view defines the kind of PAT to perform for each page, 8-, 16-, and 32-bit mode access. Each mode in each PAT view can be programmed in two different modes: direct translation and indirect translation.

15.2.5.3.7.1 PAT in Direct Translation Mode

In this mode, the PAT performs a translation of the 128-MiB virtual container as a whole in the physical address space (that is, in the SDRAM). This mode is used only for debug or in case of a DMM without a PAT.

15.2.5.3.7.2 PAT in Indirect Translation Mode

This is the most commonly used mode. In this mode, the PAT performs a translation of each 4-KiB page individually. In this way the 128-MiB virtual address space can be scattered in the whole 2 GiB of the physical address space. This is achieved by using a 32,678-word LUT that converts each page index (32,768 possible values) into 19 address bits that represent this page address in the physical memory. The main characteristic of this mode is there is no constraint on the use of the physical memory except that it is uses a multiple of 4-KiB areas located at 4-KiB boundaries in the physical memory. In this mode, the translation vector is in the internal 32-k entry PAT vector table at the index given by bits [26:12] of the input virtual address, and CONT_x = 0.

Programming sequence:

1. Set the DMM_PAT_VIEW0 register (or DMM_PAT_VIEW1, depending on the L3 CONN_ID of the initiator that is to perform the tiled accesses) with the appropriate value. For example, if the L3 CONN_ID equals 0, then the DMM_PAT_VIEW0 register must be programmed with the value 0x0000_0001 (PAT view 1 selected for initiator 0).
2. Set DMM_PAT_VIEW_MAP_BASE[31] = 0x8000_0000 (must always be programmed at 1 to select the upper 2 GiB of the physical address space that corresponds to the external memory).

3. Set all 16-bit tiled accesses in indirect translation mode by setting at least the field ACCESS_16 to 1 (DMM_PAT_VIEW_MAP_1 = 0x0000_8000), program DMM_PAT_VIEW_MAP_1 at 0x8080_8080.

15.2.5.4 Addressing an Object in Tiled Mode

This section describes how a frame-buffer with a top-left pixel at (x0,y0) in the natural view container and a bottom right pixel at (x1,y1) in the natural view container is addressed in any tiled mode and orientation.

15.2.5.4.1 Frame-Buffer Addressing

NOTE: In this section, the (x,y) coordinates are given in pixel units.

Given an (S, $\overline{Y}$, $\overline{X}$) orientation, the (x,y) coordinates of the first pixel of the frame in the oriented view (where W = the width and H = the height in pixels of the container in the considered frame mode) is:

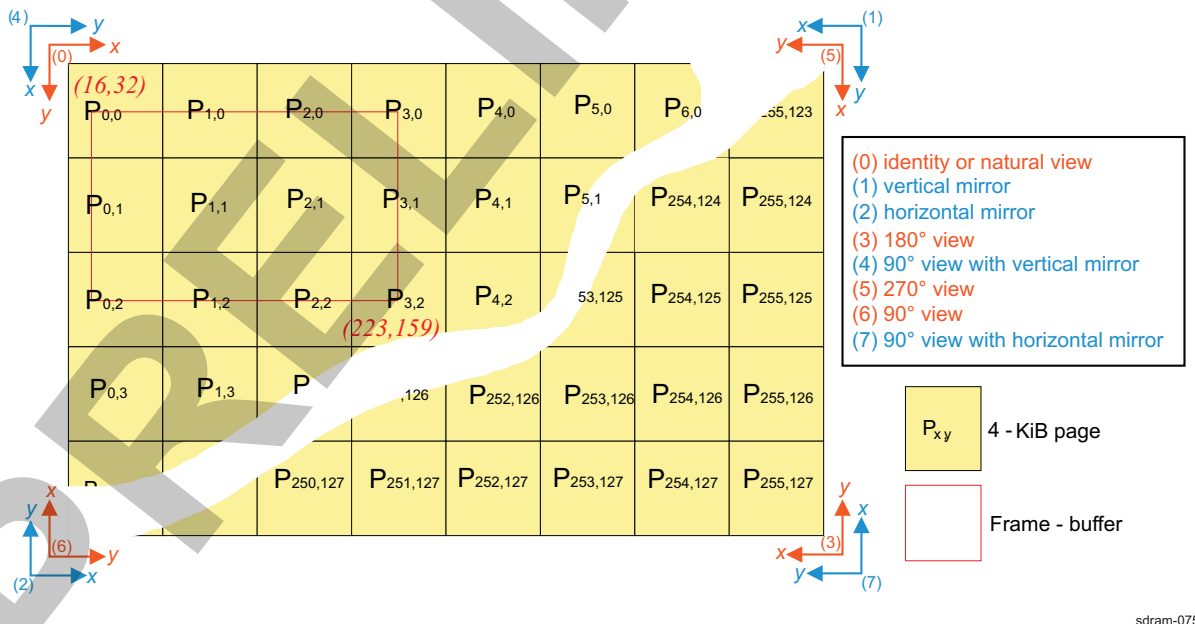
(x,y) = (x_{or}, y_{or}) when S, (y_{or}, x_{or}) otherwise
with:
x_{or} = x_0 when $\overline{X}$, W-1-x_1 otherwise
y_{or} = y_0 when $\overline{Y}$, H-1-y_1 otherwise

Given a (M_1, M_0) TILER mode where M_1 # 0 or M_0 # 0, the size in bytes of a pixel is 2^{2M1+M0}.

Therefore, given an (S, $\overline{Y}$, $\overline{X}$) orientation and a n(M_1, M_0) TILER mode where M_1 # 0 or M_0 # 0, the byte offset of the base address of the considered oriented frame in its container is:
base_address((x_0, y_0), (x_1, y_1), (S, $\overline{Y}$, $\overline{X}$), (M_1, M_0)) = (y_{or}W + x_{or}) P_5 when S, (x_{or}H + y_{or}) P_5 otherwise
with:
x_{or} = x_0 when $\overline{X}$, W-1-x_1 otherwise
y_{or} = y_0 when $\overline{Y}$, H-1-y_1 otherwise
P_5 = 2^{2M1+M0}

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

Figure 15-42. Example of 8-Bit Frame-Buffer Addressing in any Orientation



This frame-buffer address generation is independent from the page size. For instance, the 8-bit frame-buffer shown in Figure 15-42 that ranges from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-33.

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for an 8-Bit Frame-Buffer

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	16	32	00080010h	100080010h
0	0	1	16,160	32	00083F20h	120083F20h
0	1	0	16	8032	07D80010h	147D80010h
0	1	1	16,160	8032	07D83F20h	167D83F20h
1	0	0	16	32	00020020h	180020020h
1	0	1	16,160	32	07E40020h	1A7E40020h
1	1	0	16	8032	00021F60h	1C0021F60h
1	1	1	16,160	8032	07E41F60h	1E7E41F60h

In this example the TILER is addressed in 8-bit mode, which translates to addresses with all mode bits (bits 27 and 28) cleared in the 29-bit address offset in view and in the full 33-bit TILER address.

15.2.5.4.2 TILER Page Mapping

Let:

- c (c = 0, 1, or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- (x_0, y_0) be the top-left pixel and (x_1, y_1) be the bottom-right pixel of a frame in its natural orientation
- W be the width and H the height in pixels of the container in the considered frame mode

The top-left page coordinates (P_{x0}, P_{y0}) and bottom-right page coordinates (P_{x1}, P_{y1}) that correspond to the frame are given by: $P_{x0} = (64.x_0.2^{2-c}) / W$, $P_{y0} = (32.y_0.2^{2-c}) / H$, $P_{x1} = (64.x_1.2^{2-c}) / W$ and $P_{y1} = (32.y_1.2^{2-c}) / H$.

In its natural orientation, the TILER container consists of 8192 lines of 16,384 pixels of 8 bits, or 4096 lines of 16,384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32 bits.

NOTE: The page area type has the same structure as the DMM_PAT_AREA_i registers. For instance, the 8-bit frame-buffer described in Figure 15-42 and ranging from the top-left pixel at (16, 32) to the bottom-right pixel at (223, 159) in the natural orientation view, is mapped from the top-left page at P0,0 to the bottom-right page P3,2.

15.2.5.5 Addressing an Object in Page Mode

In page mode, the orientation modifies only the sequence of accessed pages, not their content. In this respect the orientation must be seen as a way to optimize the one-dimensional (1D) object allocation in a TILER container by allowing a 1D object spanning multiple pages to map a set of adjacent pages in any direction. For instance, a 1.25-MiB object, mapped on 320 pages of 4kiB can be allocated in a TILER container in any of the eight orientations (see Section 15.2.3.6.1.7.3, *Element Ordering in the TILER Container*).

The initial page can be chosen freely among all pages. In this respect, the address offset of a page in a TILER container is expressed as:

Let:

- c (c = 0, 1 or 2) be the TILER page configuration (0 for 4-kiB pages, 1 for 16-kiB pages, and 2 for 64-kiB pages)
- $(S, \overline{Y}, \overline{X})$ be the orientation of the considered 1D object in page mode
- (P_x, P_y) be the coordinate of the initial page in the natural orientation view

The byte offset of the base address of the considered initial page in its oriented container is:
$base\_address((P_x, P_y), (S, \overline{Y}, \overline{X})) = 4096.(64.y_{or}.2^{2-c} + x_{or}).2^{2.c}$ when S, $4096.(32.x_{or}.2^{2-c} + y_{or}).2^{2.c}$ otherwise with:
$x_{or} = P_x$ when $\overline{X}$, $64.2^{2-c}\text{-}1\text{-}P_x$ otherwise
$y_{or} = P_y$ when $\overline{Y}$, $32.2^{2-c}\text{-}1\text{-}P_y$ otherwise

For instance, a 1D object starting from the page P32,63 in the natural orientation view on a DMM using 4-kiB pages, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-34.

Table 15-34. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object

S	$\overline{Y}$	$\overline{X}$	x_{or}	y_{or}	29-Bit Address Offset in View	Full 33-Bit TILER Address
0	0	0	32	63	1BF20000h	11BF20000h
0	0	1	223	63	1BFDF000h	13BFDF000h
0	1	0	32	64	1C020000h	15C020000h
0	1	1	223	64	1C0DF000h	17C0DF000h
1	0	0	32	63	1903F000h	19903F000h
1	0	1	223	63	1EFBF000h	1BEFBF000h
1	1	0	32	64	19040000h	1D9040000h
1	1	1	223	64	1EFC0000h	1FEFC0000h

In this example the TILER is addressed in page mode, which translates to addresses with mode bits (bits 27 and 28) set in the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.6 Sharing Containers Between Different Modes

When allocating objects in TILER containers, ensure that no two objects physically overlap.

In this respect, and to ease the object allocation and deallocation, it is strongly advised to share a TILER page only for different objects that do both of the following:

- Belong to the same mode
- Have the same lifetime (that is, are allocated and deallocated simultaneously)

Two objects of different modes can physically overlap if:

- One physical page is mapped twice in two different locations of the DMM LUT.
- The two objects share the DMM LUT and the intersection of their two page set is not empty.

  These two issues can be easily avoided by allocating a physical page only once in the DMM LUT.

  The second issue is a bit more difficult, especially if the allocation of objects in the various TILER containers must be dynamic. Managing the fragmentation within a flat memory model in a space-constrained system is not straightforward, and is the main reason for the existence of MMUs in most current processors, which adds yet another constraint to the problem (the y dimension, which makes it even more difficult).

Returning to the CPU-analogy, the memory fragmentation issue is mostly solved by using a virtual memory space larger than the actual physical memory space and a virtual-to-physical translation system. This allows contiguous virtual memory allocation when sufficient physical memory is available and the larger contiguous physical buffer is smaller than the requested memory allocation.

Similarly, the DMM answer to this object allocation in the TILER containers is two-fold:

- The DMM must have sufficient virtual address space in all modes to permit a static allocation of a pool of virtual buffers in all TILER modes for all TILER-aware initiators.
- Each TILER-aware initiator must dynamically manage its own pool of virtual buffers.

15.2.6 DMM Register Manual

This section provides information about the DMM registers. Table 15-35 describes the DMM instance.

15.2.6.1 DMM Instance Summary

Table 15-35. DMM Instance Summary

Module Name	Base Address	Size
DMM	0x4E00 0000	32 MiB

15.2.6.2 DMM Registers

15.2.6.2.1 DMM Register Summary

Table 15-36 provides a summary of the DMM registers.

Table 15-36. DMM Registers Mapping Summary

15.3 EMIF Controller

This section describes the features and functions of the external memory interface (EMIF) module of the device.

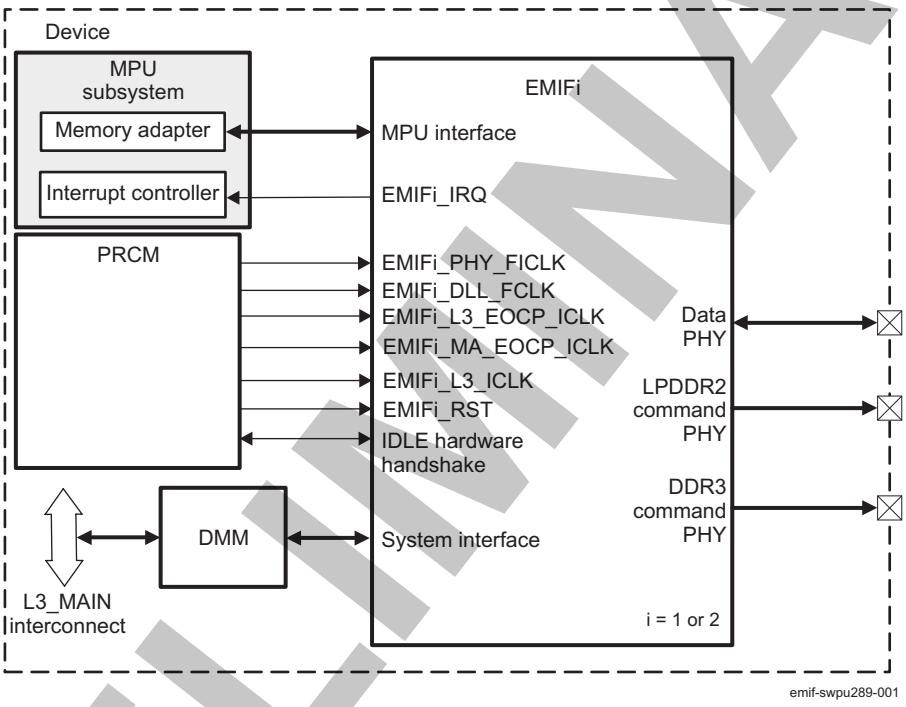
15.3.1 EMIF Module Overview

The EMIF module provides connectivity between the device and LPDDR2-type or DDR3-type of memories and manages data bus read/write accesses between external memories and the device subsystems having access to the L3_MAIN interconnect and DMA capability.

The EMIF is also introduced in Section 15.1, *Memory Subsystem Overview*.

The device includes two EMIF controllers. Figure 15-43 is an overview of the EMIF modules.

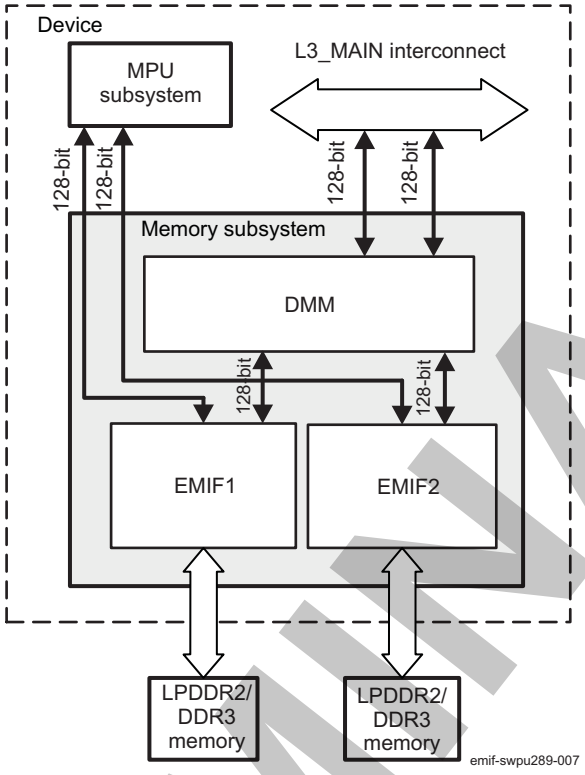
Figure 15-43. EMIF Module Overview



15.3.1.1 EMIF Overall Integration

Figure 15-44 shows the EMIF connection with the surrounding modules and SDRAM devices.

Figure 15-44. EMIF Overall Architecture



15.3.2 EMIF Environment

This section describes the EMIF application fields from an environment point of view (external connections).

NOTE: The device package restricts the physical connection to only one memory type: LPDDR2 or DDR3. See more details about device family and packaging in , *Introduction*.

Figure 15-45 shows the EMIF LPDDR2 generic configuration.

Figure 15-45. EMIF LPDDR2 Generic Configuration

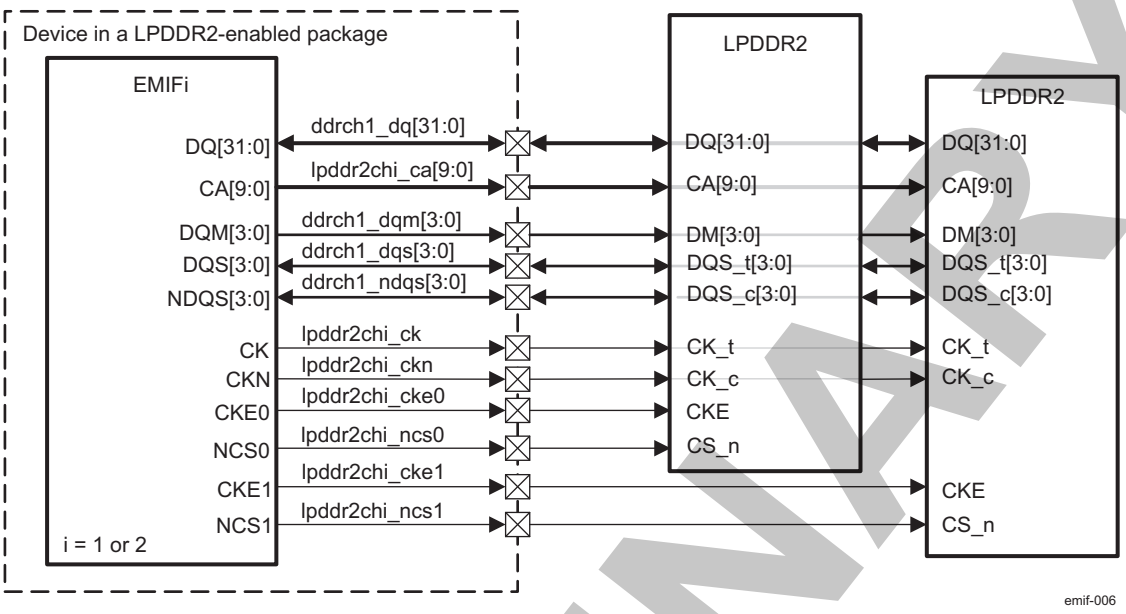


Figure 15-46 shows the EMIF DDR3 generic configuration.

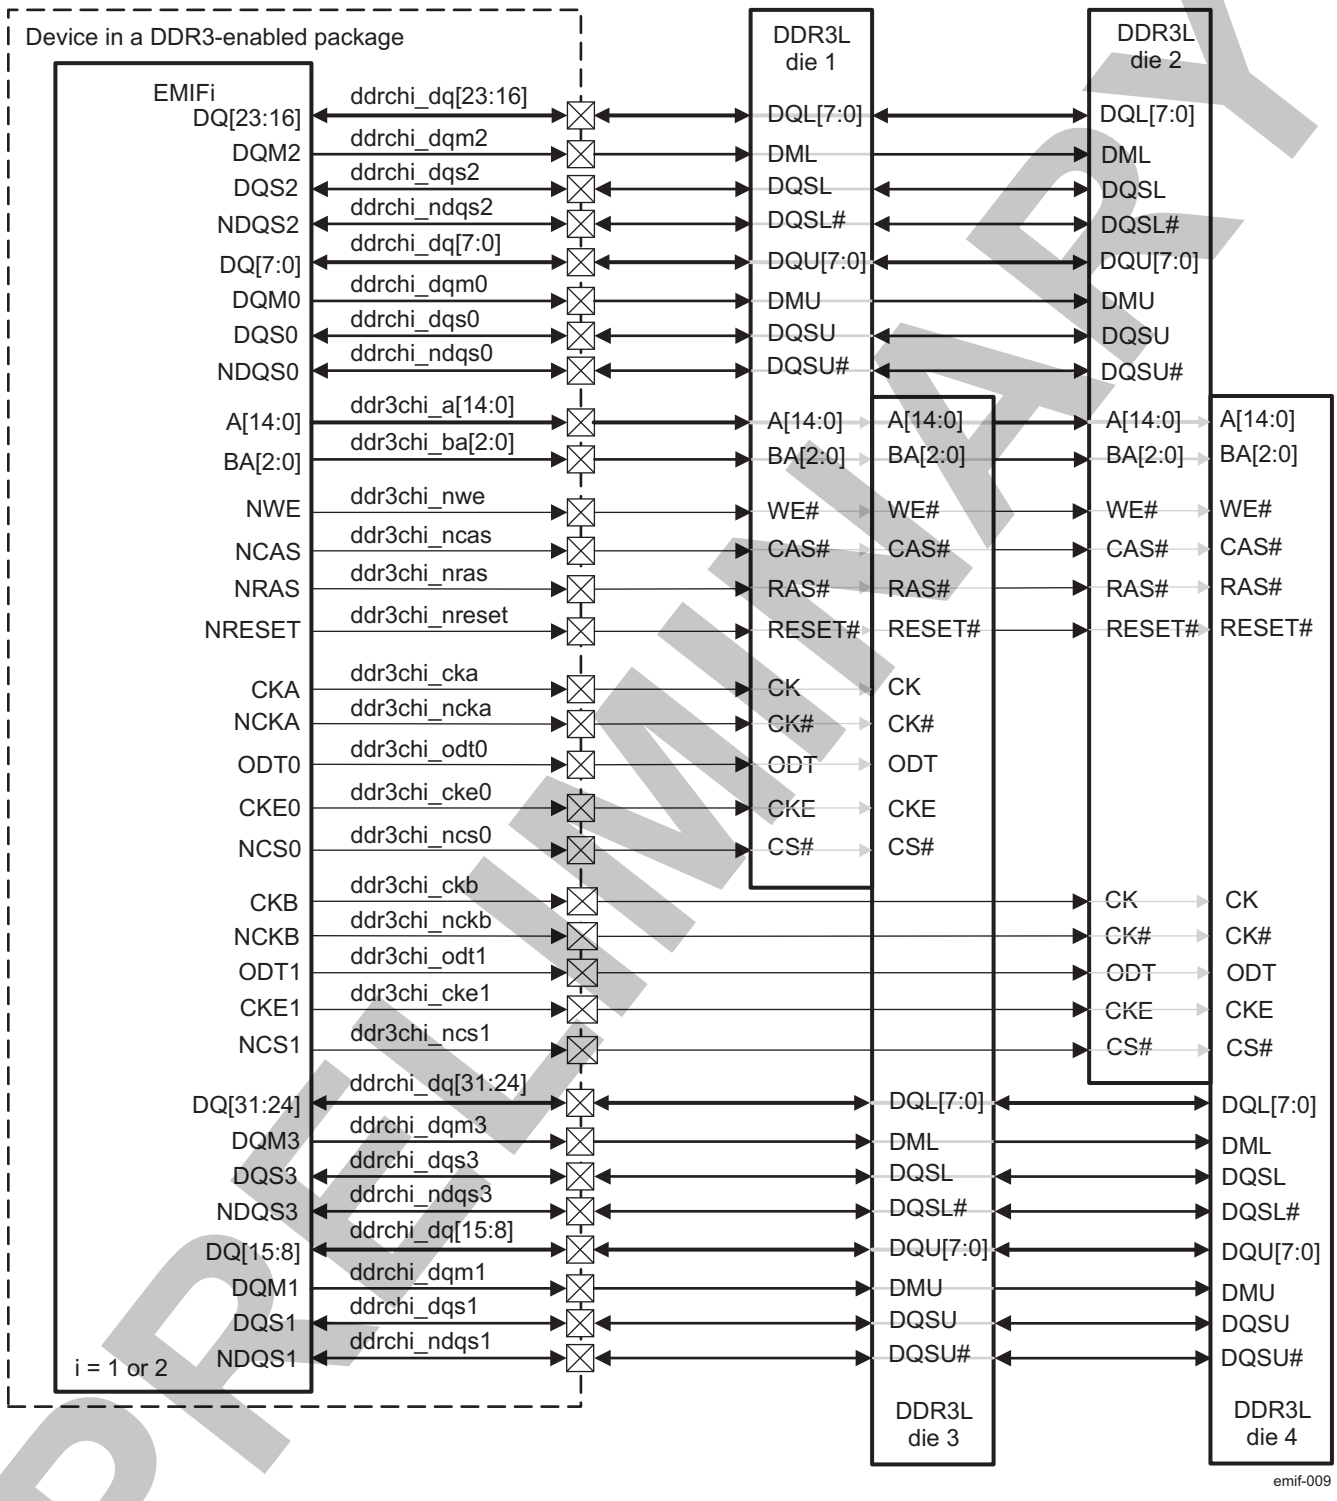
Figure 15-46. EMIF DDR3 Generic Configuration



15.3.2.1 EMIF Signals

Table 15-95 describes the module signals and specifies their links to functions used to connect LPDDR2 type of memories. LPDDR2 command PHY signals are available only on LPDDR2-enabled device packages. LPDDR2 data PHY signals are common with the DDR3 ones.

Table 15-95. LPDDR2 I/O Signals

Module Pin	Device I/O Signal	I/O[1]	Description
EMIF1 Data PHYs			
DQ[31:0]	ddrch1_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch1_dqm[3:0]	I/O	Data mask
DQS[3:0]	ddrch1_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch1_ndqs[3:0]	I/O	Data strobe invert
EMIF1 LPDDR2 Command PHY			
CA[9:0]	lpddr2ch1_ca[9:0]	O	Double-data rate (DDR) command/address
CK	lpddr2ch1_ck	O	Clock
NCK	lpddr2ch1_nck	O	Clock invert
NCS[1:0]	lpddr2ch1_ncs[1:0]	O	Chip-selects 1:0 (active low)
CKE[1:0]	lpddr2ch1_cke[1:0]	O	Clock-enables 1:0
EMIF2 Data PHYs			
DQ[31:0]	ddrch2_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch2_dqm[3:0]	I/O	Data mask
DQS[3:0]	ddrch2_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch2_ndqs[3:0]	I/O	Data strobe invert
EMIF2 LPDDR2 Command PHY			
CA[9:0]	lpddr2ch2_ca[9:0]	O	Double-data rate (DDR) command/address
CK	lpddr2ch2_ck	O	Clock
NCK	lpddr2ch2_nck	O	Clock invert
NCS[1:0]	lpddr2ch2_ncs[1:0]	O	Chip-selects 1:0 (active low)
CKE[1:0]	lpddr2ch2_cke[1:0]	O	Clock-enables 1:0

(1) I = Input; O = Output

Table 15-96 describes the module signals and specifies their links to functions used to connect DDR3 type of memories. DDR3 command PHY signals are available only on DDR3-enabled device packages. DDR3 data PHY signals are common with the LPDDR2 ones.

Table 15-96. DDR3 I/O Signals

Module Pin	Device I/O Signal	I/O[1]	Description
EMIF1 Data PHYs			
DQ[31:0]	ddrch1_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch1_dqm[3:0]	I/O	Data mask
DQS[3:0]	ddrch1_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch1_ndqs[3:0]	I/O	Data strobe invert
EMIF1 DDR3 Command PHYs			
A[15:0]	ddr3ch1_a[15:0]	O	Row/column address bus
BA[2:0]	ddr3ch1_ba[2:0]	O	Bank select
CKA	ddr3ch1_cka	O	Differential clock, set a (DDR3 command PHY 0)

EMIF2 Data PHYs			
DQ[31:0]	ddrch2_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch2_dqm[3:0]	I/O	Data mask
DQS[3:0]	ddrch2_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch2_ndqs[3:0]	I/O	Data strobe invert
EMIF2 DDR3 Command PHYs			
A[15:0]	ddr3ch2_a[15:0]	O	Row/column address bus
BA[2:0]	ddr3ch2_ba[2:0]	O	Bank select
CKA	ddr3ch2_cka	O	Differential clock, set a (DDR3 command PHY 0)
NCKA	ddr3ch2_ncka	O	Differential clock, set a (DDR3 command PHY 0)
CKB	ddr3ch2_ckb	O	Differential clock, set b (DDR3 command PHY 1)
NCKB	ddr3ch2_nckb	O	Differential clock, set b (DDR3 command PHY 1)
NCS[1:0]	ddr3ch2_ncs[1:0]	O	Rank select 1:0 (active low)
CKE[1:0]	ddr3ch2_cke[1:0]	O	Clock enable for rank 1:0
NCAS	ddr3ch2_ncas	O	Command
NRAS	ddr3ch2_nras	O	Command
NWE	ddr3ch2_nwe	O	Command
NRESET	ddr3ch2_nreset	O	Asynchronous reset (active low)
ODT[1:0]	ddr3ch2_odt[1:0]	O	On-die termination for rank 1:0

(1) I = Input; O = Output

Each SDRAM channel (that is, each EMIF controller) can be connected to two external SDRAM memories. For more information, see Section 15.2.1, *Dynamic Memory Manager*.

15.3.3 EMIF Integration

This section describes the integration of the module in the device, and includes information about clocks, resets, and hardware requests.

Figure 15-47 shows the integration of the EMIF1 module in the device.

Figure 15-47. EMIF1 Integration

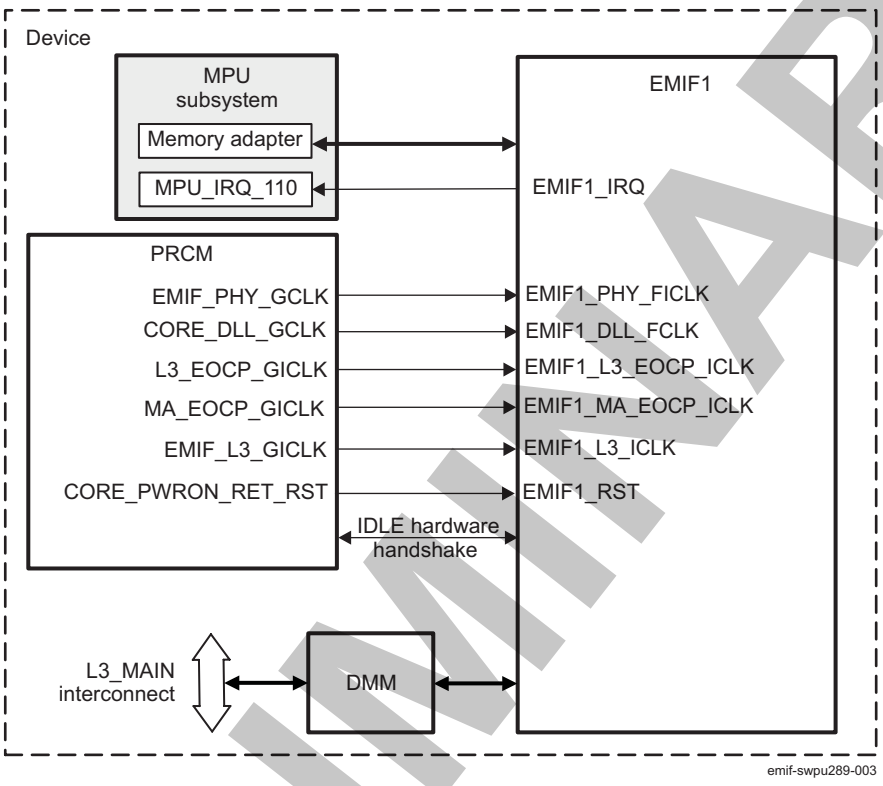

Figure 15-48 shows the integration of the EMIF2 module in the device.

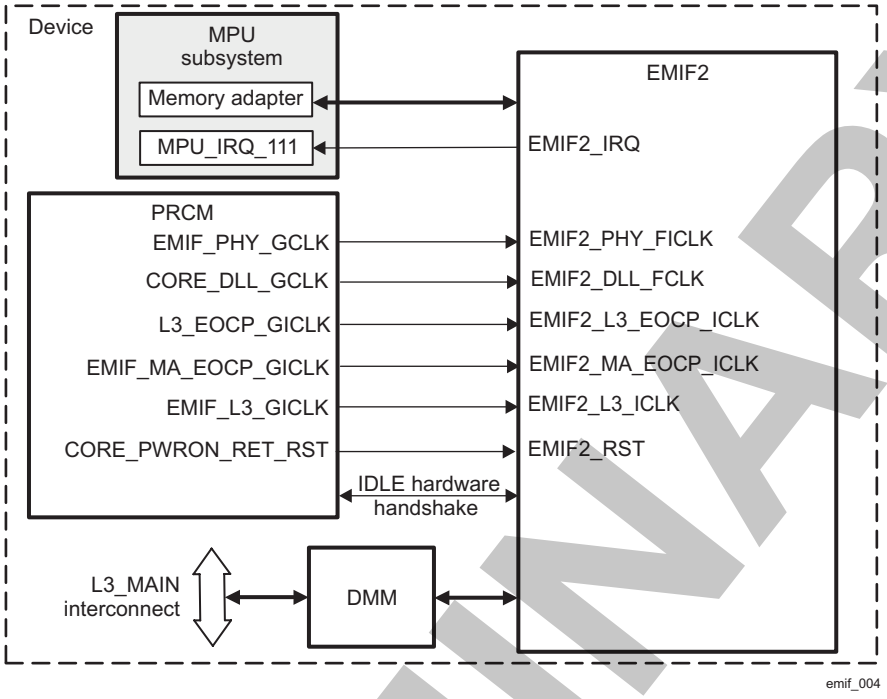
Figure 15-48. EMIF2 Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 15-97 through Table 15-99 summarize the integration of the module in the device.

Table 15-97. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
EMIF1	PD_CORE	No	L3_MAIN
EMIF2	PD_CORE	No	L3_MAIN

Table 15-98. Clocks and Resets

	Clocks			
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
EMIF1	EMIF1_L3_EOCP_ICLK	L3_EOCP _GICLK	PRCM	System interface clock
	EMIF1_L3_ICLK	EMIF_L3_GICLK	PRCM	L3_MAIN interface clock
	EMIF1_MA_EOCP_ICLK	MA_EOCP_GICLK	PRCM	MPU interface clock
	EMIF1_PHY_FICLK	EMIF_PHY_GCLK	PRCM	PHY functional clock (runs at DDR clock rate)
	EMIF1_DLL_FCLK	CORE_DLL_GCLK	PRCM	DLL functional clock
	EMIF_CORE1	EMIF1_PHY_FICLK/2	EMIF1 PHY	EMIF1 internal core functional clock (runs at half-speed DDR clock rate)
EMIF2	EMIF2_L3_EOCP_ICLK	L3_EOCP _GICLK	PRCM	System interface clock
	EMIF2_L3_ICLK	EMIF_L3_GICLK	PRCM	L3_MAIN interface clock

	EMIF2_DLL_FCLK	CORE_DLL_GCLK	PRCM	DLL functional clock
	EMIF_CORE2	EMIF2_PHY_FICLK/2	EMIF2 PHY	EMIF2 internal core functional clock (runs at half-speed DDR clock rate)
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
EMIF1	EMIF1_RST	CORE_POWERON_RET_RST	PRCM	Core/Power-on/Retention reset
EMIF2	EMIF2_RST	CORE_POWERON_RET_RST	PRCM	Core/Power-on/Retention reset

NOTE: The two clocks MA_EOCP_GICLK and L3_EOCP_GICLK are exclusive. EMIF modules are clocked by MA_EOCP_GICLK when MPU interface is active, otherwise L3_EOCP_GICLK clock is used.

NOTE: EMIF PHYs are clocked from EMIFi_PHY_FICLK which runs at the DDR clock rate. EMIF cores are clocked from EMIFi_PHY_FICLK divided by 2, that is, the so called EMIF clock rate.

Table 15-99. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
EMIF1	EMIF1_IRQ	MPU_IRQ_110	MPU interrupt controller (INTC)	Interrupt to the MPU subsystem
EMIF2	EMIF2_IRQ	MPU_IRQ_111	MPU INTC	Interrupt to the MPU subsystem

NOTE: For the description of the interrupt source, see Section 15.3.4.5, *Interrupt Requests*.

15.3.4 EMIF Functional Description

15.3.4.1 Block Diagram

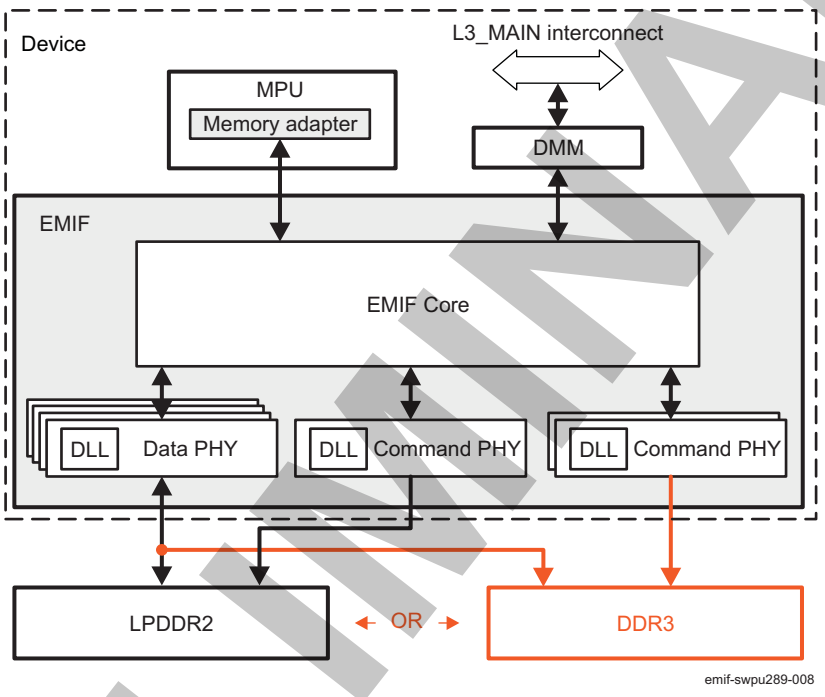
The EMIF is an L3 bus peripheral that provides an interface to SDRAM memories.

Figure 15-49 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the DDR standard.

Physical layers (PHYs) convert single-data rate (SDR) signals to DDR signals.

Figure 15-49. EMIF Block Diagram



15.3.4.1.1 Local Interface

The EMIF supports three local (on-chip) interfaces:

- System interface (from L3_MAIN interconnect)
- MPU interface (from MPU subsystem)
- Low-latency interface This interface is not connected to any subsystem in this device.

System and Low-latency interfaces are used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to and from the EMIF controller. MPU interface is used to process memory accesses. Each interface has its own clock.

Table 15-100 shows the MAddrSpace mapping to different CSs.

Table 15-100. MAddrSpace Mapping to Chip-Selects

MAddrSpace[1]	Chip-Select	Description	Exclusions
0x0	NCS[1:0]	SDRAM(s)	
0x1	NCS1	Reserved for LPDDR2-NVM	Not supported
0x2	N/A	Reserved. Any access to this area will generate an error on the L3 interface. This can be used by the software to track any unwanted access to the section defined in the DMM_LISA_MAP_i register.	Not visible to the MPU port

(1) See DMM_LISA_MAP_i [17:16] SDRC_ADDRSPC register bitfield in Section 15.2, *Dynamic Memory Manager*.

Table 15-100. MAddrSpace Mapping to Chip-Selects (continued)

MAddrSpace[1]	Chip-Select	Description	Exclusions
0x3	N/A	Internal registers	Not visible to the MPU port

Table 15-101 lists the features of the EMIF interface port.

Table 15-101. Port Features

Feature	System	LL (not connected)	MPU
64-bit bus		√	
128-bit bus	√		√
Register access	√	√	
2D access	√	√	

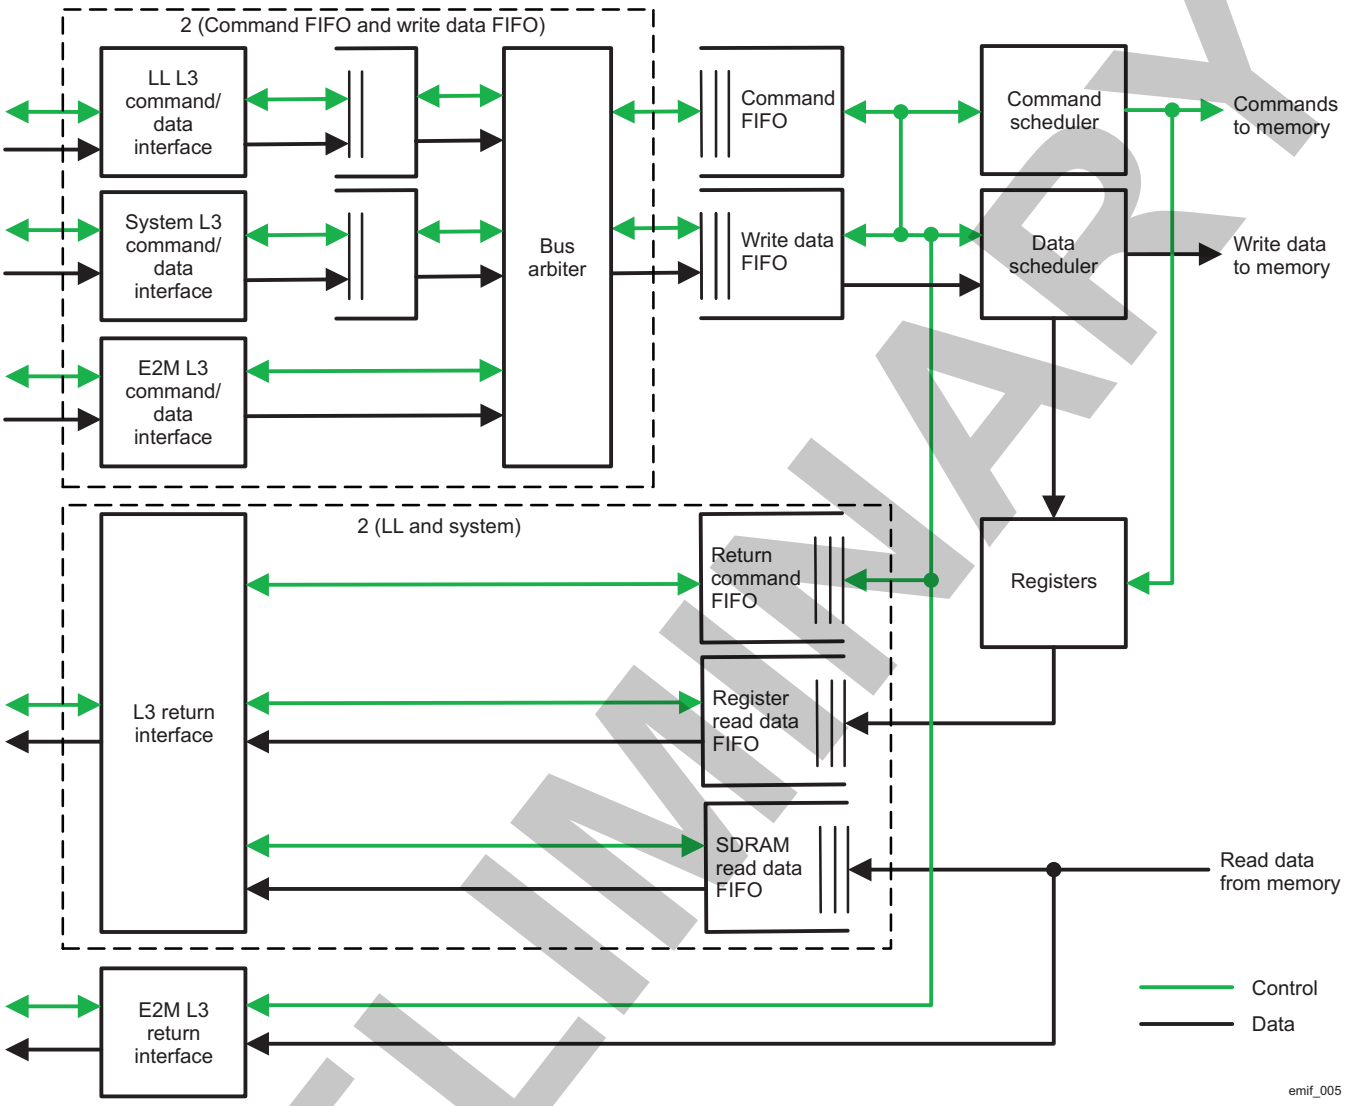
15.3.4.1.2 FIFO Description

The EMIF module contains the following FIFOs:

- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 15-50 shows the overall architecture of the EMIF FIFOs.

Figure 15-50. FIFO Block Diagram



Because the system (128-bit) local interface is the main interface, it has a higher allocation of FIFO slots than the low-latency (64-bit) local interface. Table 15-102 lists the allocation of the entries.

Table 15-102. FIFO Allocation

Parameter	System Local Interface Entries	Low-Latency Local Interface Entries	MPU Local Interface Entries
Pre Command FIFO	6	6	4
Command FIFO	Programmable (1)	Programmable (1)	Programmable (1)
Pre Write FIFO	6	6	8
Write Data FIFO (256-bit)	Up to (19 × 256 bits) + 6	Up to (19 × 256 bits) + 6	Up to 19 + 8
Return Command FIFO	22	17	24
SDRAM Read Data FIFO	22	17	24
Register Read Data FIFO	2	2	0

(1) The total number of entries in the command FIFO is 10.

The command FIFO is shared between the three local interfaces, whereas there are three different FIFOs for every other type, one dedicated to each local interface.

The command FIFO stores all the commands coming in on the local command interface. The allocation of entries in the command FIFO is programmable per local interface using the following bit fields:

- EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX
- EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX
- EMIF_OCP_CONFIG[23:20] MPU_TRESH_MAX

If the addition of the EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX and EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit fields is greater than the number of entries in the command FIFO, the allocation depends on the traffic on the interfaces. For example, if both fields are programmed to 7, then either of the interfaces can use seven entries in the command FIFO if the other interface is idle. If both interfaces have traffic, then the EMIF starts to gradually allocate entries to both interfaces until it settles down to seven entries for the low-latency interface and three entries for the system interface, because the low-latency interface has higher priority. If the low-latency interface has no traffic, the system interface can use seven entries.

The allocation also depends on the traffic on the interfaces, if the EMIF_OCP_CONFIG[27:24] SYS_THRESH_MAX and EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit fields are programmed to be equal to or greater than the number of entries in the command FIFO. For example, if both fields are programmed to 10, then the low-latency port can use all the entries if there is no traffic on the system interface. However, if there is no traffic on the low-latency interface, the system interface can use all but one entry. This is because the low-latency interface has higher priority than the system interface. The only way for the system interface to use all command FIFO entries is to set the EMIF_OCP_CONFIG[19:16] LL_THRESH_MAX bit field to 0. Writing 0 reserves no space for the associated interface. If the value is set to 0 and a request is seen for that interface, the command FIFO assumes a value of 1 for that interface.

The write data FIFO stores the write data for all the write transactions coming in on the local write data interface. The write FIFO is shared for all the ports. A similar token mechanism is used to allocate the write FIFO with the following exceptions. All ports are given a minimum of four tokens, which ensures that each has ensured access to three write FIFO locations. Any one port can only use up to 19 of the 25 write FIFO locations. Because there is a 6-word pre-FIFO, each port can have up to 25 backlogged writes. The LL interface can have up to twice the logged write data values, because the interface is 50 percent of the internal data storage.

The return command FIFO stores all the return transactions that are to be issued to the local return interface. These include the write status return and the read data return commands.

Two read data FIFOs store the read data to be sent to the local return interface. One read data FIFO stores read data from the memory mapped registers. The other read data FIFO stores read data from external memory.

A write command is executed only when four local words of the corresponding data is received in the write data FIFO, or when it is the last data, and if there is space in the return command FIFO. The EMIF schedules a read-only if the results can fit into the return command FIFO and the corresponding read data FIFOs.

15.3.4.1.3 MPU Port Restrictions

The EMIF MPU port is defined only to process memory requests. All register accesses are processed through the system or LL ports of the EMIF. The EMIF MPU port does not support 2D or register requests required or provided by the system and LL interfaces.

15.3.4.1.4 Port Priority

When Mflag = 0, or when the Mflag port override bit (EMIF_READ_WRITE_EXECUTION_THRESHOLD [31] MFLAG_OVERRIDE) is set:

1. LL port (highest priority)
2. System or MPU depending on the MPriority field of the MReqInfo bus

When Mflag = 1:

- The system port is given highest priority: EMIF guarantees one System command will be executed, before switching back to legacy priority scheme (above). This ping-pong arbitration scheme continues until Mflag is returned to 0.
- If no system command is present, the legacy priority scheme is maintained.
- If refresh_must is asserted, then only one refresh is retried, to prevent refresh cycles taking away from bandwidth during this critical time.

15.3.4.1.5 Coherency

To maintain coherency, the following rules must be followed:

- Any command arriving on any interface (MPU, system, or LL) that matches an address in the command FIFO is executed after the command in the command FIFO
- The matching address is any address within a 2,000-address boundary
- On a 2-D transfer, the starting address is the compared address. The computed addresses of the 2-D transfer are not considered in address overlapping.
- Any command arriving within a 10-cycle window of another, from the different interfaces that do not match any address in the command FIFO, but may match command addresses arriving on a different interface, can be executed in any order.

15.3.4.1.6 Arbitration of Commands in the Command FIFO

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MConnID on a particular local interface complete in order. The EMIF does not ensure ordering between commands with different MConnIDs or between commands from two local interfaces. For more information about L3 interconnect terms (MConnID, MCMD, MADDR, etc.) see Section 14.2.1, *L3 Interconnect*.

However, the EMIF does maintain data coherency. Therefore, the EMIF blocks a command, regardless of priority or the local interface, if that command is to the same block address (2048 bytes) as an older command that is not complete. Thus, the EMIF may have one pending read or write for each MConnID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of this reordering, the EMIF may now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. Commands from the low-latency local interface have a higher priority over the commands from the system local interface. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF may now have the next read and a write command. If the return command FIFO and the read data FIFO have space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the return command FIFO has space but the read data FIFO is full, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command-to-command counters are satisfied and the read-to-write or write-to-read turnaround time is met.

The EMIF does not support tag interleaving. In other words, for an local interface, the EMIF completes executing an local command before it switches to another command. The EMIF can, however, interleave execution between commands from two local interfaces.

The data coherency inside the EMIF is ensured only in a single level of local infrastructure. For example, if a write from a secondary local bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the local wait status, it must do the following:

1. Perform the required write.
2. Perform a dummy write to the EMIF_REVISION register.

3. Perform a dummy read to the EMIF_REVISION register.
4. Indicate to master B that the data is ready to be read after completion of read in Step 3. The completion of read in Step 3 ensures that the previous writes were done.

Apart from reads and writes, the EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. ZQ calibration
3. Leveling
4. local request for a read or write
5. local request for a write
6. SDRAM activate commands
7. SDRAM deactivate commands
8. SDRAM deep power-down request
9. SDRAM power-down request
10. SDRAM refresh request when refresh-may or release level is reached
11. SDRAM self-refresh request (lowest priority)

While performing the previous scheduling algorithm, the EMIF may encounter two conditions:

- A continuous stream of high-priority commands can block lower priority commands.
- A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the EMIF_SDRAM_CONFIG register is written and the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

15.3.4.2 Clock Management

The EMIF can gate EMIF_COREi. There is an internal mechanism that can stop EMIF_COREi automatically. EMIF_COREi is stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the local bus completes. The EMIF_COREi frequency can be changed only after putting the external SDRAM in self-refresh mode.

The EMIF waits for the DLL lock before performing any memory access.

EMIF_COREi frequency is equal to half of the EMIFi_PHY_FICLK frequency.

15.3.4.3 Reset

The EMIF does not support a software reset.

The EMIF supports a global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. During a leveling operation, EMIF will immediately exit the operation, and a load mode register access (DDR3) will be used to exit leveling mode.
2. EMIF completes the ongoing access, and then puts the SDRAM in self-refresh mode. If the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS field is set to 1, the EMIF does not put SDRAM in self-refresh mode. If EMIF is in LPDDR2 mode and the EMIF_LPDDR2_MODE_REG_CONFIG[30] REFRESH_EN is set to 0, the EMIF does not put LPDDR2 in self-refresh mode.

3. EMIF clears all its FIFO contents.
4. EMIF does not wait for all interrupts to be serviced.

To exit the global warm reset:

1. If the EMIF was in Self Refresh state, it will exit Self Refresh state.
2. If leveling was enabled at the time of a global warm reset, a PHY reset must occur to bring the PHY back into a known state, as it may have been left in a leveling state upon warm reset assertion. To guarantee the SDRAM memory clocks are off when issuing a PHY reset, the EMIF_POWER_MANAGEMENT_CONTROL register may be needed to enter self refresh before asserting PHY reset.
3. It is the responsibility of software to go through a full leveling.

15.3.4.4 System Power Management

15.3.4.4.1 Power-Down Mode

The EMIF supports power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains CKE pin low to maintain the power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

If the SDRAM is in power-down mode and one of the following occurs, the EMIF brings SDRAM out of power-down mode:

- EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x4 to some other value.
- An SDRAM access is requested.
- The refresh-must level is reached.

If refresh-must brings EMIF out of Power-Down, it will reenter Power-Down when the refreshes are complete if there has not been a SDRAM request.

To exit power-down, the EMIF:

1. Drives CKE high after t_cke + 1 cycles have elapsed since the power-down command was issued. The value of t_cke is taken from EMIF_SDRAM_TIMING_2[2:0] T_CKE bit field.
2. Waits for EMIF_SDRAM_TIMING_2[30:28] T_XP + 1 cycles
3. Enters its idle state and can issue any commands

15.3.4.4.2 LPDDR2 Deep Power-Down Mode

For ultimate power savings, the EMIF supports deep power-down mode for LPDDR2.

The SDRAM can be forced into deep power-down mode through software by setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 0x1. In this case the EMIF continues normal operation until all SDRAM access requests are serviced. At this point the EMIF issues a deep power-down command. The EMIF then maintains CKE pin low to maintain deep power-down mode. In deep power-down mode, the EMIF automatically stops the clocks to the SDRAM.

Setting the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit to 1 overrides the setting of the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field. Therefore, if the SDRAM is in any other power-saving mode, and the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 1, the EMIF exits those modes and goes into deep power-down mode.

When the SDRAM is in deep power-down mode, the EMIF services register accesses normally.

If the EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN bit is set to 0x0, the EMIF brings the SDRAM out of deep power-down mode.

For LPDDR2, the EMIF controller performs SDRAM initialization as specified in Section 15.3.4.7.1, *LPDDR2-SDRAM Initialization*. Note the initialization part that must be performed by the software.

15.3.4.4.3 Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIMING number of DDR clock cycles and the EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is set to 0x2. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR_TIMING, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a self-refresh command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM. The EMIF drives CKE pin low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the SDRAM is in self-refresh mode and one of the following occurs, the EMIF brings SDRAM out of self-refresh mode:

- The EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE bit field is changed from 0x2 to some other value.
- SDRAM access is requested .

To exit self-refresh, for LPDDR2, the EMIF:

1. Waits for EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the self-refresh command was issued and enables clocks
2. Drives CKE pin high
3. Waits for EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh-release level.
5. Enters its idle state and can issue any commands

To exit self-refresh, for DDR3, the EMIF:

1. Waits for EMIF_SDRAM_TIMING_2[2:0] T_CKE + 1 cycles have elapsed since the self-refresh command was issued and enables clocks
2. Drives CKE pin high
3. Waits for EMIF_SDRAM_TIMING_2[24:16] T_XSNR + 1 cycles
4. If EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL is 1, issues a load mode register command to the extended mode register 1 (pins BA[2:0] = 0x1) with the A[15:0] pins set as inTable 15-103

Table 15-103. Extended Mode Register 1 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[12]	0x0	Reserved
A[9]	DDR_TERM[2]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 26
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled
A[6]	DDR_TERM[1]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 19
A[5]	SDRAM_DRIVE[1]	SDRAM drive strength from EMIF_SDRAM_CONFIG register, bit 25
A[4:3]	0x0	Additive latency = 0
A[2]	DDR_TERM[0]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG register, bit 24

Table 15-103. Extended Mode Register 1 Value (continued)

Bits	Value	Description
A[1]	SDRAM_DRIVE[0]	SDRAM drive strength from EMIF_SDRAM_CONFIG register, bit 18
A[0]	0x1	Disable DLL

5. Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh-release level.
6. Enters its idle state and can issue any other commands except for a write or a read. A write or a read is issued only after EMIF_SDRAM_TIMING_2[15:6] T_XSRD + 1 cycles clock cycles have elapsed since pin CKE is driven high.

To use partial array self-refresh, the EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR bits must be appropriately programmed. The EMIF performs bank interleaving when EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0x0. Because the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that IBANK_POS be set to 1, 2, or 3 depending on the scheme used. If IBANK_POS is set to 0, software must move critical data into the banks that are going to be refreshed during partial array self-refresh.

15.3.4.4.4 Retention Mode

EMIF supports full-retention mode.

NOTE: It is software's responsibility to perform full leveling upon exit from retention.

15.3.4.5 Interrupt Requests

The EMIF sources two interrupts: one for the system and MPU local interfaces, and the other for the low-latency local interface. The pulse and level interrupt signals for a particular interface are sourced from the same raw interrupt internal to the module.

The EMIF sets the EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] RAW_SYS/EMIF_LOW_LATENCY_OCP_INTERRUPT_RAW_STATUS[0] RAW_LL bit (depending on which interface sent the command having an error) to 1, if an access request to an unsupported MAddrSpace is received. If such an error occurs, it is due to bad programming of the DMM. For more information about addressing, see Section 15.2.1, *Dynamic Memory Manager*.

Table 15-104 lists the event flags and their mask that can cause module interrupts.

Table 15-104. Events

Event Flag	Event Mask	Description
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[1] TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[1] EN_TA_SYS / EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[1] EN_TA_SYS	System interface interrupt for SDRAM temperature alert
EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS[0] ERR_SYS / EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[0] EN_ERR_SYS / EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[0] EN_ERR_SYS	System interface interrupt for command or address error

15.3.4.6 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0, at which point it reloads from the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field is updated.

The refresh backlog counter records the number of outstanding AUTO REFRESH commands the EMIF has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 8). The backlog counter decrements by 1 each time the EMIF issues an AUTO REFRESH command (unless it is already 0). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF must perform an auto refresh cycle (in which it issues AUTO REFRESH commands):

1. Refresh-may level is reached when the backlog count is greater than 0, which indicates there is a refresh backlog; therefore, if the EMIF is not busy and none of the SDRAM banks are open, the EMIF must perform an auto refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 4, which indicates the refresh backlog is getting bigger; therefore, if the EMIF is not busy it must perform an auto refresh cycle even if any of the banks are open.
3. Refresh-must level is reached when the backlog count is greater than 7, which indicates the refresh backlog is becoming excessive and the EMIF must perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The refresh counters do not operate when SDRAM is in self-refresh mode. Also, the refresh counters start tracking the missed refreshes only after initialization is complete in case of DDR3. For LPDDR2, the refresh counters will start tracking missed refreshes after the RESET command is issued.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting T_RFC (see EMIF_SDRAM_TIMING_3) cycles before rechecking the refresh levels. If the refresh-release level is not reached, the EMIF starts another auto refresh cycle; otherwise, it returns to idle mode where it can issue any command. The EMIF ensures that no more than eight AUTO REFRESH commands are issued in any rolling t_{REFBW} (= 4 × 8 × t_{RFC}) window.

15.3.4.7 SDRAM Initialization

15.3.4.7.1 LPDDR2 SDRAM Initialization

When coming out of reset, if the EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE bit field is equal to 4, the EMIF performs an LPDDR2 initialization sequence as follows:

1. Drives the CKE pin high and starts to issue NOP commands continuously
2. After 17 SDRAM refresh rate intervals, issues a PRECHARGE-ALL command. The SDRAM refresh rate is defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. Issues a RESET command
4. Software must initialize LPDDR2 using the EMIF_LPDDR2_MODE_REG_CONFIG and EMIF_LPDDR2_MODE_DATA registers. Software must enable refreshes by writing 1 in the EMIF_LPDDR2_MODE_REG_CONFIG[30] REFRESH_EN bit during the last MRW command.

The EMIF also performs the initialization sequence whenever the EMIF_SDRAM_CONFIG register is written and the LPDDR2 initialization was not performed previously because the EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit was set to 0. Once the EMIF performs initialization, rewriting the EMIF_SDRAM_CONFIG/EMIF_SDRAM_CONFIG_2 configuration registers does not cause reinitialization.

NOTE: The values of the bit fields in the EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2 registers are loaded by the control module at reset. These values can be modified by the configuration header (CH) feature of the ROM code or by the initial boot image running from an external XIP booting memory or internal RAM (see Section 28.3.8, *Image Format*). They must not be modified during run time, because they reflect the used hardware SDRAM memory configurations.

The EMIF does not perform any transactions until the LPDDR2 initialization sequence completes.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 17 refresh rate intervals + 8 cycles is approximately 17 × EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE / input frequency.

15.3.4.7.2 DDR3 Initialization

On coming out of reset, if EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE is equal to 3 and EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS bit is set to 0, the EMIF performs a DDR3 SDRAM initialization sequence as follows:

1. Drives the CKE pin low
2. After 17 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field.
3. After one SDRAM refresh rate interval, issues a LOAD MODE REGISTER command to the extended mode register 2 (pins BA[2:0] = 0x2) with pins A[15:0] set as in Table 15-105

Table 15-105. Extended Mode Register 2 Value

Bits	Value	Description
A[15:11]	0x0	Reserved
A[10:9]	DYN_ODT[1:0]	Dynamic ODT value from EMIF_SDRAM_CONFIG[22:21] DYN_ODT. Dynamic ODT is NOT supported. Set to 0x0 in the register bitfield.
A[8]	0x0	Reserved
A[7]	SRT	Self-refresh temperature range from EMIF_SDRAM_REFRESH_CONTROL[29] SRT
A[6]	ASR	Auto self-refresh enable from EMIF_SDRAM_REFRESH_CONTROL[28] ASR
A[5]	0x0	Reserved
A[4:3]	CWL[1:0]	CAS write latency from EMIF_SDRAM_CONFIG[17:16] CWL
A[2:0]	PASR[2:0]	Partial array self-refresh from EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR

4. Issues a LOAD MODE REGISTER command to the extended mode register 3 (pins BA[2:0] = 0x3) with A[15:0] = 0x0
5. Issues a LOAD MODE REGISTER command to the extended mode register 1 (BA[2:0] = 0x1) with A[15:0] set as in Table 15-106

Table 15-106. Extended Mode Register 1 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[10]	0x0	Reserved
A[9]	DDR_TERM[2]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG[26] DDR_TERM
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled

Table 15-106. Extended Mode Register 1 Value (continued)

Bits	Value	Description
A[6]	DDR_TERM[1]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG[25] DDR_TERM
A[5]	SDRAM_DRIVE[1]	SDRAM drive strength from EMIF_SDRAM_CONFIG[19] SDRAM_DRIVE
A[4:3]	0x0	Additive latency = 0
A[2]	DDR_TERM[0]	DDR3 termination resistor value from EMIF_SDRAM_CONFIG[24] DDR_TERM
A[1]	SDRAM_DRIVE[0]	SDRAM drive strength from EMIF_SDRAM_CONFIG[18] SDRAM_DRIVE
A[0]	0x0	Enable SDRAM DLL

6. Issues a LOAD MODE REGISTER command to the mode register 0 (BA[2:0] = 0x0) with A[15:0] set as in Table 15-107

Table 15-107. Mode Register 0 Value

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Fast exit active power-down exit time
A[11:9]	T_WR[4:0]	Write recovery for auto pre-charge from EMIF_SDRAM_TIMING_1[20:17] T_WR
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4]	CL[3:1]	CAS latency from EMIF_SDRAM_CONFIG[13:11] CL
A[3]	0x0	Sequential burst type
A[2]	CL[0]	CAS latency from EMIF_SDRAM_CONFIG[10] CL
A[1:0]	0x0	Burst length of 8

7. Issues a ZQCL command to start long ZQ calibration
8. Waits for t_{DLLK} and t_{ZQinit} to complete
9. If the EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL bit is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (BA[2:0] = 0x1) with A[15:1] set as in Table 15-106 (Step 5) and A[0] set to 0x1.
10. Issues an AUTO REFRESH command
11. The EMIF enters its IDLE state.

The EMIF also performs the initialization sequence whenever the EMIF_SDRAM_CONFIG register is written. But in this case, the EMIF starts from Step 3.

The EMIF does not perform any transactions until the DDR3 initialization sequence is complete.

NOTE: The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some DDR3 datasheets.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately 17 × REFRESH_RATE / input frequency.

15.3.4.8 DDR3 Read-Write Leveling

The EMIF supports full write/read leveling.

Full leveling has three parts:

1. Write leveling
2. Read DQS gate training

3. Read data eye training

15.3.4.8.1 Full Leveling Description

The EMIF does not perform full leveling after initialization upon reset. Full leveling must be triggered by software after the EMIF registers are properly configured. The EMIF also supports triggering of full leveling through software through the use of the EMIF_READ_WRITE_LEVELING_CONTROL[31] RDWRLVLFULL_START bit.

Full leveling will be interrupted by auto refresh if a refresh-must state is reached. Upon completion of the auto refresh, full leveling will be reentered at the point it exited and continue until completion.

15.3.4.9 EMIF Access Cycles

By default, the EMIF keeps the SDRAM CSs high (CSs are active-low signals). To direct a command to only one of the SDRAMs, the EMIF asserts the CS to the SDRAM for the duration of the command. If the EMIF_SDRAM_CONFIG[3] EBANK bit in the SDRAM configuration register is set to 0, NCS1 is always driven high except during initialization and for the REFRESH, POWER-DOWN, SELF-REFRESH, and DEEP POWER-DOWN commands.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may be needed to service a single local burst request. Table 15-108 through Table 15-112 show a few examples of how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Table 15-108. 64-Byte Linear Read Starting at Address 0x0

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11

Table 15-112. 64-Byte Linear Read Starting at Address 0x18

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from SDR to DDR is done outside the EMIF.

15.3.4.9.1 LPDDR2 Read

A read access to an LPDDR2 is initiated with a READ command. The EMIF provides the internal bank address and the column address on pins CA[9:0] with the READ command. The EMIF registers the first read data from DQ[31:0] after (EMIF_DDR_PHY_CONTROL_1[4:0] READ_LATENCY) DDR clock cycles.

15.3.4.9.2 LPDDR2 Write

A write access to an LPDDR2 is initiated with a WRITE command. The EMIF provides the internal bank address and the column address on pins CA[9:0] with the WRITE command.

The EMIF delays the write data by the appropriate write latency minus 1. Subsequent data words are provided on DQ[31:0] along with the appropriate data mask on DM[3:0] on each successive clock cycle. The DDR PHY then adds one more clock cycle delay to the write data to appropriately center the write data to the outgoing DQS.

15.3.4.10 Turnaround Time

Table 15-113 lists the turnaround time the EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

Table 15-113. Turnaround Time

Current Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM write	SDRAM write to the same CS	0
SDRAM write	SDRAM write to a different CS	EMIF_SDRAM_TIMING_3[27:24] T_CSTA + 1
SDRAM read	SDRAM read to the same CS	0
SDRAM read	SDRAM read to a different CS	EMIF_SDRAM_TIMING_3[27:24] T_CSTA + 1
SDRAM write	SDRAM read	EMIF_SDRAM_TIMING_1[2:0] T_WTR + 1 + CL
SDRAM read	SDRAM write	EMIF_SDRAM_TIMING_1[31:29] T_RTW + 1

15.3.4.11 PHY DLL Calibration

When running in normal locked mode, the PHY DLL gets a reference clock (EMIFi_DLL_FCLK) from the PRCM, which is used by the DLL master to lock to the right frequency and provide the control code for a full period phase shift to the slave. The slave uses this code as a control for its internal delay line to produce the required delay for the signal considered.

When working in locked mode, the delay lines only get an updated control value from the master DLLs when an explicit dll_calib command is issued by the EMIF controller. Failure to send such commands on a timely basis will result in inaccurate delay-line information if there is a significant voltage and temperature drift in the system. It is recommended to issue at least one command every 100 µs. EMIF automatically sends ctrl_update commands for:

- Refresh Exit
- Self Refresh Exit
- phy_ready asserted during initialization

The PHY also internally generates a control value update upon completion of a leveling operation. Control is also added for the when leveling is not used , and there are gradual voltage changes during frequency change. The EMIF_DLL_CALIB_CTRL register can be programmed to generate a phy_dll_calib for a periodic interval based on EMIF_COREi cycles, so allow continued memory access as voltage is changing. A safe window of no activity will be guaranteed for this periodic generation of phy_dll_calib. In addition, a one shot generator for phy_pll_calib has also been added that will generate a single phy_dll_calib by setting the EMIF_MISC_REG[0] DLL_CALIB_OS bit to 1.

15.3.4.12 SDRAM Address Mapping

The EMIF interleaves the internal banks for SDRAM connected to both CSs (see Table 15-114 for the SDRAM addressing space), according to the DMM (for more information, see Section 15.2.1, *Dynamic Memory Manager*). From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MiB devices are used, a 128-MiB memory block is observed. If two external 32-MiB devices are used, a 64-MiB block is observed.

Table 15-114. SDRAM Addressing Space

Module Name	Base Address	Size
EMIF1 | EMIF2-CS0-SDRAM(1)	0x8000 0000	0 to 1GiB, programmable in DMM (see Section 15.2.1, *Dynamic Memory Manager*)
EMIF1| EMIF2-CS1-SDRAM(2)	0xC000 0000	0 to 1GiB, programmable in DMM (see Section 15.2.1, *Dynamic Memory Manager*)

(1) The addressing space is interleaved on two SDRAM memory controllers (EMIF1, EMIF2), each activating itsCS0 line. These CSs can address 64, 128, 256, 512, 1024, or 2048MiB. Interleaving occurs at 128-byte granularity. EMIF1-CS0 base address is always 0x8000 0000 at reset, and occupies a 1-GiB address space at reset (interleaving disabled at reset).

(2) The addressing space is interleaved on two SDRAM memory controllers (EMIF1, EMIF2), each activating its CS1 line. These CSs are programmable to 64, 128, 256, 512, or 1024MiB. Interleaving occurs at 128-byte granularity. EMIF1-CS1 and EMIF2-CS1 are disabled at reset. Their base address is programmable to achieve a continuous address space with the respective CS0, regardless of the programmed address range. EMIF1-CS1 is disabled if the EMIF1-CS0 memory density is set to 2048MiB (2GiB) when interleaving is disabled, or if the EMIF1-CS0 + EMIF2-CS0 memory density is set to 1024MiB (1GiB) when interleaving is enabled.

When addressing SDRAM, if the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 0, the EMIF uses the following three bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[3] EBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE

If the EMIF_SDRAM_CONFIG[28:27] IBANK_POS bit field is set to 1, 2, or 3, the EMIF uses the following four bit fields to determine the mapping from the source address to the SDRAM row, column, bank, and CS:

- EMIF_SDRAM_CONFIG[6:4] IBANK
- EMIF_SDRAM_CONFIG[3] EBANK
- EMIF_SDRAM_CONFIG[2:0] PAGESIZE
- EMIF_SDRAM_CONFIG[9:7] ROWSIZE

In all cases the EMIF considers its SDRAM address space to be a single logical block, regardless of the number of physical devices or whether the devices are mapped across one or two EMIF CSs.

15.3.4.12.1 Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 0, Table 15-115 lists which source address bits (MAddr) map to the SDRAM row, column, bank, and CS bits for all combinations of IBANK, EBANK, and PAGESIZE.

Table 15-115. Local Address to 32-bit SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 0

MiB	EBANK	IBANK	PAGESIZE	MAddr																											
				31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2
64	0	0	0	-							row (16 bits DDR3 / 15 bits LPDDR2)															col (8 bits)						
128	1			-						row														cs	col							
	0	1		-						row														bnk	col							
256	1			-					row														cs	bnk	col							
	0	2		-					row														bank		col							
512	1			-				row														cs	bank		col							
	0	3		-				row														bank			col							
1G	1			-			row														cs	bank			col							
128	0	0	1	-						row														col (9 bits)								
256	1			-					row														cs	col								
	0	1		-					row														bnk	col								
512	1			-				row														cs	bnk	col								
	0	2		-				row														bank		col								
1G	1			-			row														cs	bank		col								
	0	3		-			row														bank			col								
2G	1			-		row														cs	bank			col								
256	0	0	2	-					row													col (10 bits)										
512	1			-				row														cs	col									
	0	1		-				row														bnk	col									
1G	1			-			row														cs	bnk	col									
	0	2		-			row														bank		col									
2G	1			-		row														cs	bank		col									
	0	3		-		row														bank			col									
4G	1				row														cs	bank			col									
512	0	0	3	-				row														col (11 bits)										
1G	1			-			row														cs	col										
	0	1		-			row														bnk	col										
2G	1			-		row														cs	bnk	col										
	0	2		-		row														bank		col										
4G	1				row													cs	bank		col											
	0	3			row													bank			col											
	1			row													cs	bank			col											

NOTE: ROWSIZE is unused in case of IBANK_POS = 0 and EBANK_POS = 0.

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (pin CS0). This movement along the banks of the current device continues until the page is accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if EMIF_SDRAM_CONFIG[3] EBANK = 1, pin CS1) and proceeds through the same page in all its banks before moving to the next page in the first device (pin CS0). The EMIF exploits this movement across internal banks and CSs while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, and can interleave among all of them.

15.3.4.12.2 Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

Table 15-116 list the local address to SDRAM address mapping. There are x bits for bank[2], followed by y bits for row, followed by z bits for CS, followed by s bits for bank[1:0], and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-116. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 0

MAddr[31:2]									
bank[2]		row		cs		bank[1:0]		col	
IBANK	bank[2] width (bits)	ROWSIZE	row width (bits)	EBANK	cs width (bits)	IBANK	bank[1:0] width (bits)	PAGESIZE	col width (bits)
0	0	0	9	0	0	0	0	0	8
1	0	1	10	1	1	1	1	1	9
2	0	2	11			2	2	2	10
3	1	3	12			3	2	3	11
		4	13						
		5	14						
		6	15						
		7	16						

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to four banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 8 of them.

15.3.4.12.3 Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

Table 15-117 list the local address to SDRAM address mapping. There are x bits for bank[2:1], followed by y bits for row, followed by z bits for CS, followed by s bits for bank[0], and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-117. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 0

MAddr[31:2]									
bank[2:1]		row		cs		bank[0]		col	
IBANK	bank[2:1] width (bits)	ROWSIZE	row width (bits)	EBANK	cs width (bits)	IBANK	bank[0] width (bits)	PAGESIZE	col width (bits)
0	0	0	9	0	0	0	0	0	8
1	0	1	10	1	1	1	1	1	9
2	1	2	11			2	1	2	10
3	2	3	12			3	1	3	11
		4	13						
		5	14						
		6	15						
		7	16						

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to two banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 4 of them.

15.3.4.12.4 Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

Table 15-118 list the local address to SDRAM address mapping. There are x bits for bank, followed by y bits for row, followed by z bits for CS, and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-118. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 0

MAddr[31:2]							
bank		row		cs		col	
IBANK	bank width (bits)	ROWSIZE	row width (bits)	EBANK	cs width (bits)	PAGESIZE	col width (bits)
0	0	0	9	0	0	0	8
1	1	1	10	1	1	1	9
2	2	2	11			2	10
3	3	3	12			3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3, the EMIF cannot interleave banks within a device (per CS). However, it can interleave banks between the two CSs. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only two of them.

15.3.4.12.5 Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

Table 15-119 list the local address to SDRAM address mapping. There are z bits for CS, followed by y bits for row, followed by x bits for bank, and t bits for col in MAddr[31:2] (x, y, z and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-119. Local Address to SDRAM Address Mapping for IBANK_POS = 0 and EBANK_POS = 1

MAddr[31:2]							
cs		row		bank		col	
EBANK	cs width (bits)	ROWSIZE	row width (bits)	IBANK	bank width (bits)	PAGESIZE	col width (bits)
0	0	0	9	0	0	0	8
1	1	1	10	1	1	1	9
		2	11	2	2	2	10
		3	12	3	3	3	11
		4	13				
		5	14				
		6	15				
		7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF interleaves among all the banks within a device (per CS), but cannot interleave banks between the two CSs. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two CSs) open at a time, but can interleave among only 8 of them.

15.3.4.12.6 Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

Table 15-120 list the local address to SDRAM address mapping. There are z bits for CS, followed by x bits for bank[2], followed by y bits for row, followed by s bits for bank[1:0],and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-120. Local Address to SDRAM Address Mapping for IBANK_POS = 1 and EBANK_POS = 1

MAddr[31:2]									
cs		bank[2]		row		bank[1:0]		col	
EBANK	cs width (bits)	IBANK	bank[2] width (bits)	ROWSIZE	row width (bits)	IBANK	bank[1:0] width (bits)	PAGESIZE	col width (bits)
0	0	0	0	0	9	0	0	0	8
1	1	1	0	1	10	1	1	1	9
		2	0	2	11	2	2	2	10
		3	1	3	12	3	2	3	11
				4	13				
				5	14				
				6	15				
				7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 1, and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to four banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only 4 of them.

15.3.4.12.7 Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

Table 15-121 list the local address to SDRAM address mapping. There are z bits for CS, followed by x bits for bank[2:1], followed by y bits for row, followed by s bits for bank[0],and t bits for col in MAddr[31:2] (x, y, z, s, and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-121. Local Address to SDRAM Address Mapping for IBANK_POS = 2 and EBANK_POS = 1

MAddr[31:2]									
cs		bank[2:1]		row		bank[0]		col	
EBANK	cs width (bits)	IBANK	bank[2:1] width (bits)	ROWSIZE	row width (bits)	IBANK	bank[0] width (bits)	PAGESIZE	col width (bits)
0	0	0	0	0	9	0	0	0	8
1	1	1	0	1	10	1	1	1	9
		2	1	2	11	2	1	2	10
		3	2	3	12	3	1	3	11
				4	13				
				5	14				
				6	15				
				7	16				

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF interleaves banks the same as for EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0, but the interleaving of banks within a device (per CS) is limited to two banks. Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but can interleave among only two of them.

15.3.4.12.8 Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

list the local address to SDRAM address mapping. There are z bits for CS, followed by x bits for bank, followed by y bits for row, and t bits for col in MAddr[31:2] (x, y, z and t are given depending on the value of the EMIF_SDRAM_CONFIG bit fields).

Table 15-122. Local Address to SDRAM Address Mapping for IBANK_POS = 3 and EBANK_POS = 1

MAddr[31:2]							
cs		bank		row		col	
EBANK	cs width (bits)	IBANK	bank width (bits)	ROWSIZE	row width (bits)	PAGESIZE	col width (bits)
0	0	0	0	0	9	0	8
1	1	1	1	1	10	1	9
		2	2	2	11	2	10
		3	3	3	12	3	11
				4	13		
				5	14		
				6	15		
				7	16		

For EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, the EMIF cannot interleave banks within a device (per CS). Thus, the EMIF can keep a maximum of 16 banks (eight internal banks across two CSs) open at a time, but cannot interleave among them.

NOTE: Because the EMIF interleaves among a fewer number of banks when EMIF_SDRAM_CONFIG[28:27] IBANK_POS ≠ 0 or EMIF_SDRAM_CONFIG_2[27] EBANK_POS = 1, these cases are lower in performance than the EMIF_SDRAM_CONFIG[28:27] IBANK_POS = 0 case. Thus, these cases are recommended to be used only with partial array self-refresh where performance can be traded off for power savings.

15.3.4.13 Output Impedance Calibration

The EMIF supports automatic output impedance calibration. The ZQ calibration can be enabled per CS by setting the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[31] ZQ_CS1EN and EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[30] ZQ_CS0EN bits. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCS: ZQ calibration short command
- ZQCL: ZQ calibration long command

For DDR3, the EMIF automatically issues a ZQINIT command during initialization. For LPDDR2, software must issue a ZQINIT command (MRW to mode register 10). EMIF waits and blocks any other command for (ZQ_ZQINIT_MULT + 1) × (ZQ_ZQCL_MULT + 1) × (ZQ_ZQCS + 1) number of DDR clock cycles every time a ZQINIT command is issued. The bit fields used are:

- EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[19:18] ZQ_ZQINIT_MULT
- EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT
- EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS

The EMIF issues a ZQCS command each time the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL bit field expires. In other words, the ZQ_REFINTERVAL defines the interval between ZQCS commands. When a ZQCS command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

If the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN bit field is set to 1, the EMIF issues a ZQCL command every time it exits self-refresh modes. When a ZQCL command is issued, the EMIF waits and blocks any other command for (EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT + 1) × (EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS + 1) number of DDR clock cycles.

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both CSs. To enable ZQ calibration to be performed simultaneously over both CSs, the EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[27] ZQ_DUALCALEN bit must be set to 1. If ZQ_DUALCALEN is set to 0, the EMIF performs ZQ calibration per CS serially.

15.3.4.14 LPDDR2 Temperature Monitoring

The EMIF supports automatic temperature monitoring to facilitate the software update of the refresh rate according to the temperature changes of the LPDDR2. Temperature monitoring can be enabled per CS by setting the EMIF_TEMPERATURE_ALERT_CONFIG[31] TA_CS1EN and EMIF_TEMPERATURE_ALERT_CONFIG[30] TA_CS0EN bits.

The EMIF polls the temperature of the LPDDR2 (issues an MRR command to mode register 4) every time the EMIF_TEMPERATURE_ALERT_CONFIG[21:0] TA_REFINTERVAL bit field expires. In other words, TA_REFINTERVAL defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from the MRR, which indicates the temperature has changed, the EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS bit (for system interface) and EMIF_LOW_LATENCY_OCP_INTERRUPT_STATUS[1] TA_LL bit (for low-latency interface) are set and the module sends an interrupt on the system and low-latency interrupt lines, respectively. When the interrupt is received, software must update the EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE bit field to the required value as per the temperature change.

If the EMIF_TEMPERATURE_ALERT_CONFIG[28] TA_SFEXITEN bit is set to 1, the EMIF polls for temperature change every time it exits self-refresh, active power-down, and precharge power-down modes.

Because the EMIF is performing an MRR, it needs information about how the LPDDR2 is connected. The EMIF_TEMPERATURE_ALERT_CONFIG[27:26] TA_DEVWDT and EMIF_TEMPERATURE_ALERT_CONFIG[25:24] TA_DEVCNT bit fields provide the necessary information to the EMIF for MRR data compare. For example, if TA_DEVWDT is set to 0, which indicates 8-bit devices are used, and if TA_DEVCNT is set to 2, which indicates four devices are used to form a 32-bit bus, the mask used for checking is 4'b1111; that is, the EMIF expects data on each byte lane on a 32-bit bus.

15.3.4.15 Performance Counters

The EMIF_PERFORMANCE_COUNTER_1 and EMIF_PERFORMANCE_COUNTER_2 registers can be used to monitor or calculate the EMIF bandwidth and efficiency. These counters can count events such as total SDRAM accesses, SDRAM activates, reads, writes, etc. Each counter counts events independent of the other counters. In addition to the ability to count events, the counters can also filter the events from a particular master or address space. The events to be counted and the filter enabling can be configured using the EMIF_PERFORMANCE_COUNTER_CONFIG register. The filter value to be used can be configured using the EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT register. Each counter can be configured independently.

Table 15-123 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter can be applied to an event if the following bits for Performance Counter 1 and Performance Counter 2 can be set equal to 0x1 for that event:

- Performance Counter 1: EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN
- Performance Counter 2: EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN

Table 15-123. Performance Counter Filter Configuration

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count total SDRAM accesses
0x1	0x0	0x0 or 0x1	Count total SDRAM activates
0x2	0x0 or 0x1	0x0 or 0x1	Count total reads
0x3	0x0 or 0x1	0x0 or 0x1	Count total writes

(1) n = 1 or 2

Table 15-123. Performance Counter Filter Configuration (continued)

CNTRn_CFG[1]	CNTRn_REGION_EN	CNTRn_MCONNID_EN	Description
0x4	0x0	0x0	Count number of EMIF_COREi clock cycles local Command FIFO is full
0x5	0x0	0x0	Count number of EMIF_COREi clock cycles local Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF_COREi clock cycles local Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF_COREi clock cycles local Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF_COREi clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_COREi clock cycles for which the memory data bus was transferring data.
0xB - 0xF	0x0	0x0	Reserved for future use.

NOTE: When MReqDebug is set to 1 for a particular local command, the performance counters are not incremented for that particular command if the CNTRn_CONFIG values are equal to 0x0, 0x1, 0x2, 0x3, or 0xA.

Table 15-123 shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a local master ID and/or an external chip-select to obtain performance statistics for a particular local master and/or an external chip-select.

The EMIF clock frequency is half the DDR speed.

15.3.4.15.1 Performance Counters General Examples

15.3.4.15.1.1 PERF_COUNTER_1 General Example for Counting Write Accesses

The Performance Counter 1 register must count all write accesses from the IPU subsystem:

- To enable counting writes, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CONFIG bit field must be set to 0x3.
- The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 bit field must be set to 0x44. The values programmed into the MCONNIDx bit fields are those in *ConnID Mapping (Debug View)*, in , *On-Chip Debug Support*, left-shifted by 2 bits.
- To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN bit must be set to 0x1.

With this configuration, Counter 1 counts every write made to the EMIF from master 0x44 to any address space. This does not include accesses from other masters and does not include commands other than writes.

15.3.4.15.1.2 PERF_COUNTER_2 General Example for Counting Total Access

The Performance Counter 2 register must count total accesses to SDRAM regardless of the masters or address space.

- To enable counting all SDRAM accesses, the EMIF_PERFORMANCE_COUNTER_CONFIG[19:16] CNTR2_CONFIG bit field must be set to 0x0.
- To disable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[31] CNTR2_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[30] CNTR2_REGION_EN bits must be set to 0x0.

With this configuration, Counter 2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.

15.3.4.15.1.3 PERF_COUNTER_3 General Example for Counting all Read Accesses

The Performance Counter 1 register must count all read accesses from the IPU subsystem to address space 0x0.

- To enable counting reads, the EMIF_PERFORMANCE_COUNTER_CONFIG[3:0] CNTR1_CONFIG bit field must be set to 0x2.
- The EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[15:8] MCONNID1 and EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT[1:0] REGION_SEL1 bit fields must be set to 0x44 and 0x0, respectively.
- To enable filtering, the EMIF_PERFORMANCE_COUNTER_CONFIG[15] CNTR1_MCONNID_EN and EMIF_PERFORMANCE_COUNTER_CONFIG[14] CNTR1_REGION_EN bits must be set to 0x1.

With this configuration, Counter 1 counts every read made to the EMIF from master 0x44 to address space 0x0. This does not include accesses from other masters or accesses to other address space and does not include commands other than reads.

15.3.5 EMIF Programming Guide

15.3.5.1 EMIF Low-Level Programming Models

This section describers the low-level hardware programming sequences for the configuration and use of the EMIF module.

The following programming sequences are doubled, when the two EMIF modules (EMIF1 and EMIF2) are used.

15.3.5.1.1 Global Initialization

Table 15-124. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Section 3.1.1, *Power, Reset, and Clock Management*.
Interrupt submodule of the MPU	The interrupt requests from the EMIF must be enabled (unmasked). See Section 17.1, *Interrupt Controllers*.
DMM	The EMIF is a slave to the DMM. The DMM must be enabled and configured for communication with LPDDR2 memories. See Section 15.2.1, *Dynamic Memory Manager*.

15.3.5.1.1.1 EMIF Module Global Initialization

This procedure initializes the EMIF after a power-on reset. The unused bits in all registers should be written with zeros. The values of the shadow registers are loaded in their corresponding registers a frequency update sequence is performed.

Table 15-125. EMIF Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Assign the external bank address bits from lower or higher L3 address as shown in Section 15.3.4.12, *SDRAM Address Mapping*.	EMIF_SDRAM_CONFIG_2[27] EBANK_POS	0x-
Select the SDRAM type (LPDDR2 S2 or S4, or DDR3)	EMIF_SDRAM_CONFIG[31:29] SDRAM_TYPE	0x-
Assign internal bank address bits from L3 address as shown in Section 15.3.4.12, *SDRAM Address Mapping*.	EMIF_SDRAM_CONFIG[28:27] IBANK_POS	0x-
Choose 32-bit SDRAM data bus.	EMIF_SDRAM_CONFIG[15:14] NARROW_MODE	0x0
Define CAS latency when accessing connected SDRAM devices.	EMIF_SDRAM_CONFIG[13:10] CL	0x-
Define the number of row address bits of connected SDRAM device.	EMIF_SDRAM_CONFIG[9:7] ROWSIZE	0x-
Define the number of banks inside connected SDRAM device.	EMIF_SDRAM_CONFIG[6:4] IBANK	0x-
Define whether SDRAM accesses use 1 or 2 chip-select lines.	EMIF_SDRAM_CONFIG[3] EBANK	0x-
Define the internal page size of connected SDRAM device.	EMIF_SDRAM_CONFIG[2:0] PAGESIZE	0x-
Configure the DDR PHY-specific settings. Refer to register descriptions of EMIF_DDR_PHY_CONTROL_1, and EMIF_EXT_PHY_CONTROL_1 through EMIF_EXT_PHY_CONTROL_24	EMIF_DDR_PHY_CONTROL_1, and EMIF_EXT_PHY_CONTROL_1 through EMIF_EXT_PHY_CONTROL_24	0x-
Initialize MR LPDDR2 registers	External LPDDR2 initialization, seeTable 15-128	
Define timings and clock parameters	EMIF Timing Initialization, see Table 15-126	

Table 15-125. EMIF Global Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Configure the SDRAM Output Impedance Calibration parameters	EMIF Output Impedance Calibration Mode, see Table 15-129	
Configure the Temperature Alert parameters	EMIF Temperature Monitoring Mode, see Table 15-138	
(Optional) Configure the Performance Counter Config Register	EMIF_PERFORMANCE_COUNTER_CONFIG	0x-
(Optional) Configure the Performance Counter Master Region Select Register	EMIF_PERFORMANCE_COUNTER_MASTER_REGION_SELECT	0x-
Configure the System, MPU and LL max number of transactions in the command FIFO	EMIF_OCP_CONFIG	0x-
Clear all eventual previous indications of treated interrupts.	EMIF_SYSTEM_OCP_INTERRUPT_STATUS, EMIF_LOW_LATENCY_OCP_INTERRUPT_STATUS	0x-
(Optional) Enable System L3 interrupt for Command or Address Error.	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[0] EN_ERR_SYS	0x1
DDR3-specific settings		
DDR3 write latency (WL)	EMIF_SDRAM_CONFIG[17:16] CWL	0x-
SDRAM drive strength	EMIF_SDRAM_CONFIG[19:18] SDRAM_DRIVE	0x-
Disable(=1)/enable DLL inside SDRAM	EMIF_SDRAM_CONFIG[20] DDR_DISABLE_DLL	0x-
DDR3 termination resistor value	EMIF_SDRAM_CONFIG[26:24] DDR_TERM	0x-
Partial array self refresh	EMIF_SDRAM_REFRESH_CONTROL[26:24] PASR	0x-
DDR3 auto self refresh enable(=1)/disable	EMIF_SDRAM_REFRESH_CONTROL[28] ASR	0x-
When the EMIF_SDRAM_REFRESH_CONTROL[28] ASR field is set to 0, set to 0 for normal operating temperature range and set to 1 for extended operating temperature range. Set to 0 if ASR field is set to 1.	EMIF_SDRAM_REFRESH_CONTROL[29] SRT	0x-

Table 15-126. Sub-process call summary for Main Sequence - EMIF Global Initialization

Sub-process Name	Crossreference
EMIF Timing Initialization	Table 15-127

EMIF Temperature Monitoring Mode	Table 15-138
External LPDDR2 initialization	Table 15-128

15.3.5.1.1.2 Subsequence - EMIF Timing Initialization

Table 15-127. Subsequence - EMIF Timing Initialization

Step	Register/ Bit Field / Programming Model	Value
Determine the the required wait time after a phy_dll_calib is generated before another command can be sent	EMIF_DLL_CALIB_CTRL[19:16] ACK_WAIT	0x-
Determine the interval between phy_dll_calib generation	EMIF_DLL_CALIB_CTRL[8:0] DLL_CALIB_INTERVAL	0x-
Write the Shadow register of the EMIF_DLL_CALIB_CTRL with the same value.	EMIF_DLL_CALIB_CTRL_SHADOW	EMIF_DLL_CALIB_CTRL

Table 15-127. Subsequence - EMIF Timing Initialization (continued)

Step	Register/ Bit Field / Programming Model	Value
Define the minimum number of DDR clock cycles from Precharge to Activate or Refresh, minus one.	EMIF_SDRAM_TIMING_1[28:25] T_RP	0x-
Define minimum number of DDR clock cycles from Activate to Read or Write, minus one.	EMIF_SDRAM_TIMING_1[24:21] T_RCD	0x-
Define minimum number of DDR clock cycles from last Write transfer to Precharge, minus one.	EMIF_SDRAM_TIMING_1[20:17] T_WR	0x-
Define minimum number of DDR clock cycles from Activate to Precharge, minus one.	EMIF_SDRAM_TIMING_1[16:12] T_RAS	0x-
Define Minimum number of DDR clock cycles from Activate to Activate, minus one.	EMIF_SDRAM_TIMING_1[11:6] T_RC	0x-
Define Minimum number of DDR clock cycles from Activate to Activate for a different bank, minus one.	EMIF_SDRAM_TIMING_1[5:3] T_RRD	0x-
Define Minimum number of DDR clock cycles from last Write to Read, minus one.	EMIF_SDRAM_TIMING_1[2:0] T_WTR	0x-
Write the Shadow register of the EMIF_SDRAM_TIMING_1 (1).	EMIF_SDRAM_TIMING_1_SHADOW (1)	0x-
Define minimum number of DDR clock cycles from Powerdown exit to any command other than a Read, minus one.	EMIF_SDRAM_TIMING_2[30:28] T_XP	0x-
Define minimum number of DDR clock cycles from Self-Refresh exit to any command other than a Read command, minus one.	EMIF_SDRAM_TIMING_2[24:16] T_XSNR	0x-
Define minimum number of DDR clock cycles from Self-Refresh exit to a Read command, minus one.	EMIF_SDRAM_TIMING_2[15:6] T_XSRD	0x-
Define minimum number of DDR clock cycles for the last read command to a Precharge command, minus one.	EMIF_SDRAM_TIMING_2[5:3] T_RTP	0x-
Write the Shadow register of the EMIF_SDRAM_TIMING_2 (2).	EMIF_SDRAM_TIMING_2_SHADOW (2)	0x-
Define minimum number of DDR clock cycles for which LPDDR2 must remain in Self Refresh, minus one.	EMIF_SDRAM_TIMING_3[23:21] T_CKESR	0x-
Define number of DDR clock cycles for a ZQCS command duration, minus one.	EMIF_SDRAM_TIMING_3[20:15] ZQ_ZQCS	0x-
Define number of DDR clock that satisfies tDQSCKmax for LPDDR2, minus one.	EMIF_SDRAM_TIMING_3[14:13] T_TDQSCKMAX	0x-
Define minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one.	EMIF_SDRAM_TIMING_3[12:4] T_RFC	0x-
Define maximum number of EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE intervals from Activate to Precharge command.	EMIF_SDRAM_TIMING_3[3:0] T_RAS_MAX	0x-
Write the Shadow register of the EMIF_SDRAM_TIMING_3 (2).	EMIF_SDRAM_TIMING_3_SHADOW (2)	0x-
Define the rate at which the connected SDRAM devices are refreshed.	EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE	0x-
Write the Shadow register of the EMIF_SDRAM_REFRESH_CONTROL with the same value.	EMIF_SDRAM_REFRESH_CONTROL_SHADOW	EMIF_SDRAM_REFRESH_CONTROL

(1) Values loaded in these registers depend on OPP.
(2) Values loaded in these registers depend on OPP.

15.3.5.1.1.3 Subsequence - External LPDDR2 Initialization

Table 15-128. Subsequence - External LPDDR2 Initialization

Step	LPDDR2 mode registers (MR)	Value
Wait until MR0[0]=0 (MR0[0] = 0 indicates that memory auto – initialization is completed).	MR0[0]	=0
Issue ZQINIT calibration command.	MR10	0xFF
Configure BT, BL, WC.	MR1	0x-
Configure the memory latency settings (RL and WL).	MR2 (1)	0x-
Unmask memory banks.	MR16	0x-
Unmask memory segments.	MR17	0x-

(1) Memory latency settings (RL and WL) depend on OPP.

15.3.5.1.2 Operational Modes Configuration

15.3.5.1.2.1 EMIF Output Impedance Calibration Mode

Table 15-129. EMIF Output Impedance Calibration Mode

Step	Register/ Bit Field / Programming Model	Value
IF : Calibration per CS		
Determine on which chip select 1 or 0 the calibration is enabled.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[31:30] ZQ_CS1/0EN	0x-
ELSE : (Calibration on both the CS0 and CS1)		
Enable automatic output impedance calibration for both the chip selects simultaneously.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[29] ZQ_DUALCALEN	0x1
ENDIF		
Define the interval (number of refresh periods) between ZQCS commands.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[15:0] ZQ_REFINTERVAL	0x-
Define the number of ZQCL durations that build the ZQINIT duration.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[19:18] ZQ_ZQINIT_MULT	0x-
Define the number of ZQCS intervals that build the ZQCL duration.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[17:16] ZQ_ZQCL_MULT	0x-
Enable the issuing of ZQ-Long Command on Self-Refresh exit.	EMIF_SDRAM_OUTPUT_IMPEDANCE_CALIBRATION_CONFIG[28] ZQ_SFEXITEN	0x1

15.3.5.1.2.2 EMIF MR Read

Table 15-130. EMIF MR Read

Step	Register/ Bit Field / Programming Model	Value
Choose chip-select 0 or 1 to issue mode register read command	EMIF_LPDDR2_MODE_REG_CONFIG[31] CS	0x-
Write the mode register (MR) address	EMIF_LPDDR2_MODE_REG_CONFIG[7:0] ADDRESS	0x-
Initiate Read command by reading the register	EMIF_LPDDR2_MODE_REG_DATA[7:0]	0x-

15.3.5.1.2.3 EMIF MR Write

Table 15-131. EMIF MR Write

Step	Register/ Bit Field / Programming Model	Value
Choose chip-select 0 or 1 to issue mode register write command	EMIF_LPDDR2_MODE_REG_CONFIG[31] CS	0x-
Write the mode register (MR) address	EMIF_LPDDR2_MODE_REG_CONFIG[7:0] ADDRESS	0x-
Supply the Data Byte to be written and initiate Write command by writing the register	EMIF_LPDDR2_MODE_REG_DATA[7:0] VALUE_0	0x-

15.3.5.1.2.4 EMIF SDRAM Self-Refresh

Table 15-132. EMIF SDRAM Self-Refresh Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Self Refresh mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[7:4] SR_TIM	0x-
Enable the Self-Refresh mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x2
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 15-133. EMIF SDRAM Self-Refresh Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x2 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

15.3.5.1.2.5 EMIF LPDDR2 Power-Down Mode

Table 15-134. EMIF SDRAM Power-Down Mode Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power Down mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[15:12] PD_TIM	0x-
Enable (enter) the Power-down mode	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x4
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 15-135. EMIF SDRAM Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Change LP_MODE bitfield from 0x4 to any value.	EMIF_POWER_MANAGEMENT_CONTROL[10:8] LP_MODE	0x-
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

15.3.5.1.2.6 EMIF LPDDR2-SDRAM Deep Power-Down Mode

Table 15-136. EMIF LPDDR2-SDRAM Deep Power-Down Mode Entering

Step	Register/ Bit Field / Programming Model	Value
Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power saving mode, when EMIF is idle.	EMIF_POWER_MANAGEMENT_CONTROL[3:0] CS_TIM	0x-
Enable (enter) the Deep Power-Down mode	EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN	0x1
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

Table 15-137. EMIF LPDDR2-SDRAM Deep Power-Down Mode Exiting

Step	Register/ Bit Field / Programming Model	Value
Clear DPD_EN bit.	EMIF_POWER_MANAGEMENT_CONTROL[11] DPD_EN	0
Write the shadow register of EMIF_POWER_MANAGEMENT_CONTROL	EMIF_POWER_MANAGEMENT_CONTROL_SHADOW	0x-

NOTE: After Deep Power-Down exit, software must perform initialization as specified in Table 15-128.

15.3.5.1.2.7 LPDDR2 Temperature Monitoring Mode

Table 15-138. LPDDR2 Temperature Monitoring Mode

Step	Register/ Bit Field / Programming Model	Value
Determine which chip-select 1 or 0 is used for Temperature Alert Polling	EMIF_TEMPERATURE_ALERT_CONFIG[31] TA_CS1EN EMIF_TEMPERATURE_ALERT_CONFIG[30] TA_CS0EN	0x-
Define the interval (number of refresh periods) between temperature alert polls.	EMIF_TEMPERATURE_ALERT_CONFIG[21:0] TA_REFINTERVAL	0x-
Define the width of the physical memory device	EMIF_TEMPERATURE_ALERT_CONFIG[27:26] TA_DEVWDT	0x-
Define which external byte lanes contain a device for temperature monitoring (which devices to be polled).	EMIF_TEMPERATURE_ALERT_CONFIG[25:24] TA_DEVCNT	0x-
(Optional) Enable the issuing of a temperature alert poll on Self-Refresh exit (poll for temperature change every time EMIF exits Self-Refresh, Active Power-Down, and Precharge Power-Down modes).	EMIF_TEMPERATURE_ALERT_CONFIG[28] TA_SFEXITEN	0x1
Enable System L3 interrupt for SDRAM temperature alert.	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_SET[1] EN_TA_SYS	0x1

15.3.5.1.3 EMIF Events Servicing

15.3.5.1.3.1 Interrupt Servicing

This section covers the event servicing (interrupt treatment) of the EMIF module.

Please, have in mind that the following Interrupt mechanism is double as there are two EMIF modules with different register addresses and 2 Interrupt lines - EMIF1_IRQ and EMIF2_IRQ.

Table 15-139. EMIF Event Servicing

Step	Register/ Bit Field / Programming Model	Value
Read the status registers:	EMIF_SYSTEM_OCP_INTERRUPT_STATUS	
IF :	EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0]	=1
Read the Error Log register and determine the Addressing mode, Command type and the Connection ID of the first errored transaction.	EMIF_OCP_ERROR_LOG	
Clear corresponding status flag	EMIF_SYSTEM_OCP_INTERRUPT_STATUS[0] ERR_SYS	0x1
ELSE IF :	EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1]	=1
Update the REFRESH_RATE to the required value as per the temperature change.	EMIF_SDRAM_REFRESH_CONTROL[15:0] REFRESH_RATE	0x-
Clear corresponding status flag	EMIF_SYSTEM_OCP_INTERRUPT_STATUS[1] TA_SYS	0x1
ENDIF		
Disable interrupts if needed	EMIF_SYSTEM_OCP_INTERRUPT_ENABLE_CLEAR[0] EN_ERR_SYS	0x1

15.3.6 EMIF Register Manual

Table 15-140 lists the EMIF instance.

15.3.6.1 EMIF Instance Summary

Table 15-140. EMIF Instance Summary

Module Name	Base Address	Size
EMIF1	0x4C00 0000	16 MiB
EMIF2	0x4D00 0000	16 MiB

15.3.6.2 EMIF Registers

Many register values are programmed with full-speed DDR clock cycles, whereas EMIF always runs at half the speed of this clock. Because EMIF is only capable of decrementing these values at half speed (taking into account the minus 1 programming model) the following model applies for data issued on a lower bus:

- REG_VALUE = 0 → 2 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 4 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 6 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 8 DDR clocks
- REG_VALUE = 7 → 8 DDR clocks

Activate and deactivate commands use the upper bus. Register values associated with these operations follow the general rule:

- REG_VALUE = 0 → 1 DDR clocks
- REG_VALUE = 1 → 2 DDR clocks
- REG_VALUE = 2 → 2 DDR clocks
- REG_VALUE = 3 → 4 DDR clocks
- REG_VALUE = 4 → 4 DDR clocks
- REG_VALUE = 5 → 6 DDR clocks
- REG_VALUE = 6 → 6 DDR clocks

NOTE: Shadow registers are loaded on any frequency change or SidleReq/SidleAck transition at the point where the EMIF has put SDRAM into self-refresh mode.

CAUTION

All EMIF registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Table 15-141 summarizes the EMIF register mapping.

15.3.6.2.1 EMIF Register Summary

Table 15-141. EMIF Registers Mapping Summary

REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	Module revision	R	0x- [1]

[1] TI internal data

Table 15-143. Register Call Summary for Register EMIF_REVISION

EMIF Controller

- Arbitration of Commands in the Command FIFO: [0] [1]
- EMIF Register Summary: [2]

Table 15-144. EMIF_STATUS

Address Offset	0x0000 0004		
Physical Address	0x4C00 0004 0x4D00 0004	**Instance**	EMIF1 EMIF2
Description	SDRAM Status Register (STATUS)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BE	DUAL_CLK_MODE	FAST_INIT	RESERVED																						RDLVLGATETO	RDLVLTO	WRLVLTO	RESERVED	PHY_DLL_READY	RESERVED	

Bits	Field Name	Description	Type	Reset
31	BE	Big endian mode select for 8 and 16-bit devices, set to 1 for big endian or 0 for little endian operation. In current implementation, only 32-bit devices are supported - this bit is don't care.	R	0
30	DUAL_CLK_MODE	Dual Clock mode. Defines whether the EMIFi_L3_ICLK and EMIF_COREi clock are asynchronous. EMIFi_L3_ICLK and EMIF_COREi clock are asynchronous, if set to 1.	R	0
29	FAST_INIT	Fast Init. Defines whether the EMIF fast initialization mode has been enabled. Fast initialization is enabled if set to 1.	R	0
28:7	RESERVED	Reserved	R	0x00 0000
6	RDLVLGATETO	Read DQS Gate Training Timeout. Value of 1 indicates read DQS gate training has timed out because read DQS gate training done was not received from the PHY.	R	0
5	RDLVLTO	Read Data Eye Training Timeout. Value of 1 indicates read data eye training has timed out because read data eye training done was not received from the PHY.	R	0

Bits	Field Name	Description	Type	Reset
4	WRLVLTO	Write Leveling Timeout. Value of 1 indicates write leveling has timed out because write leveling done was not received from the PHY.	R	0
3	RESERVED		R	0
2	PHY_DLL_READY	DDR PHY Ready. The DDR PHY is ready for normal operation, if set to 1.	R	0
1:0	RESERVED	Reserved	R	0x0

Table 15-145. Register Call Summary for Register EMIF_STATUS

EMIF Controller

- EMIF Register Summary: [0]

Table 15-146. EMIF_SDRAM_CONFIG

Address Offset	0x0000 0008		
Physical Address	0x4C00 0008 0x4D00 0008	**Instance**	EMIF1 EMIF2
Description	SDRAM Config Register. A write to this register will cause the EMIF to start the SDRAM initialization sequence. For LPDDR2, initialization is only re-started if it was not performed previously because EMIF_SDRAM_REFRESH_CONTROL[31] INITREF_DIS was a zero. **CAUTION:** This register is loaded with values by control module at device reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDRAM_TYPE			IBANK_POS		DDR_TERM			DDR2_DDQS	DYN_ODT		DDR_DISABLE_DLL	SDRAM_DRIVE		CWL		NARROW_MODE	CL		ROWSIZE		IBANK		EBANK	PAGESIZE						

Bits	Field Name	Description	Type	Reset
31:29	SDRAM_TYPE	SDRAM Type selection. This field is loaded from e-fuse. Set to 3 for DDR3 Set to 4 for LPDDR2 All other values are reserved.	RW	0x0
28:27	IBANK_POS	Internal bank position. See section Section 15.3.4.12, *SDRAM Address Mapping*.	RW	0x0
26:24	DDR_TERM	DDR3 termination resistor value. Set to 0 to disable termination. For DDR3, set to 1 for RZQ/4, set to 2 for RZQ/2, set to 3 for RZQ/6, set to 4 for RZQ/12, and set to 5 for RZQ/8. All other values are reserved.	RW	0x0
23	DDR2_DDQS	DDR2 differential DDQS enable. NOT SUPPORTED. Set to 1 for compatibility.	RW	0
22:21	DYN_ODT	DDR3 Dynamic ODT. NOT SUPPORTED. Set to 0 to turn off dynamic ODT.	RW	0x0
20	DDR_DISABLE_DLL	Disable DLL select. Set to 1 to disable DLL inside SDRAM.	RW	0
19:18	SDRAM_DRIVE	SDRAM drive strength.For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. All other values are reserved.	RW	0x0

Bits	Field Name	Description	Type	Reset
17:16	CWL	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.	RW	0x0
15:14	NARROW_MODE	SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved. In the current implementation, only 32-bit devices are supported. Two DDR3 devices are used in parallel to make one 32-bit device.	RW	0x0
13:10	CL	CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Values of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. Values of 2, 4, 6, 8, 10, 12, and 14 (CAS latency of 5, 6, 7, 8, 9, 10, and 11) are supported for DDR3. All other values are reserved. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard. Also program the EMIF_DDR_PHY_CONTROL_1[4:0] READ_LATENCY	RW	0x0
9:7	ROWSIZE	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG[28:27] IBANK_POS field is set to 1, 2, or 3 or EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1.	RW	0x0
6:4	IBANK	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved.	RW	0x0
3	EBANK	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use NCS0 only. Set to 1 to use NCS[1:0]. This bit will automatically be set to 0 if EMIF_SDRAM_CONFIG_2[30] CS1NVMEN field is set to 1.	RW	0
2:0	PAGESIZE	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved.	RW	0x0

Table 15-150. EMIF_SDRAM_REFRESH_CONTROL

Address Offset	0x0000 0010		
Physical Address	0x4C00 0010 0x4D00 0010	**Instance**	EMIF1 EMIF2
Description	SDRAM Refresh Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITREF_DIS	RESERVED	SRT	ASR	RESERVED	PASR			RESERVED								REFRESH_RATE															

Bits	Field Name	Description	Type	Reset
31	INITREF_DIS	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.	RW	0
30	RESERVED		R	0
29	SRT	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the ASR field is set to 0. This bit must be set to 0 if the ASR field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
28	ASR	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the SRT field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0
27	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
26:24	PASR	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of DDR3 during initialization. For DDR3, set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.	RW	0x0
23:16	RESERVED		R	0x00
15:0	REFRESH_RATE	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = REFRESH_RATE / EMIFi_PHY_FICLK. A 533-MHz DDR clock rate system that requires a 7.8 µs refresh rate would need 7.8 × 533 = 4157 or 0x103D value to be written. To avoid lock-up situations, the programmer must not program REFRESH_RATE < (6 × EMIF_SDRAM_TIMING_3[12:4] T_RFC).	RW	0x0000

Address Offset	0x0000 0028		
Physical Address	0x4C00 0028 0x4D00 0028	**Instance**	EMIF1 EMIF2
Description	SDRAM Timing 3 Register. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.		
Type	RW		

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14	13 12 11 10 9 8	7 6 5 4	3 2 1 0
T_PDLL_UL	T_CSTA	T_CKESR	ZQ_ZQCS	T_TDQSCKMAX	T_RFC		T_RAS_MAX

Bits	Field Name	Description	Type	Reset
31:28	T_PDLL_UL	Minimum number of DDR clock cycles for PHY DLL to unlock. A value of N will be equal to N x 128 clocks.	RW	0x0
27:24	T_CSTA	Minimum number of DDR clock cycles between write-to-write or read-to-read data phases to different chip selects, minus one.	RW	0x0
23:21	T_CKESR	Minimum number of DDR clock cycles for which SDRAM must remain in Self Refresh, minus one.	RW	0x0
20:15	ZQ_ZQCS	Number of DDR clock cycles for a ZQCS command, minus one.	RW	0x00
14:13	T_TDQSCKMAX	Number of DDR clock that satisfies tDQSCKmax for LPDDR2, minus one.	RW	0x0
12:4	T_RFC	Minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one.	RW	0x000
3:0	T_RAS_MAX	Maximum number of REFRESH_RATE intervals from Activate to Precharge command. This field must be equal to ((tRASmax / tREFI)-1) rounded down to the next lower integer. Value for T_RAS_MAX can be calculated as follows: If tRASmax = 120 us and tREFI = 15.7 us, then T_RAS_MAX = ((120/15.7)-1) = 6.64. Round down to the next lower integer. Therefore, the programmed value must be 6.	RW	0x0

Address Offset	0x0000 0098		
Physical Address	0x4C00 0098 0x4D00 0098	**Instance**	EMIF1 EMIF2
Description	Control register to force idle window time to generate a phy_dll_calib that can be used for updating PHY DLLs during voltage ramps. NOTE: Should always be loaded via the shadow register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												ACK_WAIT				RESERVED								DLL_CALIB_INTERVAL							

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	ACK_WAIT	The ack_wait determines the required wait time after a phy_dll_calib is generated before another command can be sent. Value program is in terms of EMIF_COREi cycle count. **CAUTION:** 5 must be the minimum value ever programmed.	RW	0x9
15:9	RESERVED		R	0x00
8:0	DLL_CALIB_INTERVAL	This field determines the interval between phy_dll_calib generation. This value is multiplied by a precounter of 16 EMIF_COREi cycles. Program this field one less the value you are targeting; program 1 to achieve interval of 2 (minimum interval supported). Programming zero turns off function. Note the final intervals between dll_calib generation is also a function of ACK_WAIT. Final periodic interval is calculated by: ((DLL_CALIB_INTERVAL + 1) × 16) + ACK_WAIT	RW	0x000

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	ACK_WAIT_SHDW	Shadow field for ACK_WAIT. This field is loaded into ACK_WAIT field in EMIF_DLL_CALIB_CTRL register when SIdleAck is asserted	RW	0x9
15:9	RESERVED		R	0x00
8:0	DLL_CALIB_INTERVAL_SHDW	Shadow field for DLL_CALIB_INTERVAL. This field is loaded into DLL_CALIB_INTERVAL field in the EMIF_DLL_CALIB_CTRL register when SIdleAck is asserted	RW	0x000

Table 15-195. Register Call Summary for Register EMIF_DLL_CALIB_CTRL_SHADOW

EMIF Controller

- Subsequence - EMIF Timing Initialization: [0]
- EMIF Register Summary: [1]

Table 15-196. EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS

Address Offset	0x0000 00A4		
Physical Address	0x4C00 00A4 0x4D00 00A4	**Instance**	EMIF1 EMIF2
Description	System OCP Interrupt Raw Status Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													DNV_SYS	TA_SYS	ERR_SYS

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Reserved for future use.	R	0x0000 0000
2	DNV_SYS	Raw status of system OCP interrupt for LPDDR2 NVM data not valid. Write 1 to set the (raw) status, typically for debug. Writing 0 has no effect.	RW	0
1	TA_SYS	Raw status of system OCP interrupt for SDRAM temperature alert. Write 1 to set the (raw) status, mostly for debug. Writing a 0 has no effect.	RW	0
0	ERR_SYS	Raw status of system OCP interrupt for command or address error. Write 1 to set the (raw) status, mostly for debug. Writing a 0 has no effect.	RW	0

Table 15-197. Register Call Summary for Register EMIF_SYSTEM_OCP_INTERRUPT_RAW_STATUS

EMIF Controller

- Interrupt Requests: [0] [2] [3]
- EMIF Register Summary: [4]

Table 15-198. EMIF_LOW_LATENCY_OCP_INTERRUPT_RAW_STATUS

Address Offset	0x0000 00A8		
Physical Address	0x4C00 00A8 0x4D00 00A8	**Instance**	EMIF1 EMIF2
Description	Low-Latency OCP Interrupt Raw Status Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																													DNV_LL	TA_LL	ERR_LL

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Reserved for future use.	R	0x0000 0000
2	DNV_LL	Raw status of low-latency OCP interrupt for LPDDR2 NVM data not valid. Write 1 to set the (raw) status, typically for debug. Writing 0 has no effect.	RW	0
1	TA_LL	Raw status of low-latency OCP interrupt or SDRAM temperature alert. Write 1 to set the (raw) status, mostly for debug. Writing a 0 has no effect.	RW	0
0	ERR_LL	Raw status of low-latency OCP interrupt for command or address error. Write 1 to set the (raw) status, mostly for debug. Writing a 0 has no effect.	RW	0
