Table 15-224. EMIF_DDR_PHY_CONTROL_1

Address Offset	0x0000 00E4		
Physical Address	0x4C00 00E4 0x4D00 00E4	**Instance**	EMIF1 EMIF2
Description	PHY control register 1		
Type	RW		

31 30 29 28	27	26	25	24	23 22	21	20	19	18	17 16	15 14 13 12 11 10	9	8	7 6 5 4	3 2 1 0
RESERVED	RDLVL_MASK	RDLVLGATE_MASK	WRLVL_MASK	RESERVED		PHY_HALF_DELAYS	PHY_CLK_STALL_LEVEL	PHY_DIS_CALIB_RST	PHY_INVERT_CLKOUT	PHY_DLL_LOCK_DIFF		PHY_FAST_DLL_LOCK	RESERVED		READ_LATENCY

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	RW	0x0
27	RDLVL_MASK	Writing a 1 to this field will mask read data eye training during full leveling command, plus drives reg_phy_use_rd_data_eye_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
26	RDLVLGATE_MASK	Writing a 1 to this field will mask dqs gate training during full leveling command, plus drives reg_phy_use_rd_dqs_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
25	WRLVL_MASK	Writing a 1 to this field will mask write leveling training during full leveling command, plus drives reg_phy_use_wr_level control low to allow user to use programmed ratio values. Incremental training needs to be disabled using incremental training registers.	RW	0
24:22	RESERVED	Reserved	RW	0x0
21	PHY_HALF_DELAYS	Adjust slave delay line delays to support 2× mode 1: 2× mode (MDLL clock is half the rate of PHY) - OPP_NOM 0: 1× mode (MDLL clock rate is same as PHY) - OPP_BOOT	RW	0
20	PHY_CLK_STALL_LEVEL	Enable variable idle value for delay lines. Enable during normal operations to avoid differential aging in the delay lines.	RW	0
19	PHY_DIS_CALIB_RST	Disable the dll_calib (internally generated) signal from resetting the Read Capture FIFO pointers and portions of data PHYs. Debug only. Note: dll_calib is generated by 1. EMIF_MISC_REG[0] DLL_CALIB_OS set to 1,or 2. by the PHY when it detects that the clock frequency variation has exceeded the bounds set by PHY_DLL_LOCK_DIFF or 3. periodically throughout the leveling process.	RW	0
18	PHY_INVERT_CLKOUT	Inverts the polarity of DRAM clock. This bit must be set to 0 when in LDDDR2 mode. 0: core clock is passed on to DRAM 1: inverted core clock is passed on to DRAM	RW	0
17:10	PHY_DLL_LOCK_DIFF	The maximum number of delay line taps variation while maintaining the master DLL lock. When the PHY is in locked state and the variation on the clock exceeds the variation indicated by this field, the lock signal is de-asserted and a dll_calib signal is generated. To prevent the dll_calib signal from being asserted in the middle of traffic when the clock jitter exceeds the variation, this register needs to be set to a value which will ensure that the lock will not be lost. Recommended value is 16.	RW	0x02

Bits	Field Name	Description	Type	Reset
9	PHY_FAST_DLL_LOCK	Controls master DLL to lock fast or average logic must be part of locking process. Set to 1 before OPP transition commences, and set back to 0 after OPP transition completes. 1: MDLL lock is asserted based on single sample 0: MDLL lock is asserted based on average of 16 samples.	RW	0
8:5	RESERVED	Reserved	RW	0x00
4:0	READ_LATENCY	This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. This field is used by the EMIF as well as the PHY. READ_LATENCY = RL + reg_phy_rdc_we_to_re -1. EMIF uses above equation to calculate reg_phy_rdc_we_to_re and forward it to the PHY. For DDR3, the true RL is used, not the decoded value. See JEDEC spec. The write latency (WL) is tied to the RL for the LPDDR2. See the LPDDR2 SDRAM standard.	RW	0x01E

Table 15-228. EMIF_READ_WRITE_EXECUTION_THRESHOLD

Address Offset	0x0000 0120		
Physical Address	0x4C00 0120 0x4D00 0120	**Instance**	EMIF1 EMIF2
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MFLAG_OVERRIDE	LL_BUBBLE_ENABLE	RESERVED														WR_THRSH								RESERVED			RD_THRSH				

Bits	Field Name	Description	Type	Reset
31	MFLAG_OVERRIDE	Mflag override. When set to 1, forces Mflag internally to be zero (compatibility mode). **NOTE**: MFLAG_OVERRIDE must be considered a static control.	RW	0
30	LL_BUBBLE_ENABLE	LL bubble enable. When set to 1, enables LL bubble function. Allows one access (one beat of burst), for any bank that is open. This gives performance improvement and avoids bank thrashing (in other words, have gone thru activation stage and should allow one access, even if higher priority LL port command comes thru)	RW	0
29:13	RESERVED	Reserved	R	0x0000
12:8	WR_THRSH	Write Threshold. Number of SDRAM write bursts after which the EMIF arbitration will switch to executing read commands. The value programmed is always minus one the required number	RW	0x03
7:5	RESERVED	Reserved	R	0x0
4:0	RD_THRSH	Read threshold. Number of SDRAM read bursts after which the EMIF arbitration will switch to executing write commands. The value that is programmed is always minus one the required number	R	0x05

Description			
Type	RW		

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	RW	0x0000 0000
1	PHY_GATELVL_INIT_MODE	The user programmable init ratio selection mode. This bit must be 1 when in LPDDR2 mode. 1: selects a starting ratio value based on PHY_GATELVL_INIT_RATIO fields. 0: selects a starting ratio value based on Write Leveling of the same data PHY. This mode is only supported when write leveling has been run before gate leveling.	RW	1

Bits	Field Name	Description	Type	Reset
0	PHY_USE_RANK0_DELAYS	Delay selection. Must be set to 1 for LPDDR2, not recommended in DDR3 mode. 1: Rank 0 delays are used for both ranks during read/write. 0: Each Rank uses its own delay.	RW	0

15.4 General-Purpose Memory Controller

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmultiplexed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

The GPMC is also introduced in Section 15.1, *Memory Subsystem Overview*.

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- Figure 15-51 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol uses fewer address pins) external memory device.
- Figure 15-52 shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- Figure 15-53 shows a connection between the GPMC and a 8-bit NAND device.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0]/gpmc_ad[7:0] data bus (rather than D[15:8]/gpmc_ad[15:8]) of the GPMC controller. This limits the use of 8-bit-wide device interfacing to byte-alias access.

Figure 15-51. GPMC to 16-Bit Address/Data-Multiplexed Memory

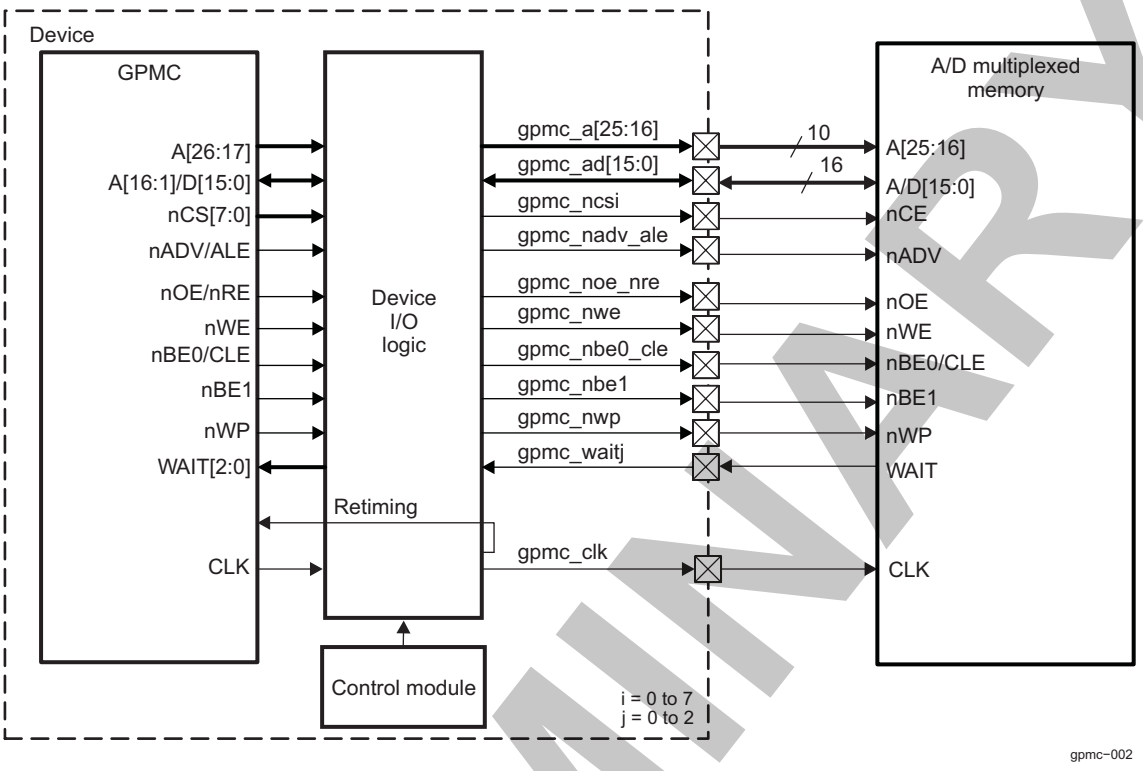

Figure 15-52. GPMC to 16-Bit Nonmultiplexed Memory

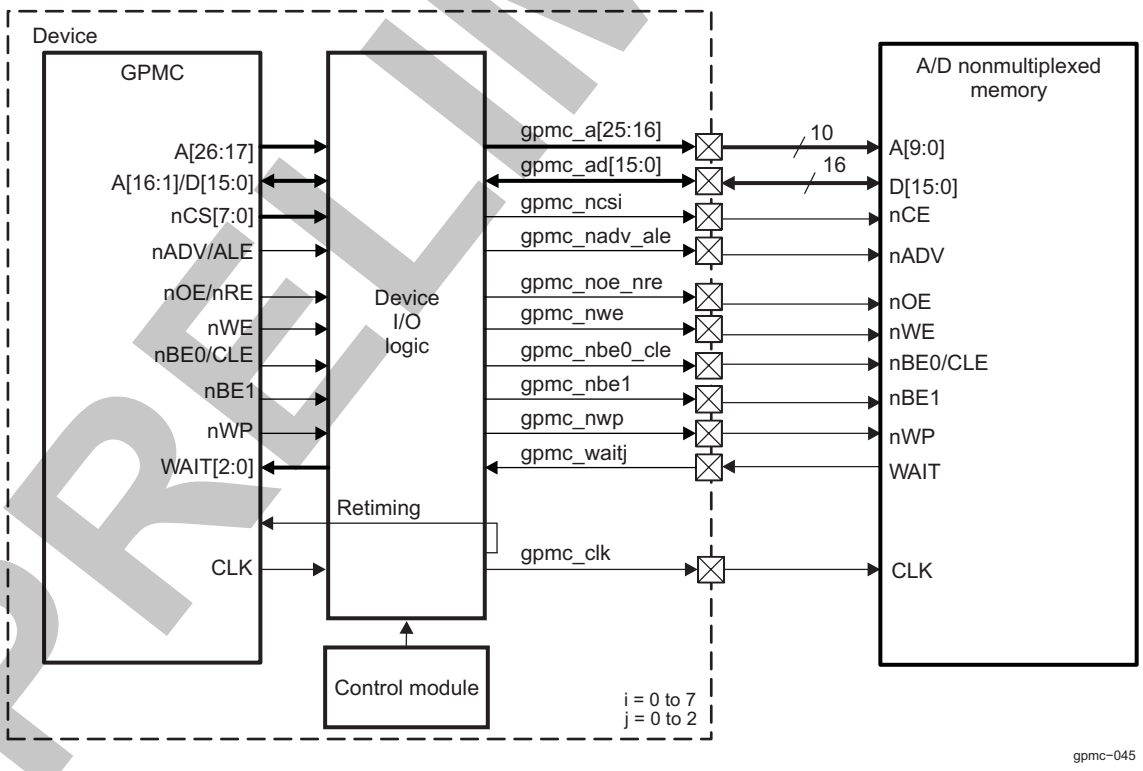

Figure 15-53. GPMC to 8-Bit NAND Device

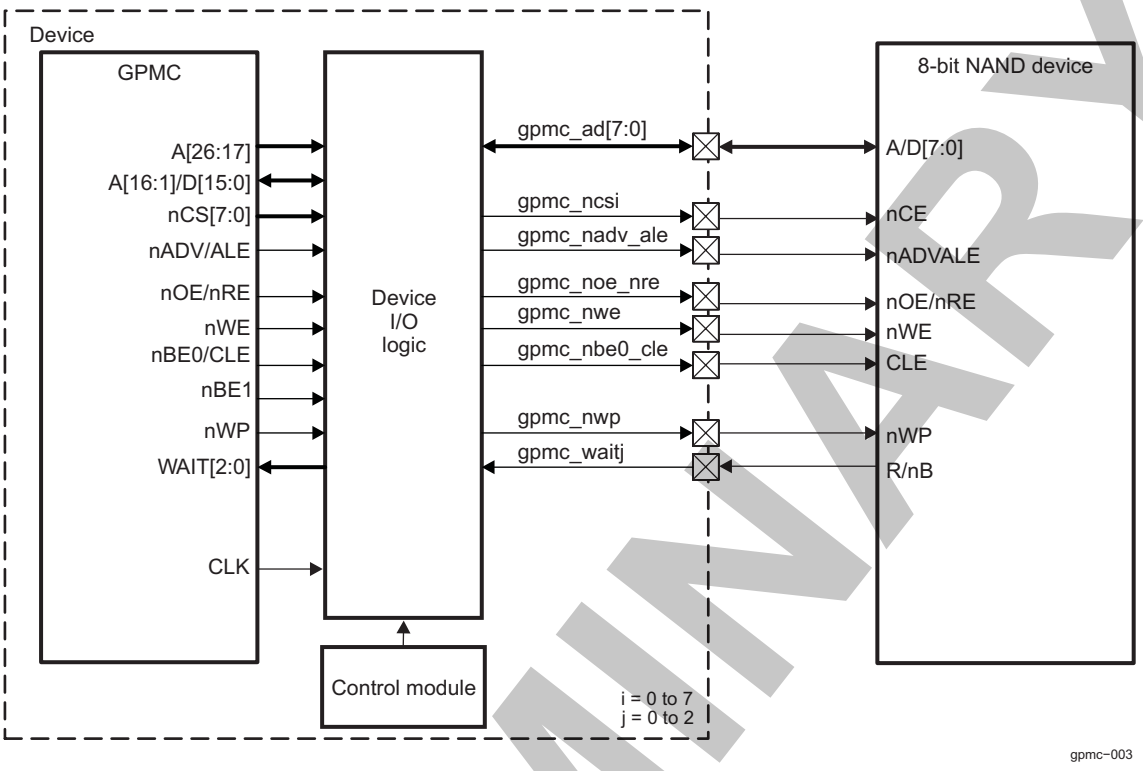

15.4.2.2 GPMC Signals

Table 15-332 lists the GPMC subsystem input/output (I/O) pins.

Table 15-332. GPMC I/O Description

Pin Name	Device Signal	I/O[1]	Description
A[26:17]	gpmc_a[25:16]	O	Address
A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[7:0]	gpmc_ncs[7:0]	O	Chip-selects (active low)
CLK	gpmc_clk	O[2]	Clock generated for the external memory or device
nADV/ALE	gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_nwe	O	Write enable (active low)
nBE0/CLE	gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_nbe1	O	Upper-byte enable (active low).
nWP	gpmc_nwp	O	Write protect (active low)
WAIT[2:0]	gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select.

(1) I = Input; O = Output

(2) This output signal is also used as retiming input. During synchronous operation, the INPUTENABLE bit of the CONTROL_CORE_PAD0_GPMC_NWP_PAD1_GPMC_CLK register must be set to 1.

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

Table 15-333 shows the use of address and data GPMC controller pins based on the type of external device.

Table 15-333. GPMC Pin Multiplexing Options

GPMC Pin	Multiplexed Address Data 16-Bit Device	Nonmultiplexed Address Data 16-Bit Device With LIMITED-ADDRESS Bit Enabled	16-Bit NAND Device	8-Bit NAND Device
gpmc_a[25]	A26	A10	Not used	Not used
gpmc_a[24]	A25	A9	Not used	Not used
gpmc_a[23]	A24	A8	Not used	Not used
gpmc_a[22]	A23	A7	Not used	Not used
gpmc_a[21]	A22	A6	Not used	Not used
gpmc_a[20]	A21	A5	Not used	Not used
gpmc_a[19]	A20	A4	Not used	Not used
gpmc_a[18]	A19	A3	Not used	Not used
gpmc_a[17]	A18	A2	Not used	Not used
gpmc_a[16]	A17	A1	Not used	Not used
gpmc_ad[15]	A16/D15	D15	D15	Not used
gpmc_ad[14]	A15/D14	D14	D14	Not used
gpmc_ad[13]	A14/D13	D13	D13	Not used
gpmc_ad[12]	A13/D12	D12	D12	Not used
gpmc_ad[11]	A12/D11	D11	D11	Not used
gpmc_ad[10]	A11/D10	D10	D10	Not used
gpmc_ad[9]	A10/D9	D9	D9	Not used
gpmc_ad[8]	A9/D8	D8	D8	Not used
gpmc_ad[7]	A8/D7	D7	D7	D7
gpmc_ad[6]	A7/D6	D6	D6	D6
gpmc_ad[5]	A6/D5	D5	D5	D5
gpmc_ad[4]	A5/D4	D4	D4	D4
gpmc_ad[3]	A4/D3	D3	D3	D3
gpmc_ad[2]	A3/D2	D2	D2	D2
gpmc_ad[1]	A2/D1	D1	D1	D1
gpmc_ad[0]	A1/D0	D0	D0	D0

When using nonmultiplexed memories, it is recommended to enable the GPMC_CONFIG[1] LIMITEDADDRESS bit. This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2 KiB of memory address space is accessible, regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit-wide devices:

- The NOR flash memory controller still supports nonmultiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

NOTE: The numbering for A (address) starts from 1 instead of 0, such as D (data), because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is relevant only to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible; that is, each 16-bit-aligned 8-bit word is mapped, but not the non-16-bit aligned ones. Any access to a nonaligned word results in accessing the associated aligned word, at address A1 instead of address A.

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the microprocessor unit (MPU) interrupt controller (INTC) and to the DSP subsystem
- One clock for functional and interface domains

Figure 15-54 shows GPMC integration.

Figure 15-54. GPMC Integration

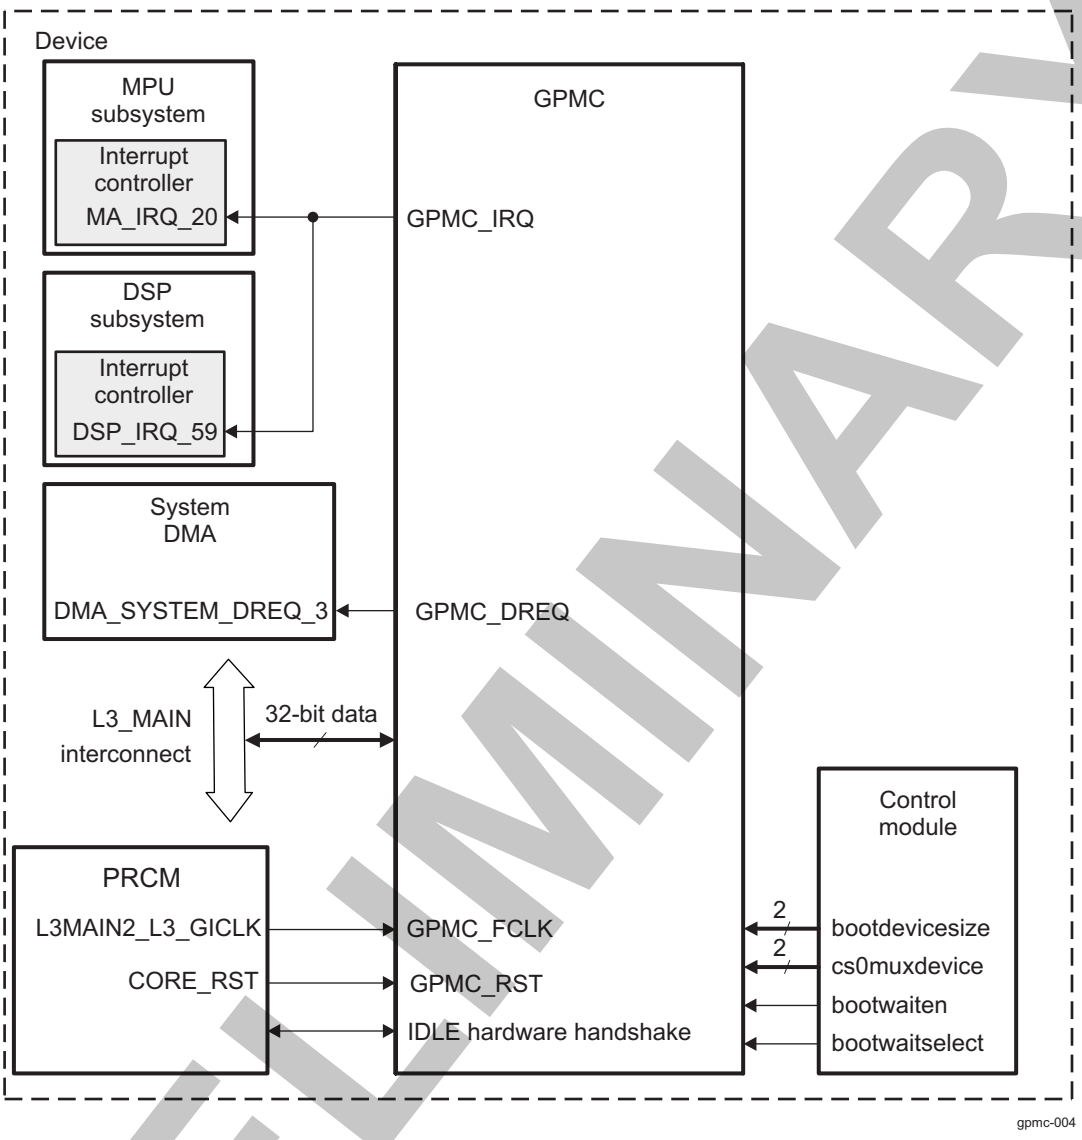

Table 15-334 through Table 15-336 summarize the integration of the module in the device.

Table 15-334. GPMC Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
GPMC	PD_CORE	No	L3_MAIN

NOTE:

- For the description of the operation performance point (OPP) configuration, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 15-335. GPMC Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_FCLK	L3MAIN2_L3_GICLK	PRCM	Functional clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPMC	GPMC_RST	CORE_RET_RST	PRCM	GPMC reset

NOTE: For the clock description, see Section 15.4.4.2, *GPMC Clock Configuration*.

Table 15-336. GPMC Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
GPMC	GPMC_IRQ	DSP_IRQ_59	DSP	GPMC interrupt to DSP subsystem
	GPMC_IRQ	MPU_IRQ_20	MPU	GPMC interrupt to MPU subsystem
DMA Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
GPMC	GPMC_DREQ	DMA_SYSTEM_DREQ_3	sDMA	GPMC request from prefetch engine to sDMA

NOTE:

- For the description of the interrupt source, see Section 15.4.4.5, *GPMC Interrupt Requests*.
- For the description of the DMA source, see Section 15.4.4.6, *GPMC DMA Requests*.

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait-state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

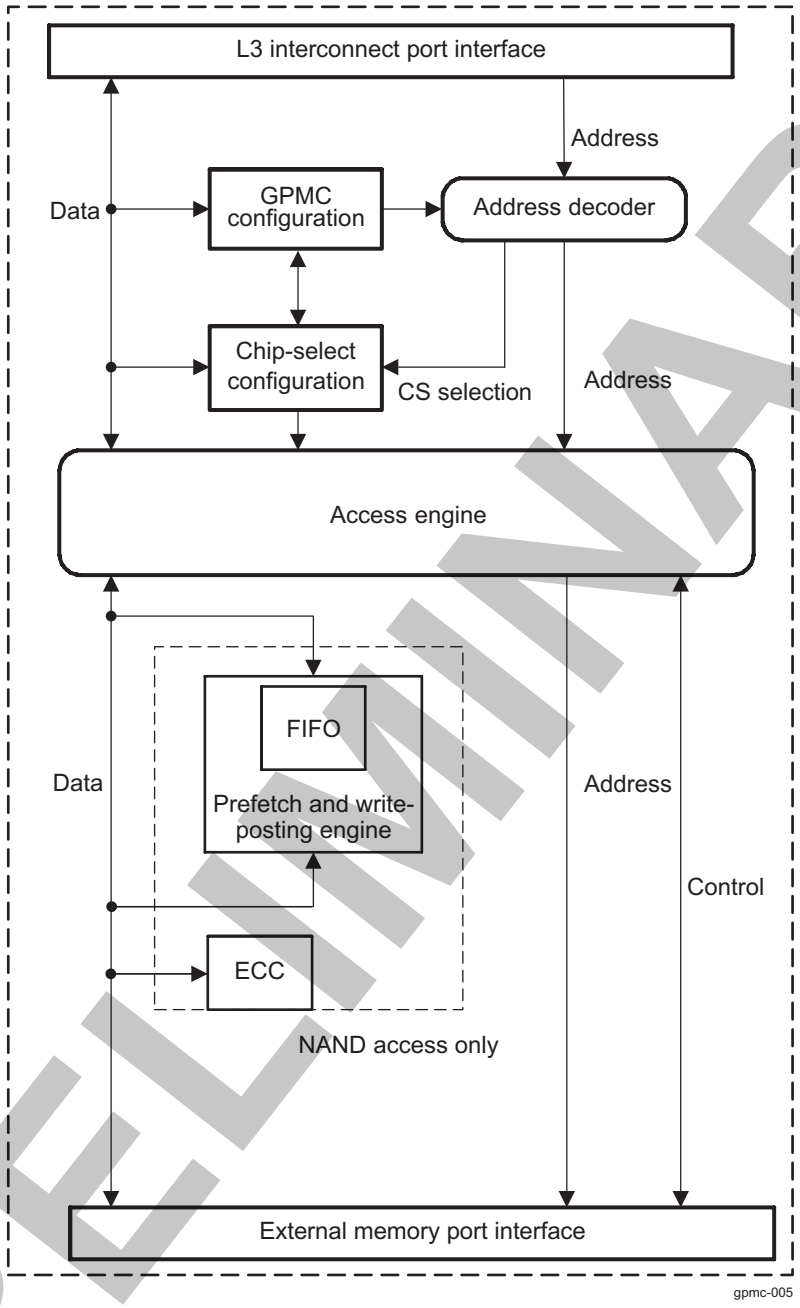
- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

Figure 15-55 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 15-55. GPMC Block Diagram



The GPMC can access various external devices through the L3_MAIN Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC can generate the timing of all control signals depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate control signal timing for the device type.

15.4.4.2 GPMC Clock Configuration

Table 15-337 describes the GPMC clocks.

Table 15-337. GPMC Clocks

Signal	I/O[1]	Description
GPMC_FCLK	I	Functional and interface clock
gpmc_clk	O	External clock provided to synchronous external memory devices

(1) I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in Table 15-335. The gpmc_clk is configured using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), as shown in Table 15-338.

Table 15-338. gpmc_clk Configuration

Source Clock	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	gpmc_clk Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the GPMC_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. Software must ensure that the software reset completes before performing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

Table 15-339 describes the power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.
- For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Section 3.1.1, *Power, Reset, and Clock Management*.

Table 15-339. GPMC Local Power-Management Features

Feature	Registers	Description
Clock autogating	GPMC_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave idle modes	GPMC_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle and smart-idle wake-up modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt request (see Figure 15-54).

Table 15-340 lists the event flags, and their mask, that can cause module interrupts.

Table 15-340. GPMC Interrupt Events

Event Flag	Event Mask	Sensitivity	Description
GPMC_IRQSTATUS[10] WAIT2EDGE DETECTIONSTATUS	GPMC_IRQENABLE[10] WAIT2EDGE DETECTIONENABLE	Edge	Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through the GPMC_CONFIG[10] WAIT2PINPOLARITY bit.
GPMC_IRQSTATUS[9] WAIT1EDGE DETECTIONSTATUS	GPMC_IRQENABLE[9] WAIT1EDGE DETECTIONENABLE	Edge	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through the GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTATUS[8] WAIT0EDGE DETECTIONSTATUS	GPMC_IRQENABLE[8] WAIT0EDGE DETECTIONENABLE	Edge	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through the GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTATUS[1] TERMINAL COUNTSTATUS	GPMC_IRQENABLE[1] TERMINAL COUNTENABLE	Level	Terminal count event: Triggered on prefetch process completion; that is, when the number of currently remaining data to be requested reaches 0
GPMC_IRQSTATUS[0] FIFOEVENTSTATUS	GPMC_IRQENABLE[0] FIFOEVENTENABLE	Level	FIFO event interrupt: Indicates available FIFO levels for write-posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1[2] DMAMODE must be set to 0.

15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event (see Figure 15-54).

15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including a 16 × 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-, 16-, or 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32, and 16 × 32, with the burst base address aligned on the total burst size, are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line for specific event control.

It is recommended to program the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field according to the page length of the effective attached device and to enable the GPMC_CONFIG1_i[31] WRAPBURST bit if the attached device supports wrapping burst.

It is possible, however, to emulate wrapping burst on a nonwrapping memory by providing relevant addresses within the page or by splitting transactions. Bursts larger than the memory page length are chopped into multiple burst transactions. Because of the alignment requirements, a page boundary is never crossed.

15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2KiB.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, A26–A11 are not modified during an external memory access. This limits the memory address space to 2KiB, regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit-wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit-wide NAND devices do not use GPMC I/O: gpmc_a[25:16].
- 8-bit-wide NAND devices do not use GPMC I/O: gpmc_a[25:16] and GPMC I/O: gpmc_ad[15:8].

CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

15.4.4.8.1 GPMC I/O Configuration Setting

NOTE: In this section and the following sections, the i in GPMC_CONFIGx_i stands for the GPMC chip-select i, where i = 0 to 7.

To select a NAND device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b10
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00

To select an address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b01

To select an address/data-nonmultiplexed device (limited to a 2-KiB address range), program the following register fields:

- GPMC_CONFIG1_i[11:10] DEVICETYPE = 0b00
- GPMC_CONFIG1_i[9:8] MUXADDDATA = 0b00
- GPMC_CONFIG[1] LIMITEDADDRESS = 1

NOTE: The GPMC_CONFIG[1] LIMITEDADDRESS bit applies only to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

15.4.4.8.2 GPMC CS0 Default Configuration at Device Reset

To ensure a correct, fast external boot (see Section 28.3.6, *Fast External Booting*, in Section 28.1, *Initialization*) with a GPMC access on device reset, several pins are sampled:

- The sys_boot[3:0] pins (device boundary) define the sequence of interfaces and devices to use for booting. They are sampled by the control module at reset and used later by the device ROM code. For more information, see Section 28.2.4, *Boot Configuration*, in Section 28.1, *Initialization,* .
- Additional pins are used to configure reset values in the GPMC_CONFIG1_i register (where i = 0) as explained in the following and in Table 15-341:
  - The *bootdevicesize* input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 (CS0) and is used to configure the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0). The BOOT_DEVICE_TYPE signal is propagated from the device control module. Its value is fixed for the device at 0x1 at device reset, which means that only 16-bit memories are supported for booting.
  - The *cs0muxdevice* input pin (at the GPMC boundary) selects whether or not the device attached to CS0 is an address/data-multiplexed device. The input pin is used to configure the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0). The CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed for the device at 0x2 at device reset, which means only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
  - The *bootwaiten* input pin (at the GPMC boundary) enables the monitoring on CS0 of the wait pin at device reset release time for read accesses. The input pin is used to configure the GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where i = 0). The BOOT_WAIT_ENABLE signal is propagated from the system control module (SCM). When sys_boot[5:0] = 0b11 1111, the BOOT_WAIT_ENABLE signal is activated, which causes the wait pin to be monitored for read accesses.
  - The *bootwaitselect* input pin selects the WAIT signal at device reset release time between the WAIT0, WAIT1, and WAIT2 input pins. At device reset release time, these three pins have different polarity.

Table 15-341. Boot Control Interface Input Signals Description

Signal Name	Width	Description
bootdevicesize	2	Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved
cs0muxdevice	2	Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/data-multiplexed device on CS0 0b11: Reserved
bootwaiten	1	Wait monitoring on CS0 at device reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored
bootwaitselect	1	Selection of the wait pin 0: WAIT0 input pin 1: WAIT1 input pin 2: WAIT2 input pin

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. For more information, see Section 28.3.7, *Memory Booting*, and Section 28.3.8 , *Image Format*, in Section 28.1, *Initialization*. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2-KiB address range device attached to CS0

At reset time, the device can boot from the internal ROM.

The reset values of the timing control parameters are defined to cope with direct boot on address and data-multiplexed NOR flash devices, nonmultiplexed NOR flash devices, or any asynchronous device with large timing margins, assuming a low GPMC_FCLK frequency (for example, 19.2 MHz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0], while the high-order bits are presented onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edges. The first rising edge latches the address most-significant bit (MSB) down to bit 17, while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file must be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). Section 15.4.7,*GPMC Register Manual*, provides the GPMC register locations. For the map of GPMC memory locations, see Section 2.2 , *Memory Mapping*.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

15.4.4.9.1 Chip-Select Base Address and Region Size

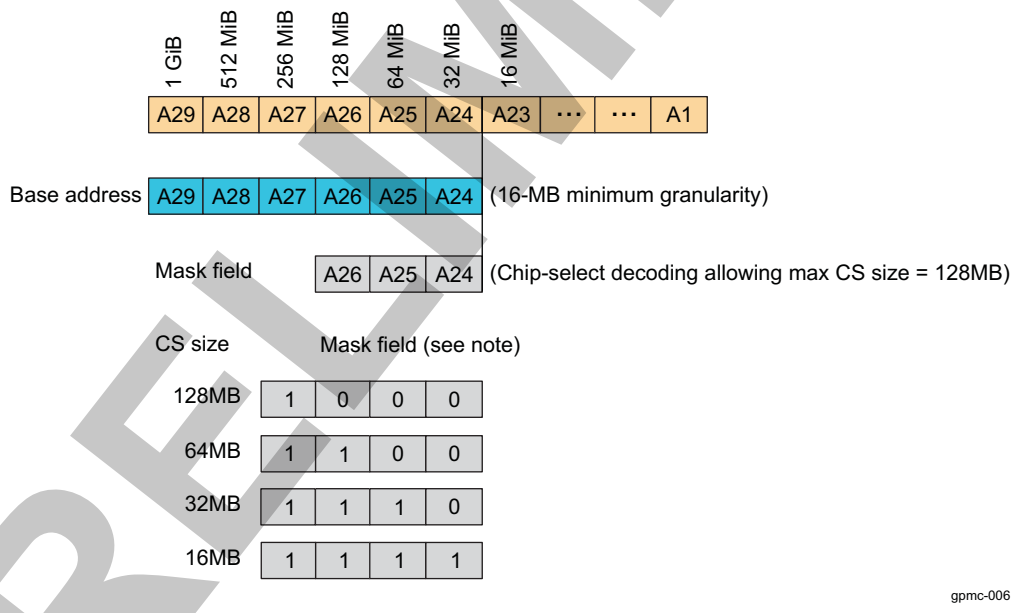
Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-MiB contiguous address space. For more information, see Section 2.2, *Memory Mapping*.

The GPMC 512-MiB address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable chip-select size. The chip-select size is programmable from 16MiB to 128MiB (must be a power-of-two) and is defined by the mask field. Attached memory smaller than the programmed chip-select region size is accessed through the entire chip-select region (aliasing).

Each chip-select has a 6-bit base address encoding and 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-two address value. During access decoding, the value of the register base address is used to compare the address with the address bit line mapping, as shown in Figure 15-56 (with A0 as the device system byte-address line). The base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The value of the register mask must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 15-56. Chip-Select Address Mapping and Decoding Mask



Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC_CONFIG7_i[6] CSVALID bit (where i stands for the GPMC chip-select value, 0 to 7). In addition, a chip-select configuration can be disabled only if there is no ongoing access to that chip-select. This requires monitoring the activity of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of overlapping chip-selects, an error is generated and no access occurs on either chip-select.

CS0 is the only chip-select region enabled after a power up or GPMC reset.

CAUTION

Although the GPMC interface can drive up to four chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers to allow the slowest device to maintain the total load on the lines.

15.4.4.9.2 Access Protocol

15.4.4.9.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory, such as NOR flash and SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see Section 15.4.4.13, *NAND Device Basic Programming Model*, and Section 15.4.4.13.1, *NAND Memory Device in Byte or Word16 Stream Mode*.

15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC_CONFIG1_i[13:12] DEVICESIZE bit field (where i = 0 to 7) to interface with a 16- or 8-bit-wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit-wide device interfacing (for multiplexed and nonmultiplexed protocols). It limits the use of 8-bit-wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8- or 16-bit-wide devices).

15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC_CONFIG1_i[9:8] MUXADDDATA bit field (where i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See Section 15.4.3, *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data-multiplexing protocol. See Section 15.4.4.13, *NAND Device Basic Programming Model*.

15.4.4.9.3 External Signals

15.4.4.9.3.1 Wait Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled using only the GPMC internal RDACCESSTIME, WRACCESSTIME, and PAGEBURSTACCESSTIME wait-state generator.

The GPMC features three input wait pins: gpmc_wait2, gpmc_wait1, and gpmc_wait0. These pins allow control of external devices with different wait pin polarity. They also allow the overlap of wait pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC_CONFIG1_i[17:16] WAITPINSELECT bit field (where i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When a wait pin is inactive, data is valid.

The GPMC access engine can be configured per chip-select to monitor or not the wait pin of the external memory device, based on the access type: read or write.

- The GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether or not the wait pin must be monitored during read accesses.
- The GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether or not the wait pin must be monitored during write accesses.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC_CONFIG1_i[29] READTYPE and GPMC_CONFIG1_i[27] WRITETYPE bits).

15.4.4.9.3.1.1 Wait Monitoring During Asynchronous Read Access

When wait pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a wait invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait monitoring pipelining is also applicable to multiple accesses (access within a page).

- Wait monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

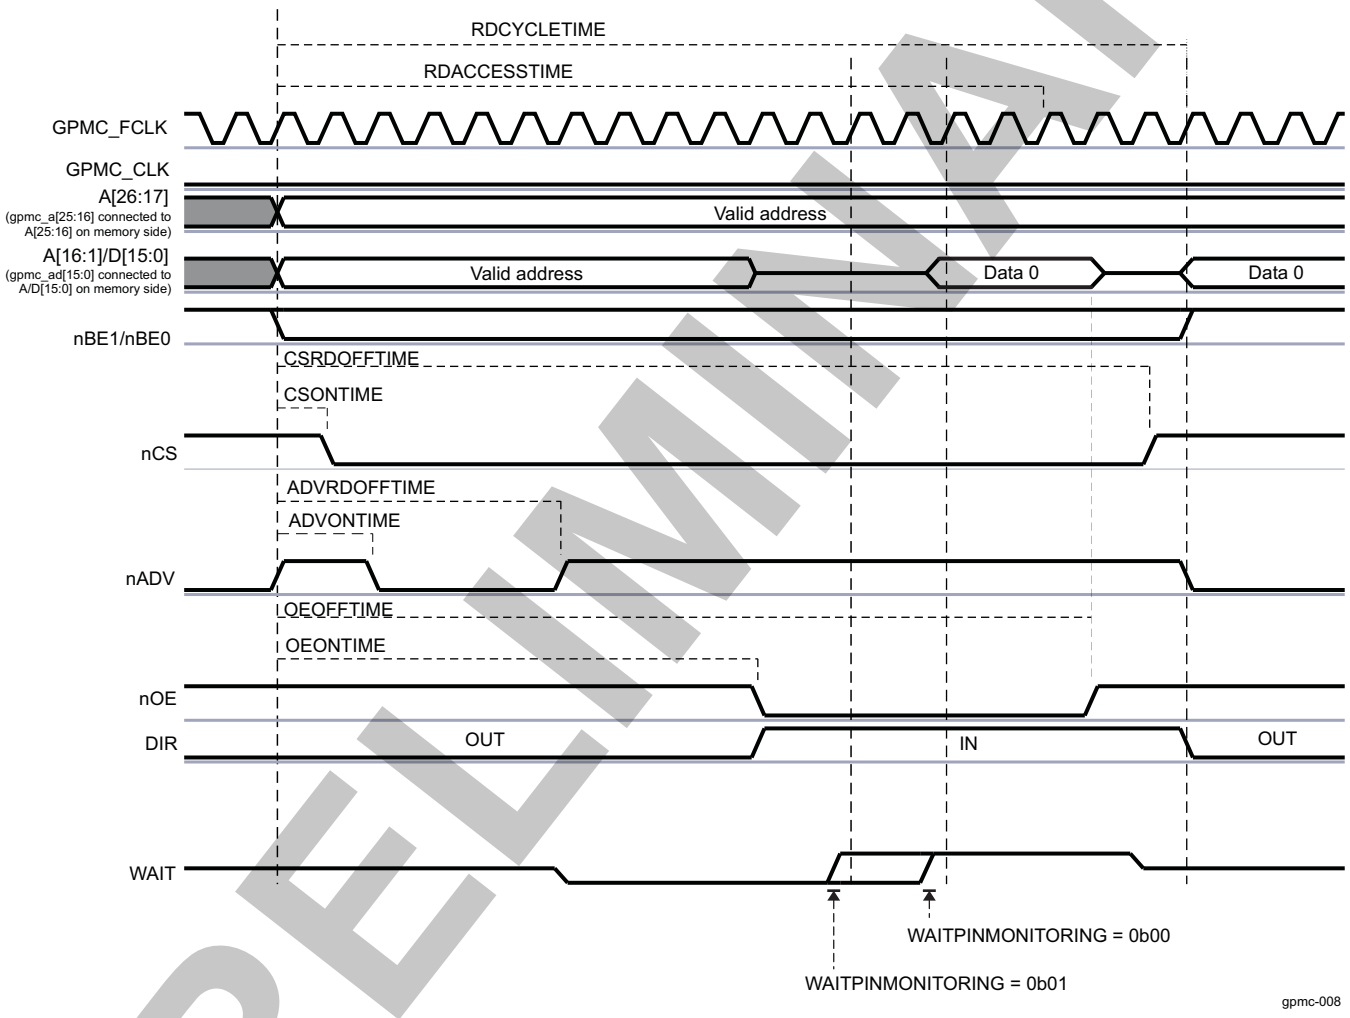
When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, because GPMCFCLKDIVIDER is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-57 shows wait behavior during an asynchronous single read access.

Figure 15-57. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)



NOTE: The WAIT signal is active low. GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.

15.4.4.9.3.1.2 Wait Monitoring During Asynchronous Write Access

When wait pin monitoring is enabled for write accesses (GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the wait invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- Wait monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is

not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.

- Wait monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, because the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is used as a divider for the GPMC clock, it must be programmed to define the correct WAITMONITORINGTIME delay.

15.4.4.9.3.1.3 Wait Monitoring During Synchronous Read Access

During synchronous accesses with wait pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle in which it is captured. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle to which it applies. This pipelining is applicable to the entire burst access and to all data phases in the burst access. This wait pipelining depth is programmed in the GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME bit field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait pin monitoring is enabled (the GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state detection.

Depending on the programmed value of WAITMONITORINGTIME, the wait pin must be at a valid level, either asserted or deasserted:

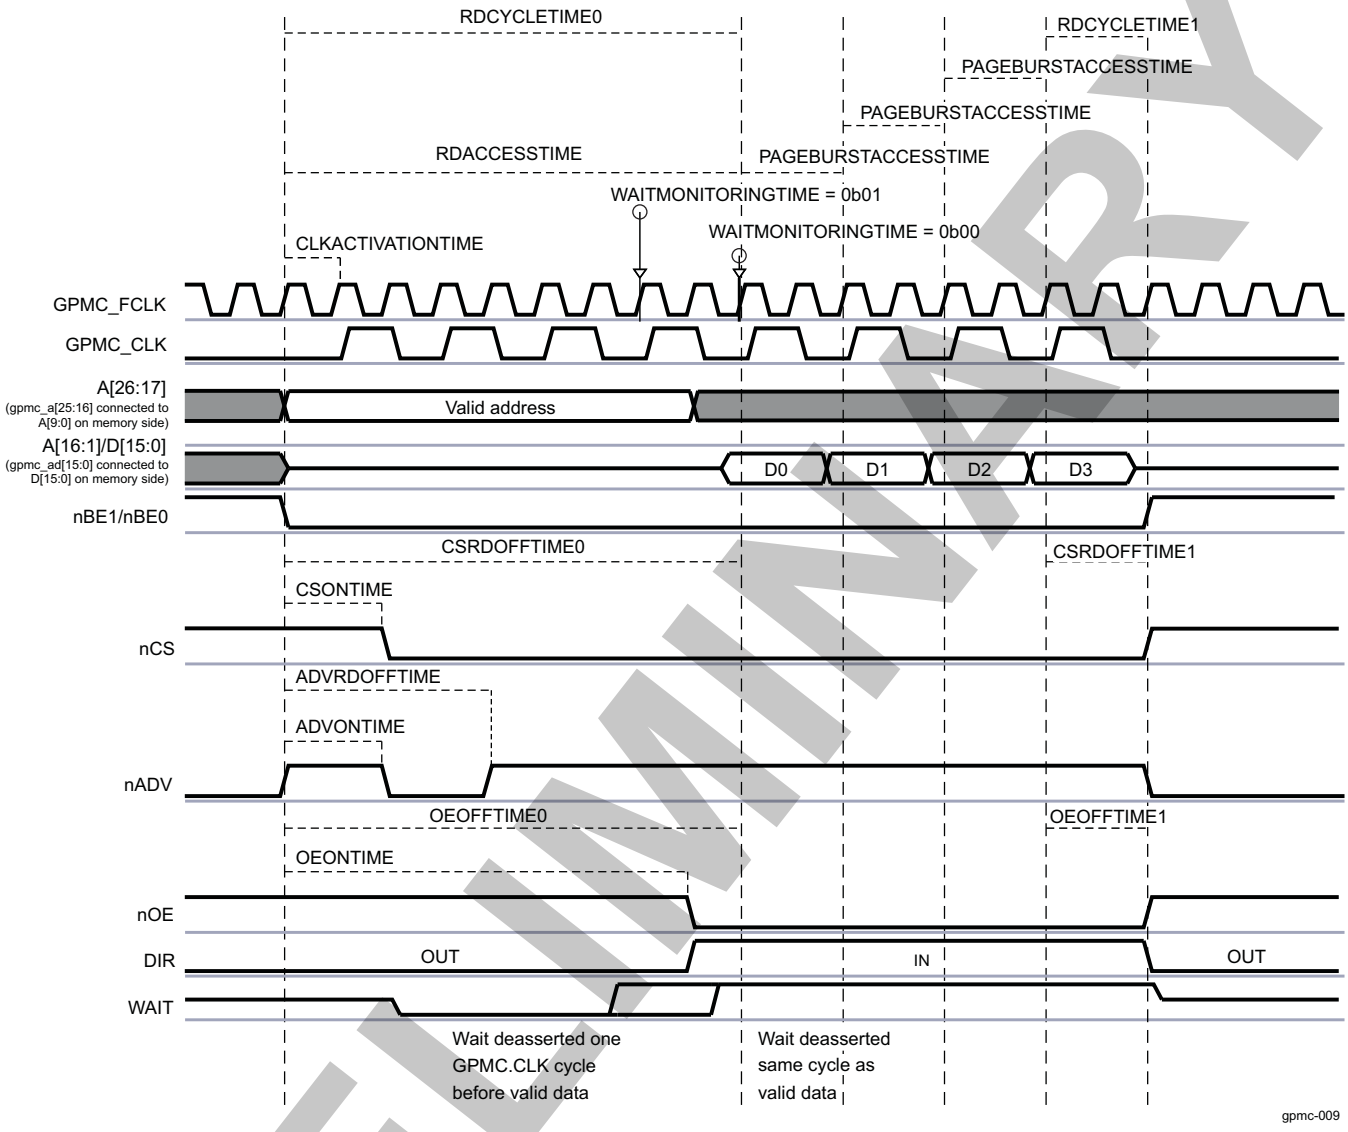
- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the WAIT-INACTIVE state. The wait pipelining-depth programming applies to the whole burst access.

- Wait monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), wait monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- Wait monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), wait monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 15-58 shows wait behavior during a synchronous read burst access.

Figure 15-58. Wait Behavior During a Synchronous Read Burst Access



NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.9.3.1.4 Wait Monitoring During Synchronous Write Access

During synchronous accesses with wait pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait pin monitoring can be used in combination with WRACCESSTIME to delay the GPMC_CLK capture edge of the effective memory device.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME is not equal to 0

Wait-monitoring pipelining definition applies to whole burst accesses:

- Wait monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- Wait monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, wait monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x0 (where i = 0 to 7) for write bursts with a clock divider of 1 or 2 (the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field is equal to 0x0 or 0x1, respectively).

15.4.4.9.3.1.5 Wait With NAND Device

For information about the use of the wait pin for communication with a NAND flash external device, see Section 15.4.4.13.2, *NAND Device-Ready Pin*.

15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE deassertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE deassertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where i = 0 to 7).

After a read access to a chip-select with a nonzero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (the same or different chip-select from which the data was read)
- A read access to a different chip-select than the chip-select from which the data was read access
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus does not have enough time to go into high-impedance even though it can be driven with the same value before bus turnaround timing.

BUSTURNAROUND delay runs in parallel with GPMC_CONFIG6_i[3:0] CYCLE2CYCLEDELAY bi field delays. BUSTURNAROUND is a timing parameter for the ending chip-select access, while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access (see Figure 15-59 through Figure 15-61).

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but it also affects all accesses of this specific chip-select.

Figure 15-59. Read-to-Read for an Address-Data Multiplexed Device, on Different Chip-Select, Without Bus Turnaround (nCS Attached to a Fast Device)

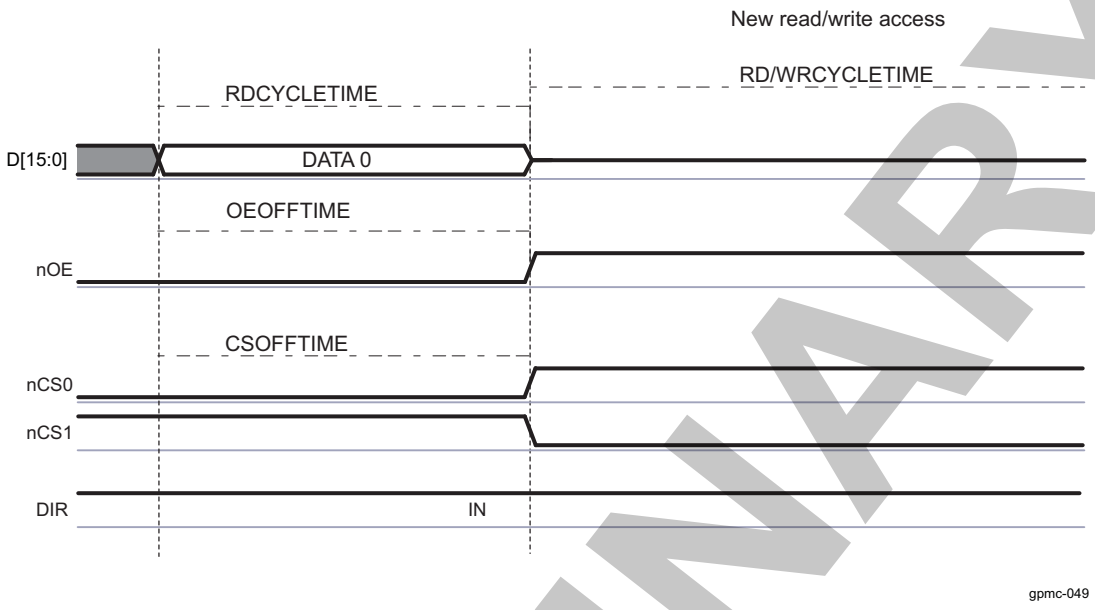


Figure 15-60. Read- to-Read/Write for an Address-Data Multiplexed Device, on Different Chip-Select, With Bus Turnaround

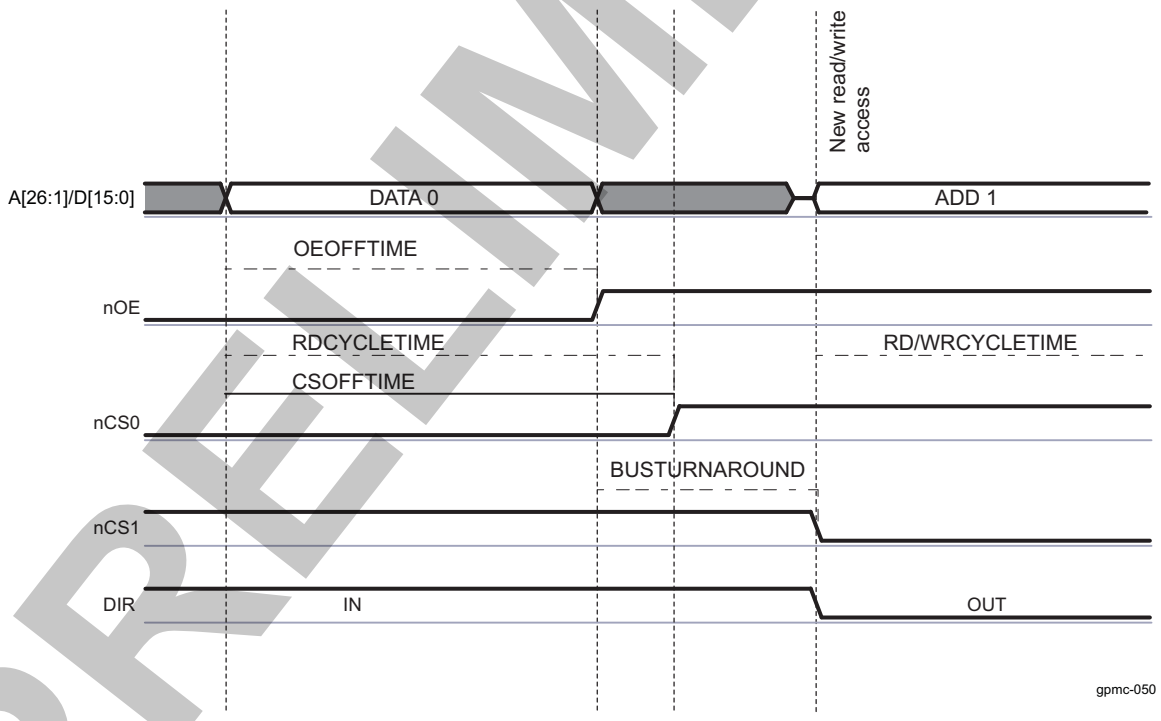

Figure 15-61. Read-to-Read/Write for a Address-Data or AAD-Multiplexed Device, on Same Chip-Select, With Bus Turnaround

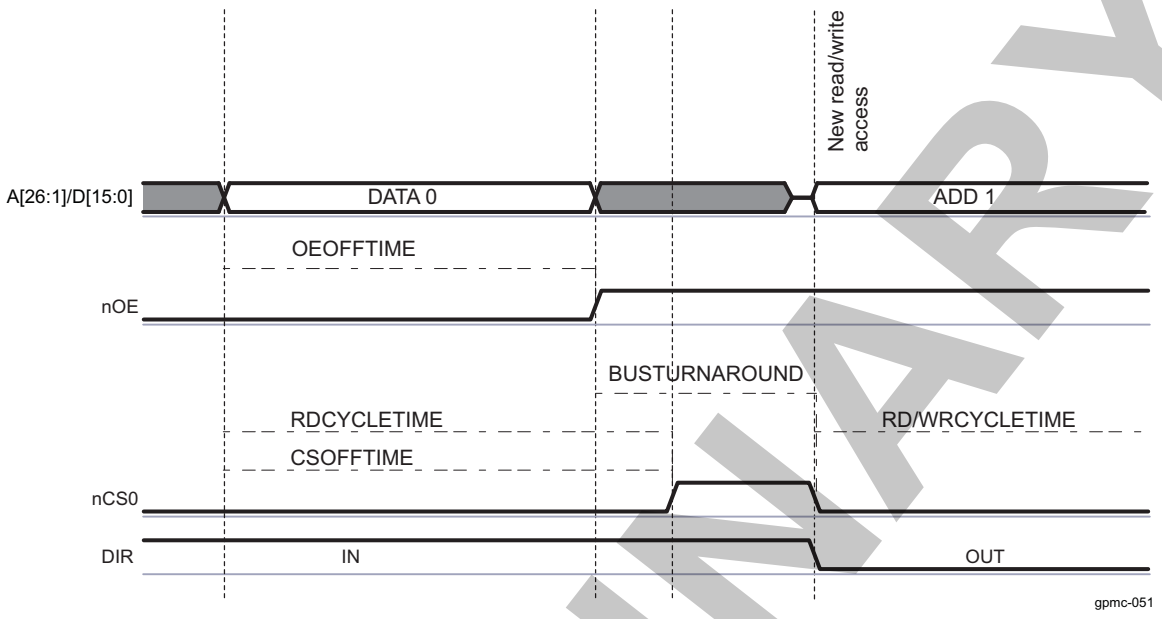


15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit (where i = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and deassertion timing parameters and on the device timing parameters, the assertion times of some control signals may overlap between the successive accesses to a different chip-select. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If the GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN bit is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN must be set in the GPMC_CONFIG6_i registers to get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select, respectively.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. The BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, because bus turnaround does not apply to all access types. For more information about bus turnaround, see Section 15.4.4.9.3.1.6.1, *Bus Turnaround (BUSTURNAROUND)*.

Table 15-342 describes the configuration required for idle cycle insertion.

Table 15-342. Idle Cycle Insertion Configuration

1st Access Type	BUSTURNAROUND Timing Parameter	Second Access Type	Chip-Select	Add/Data Multiplexed	CYCLE2CYCLESAMECSEN Parameter	CYCLE2CYCLEDIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	= 0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	> 0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	> 0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	> 0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	= 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	= 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	> 0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	> 0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, 0 to 7). Increasing all access timing parameters allows support of slow devices.

15.4.4.9.3.2 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_ad[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT-to-IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
  - The gpmc_io_dir pin goes from IN-to-OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
  - After an asynchronous read access, the gpmc_io_dir pin goes from IN-to-OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the gpmc_io_dir pin goes from IN-to-OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see Section 15.4.4.10.10, *Bus Keeping Support*).

In nonmultiplexed devices, the gpmc_io_dir pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit-wide device support is limited to 2KiB).

15.4.4.9.3.3 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see Section 3.1.1, *Power, Reset, and Clock Management*.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

15.4.4.9.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all chip-selects.

15.4.4.9.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.9.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC_ERR_ADDRESS register. The GPMC keeps only the first error abort information until the GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC_ERR_TYPE[0] ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match

any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KiB.

- ERRORNOTSUPPMCMD occurs when an unsupported command request is decoded at the L3 interconnect interface.
- ERRORTIMEOUT: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC_TIMEOUT_CONTROL register and enabled with the GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.10 Timing Setting

The GPMC offers maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information about GPMC_CLK and GPMC_FCLK see Section 15.4.4.10.6, *GPMC_CLK*.

NOTE: In the following sections, the start access time refers to the time at which the access begins.

15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC_CONFIG5_i[12:8] WRCYCLETIME bit fields (where i = 0 to 7) define the address bus and byte-enable valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle. The RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

When RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (nCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

NOTE: All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles.

If no inactive cycles are required between successive accesses to the same chip-select or a different chip-select (GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN = 0 or GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN = 0, where i = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses (that is, CYCLE2CYCLESAMECSEN = 1 or CYCLE2CYCLEDIFFCSEN = 1), the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY.

15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC_CONFIG2_i[12:8] CSRDOFFTIME (read access) and GPMC_CONFIG2_i[20:16] CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

The CSONTIME, CSRDOFFTIME, and CSWROFFTIME parameters apply to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte-enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte-enable hold time after chip-select deassertion.

nCS signal transitions, as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME, can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but it can also be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters that control nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The GPMC_CONFIG3_i[3:0] ADVONTIME field (where i = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME (read access) and GPMC_CONFIG3_i[20:16] ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte-enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte-enable valid hold time control after nADV/ALE deassertion. ADVRDOFFTIME and ADVWROFFTIME apply to synchronous and asynchronous modes.

The nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME, GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME, and GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. The user must ensure that ADVAADMUXxxOFFTIME is programmed to a value less than or equal to ADVxxOFFTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-multiplexed address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

For more information about the use of ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME and ADVAADMUXWROFFTIME for command latch enable (CLE) and address latch enable (ALE) use for a NAND flash interface, see Section 15.4.4.13, *NAND Access Description*.

15.4.4.10.4 nOE/nRE: Output Enable/Read Enable Signal Control Assertion/Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The GPMC_CONFIG4_i[3:0] OEONTIME bit field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It applies only to read accesses.

The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field defines the nOE/nRE signal deassertion time relative to start access time. It applies only to read accesses. nOE/nRE is not asserted during a write cycle.

The OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME parameters apply to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte-enable valid hold time control after nOE/nRE assertion.

The OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. The user mut ensure that OEAADMUXOFFTIME is programmed to a value less than OEONTIME. Functionality in AAD-multiplexed mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME must never be equal to OEONTIME because the AAD-multiplexed protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME, and OEAADMUXOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on the nOE/RE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than the nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.10.5 nWE: Write Enable Signal Control Assertion/Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The GPMC_CONFIG4_i[19:16] WEONTIME bit field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field defines the nWE signal-deassertion time relative to start access time. These bit fields apply only to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte-enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte-enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by a half-GPMC_FCLK period by enabling the GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half-GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to ensure proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where i = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is activated only when the access in progress is defined as synchronous (read or write access).
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When the cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the required 50-percent duty cycle, the user must extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
- The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).

15.4.4.10.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field (where i = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of the control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by a half-GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read/write access time durations can be programmed independently through the GPMC_CONFIG5_i[20:16] RDACCESSTIME and GPMC_CONFIG6_i[28:24] WRACCESSTIME bit fields (where i = 0 to 7). This allows nOE and GPMC data-capture timing parameters to be independent of nWE and memory device data capture timing parameters. The RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through the GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.10.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field (where i = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK, which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field must be greater than RDACCESSTIME to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in asynchronous and synchronous modes. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a wait invalid timing window and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

In synchronous write mode , for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from the start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data-capture GPMC_CLK edge for a synchronous write access. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

The GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (where i = 0 to 7) can be set with a granularity of 1 or 2 through theGPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit.

15.4.4.10.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME bit field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory device data capture GPMC_CLK edge in synchronous write mode. For more information about wait monitoring, see Section 15.4.4.9.3.1, *Wait Pin Monitoring Control*.

15.4.4.10.10 Bus Keeping Support

At the end cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completes to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as asynchronous or synchronous access through the GPMC_CONFIG1_i[29] READTYPE bit (where i = 0 to 7). For each chip-select configuration, the write access can be specified as synchronous or asynchronous access through the GPMC_CONFIG1_i[27] WRITETYPE bit where (i = 0 to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For more information about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

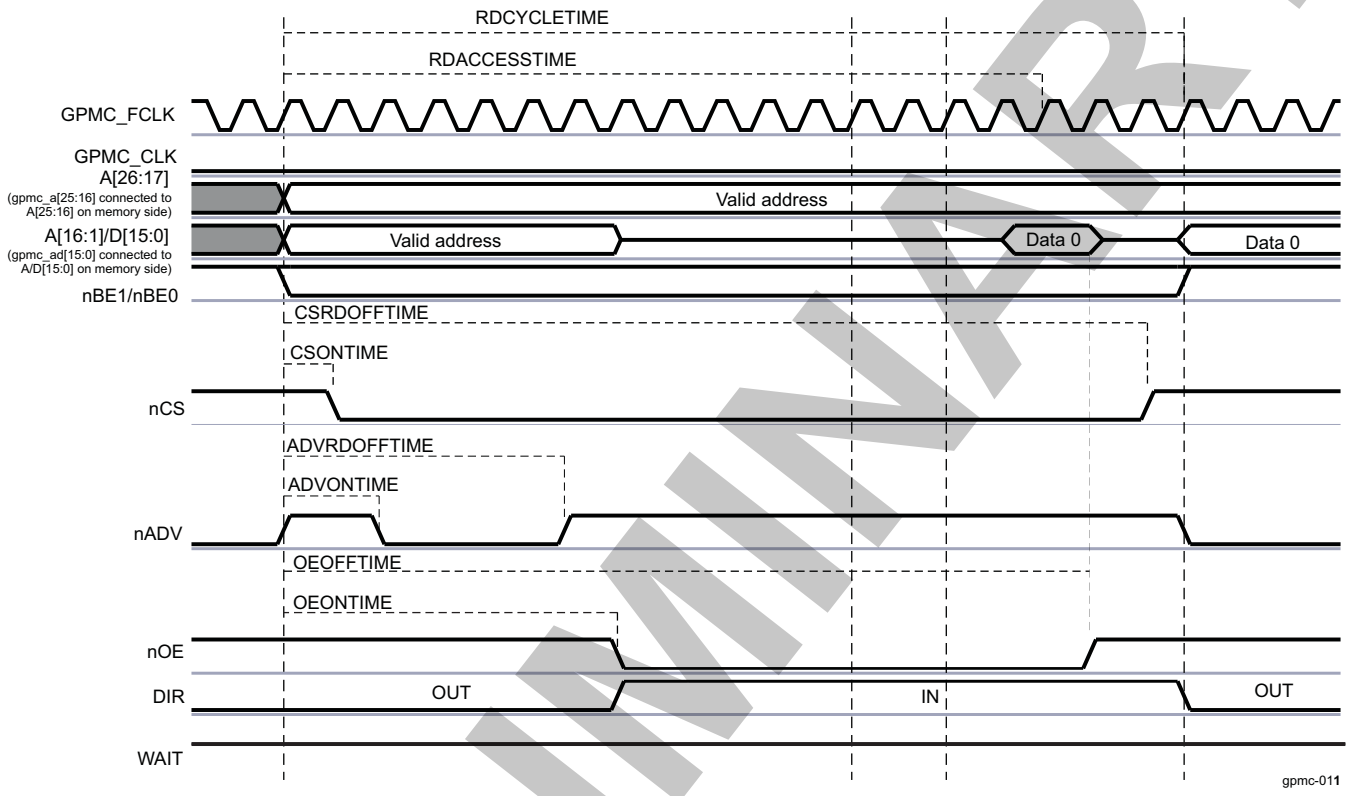
In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-62 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-62. Asynchronous Single Read on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field. It controls the address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

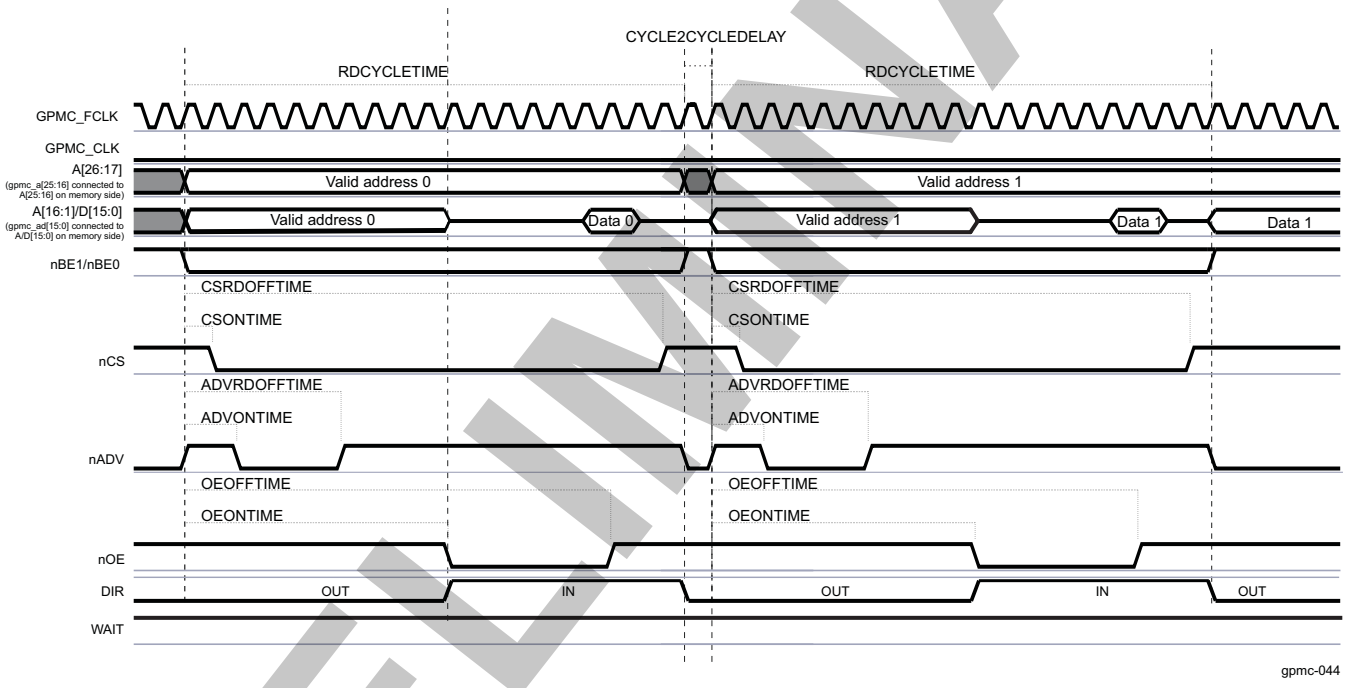
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see Section 15.4.4.11.5, *System Burst Versus External Device Burst Support*.

Between two successive accesses, if an nCS pulse is needed:

- The GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY bit field can be programmed with the GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSEN bit enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

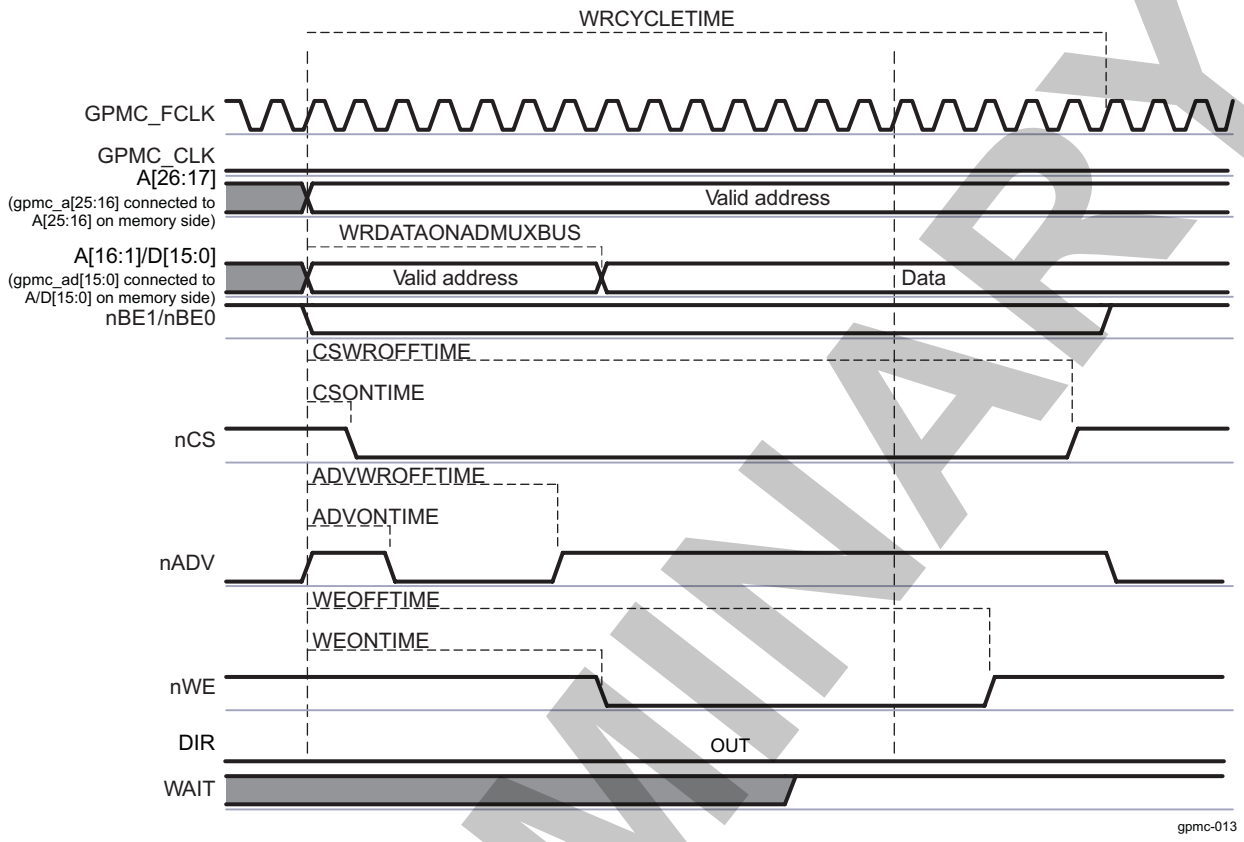
Figure 15-63. Two Asynchronous Single-Read Accesses on an Address/Data-Multiplexed Device (32-Bit Read Split Into 2 x 16-Bit Read)



15.4.4.11.1.1.2 Asynchronous Single-Write Operation on an Address/Data-Multiplexed Device

Figure 15-64 shows an asynchronous single-write operation on an address/data-multiplexed device.

Figure 15-64. Asynchronous Single-Write on an Address/Data-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

The nCS and nADV signals are controlled in the same way as for a asynchronous single-read operation on an address/data-multiplexed device.

- Write enable signal nWE:
  - nWE assertion indicates a write cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC_CONFIG5_i[12:8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

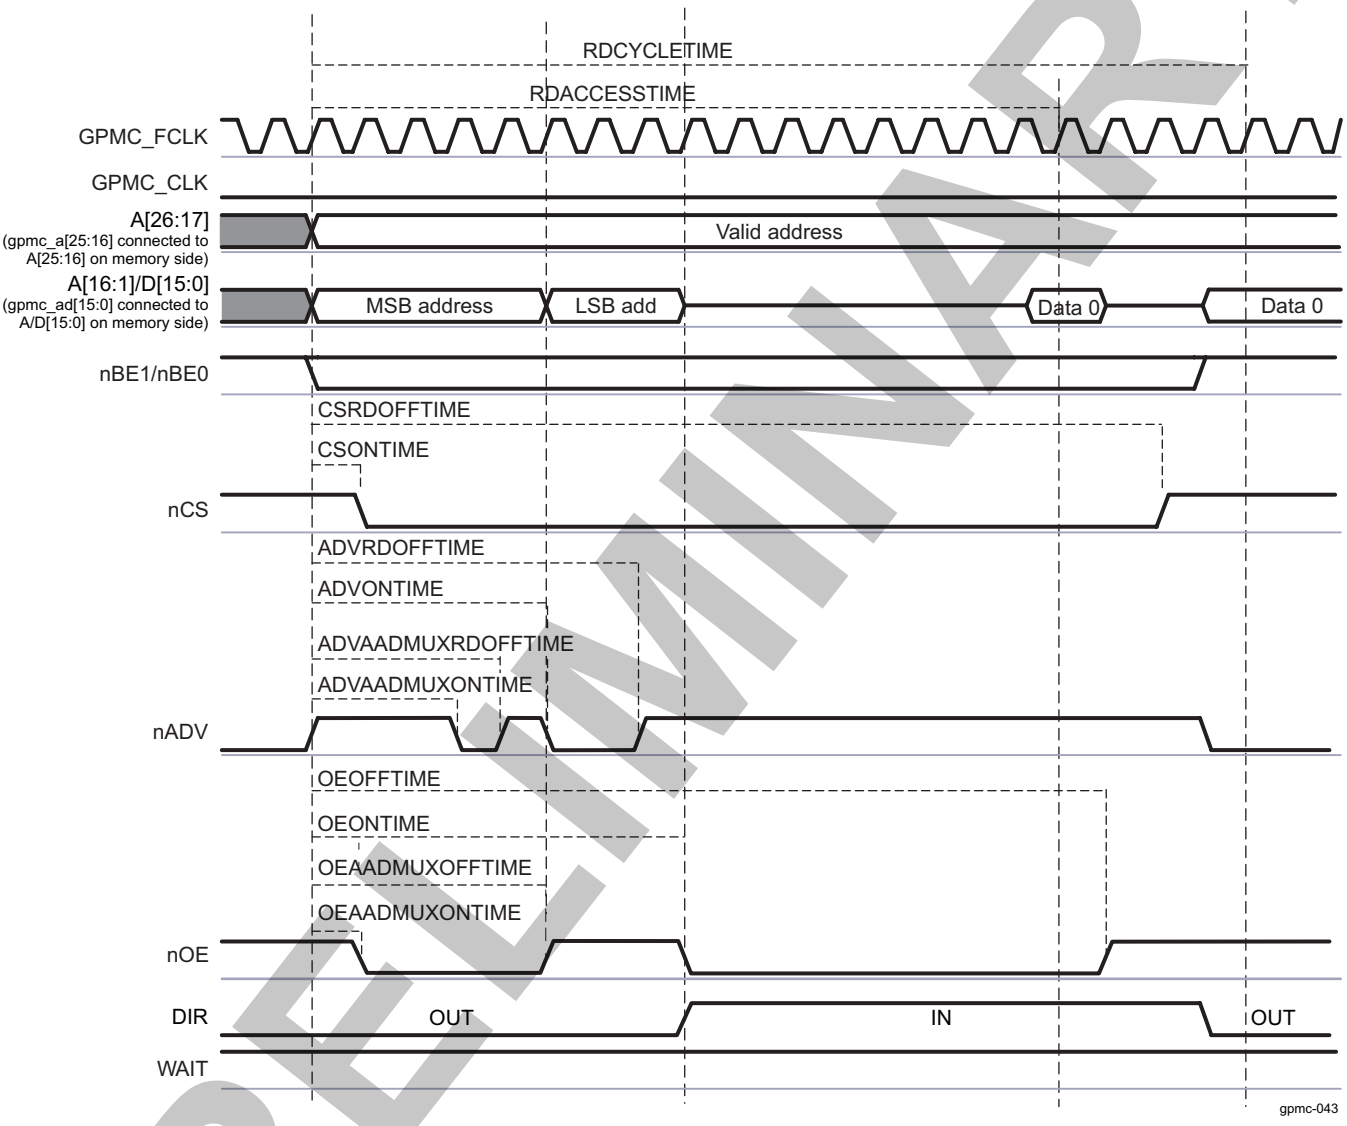
For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

15.4.4.11.1.2 Access on Address/Address/Data-Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single-read operation on an AAD-multiplexed device.

Figure 15-65. Asynchronous Single Read on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS and DIR signals are controlled in the same way as for an asynchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.

- nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
- nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
- nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.

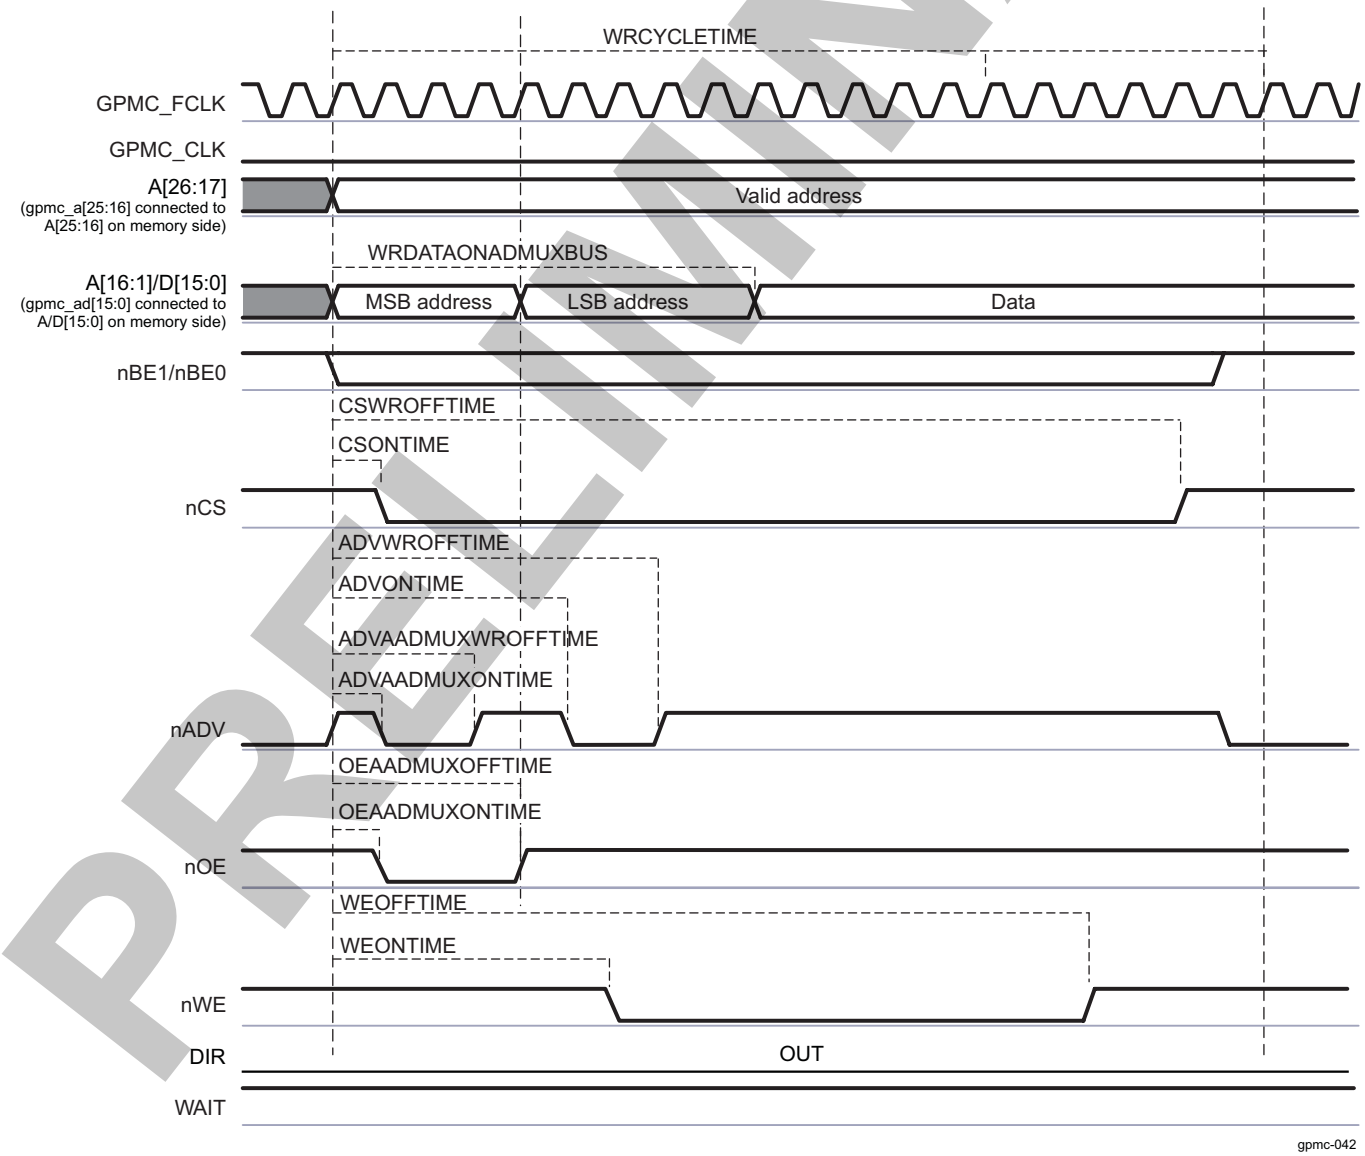
• Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):

- nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
- nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
- nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
- nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

15.4.4.11.1.2.2 Asynchronous Single-Write Operation on an AAD-Multiplexed Device

Figure 15-66 shows an asynchronous single-write operation on an AAD-multiplexed device.

Figure 15-66. Asynchronous Single Write on an AAD-Multiplexed Device



For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for an asynchronous single-write operation on an address/data-multiplexed device. See Table 15-365.

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[30:28] ADVAADMUXWROFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Output enable signal nOE is asserted during the address phase of a write transaction:
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS parameter.

15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If the GPMC_CONFIG1_i[28] WRITEMULTIPLE bit is enabled (0x1) with the GPMC_CONFIG1_i[27] WRITETYPE bit as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.11.2 Synchronous Access Description

This section describes read and write synchronous accesses on address/data-multiplexed devices. All information in this section can be applied to any type of memory (nonmultiplexed, address and data-multiplexed, or AAD-multiplexed) with the difference limited to the address phase. For accesses on nonmultiplexed devices, see Section 15.4.4.11.3, *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field. In the following section i stands for the chip-select number, i = 0 to 7.
- The GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME bit field specifies that the GPMC_CLK is provided outside the GPMC for 0 to 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completes.

15.4.4.11.2.1 Synchronous Single Read

Figure 15-67 and Figure 15-68 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 15-67. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

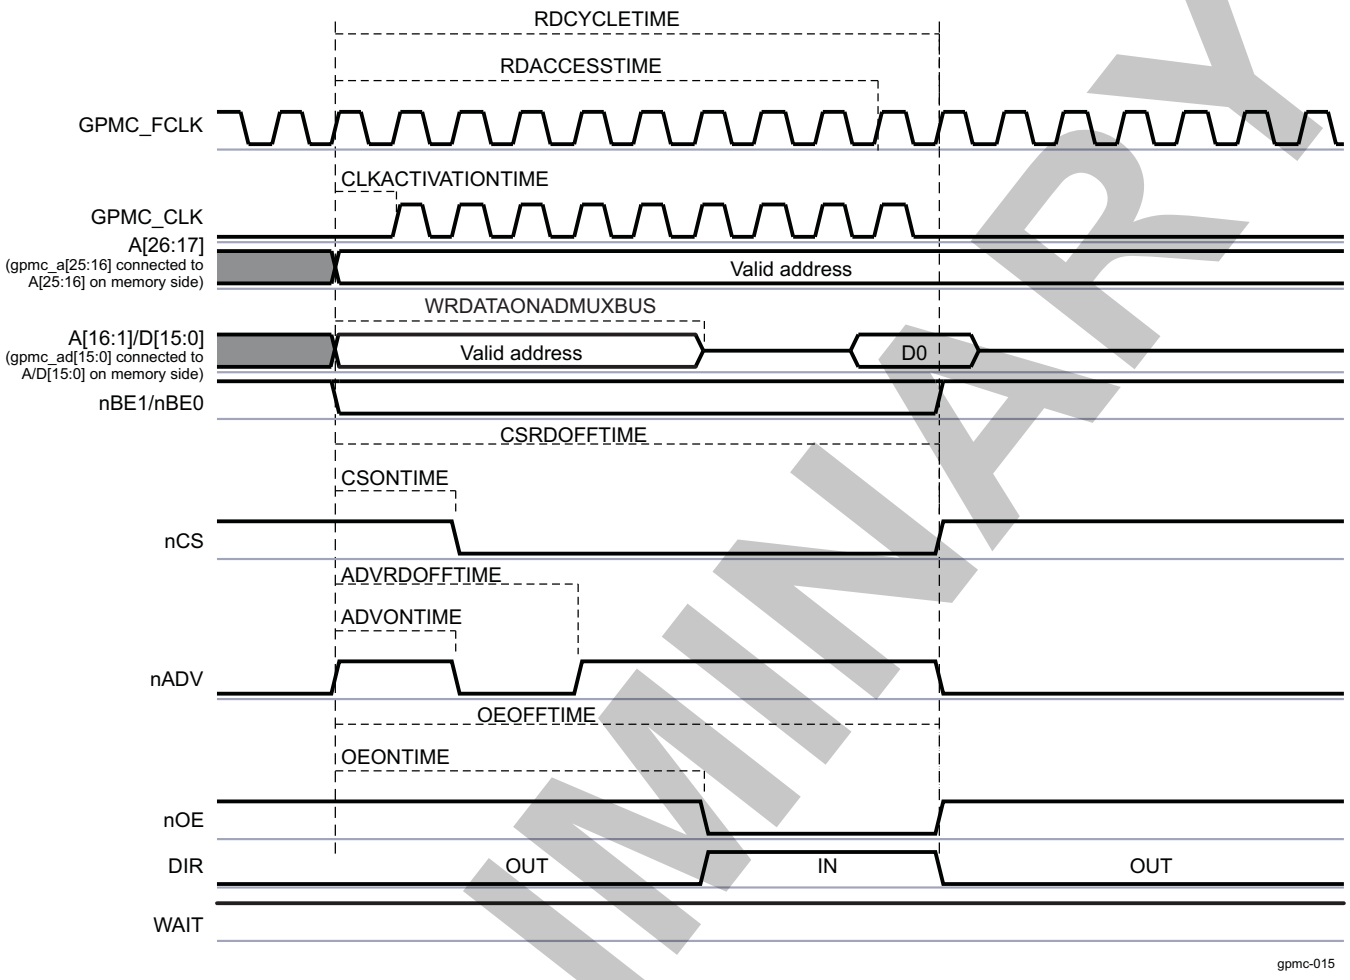


Figure 15-68. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

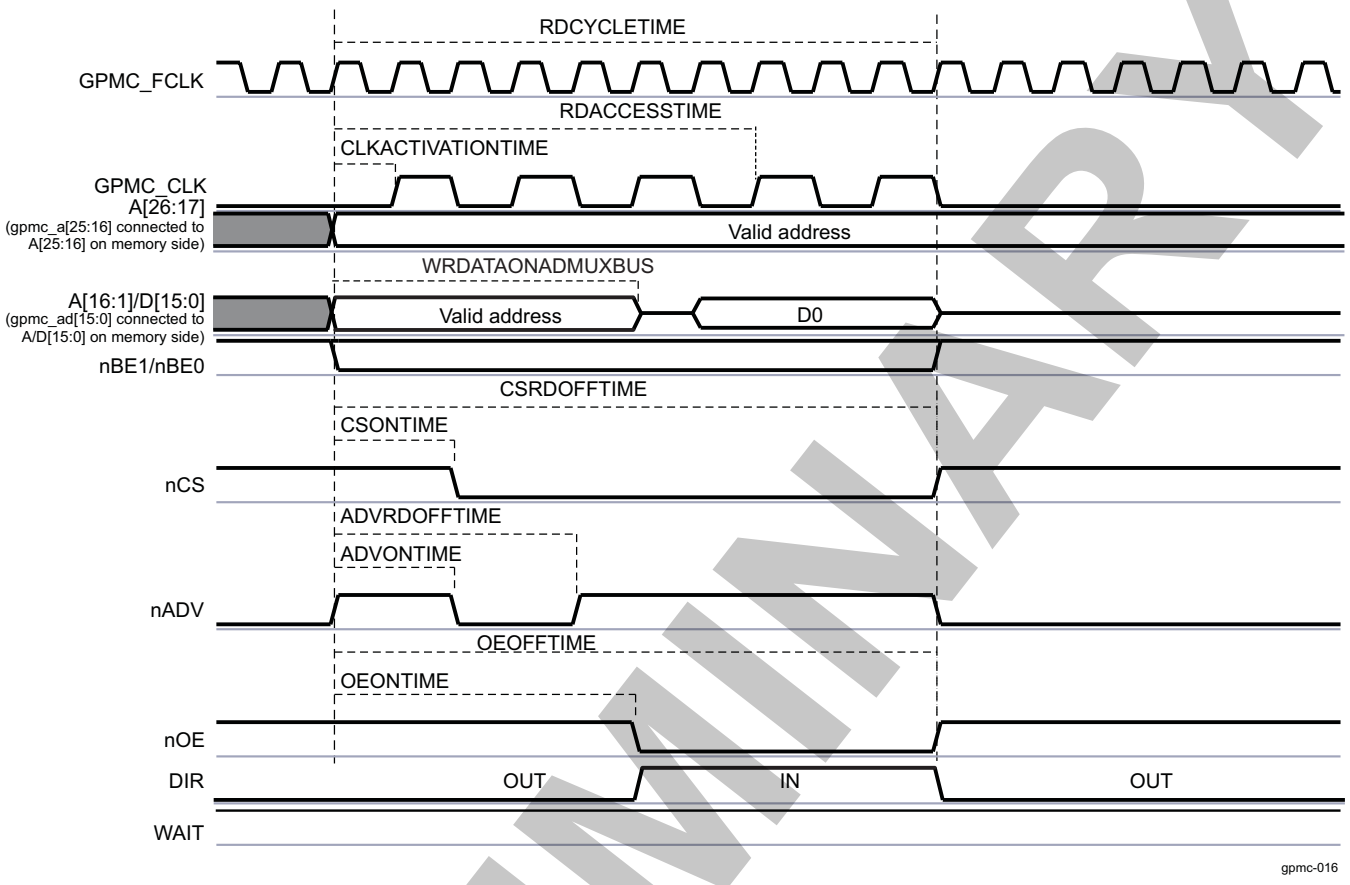

For formulas to calculate timing parameters, see Section 15.4.5.6.1, *GPMC Timing Parameters Formulas*.

Table 15-374 lists the timing bit fields to set up to configure the GPMC in asynchronous single-read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field and ensures address setup time to nCS assertion.
  - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output enable signal nOE:
  - nOE assertion indicates a read cycle.
  - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.
- Initial latency for the first read data is controlled by GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field or by monitoring the WAIT signal.
- Total access time (the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS and DIR signals are controlled in the same way as for a synchronous single-read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG3_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 15-69 and Figure 15-70 show a synchronous multiple-read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

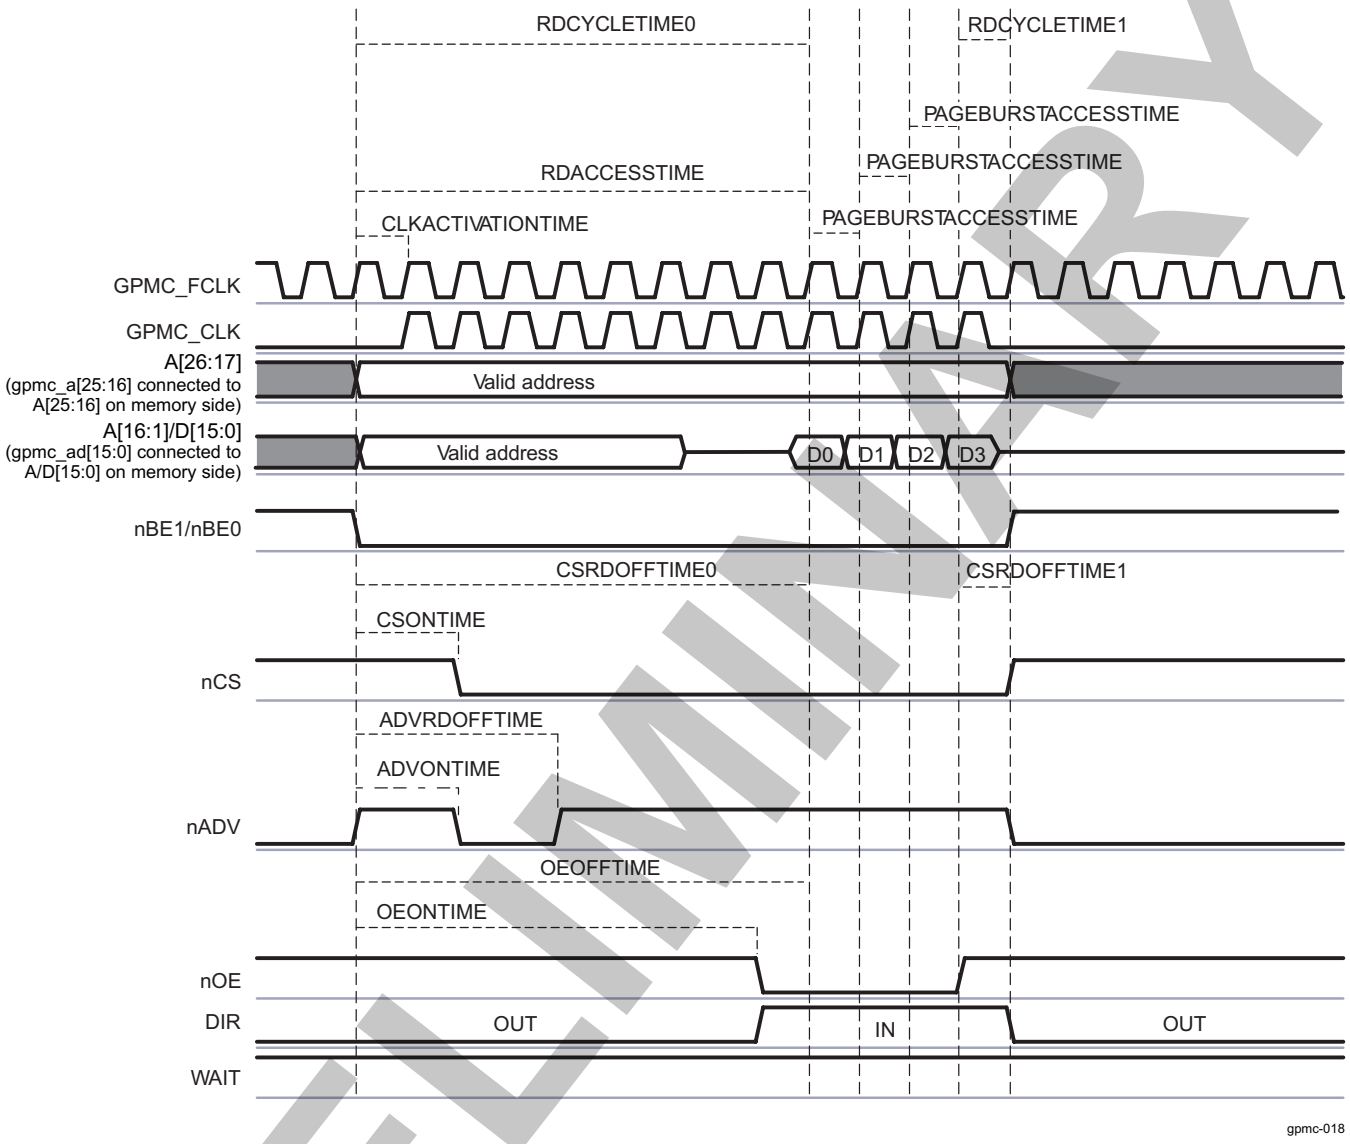

Figure 15-70. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

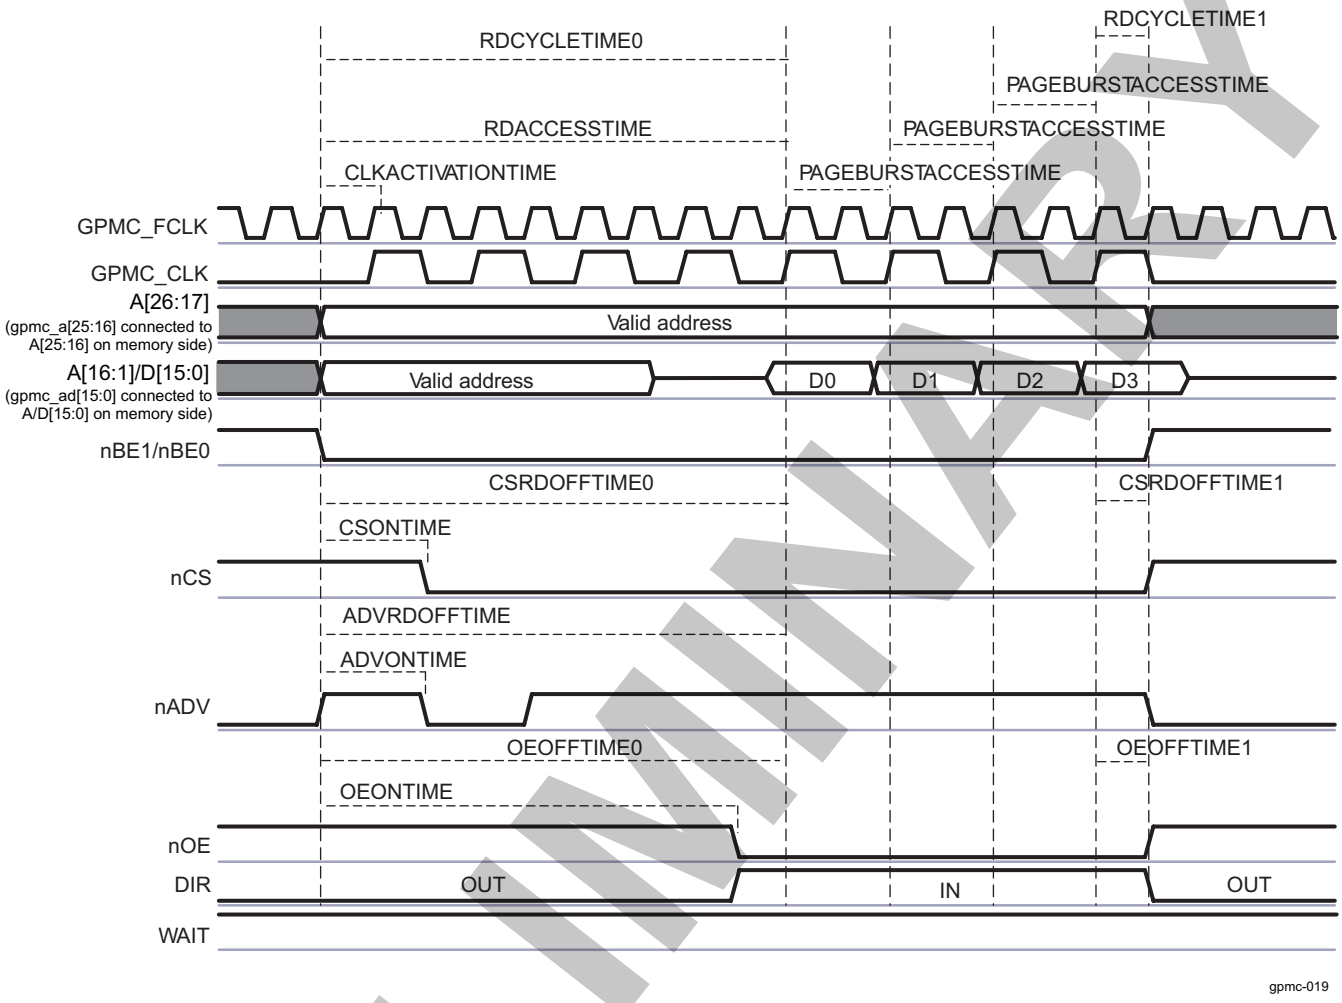


When the GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as for a synchronous single-read operation. See Table 15-360.

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device every one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with the GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field and the memory-device internal configuration. Depending on the device page length, the GPMC checks the device page crossing during a new burst request and purposely inserts initial latency (of RDACCESSTIME) when required.

Total access time GPMC_CONFIG5_i[4:0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-70, the programmed value of RDCYCLETIME equals RDCYCLETIME0 + RDCYCLETIME1.

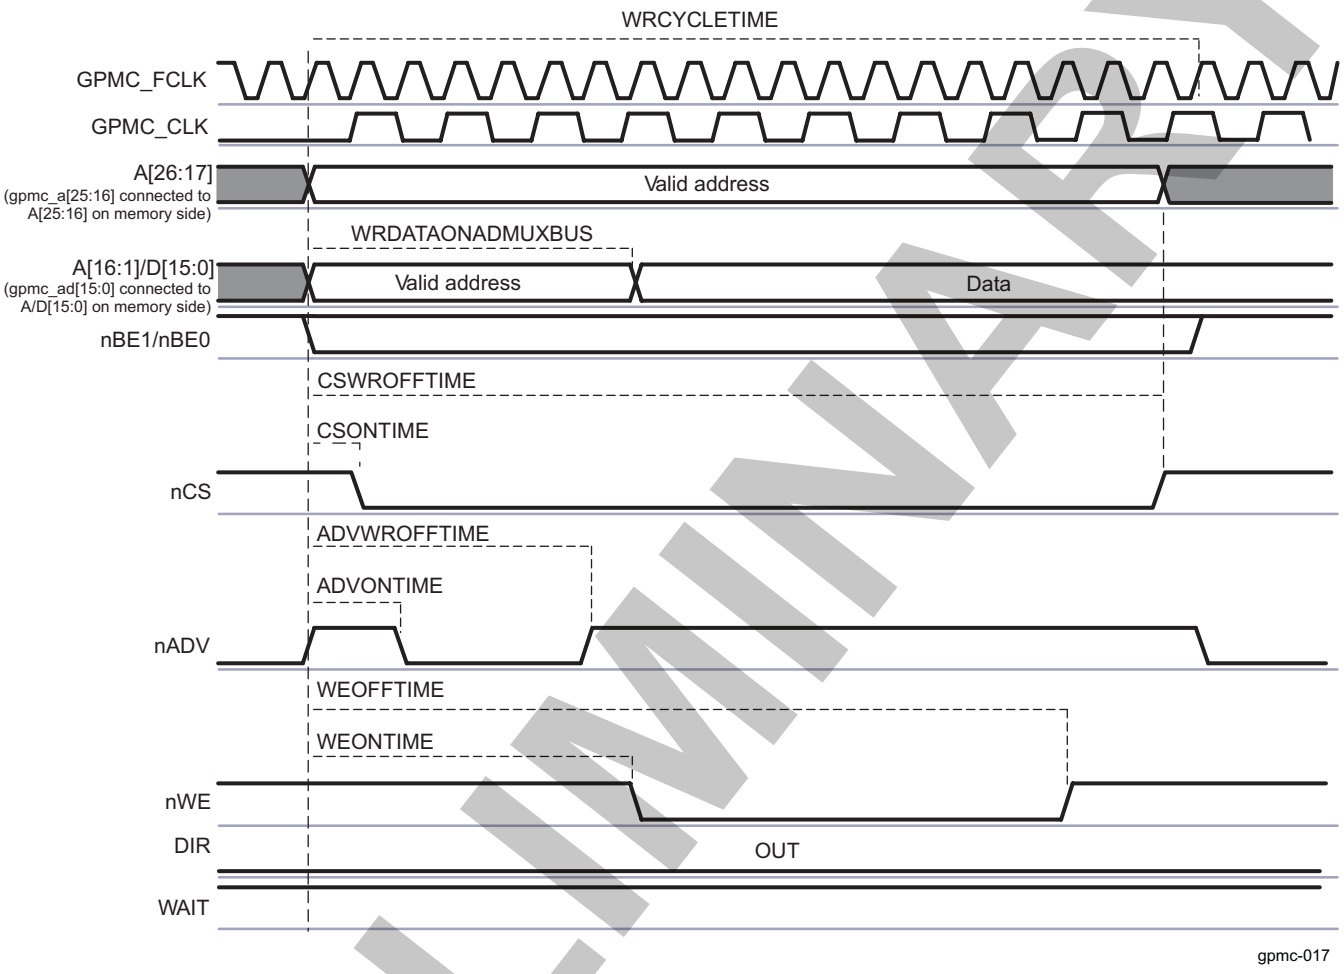
After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 15.4.4.10.10, *Bus Keeping Support*.

Burst wraparound is enabled through the GPMC_CONFIG1_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field.

15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 15-71. Synchronous Single Write on an Address/Data-Multiplexed Device



When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field time. The first data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

Figure 15-72 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

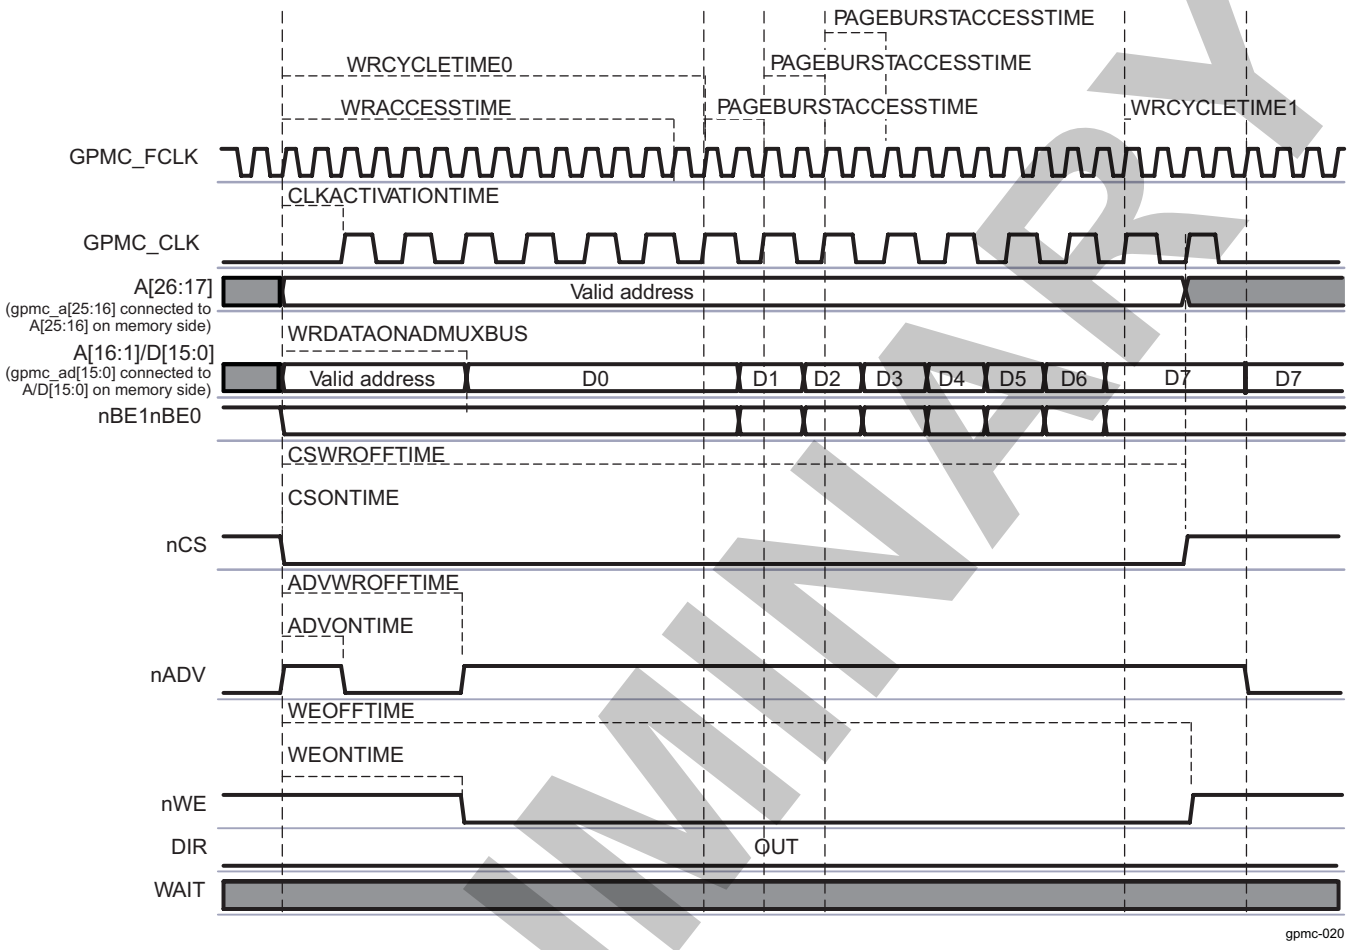


Figure 15-73 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

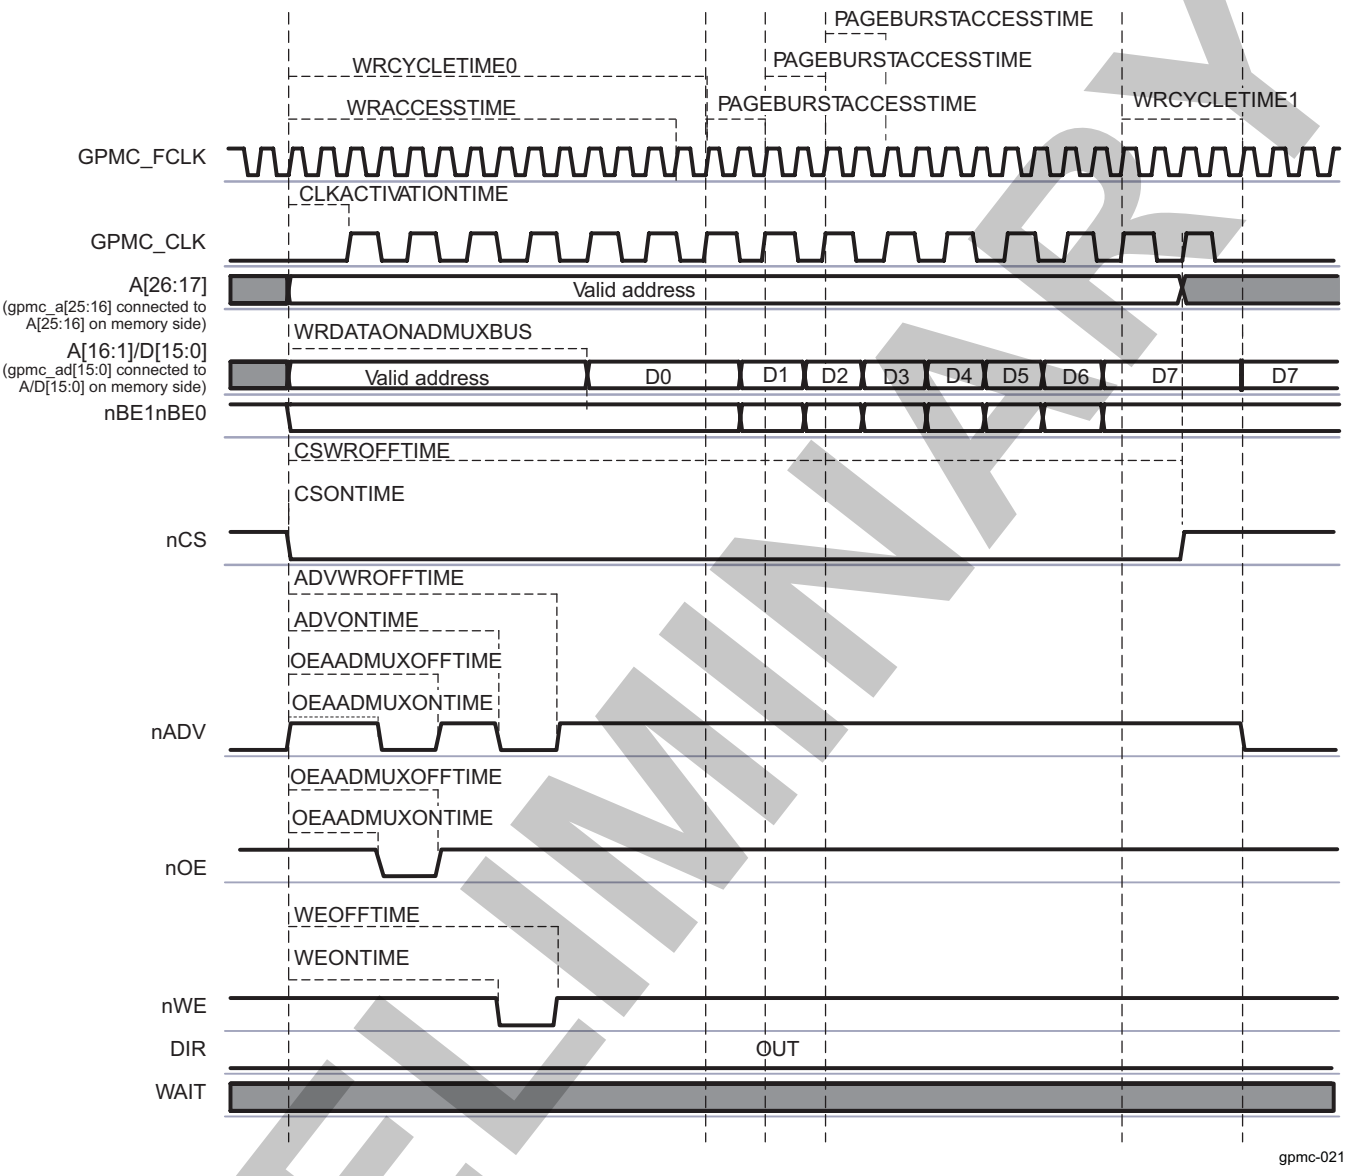
Figure 15-73. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode



The first data of the burst is driven on the A/D bus at the GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS bit field.

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For more information, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

- Chip-select signal nCS:
  - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CSONTIME bit field (where i = 0 to 7) and ensures address setup time to nCS assertion.
  - nCS deassertion time controlled by the GPMC_CONFIG2_i[20:16] CSWROFFTIME bit field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
  - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.

  - nADV deassertion time is controlled by the GPMC_CONFIG3_i[20:16] ADVWROFFTIME bit field.
- Write enable signal nWE:
  - nWE assertion indicates a read cycle.
  - nWE assertion time is controlled by the GPMC_CONFIG4_i[19:16] WEONTIME bit field.
  - nWE deassertion time is controlled by the GPMC_CONFIG4_i[28:24] WEOFFTIME bit field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus, because some new devices require the nWE signal to be low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as previously described..

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
  - nADV first assertion time is controlled by the GPMC_CONFIG3_i[6:4] ADVAADMUXONTIME bit field.
  - nADV first deassertion time is controlled by the GPMC_CONFIG3_i[26:24] ADVAADMUXRDOFFTIME bit field.
  - nADV second assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADVONTIME bit field.
  - nADV second deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
  - nOE first assertion time is controlled by the GPMC_CONFIG4_i[6:4] OEAADMUXONTIME bit field.
  - nOE first deassertion time is controlled by the GPMC_CONFIG4_i[15:13] OEAADMUXOFFTIME bit field.
  - nOE second assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME bit field.
  - nOE second deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME bit field.

First write data is driven by the GPMC at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS, when in address/data-multiplexed configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until GPMC_CONFIG5_i[12:8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC_CONFIG6_i[28:24] bit field.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC_CONFIG5_i[12:8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In Figure 15-72, the programmed value of WRCYCLETIME equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See Section 15.4.4.10.10, *Bus Keeping Support*.

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is available only in nonmultiplexed mode. Nonmultiplexed mode is described in this section even though its use is limited (address space limited to 2KiB).

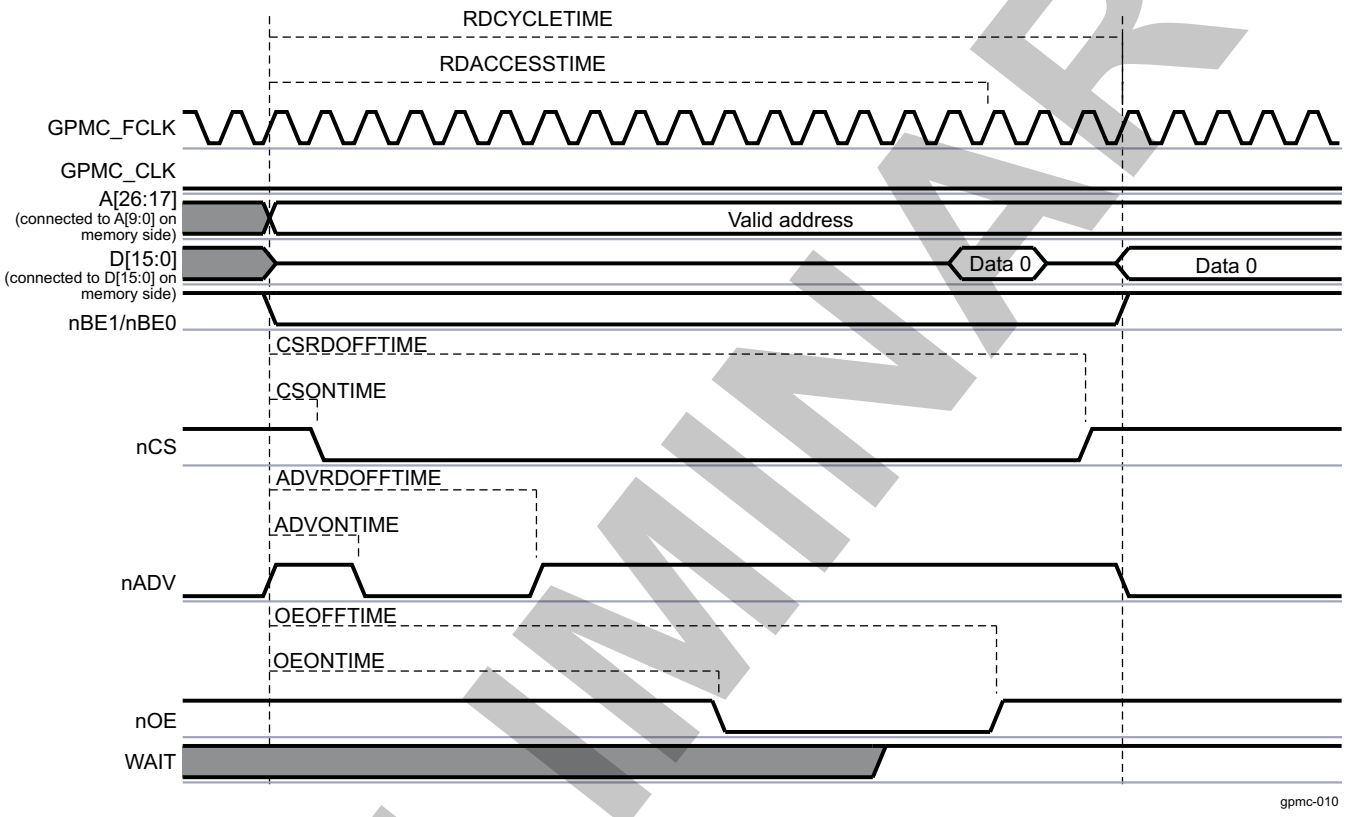
- Asynchronous single-read operation on a nonmultiplexed device
- Asynchronous single-write operation on a nonmultiplexed device

- Asynchronous multiple- (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single-Read Operation on Nonmultiplexed Device

Figure 15-74 shows an asynchronous single-read operation on a nonmultiplexed device.

Figure 15-74. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC_CONFIG1_5[20:16] RDACCESSTIME completion time. The end of the access is defined by the GPMC_CONFIG1_5[4:0] RDCYCLETIME parameter.

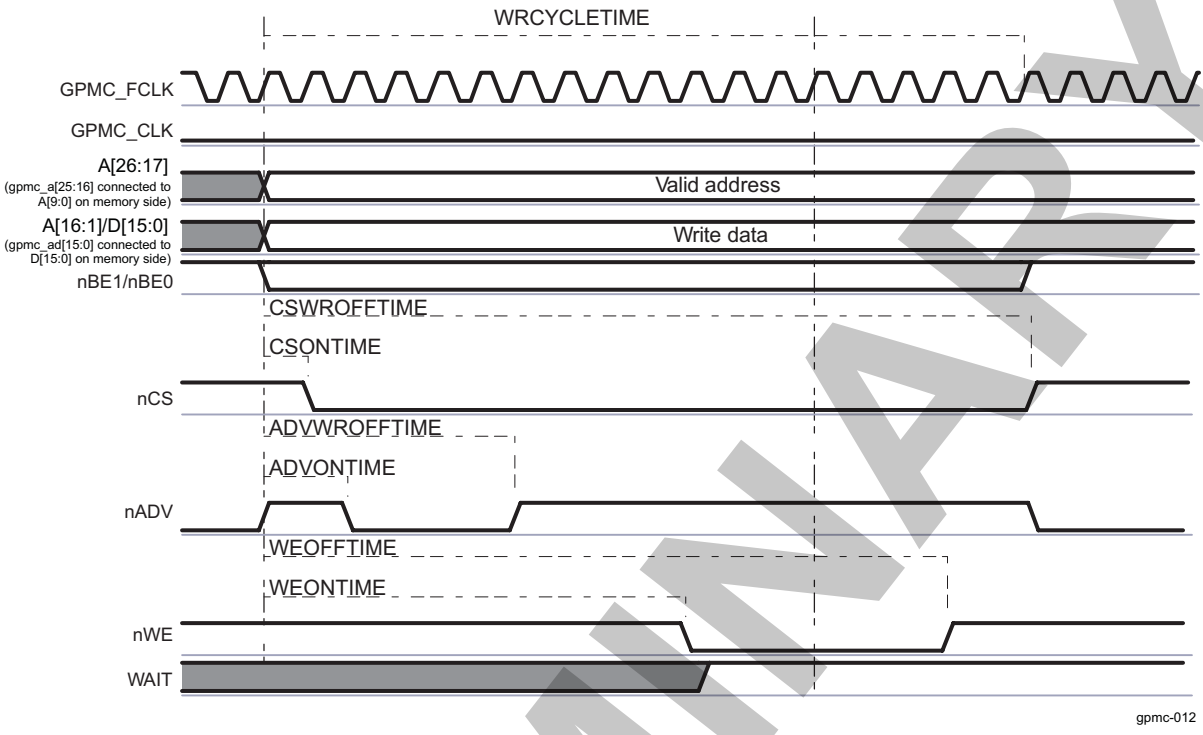
Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

15.4.4.11.3.2 Asynchronous Single-Write Operation on Nonmultiplexed Device

Figure 15-75 shows an asynchronous single-write operation on a nonmultiplexed device.

Figure 15-75. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device



The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

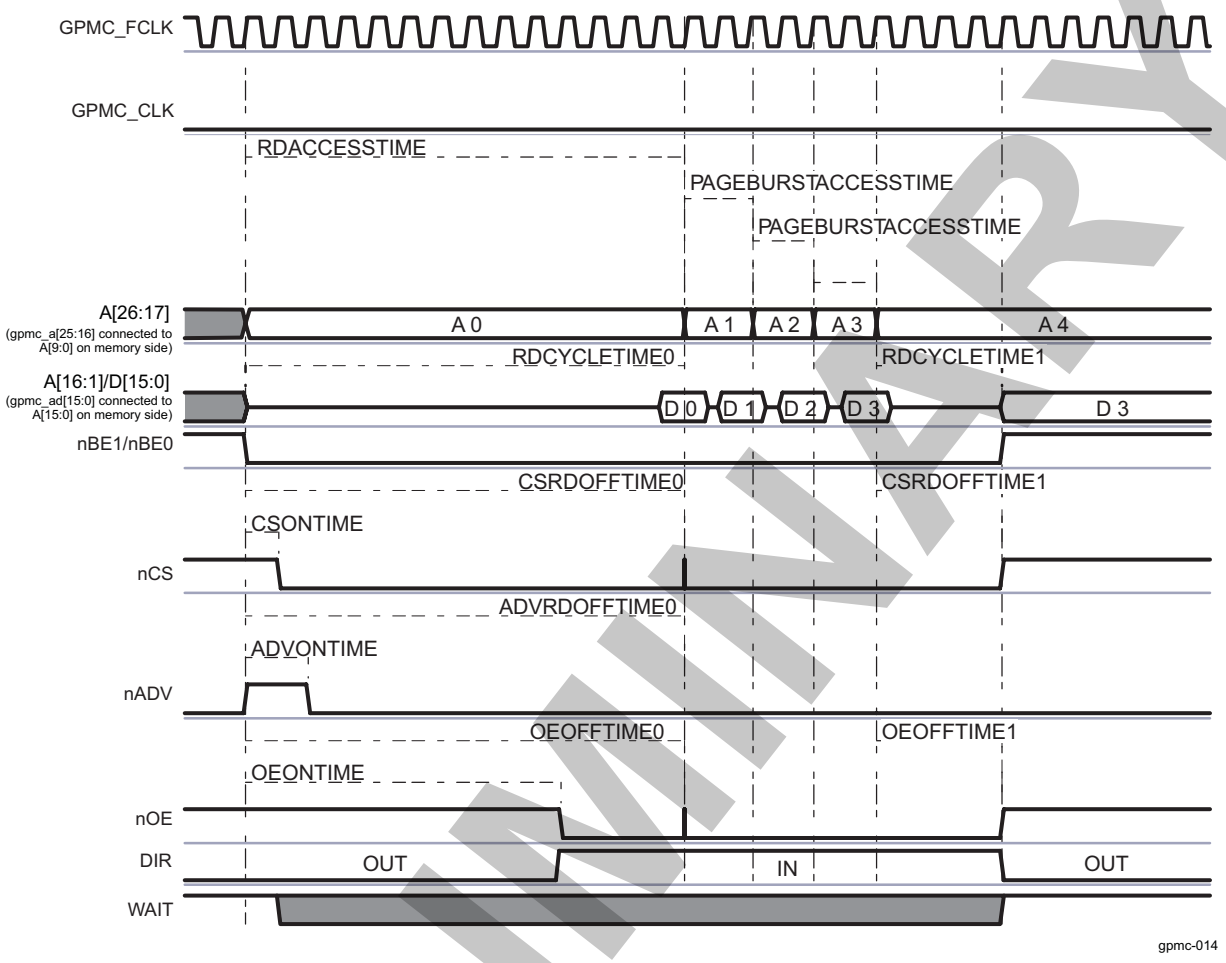
Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

The nCS, nADV, nWE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on Nonmultiplexed Device

Figure 15-76 shows an asynchronous multiple-read operation on a nonmultiplexed device in which two word32 host read accesses to the GPMC are split into one multiple- (page mode of 4 word16) read access to the attached device.

Figure 15-76. Asynchronous Multiple (Page Mode) Read



NOTE: The WAIT signal is active low.

The nCS, nADV, nOE, and DIR signals are controlled in the same way as address/data-multiplexed accesses (see Table 15-365).

When RDACCESSTIME completes, control signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC_CONFIG5_i[20:16] RDACCESSTIME completion time (where i = 0 to 7). The end of the access is defined by the GPMC_CONFIG5_i[4:0] RDCYCLETIME parameter.

Set GPMC_CONFIG[1] LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Page crossing is possible only with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME, plus the address hold time, starting from the nCS deassertion.

- The read cycle time is defined in the GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field.
- In Figure 15-76, the programmed value of RDCYCLETIME equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data-multiplexed or AAD-multiplexed accesses. The only difference resides in the address phase. See Section 15.4.5.3, *GPMC Configuration in NOR Mode*.

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITMULTIPLE bits (where i = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
- 8-bit-wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing

15.4.4.11.5 System Burst vs External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte-enable-controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two, four, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length bursts. The maximum length that can be issued is defined per chip-select by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field (where i = 0 to 7). When the value of ATTACHEDDEVICEPAGELENGTH is less than the length of the system burst request (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the value of the ATTACHEDDEVICEPAGELENGTH bit field must correspond to the maximum length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (where i = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting 4 and 8 Word16-length-wrapping burst, respectively.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the value of ATTACHEDDEVICEPAGELENGTH.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed-burst length mode and a continuous-burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH bit field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-word boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the value of ATTACHEDDEVICEPAGELENGTH. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait-states between data accesses. If the memory does not behave this way (nonzero wait-state burstable memory), wait pin monitoring must be enabled to dynamically control data access completion within the burst.

NOTE: When the system burst request length is less than the value of ATTACHEDDEVICEPAGELENGTH, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC_CONFIG1_i[11:10] DEVICETYPE bit field (where i = 0 to 7) must be set to 0b00.

The pSRAM device uses the NOR protocol. It supports the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or they can automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as ALE (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as CLE (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC_CONFIG7_i register (where i = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16MiB, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters listed in Table 15-343. Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-343. Chip-Select Configuration for NAND Interfacing

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1_i[31] (1)	0	No wrap
READMULTIPLE	GPMC_CONFIG1_i[30]	0	Single access
READTYPE	GPMC_CONFIG1_i[29]	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1_i[28]	0	Single access
WRITETYPE	GPMC_CONFIG1_i[27]	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1_i[26:25]	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1_i[24:23]	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1_i[22]	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1_i[21]	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1_i[19:18]	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1_i[17:16]		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1_i[13:12]	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1_i[11:10]	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1_i[9:8]	0b00	Nonmultiplexed mode

(1) i = 0 to 7

Table 15-343. Chip-Select Configuration for NAND Interfacing (continued)

Bit Field	Register	Value	Comments
TIMEPARAGRANULARITY	GPMC_CONFIG1_i[4]	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1_i[1:0]	Don't care	Asynchronous mode

The GPMC_CONFIG1_i to GPMC_CONFIG4_i registers (where i = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver must issue the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations (where i = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i register locations must be posted for faster operations (where i = 0 to 7). The GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

The GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers (where i = 0 to 7) are 32-bit word locations, which means any 32-or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit-wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32- or 16-bit word access to these registers, but it must consider the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to the GPMC_NAND_COMMAND_i and GPMC_NAND_ADDRESS_i registers can be used, and any of the four byte locations of the registers is valid.

The same applies to a GPMC_NAND_COMMAND_i and a GPMC_NAND_ADDRESS_i (where i = 0 to 7) 32-bit word write access to a 16-bit-wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

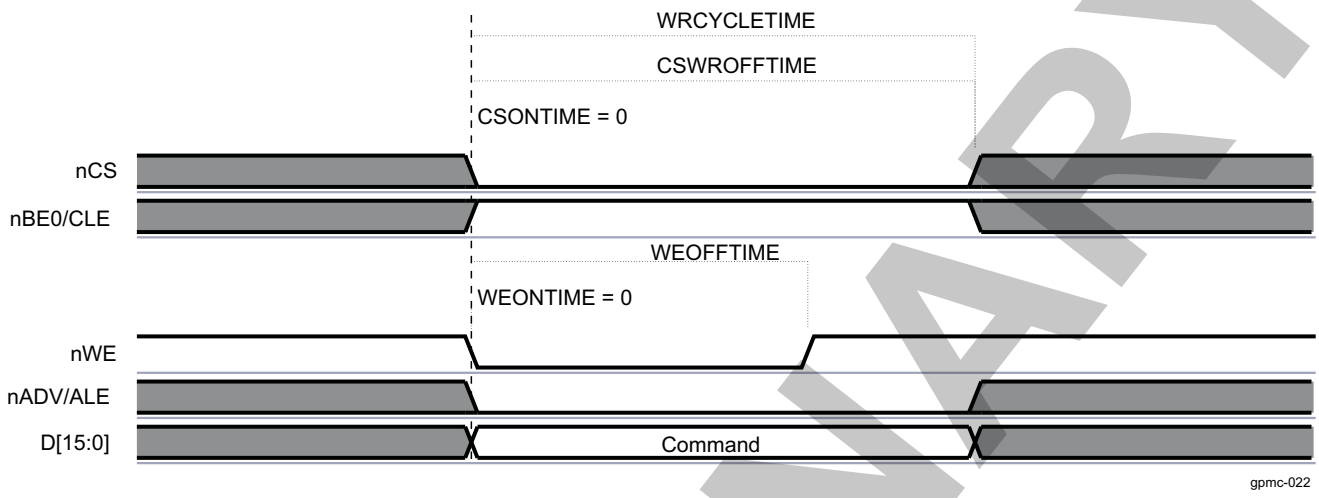
Writing data at the GPMC_NAND_COMMAND_i location (where i = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND command latch cycle.

Figure 15-77. NAND Command Latch Cycle



NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND flash memories do not use byte-enable signals.

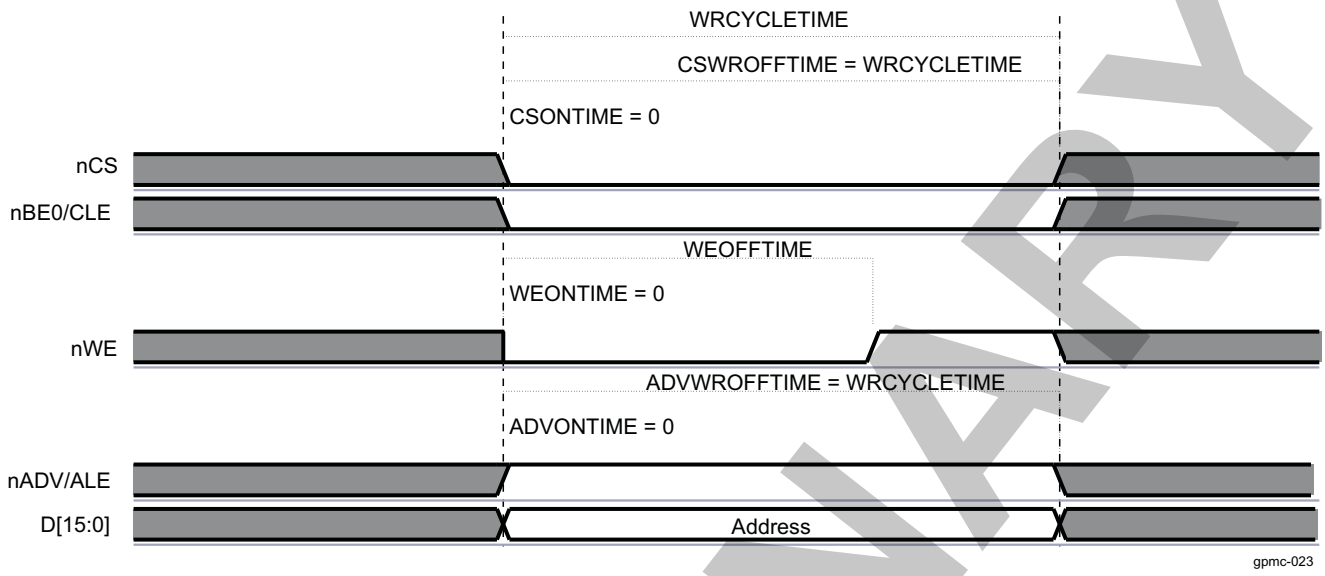
15.4.4.13.1.4 Address Latch Cycle

Writing data at the GPMC_NAND_ADDRESS_i location (where i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-78 shows the NAND address latch cycle.

Figure 15-78. NAND Address Latch Cycle



NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC_NAND_DATA_i location (where i = 0 to 7) mapped in the chip-select-associated control register region. GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

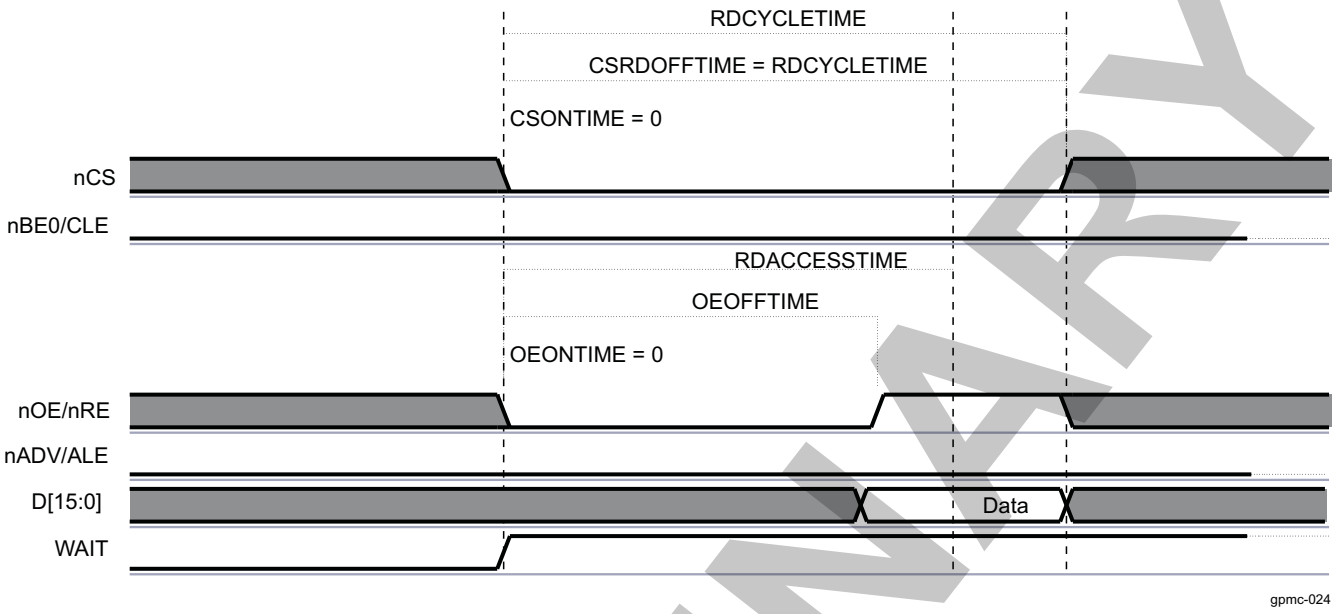
Reading data from the GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 15-79 shows the NAND data read cycle.

Figure 15-79. NAND Data Read Cycle

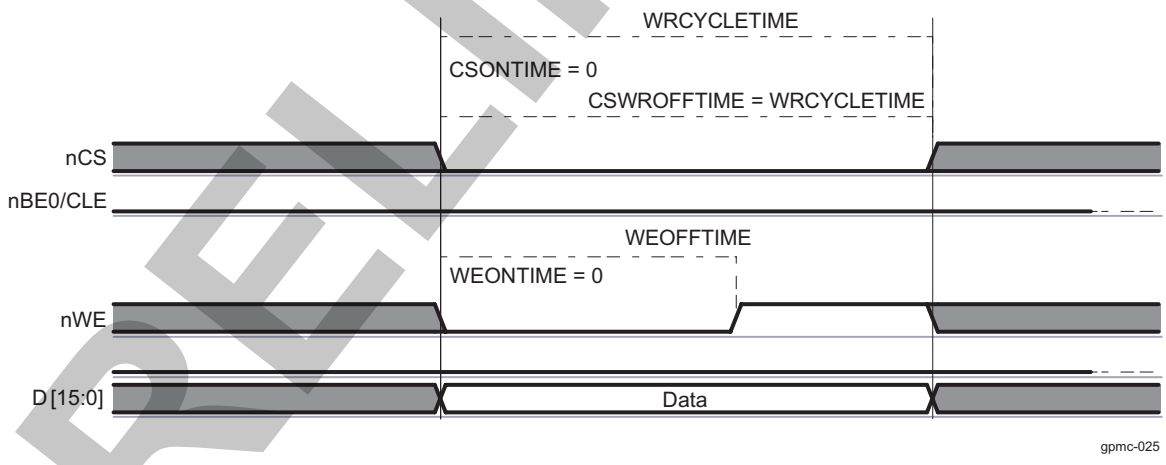


Writing data to the GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-80 shows the NAND data write cycle.

Figure 15-80. NAND Data Write Cycle



15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce the following on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSRDOFFTIME
- CSWROFFTIME
- ADVRDOFFTIME
- ADVWROFFTIME
- OEOFFTIME
- WEOFFTIME

For more information about optimal prefetch engine access, see Section 15.4.4.13.4, *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high-to-data bus in three-state mode. This requires a bus turnaround setting (BUSTURNAROUND = 1) so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-Bit-Wide NAND Device

Host 16- and 32-bit word read and write access requests to a chip-select associated with an 8-bit-wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit-wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the cs is associated with an 8-bit-wide NAND device.

15.4.4.13.1.7.2 16-Bit-Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit-wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit-wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit-wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit-wide NAND device must be avoided, especially when ECC calculation is enabled. 8- or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit-wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the wait GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC_CONFIG1_i[21] WAITWRITEMONITORING and GPMC_CONFIG1_i[22] WAITREADMONITORING bits to 0, where i = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITxSTATUS bit (where x = 0 to 2) of the GPMC_STATUS .
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed wait bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC_STATUS WAITxSTATUS bit (where x = 0 to 2). Software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC_CONFIG WAITxPINPOLARITY bits (where x = 0 to 2) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (where x = 0 to 2) of the GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME bit field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC_IRQSTATUS register according to the gpmc_wait pin used for NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The GPMC includes an error code correction (ECC) calculator circuitry that enables ECC calculation on the fly during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND flash organized with page size greater than 512 bytes
2. Bose-Chaudhurl-Hocquenghem (BCH) code for 4- to 16-bit error correction

The GPMC does not handle the error code correction directly. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (2D) (row and column) bit parity accumulation. This parity accumulation is accomplished on the programmed number of bytes or 16-bit words read from the memory device, or is written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC_ECC_CONFIG[3:1] ECCCS bit field. Even if two chip-selects use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to ECC in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a 2D (row and column) bit parity accumulation known as the Hamming code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and the software NAND driver must read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time, and parallel computations on different chip-selects are not possible. Because it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. Software must ensure that only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is complete.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC_ECCj_RESULT, where j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially: one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC_ECCj_RESULT register is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC_ECC_CONTROL[3:0] ECCPOINTER bit field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC_ECCj_RESULT register (where j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC_ECCj_RESULT register (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC_ECCj_RESULT register, where j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZE bits (where j = 1 to 9) in the GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in the GPMC_ECCj_RESULT register).

The ECCSIZE0 and ECCSIZE1 bit fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2-KiB data page, 8-bit-wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC_ECCj_RESULT registers (j = 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8] RESULTSIZE bits are set to 0, and the ECC9RESULTSIZE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The GPMC_ECC_CONFIG[3:1] ECCCS bit field selects the allocated chip-select. The GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The following fields must not be changed or cleared while an ECC computation is in progress:

- CCPOINTER
- ECCCLEAR
- ECCSIZE
- ECCjRESULTSIZE (where j = 1 to 9)
- ECC16B
- ECCCS

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 15-344 describes the ECC enable settings.

Table 15-344. ECC Enable Settings

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0–3	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLEAR	GPMC_ECC_CONTROL	0–7	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CONTROL	0–7	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.

Table 15-344. ECC Enable Settings (continued)

Bit Field	Register	Value	Comments
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0x00–0xFF	Defines ECCSIZE0
ECCjRESULTSIZE (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 15-81 and Figure 15-82. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

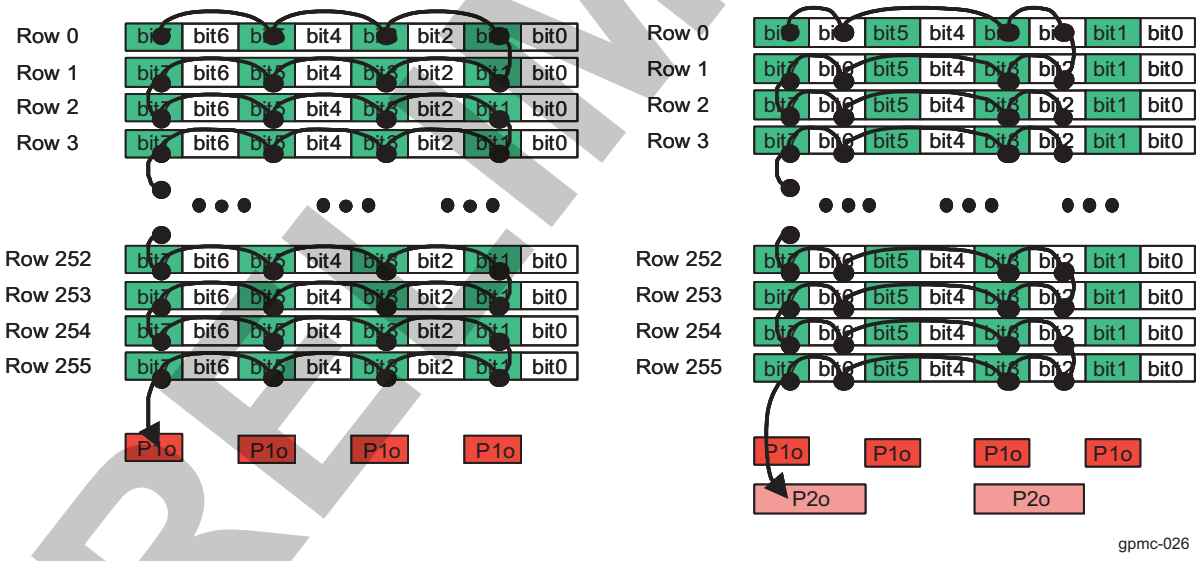
P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream
P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream
P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 15-81. Hamming Code Accumulation Algorithm (1/2)

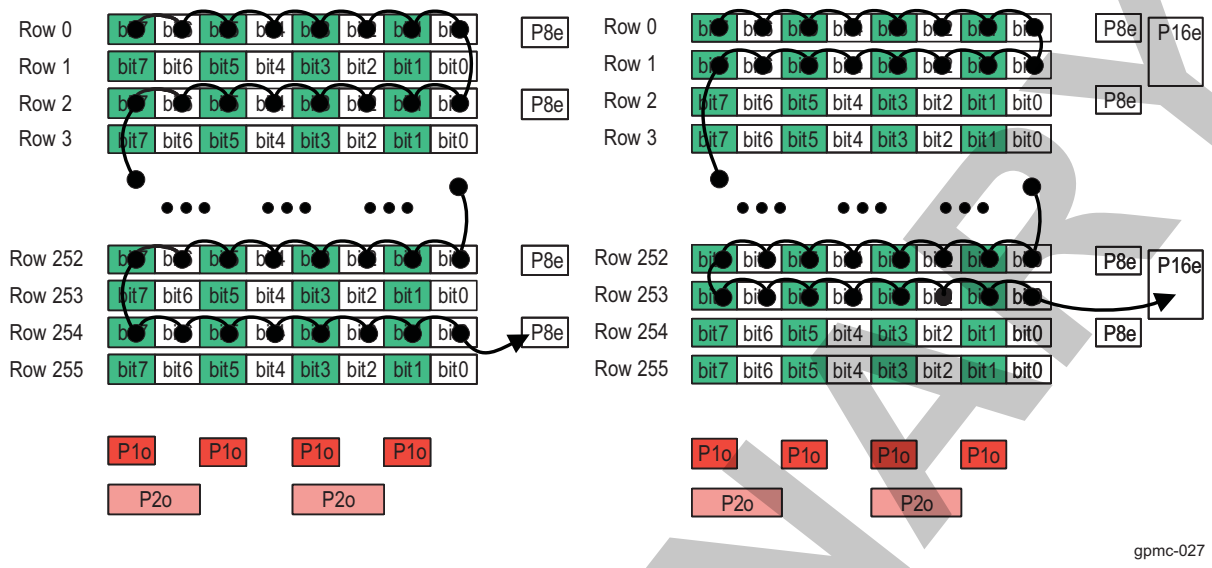


For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR ... XOR row254
P8o = row1 XOR row3 XOR row5 XOR ... XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253
P16o = row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255

Figure 15-82. Hamming Code Accumulation Algorithm (2/2)



Unused parity bits in the result registers are set to 0.

Figure 15-83 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 15-83. ECC Computation for a 256-Byte Data Stream (Read or Write)

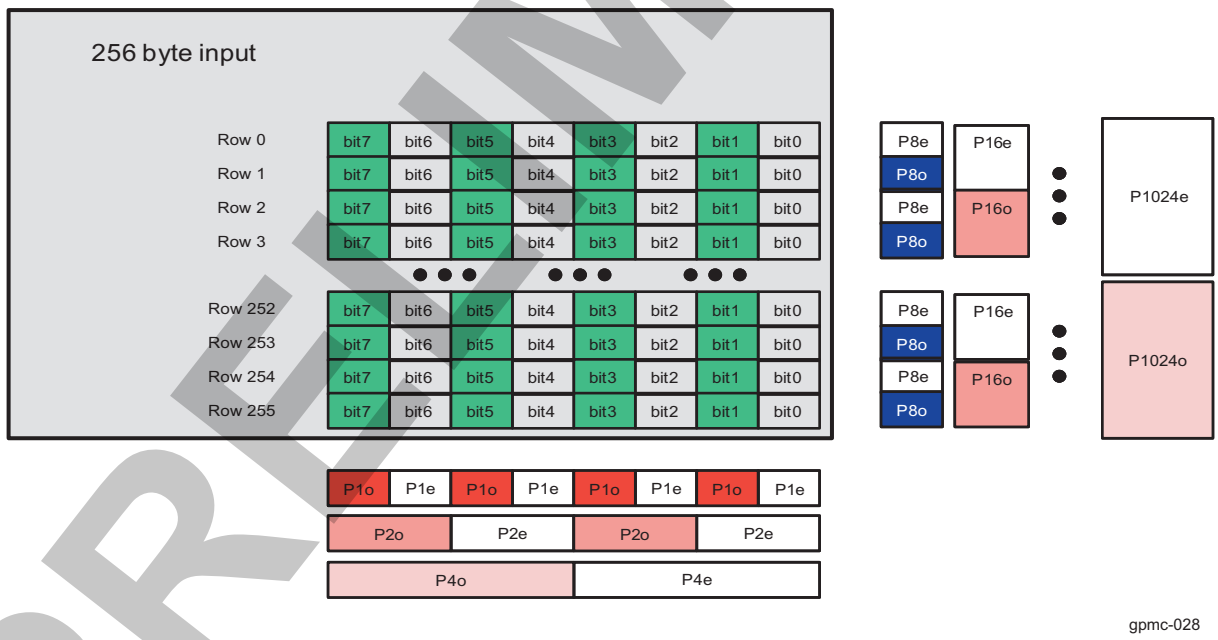


Figure 15-84 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

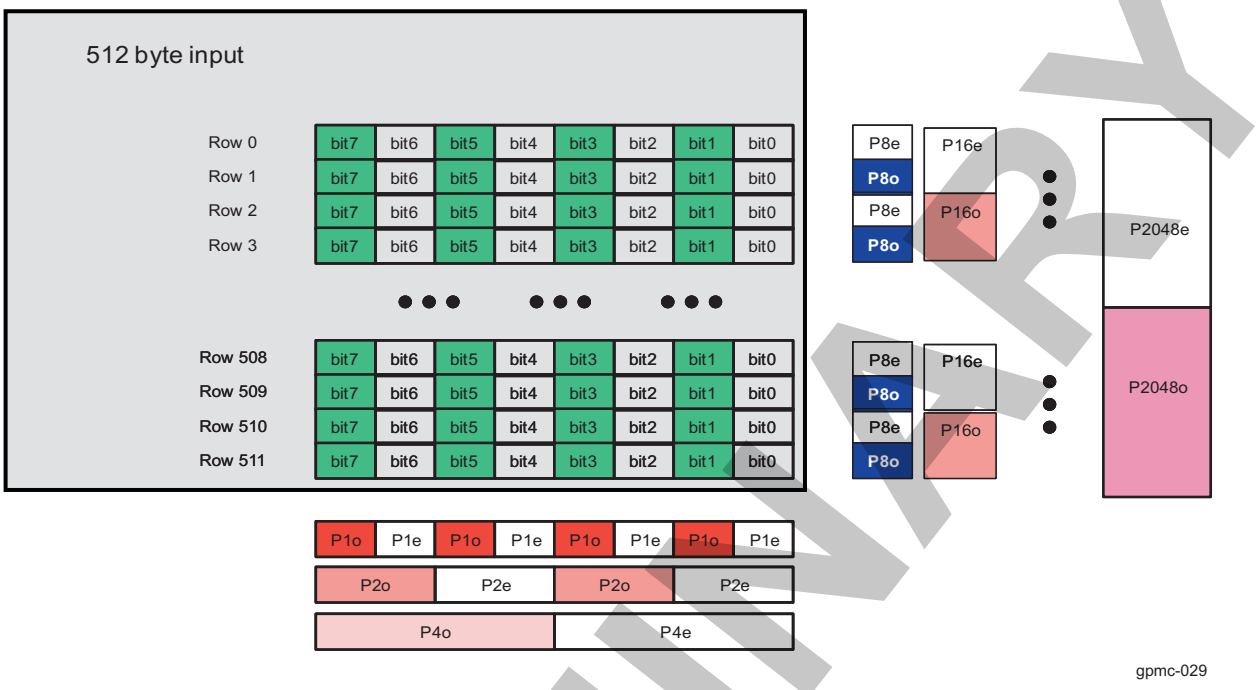
Figure 15-84. ECC Computation for a 512-Byte Data Stream (Read or Write)



For a 2-KiB page, four 512 bytes ECC calculations plus 1 for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers (where j = 1 to 9).

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, 1 bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). Software must correct the corresponding bit.
- If only 1 bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit-based ECC computation is used for 8-bit-wide NAND device interfacing.

The 8-bit-based ECC computation can be used for 16-bit-wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit-wide NAND devices. In this case, the 16-bit-wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the LSB of the 16-bit-wide data is ordered first in the byte stream used for 8-bit-based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on an 16-bit word is used for 16-bit-wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit-wide NAND device, and the GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit-wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit-based ECC and on columns for a 16-bit based ECC. Figure 15-85 and Figure 15-86 show a 128 Word16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 15-85. 128 Word16 ECC Computation

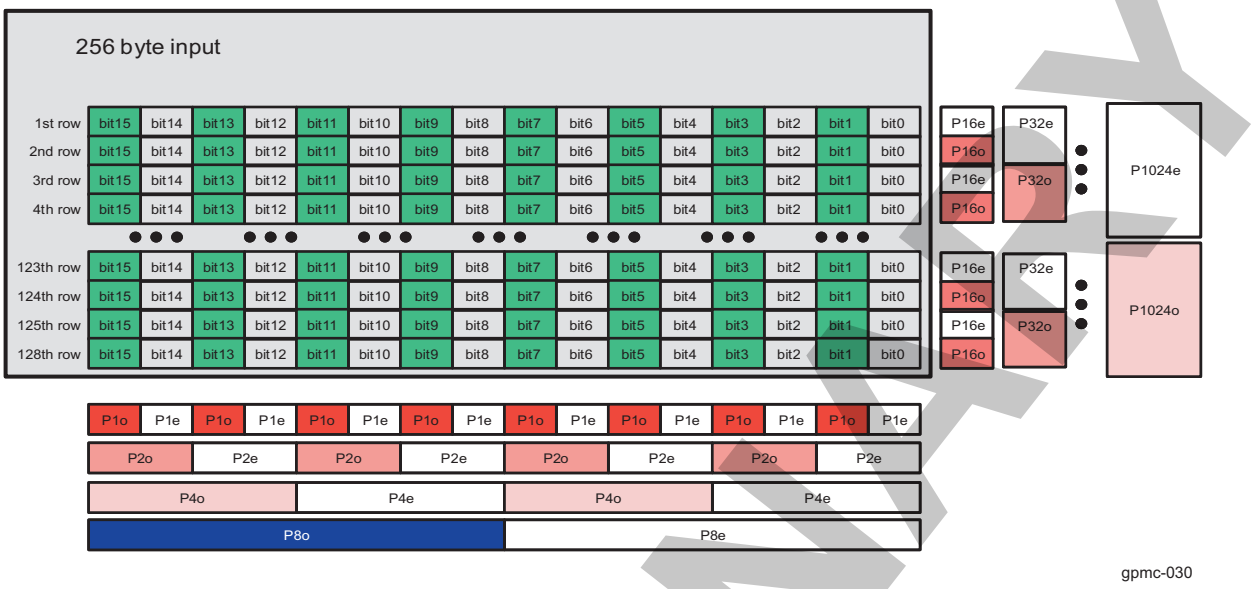


Figure 15-86. 256 Word16 ECC Computation

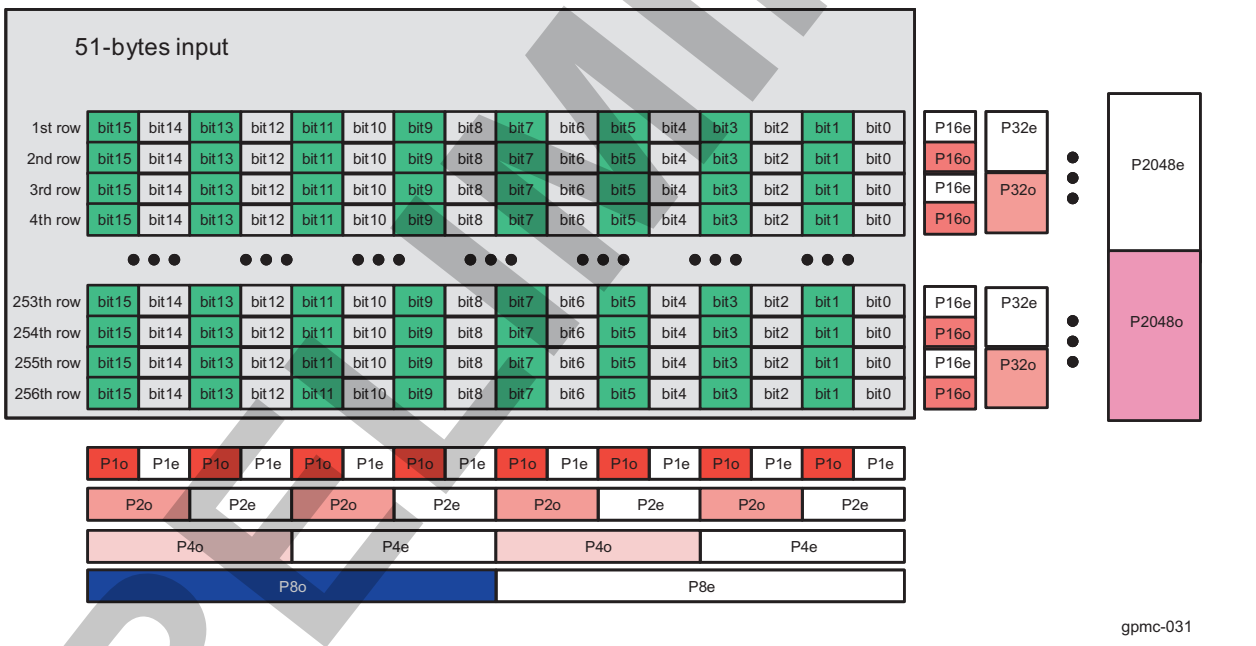

15.4.4.13.3.2 BCH Code

All references to ECC in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, and then some spare bytes, including the BCH ECC (and other information). The NAND device can cache a full page, including spares, for read and write accesses.
   - Typical page write sequence:
     - Sequential write to NAND cache of main data plus spare data, for a page. ECC is calculated on the fly. Calculated ECC can be inserted on the fly in the spares or replaced by dummy

accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array.

- Typical page read sequence:
  - Sequential read of a page. ECC is calculated on the fly.
  - The status of the ECC module buffers determines the presence of errors.

2. Accesses to several memories can be interleaved by the GPMC, but only one of those memories at a time can be a NAND using the BCH engine; in other words, only one BCH calculation (for example, for a single page) can be ongoing at any time. The sequential nature of NAND accesses ensures that the data is always written or read out in the same order. BCH-relevant accesses are selected by the chip-selects of the GPMC.
3. Each page can hold up to 4KiB of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Because all the data is written or read out first, followed by the BCH ECC, the BCH engine must be able to hold eight 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

   The BCH module can store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least four cycles of the GPMC internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least four clock cycles after optimization when using the BCH calculator.
5. The spare area is assumed to be large enough to hold the BCH ECC; that is, to have a message of at least 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (the maximum codeword is 1023 bytes long, ECC included, which leaves much space to cover spare bytes).

15.4.4.13.3.2.2 Memory Mapping of BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In a standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} – 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, 104 bits are required for 8-bit error correction, and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x), as described in Table 15-345.

Table 15-345. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

	Message M(x)			ECC R(x)		
Bit Number	M4095	...	M0	R103	...	R0

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) × 8) – 1 = 4119, for a total of 3 + 13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in the following registers (where i = 0 to 7):

- GPMC_BCH_RESULT0_i
- GPMC_BCH_RESULT1_i
- GPMC_BCH_RESULT2_i
- GPMC_BCH_RESULT3_i

15.4.4.13.3.2.2.1 Memory Mapping of Data Message

The data message mapping must follow the following rules:

- Bit endianness within a byte is little-endian; that is, the bytes LSB is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LSB) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + ... + b0 * x^{i}$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the 16-bit words in the NAND is big-endian (that is, the same message mapped in 8- and 16-bit memories has the same content at the same byte address).

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data words the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, which produces the mapping patterns described in the following.

Table 15-346 and Table 15-347 describe the mapping of the same 512-byte vector (typically, a BCH message) in the NAND memory space. The byte address is only an offset modulo 512 (0x200), because the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are, respectively, the bits M0 and $M(2^{12}–1)$ of the codeword mapping discussed previously. In both cases the data vectors are aligned; that is, their boundaries coincide with the RAM data word boundaries.

Table 15-346. Aligned Message Byte Mapping in 8-Bit NAND

Byte Offset	8-Bit Word
0x000	(MSB) Byte 511 (0x1FF)
0x001	Byte 510 (0x1FE)
...	...
0x1FF	Byte 0 (0x0) (LSB)

Table 15-347. Aligned Message Byte Mapping in 16-Bit NAND

Byte Offset	16-Bit Word MSB	16-Bit Word LSB
0x000	Byte 510 (0x1FE)	(MSB) Byte 511 (0x1FF)
0x002	Byte 508 (0x1FC)	Byte 509 (0x1FD)
...	...	...
0x1FE	Byte 0 (0x0)	(LSB) Byte 1 (0x1)

Table 15-348 through Table 15-353 list the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on the ECC of another sector).

Table 15-348. Aligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
...	...	...
S/2 – 2	Nibble 3	Nibble 2
S/2 – 1	Nibble 1	Nibble 0 (LSB)

Table 15-349. Misaligned Nibble Mapping of Message in 8-Bit NAND

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Least Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2

(S + 3) / 2 – 2			Nibble 0 (LSB)	

Many other cases exist than those given in the previous tables; for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. Software must fetch those 13 bytes (or 6 bytes) from the module interface and then store them to the spare area (page write) in the NAND or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is software-controlled.

It is advised, however, to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error is detected. The creation of this codeword must be made as straightforward as possible.

There are cases in which the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on the fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on the fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described as follows. To better understand and see the real-life read and write sequences implemented with each mode, see Section 15.4.4.13.3.2.3, *Supported NAND Page Mappings and ECC Schemes*.

For each mode:

- A sequence describes the mode in pseudo language, with, for each section, the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0, and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the module behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Wrapping modes 8 through 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.13.3.2.2.4 Manual Mode (0x0)

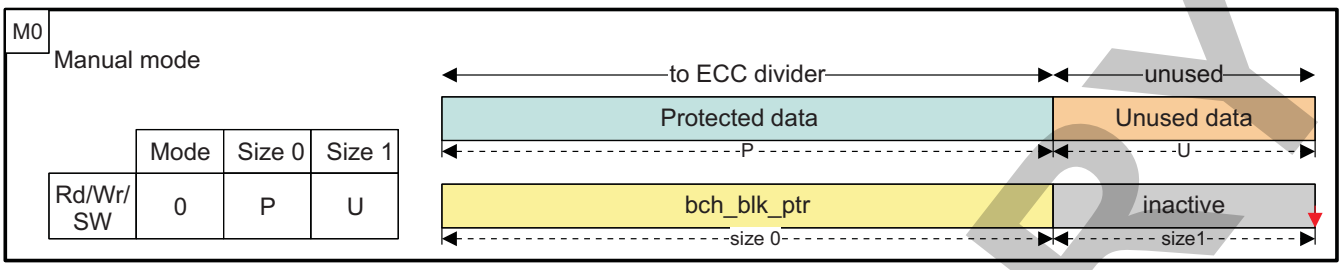
This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port, containing the appropriate data, must be made. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles must be skipped, a number of unused nibbles must be programmed in GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 In the same example, 5 nibbles to process + 3 to discard = 8 nibbles = 2 × 16-bit accesses. Software must set:

- GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 = 0x5
- GPMC_ECC_SIZE_CONFIG[29:22] ECCSIZE1 = 0x3

NOTE: In the following figures, size and size0 are the same parameter.

Figure 15-87. Manual Mode Sequence and Mapping



Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.13.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.13.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.13.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.13.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.13.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.13.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.13.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – size1)

15.4.4.13.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON

- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S – (1 + size1))

15.4.4.13.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.13.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S – (size0 + 1 + size1)

15.4.4.13.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S – (size0 + size1)

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply to the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in Section 15.4.4.13.3.2.2.1, *Memory Mapping of Data Message*.

Each of the following sections gives a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In Figure 15-88 through Figure 15-90, the tables on the left summarize the mode, size0, and size1 parameters to program for, respectively, write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC (in nibbles)
- S is the number of Sectors per page (two in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. The processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1 KiB + spares; that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can happen only in the codeword that was actually written to the NAND, not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits; that codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, the programmed sizes, and the sector number (all sizes in nibbles):

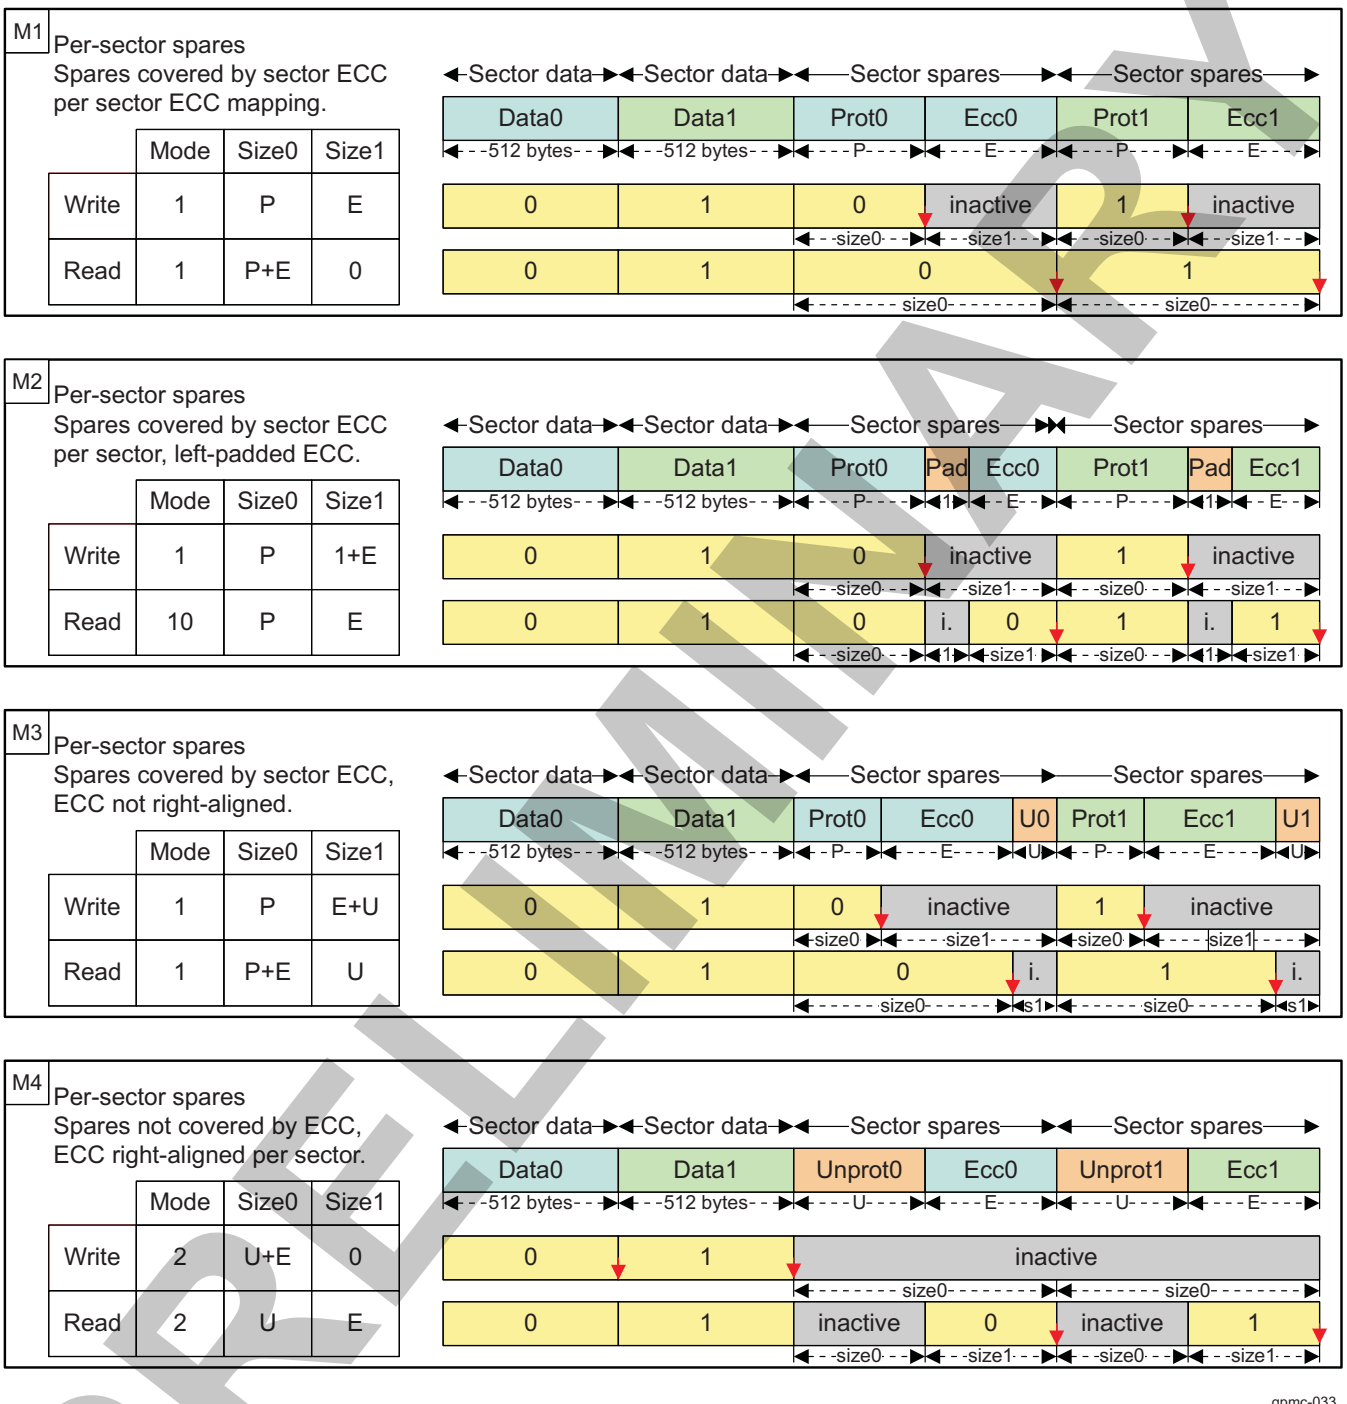
- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
  - All sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
  - Sector 0 codeword: (512) + P + E
  - Other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
  - All codewords (512) + E

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- Other data, which may or may not be protected by the ECC for its sector.

Figure 15-88. NAND Page Mapping and ECC: Per-Sector Schemes



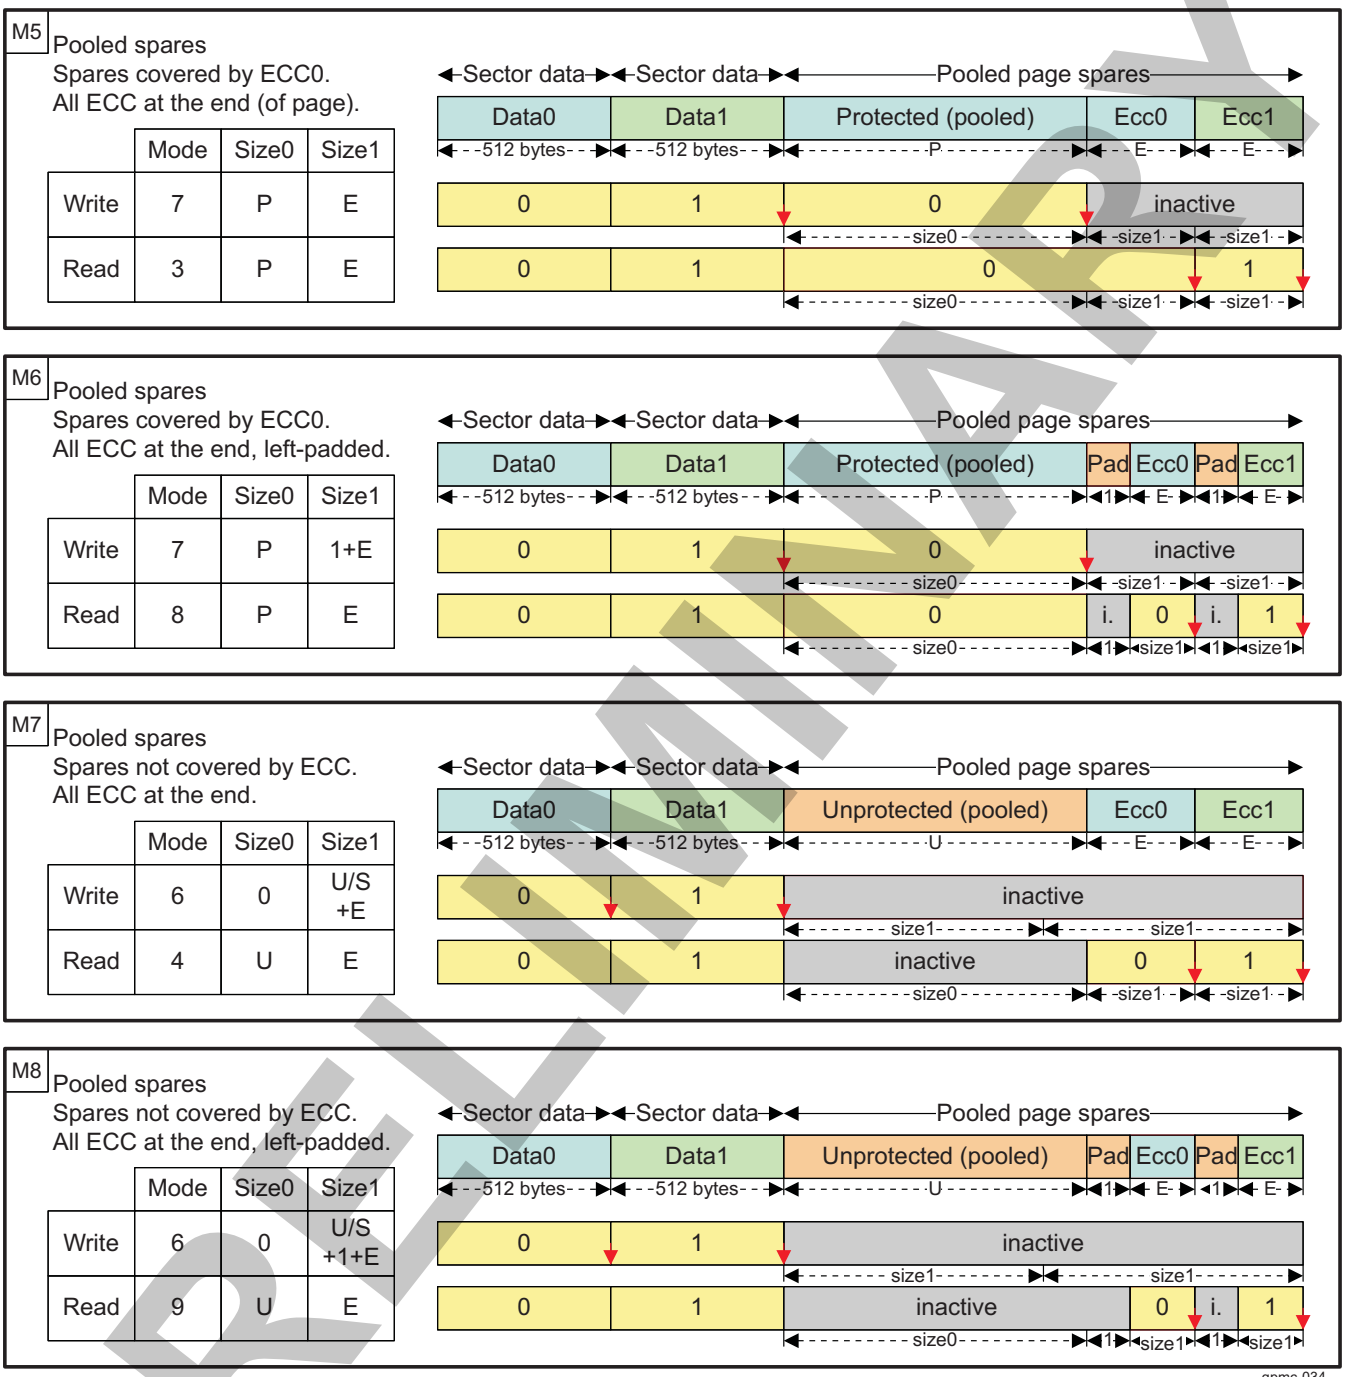
gpmc-033

15.4.4.13.3.2.3.2 Pooled Spare Mapping

In the following schemes, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0.

Figure 15-89. NAND Page Mapping and ECC: Pooled Spare Schemes

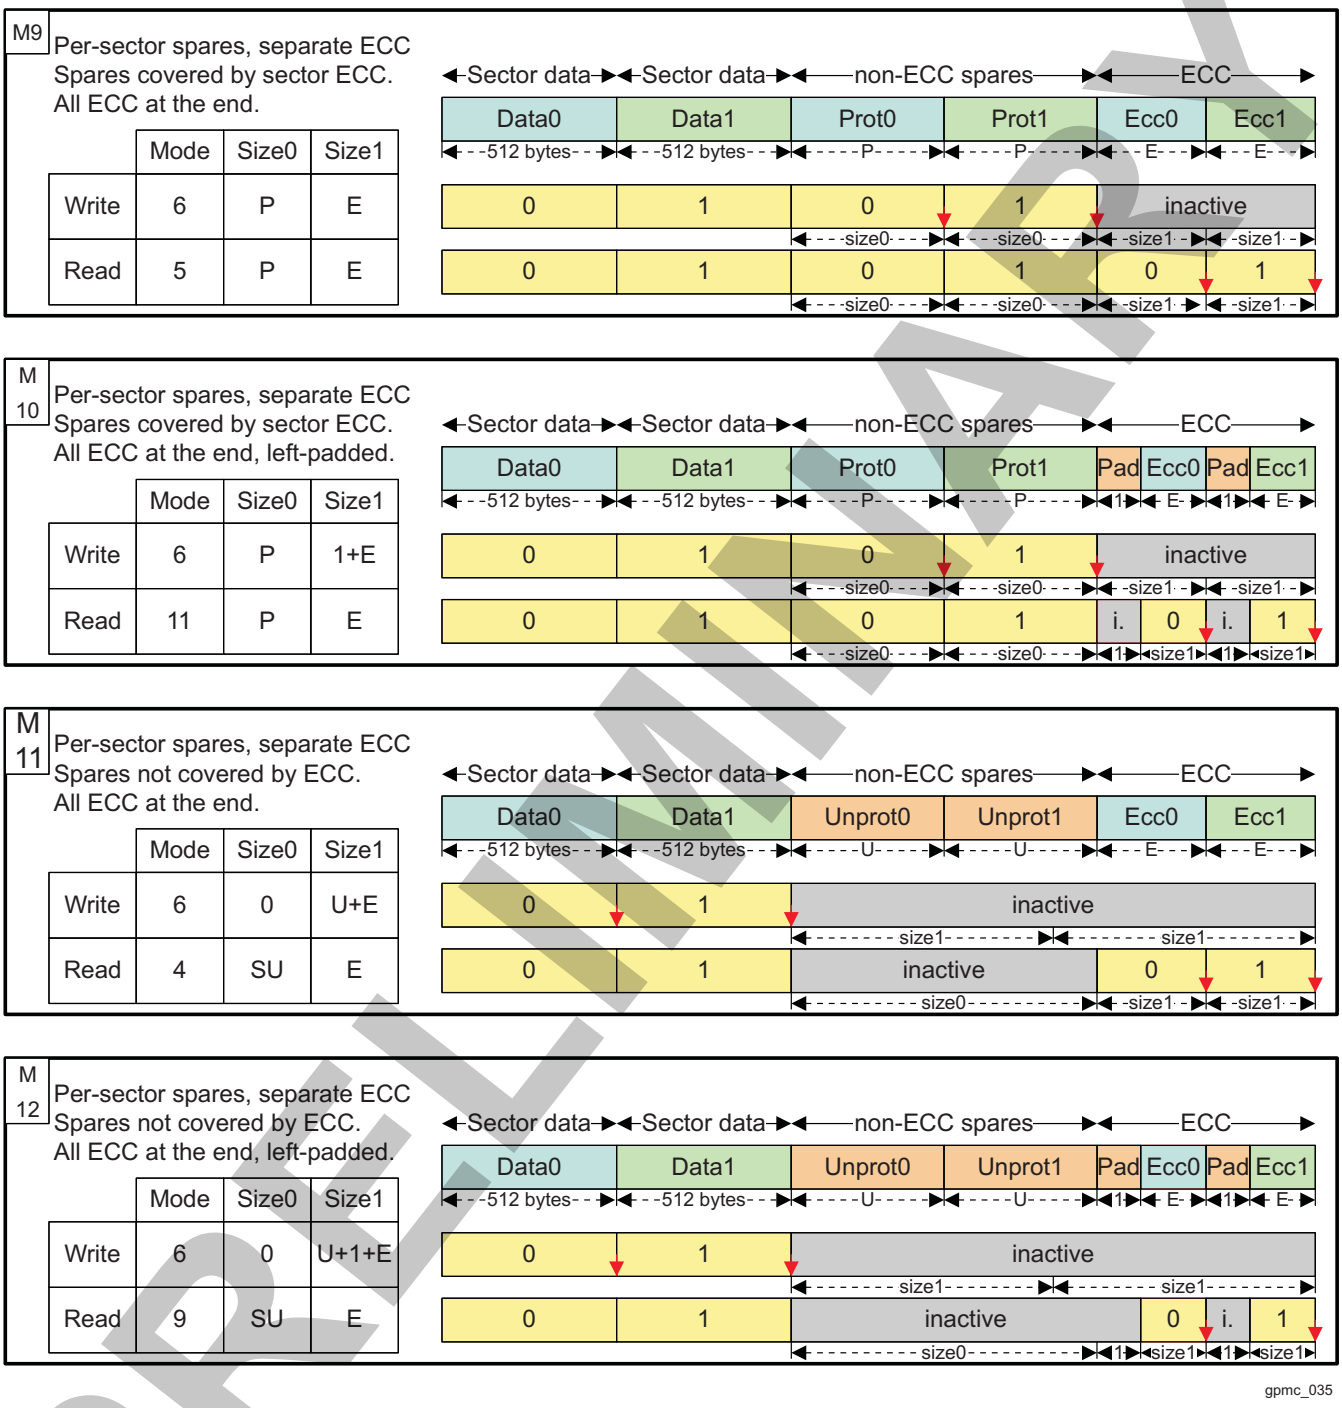


15.4.4.13.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- Other data section, aligned before the ECCs, each of which may or may not be protected by the ECC for its sector.

Figure 15-90. NAND Page Mapping and ECC: Per-Sector Schemes, With Separate ECC



15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor affect the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default, the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64-byte (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or by the sDMA through DMA request synchronization, with a programmable request byte size in prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. As a consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, engine data read and write sequencing is based solely on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR bit field.

In prefetch and write-posting modes, the engine uses byte or 16-bit word access requests, respectively, for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT bit fields must be programmed accordingly as a number of bytes.

When the GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the following registers (where i = 0 to 7):

- GPMC_NAND_COMMAND_i
- GPMC_NAND_ADDRESS_i
- GPMC_NAND_DATA_i

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots that can be written in write-posting mode. The GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field monitors the number of remaining bytes to be read or written by the engine according to the value of the TRANSFERCOUNT bit field. The FIFOPOINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit-wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPOINTER equals 0 (that is, the FIFO is empty), a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPOINTER equals 0 (that is, the FIFO is full), a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started so that the ECC is computed correctly on all data read by the prefetch engine.

When the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it sets the STARTENGINE bit only when the NAND device is in a ready state (that is, data is valid for prefetching).

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active-to-inactive WAIT signal transition is detected. The transition detector must be cleared before any transition detection (see Section 15.4.4.13.2.2, *Ready Pin Monitored by Hardware Interrupt*). The GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR bit field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit before NAND address phase completion when in synchronized mode. The prefetch engine starts when an active-to-inactive WAIT signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by the GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT bit field.

Table 15-354 describes the prefetch mode configuration.

Table 15-354. Prefetch Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Prefetch engine can be configured only if STARTENGINE is set to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1[17:16]	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 0x1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC_PREFETCH_STATUS[30:24] FIFOPOINTER bit field or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPOINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is valid only when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel that owns this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are calculated properly on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses are complete.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must be issued only when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-355 describes the write-posting configuration.

Table 15-355. Write-Posting Mode Configuration

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	0	Write-posting engine can be configured only if STARTENGINE is set to 0.

Table 15-355. Write-Posting Mode Configuration (continued)

Bit Field	Register	Value	Comments
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1[26:24]	0 to 3	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1[0]	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1[14:8]		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2[13:0]		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1[3]	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1[27]	0/1	See Section 15.4.4.13.4.6, *Optimizing NAND Access Using the Prefetch and Write-Posting Engine*.
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1[30:28]		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1[7]	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONTROL[0]	1	Starts the prefetch engine

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPOINTER or through the GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPOINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO or to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared before asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC_PREFETCH_STATUS[13:0] COUNTVALUE bit field. COUNTVALUE indicates the current number of remaining data to be written based on the value of the TRANSFERCOUNT bit field. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared before asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The value of the COUNTVALUE bit field is valid only if the write-posting engine is active and started, and an interrupt is issued only when COUNTVALUE reaches 0; that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel that owns this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request completes.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive-to-active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or MPU fills the FIFO with no consideration for the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

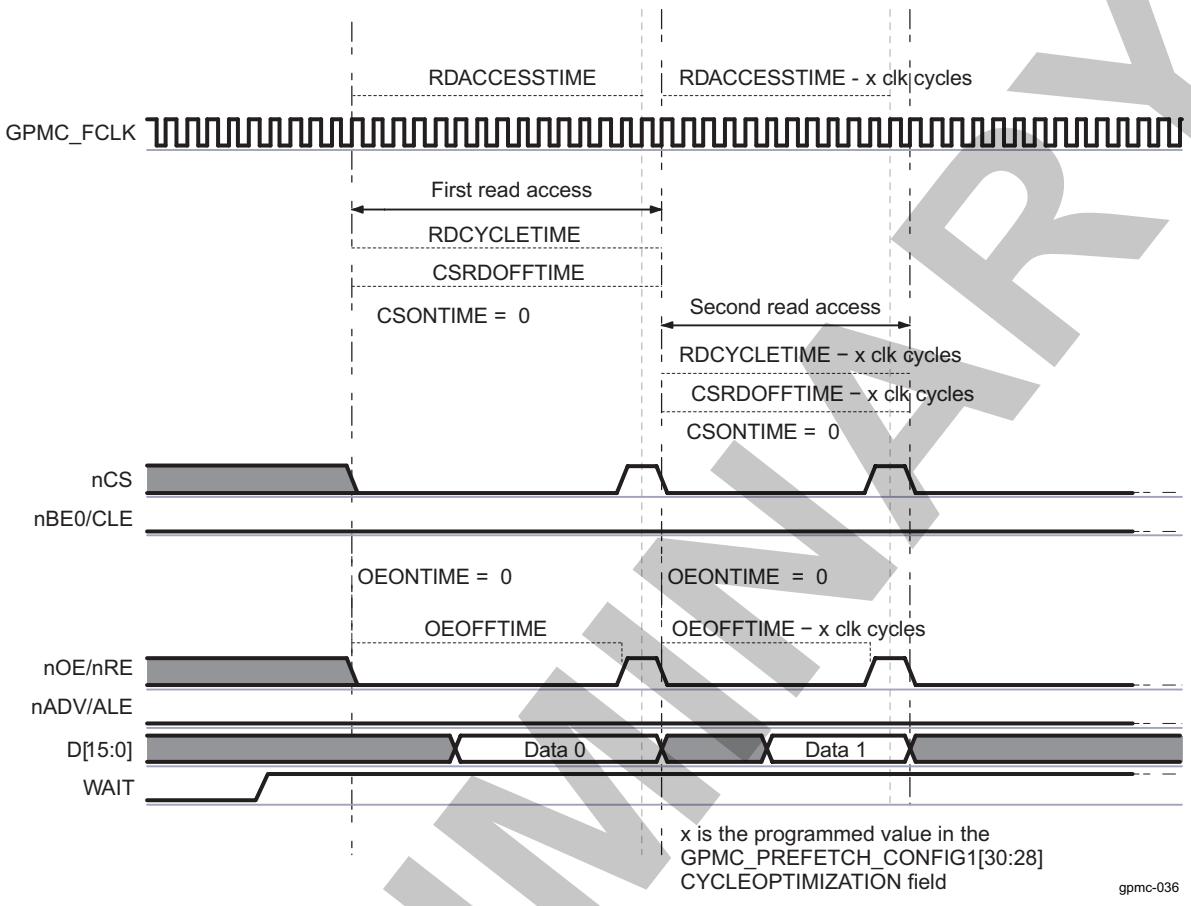
Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC_NAND_DATA_i location, where i = 0 to 7) are never optimized.

The GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field defines the number of GPMC_FCLK cycles to be suppressed from the following timing parameters:

- RDCYCLETIME
- WRCYCLETIME
- RDACCESSTIME
- WRACCESSTIME
- CSOFFTIME
- ADVOFFTIME
- OEOFFTIME
- WEOFFTIME

Figure 15-91 shows that in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION bit field.

Figure 15-91. NAND Read Cycle Optimization Timing Description



15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering that the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top-down approach to users that need to configure the GPMC module.

Figure 15-92 and Table 15-356 through Table 15-358 show a programming model top-level diagram for the GPMC, and a description of each step. Each block of the diagram is described in one of the following sections through a set of registers to configure.

Figure 15-92. Programming Model Top-Level Diagram

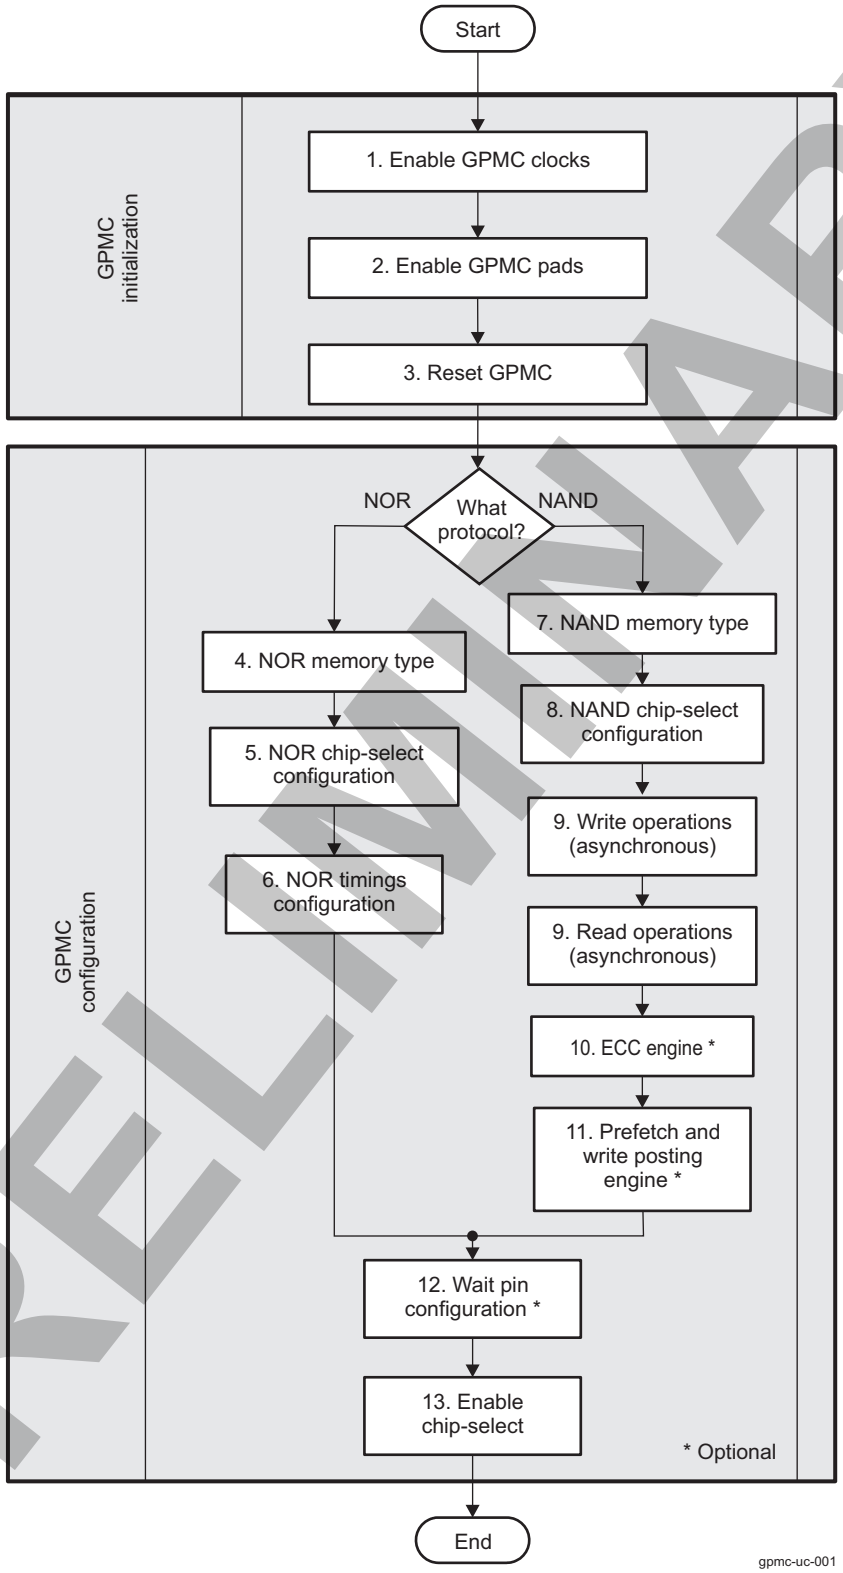


Table 15-356. GPMC Initialization

Step	Description
Enable GPMC clocks.	Module interface and functional clocks must be enabled. See Section 3.1.1, *Power, Reset, and Clock Management*.
Enable GPMC pads.	Module-specific pad multiplexing and configuration must be set in the control module. See Figure 18-1, *Control Module*.
Reset GPMC.	See Table 15-359.

Table 15-357. GPMC Configuration in NOR Mode

Step	Description
NOR Memory Type	See Table 15-360.
NOR Chip-Select Configuration	See Table 15-361.
NOR Timings Configuration	See Table 15-362.
Wait Pin Configuration	See Table 15-370.
Enable Chip-Select	See Table 15-371.

Table 15-358. GPMC Configuration in NAND Mode

Step	Description
NAND Memory Type	See Table 15-365.
NAND Chip-Select Configuration	See Table 15-366.
Write Operations (Asynchronous)	See Table 15-367.
Read Operations (Asynchronous)	See Table 15-367.
ECC Engine	See Table 15-368.
Prefetch and Write-Posting Engine	See Table 15-369.
Wait Pin Configuration	See Table 15-370.
Enable Chip-Select	See Table 15-371.

15.4.5.2 GPMC Initialization

Table 15-387 describes the settings required to prepare the GPMC; that is enabling its clock and pads, and proceeding to a GPMC reset.

Table 15-359. Reset GPMC

Subprocess Name	Register/Bit Field	Value
Start a software reset.	GPMC_SYSCONFIG[1] SOFTRESET	0x1
Wait until	GPMC_SYSSTATUS[0] RESETDONE =	0x1

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-360. NOR Memory Type

Subprocess Name	Register / Bit Field	Value
Set the NOR protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x0
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Select an address and data multiplexing protocol.	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length.	GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities.	GPMC_CONFIG1_i[31] WRAPBURST	x

Table 15-360. NOR Memory Type (continued)

Subprocess Name	Register / Bit Field	Value
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency (1).	GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER	x
Choose an output clock activation time (1).	GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations (1).	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations.	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations.	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations.	GPMC_CONFIG1_i[27] WRITETYPE	x

(1) Applies only to synchronous configurations (or nonmultiplexed asynchronous for multiple access one)

Table 15-361. NOR Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select mask address.	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-362. NOR Timings Configuration

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in various memory modes.	See Section 15.4.5.6, *GPMC Timing Parameters*	

Table 15-363. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Enable or disable wait pin monitoring for read operations.	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations.	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time.	GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select.	GPMC_CONFIG1_i[17:16] WAITPINSELECT	x

Table 15-364. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-365. NAND Memory Type

Subprocess Name	Register/Bit Field	Value
Set the NAND protocol.	GPMC_CONFIG1_i[11:10] DEVICETYPE	0x2
Set a device size.	GPMC_CONFIG1_i[13:12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device.	GPMC_CONFIG1_i[9] MUXADDDATA	0x0
Select a timing signals latencies factor.	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations.	See Section 15.4.5.5, *Set Memory Access*.	x

Table 15-366. NAND Chip-Select Configuration

Subprocess Name	Register/Bit Field	Value
Select the chip-select base address.	GPMC_CONFIG7_i[5:0] BASEADDRESS	x
Select the chip-select minimum granularity (16MiB).	GPMC_CONFIG7_i[11:8] MASKADDRESS	x

Table 15-367. Asynchronous Read and Write Operations

Subprocess Name	Register/Bit Field	Value
Configure adequate timing parameters in asynchronous modes	See Section 15.4.5.6, *GPMC Timing Parameters*.	

Table 15-368. ECC Engine

Subprocess Name	Register/Bit Field	Value
Select the ECC result register where the first ECC computation is stored (applies only to Hamming).	GPMC_ECC_CONTROL[3:0] ECCPOINTER	x (1)
Clear all ECC result registers.	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear.
Define ECCSIZE0 and ECCSIZE1.	GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1	x (2)
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1).	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9	x
Select the chip-select where ECC is computed.	GPMC_ECC_CONFIG[3:1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use.	GPMC_ECC_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation.	GPMC_ECC_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process.	GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR	x
Enable the ECC computation.	GPMC_ECC_CONFIG[0] ECCENABLE	0x1

(1) This parameter depends on the numbers of sectors in a page.
(2) Depends on the size of each sector in the NAND page

Table 15-369. Prefetch and Write-Posting Engine

Subprocess Name	Register/Bit Field	Value
Disable the engine before configuration.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x0
Select the chip-select associated with a NAND device where the prefetch engine is active.	GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request.	GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD	x
Select DMA synchronized mode or software manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (for all back-to-back accesses to the NAND flash except the first one).	GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION	x
Enable the prefetch postwrite engine.	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	0x1
Select the number of bytes to be read or written by the engine to the selected chip-select.	GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT	x
Start the prefetch engine.	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0x1

Table 15-370. Wait Pin Configuration

Subprocess Name	Register/Bit Field	Value
Selects when the engine starts the access to chip-select.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode.	GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR	x

Table 15-371. Enable Chip-Select

Subprocess Name	Register/Bit Field	Value
When all parameters are configured, enable the chip-select.	GPMC_CONFIG7_i[6] CSVALID	x

15.4.5.5 Set Memory Access

This section describes the bit field to configure to set the GPMC in various memory modes. Table 15-372 and Table 15-373 provide check lists for mode parameters and access type parameters, respectively.

Table 15-372. Mode Parameters Check List

Register	Bit	Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0x0	–	0x1 (1)	N/S	0x0	–	0x1	–
GPMC_CONFIG1_i	29	READTYPE	0x0	–	0x0 (1)	N/S	0x1	–	0x1	–
GPMC_CONFIG1_i	28	WRITEMULTIPLE	–	0x0	- (1)	N/S	–	0x0	–	0x1
GPMC_CONFIG1_i	27	WRITETYPE	–	0x0	- (1)	N/S	–	0x1	–	0x1

(1) Multiple read is not supported in address/data-multiplexed and AAD-multiplexed modes. Multiple read is supported in nonmultiplexed mode.

Table 15-373. Access Type Parameters Check List

Register	Bit	Name	Access Type		
			Nonmultiplexed	Address/ Data-Multiplexed	AAD-Multiplexed
GPMC_CONFIG1_i	9:8	MUXADDDATA	0x0	0x2	0x1
GPMC_CONFIG	1	LIMITEDADDRESS (1)	0x1	0x0	0x0

(1) This parameter applies to all chip-selects. There is no per-chip-select configuration for this parameter.

15.4.5.6 GPMC Timing Parameters

Figure 15-93 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 15-93. NOR Interfacing Timing Parameters Diagram

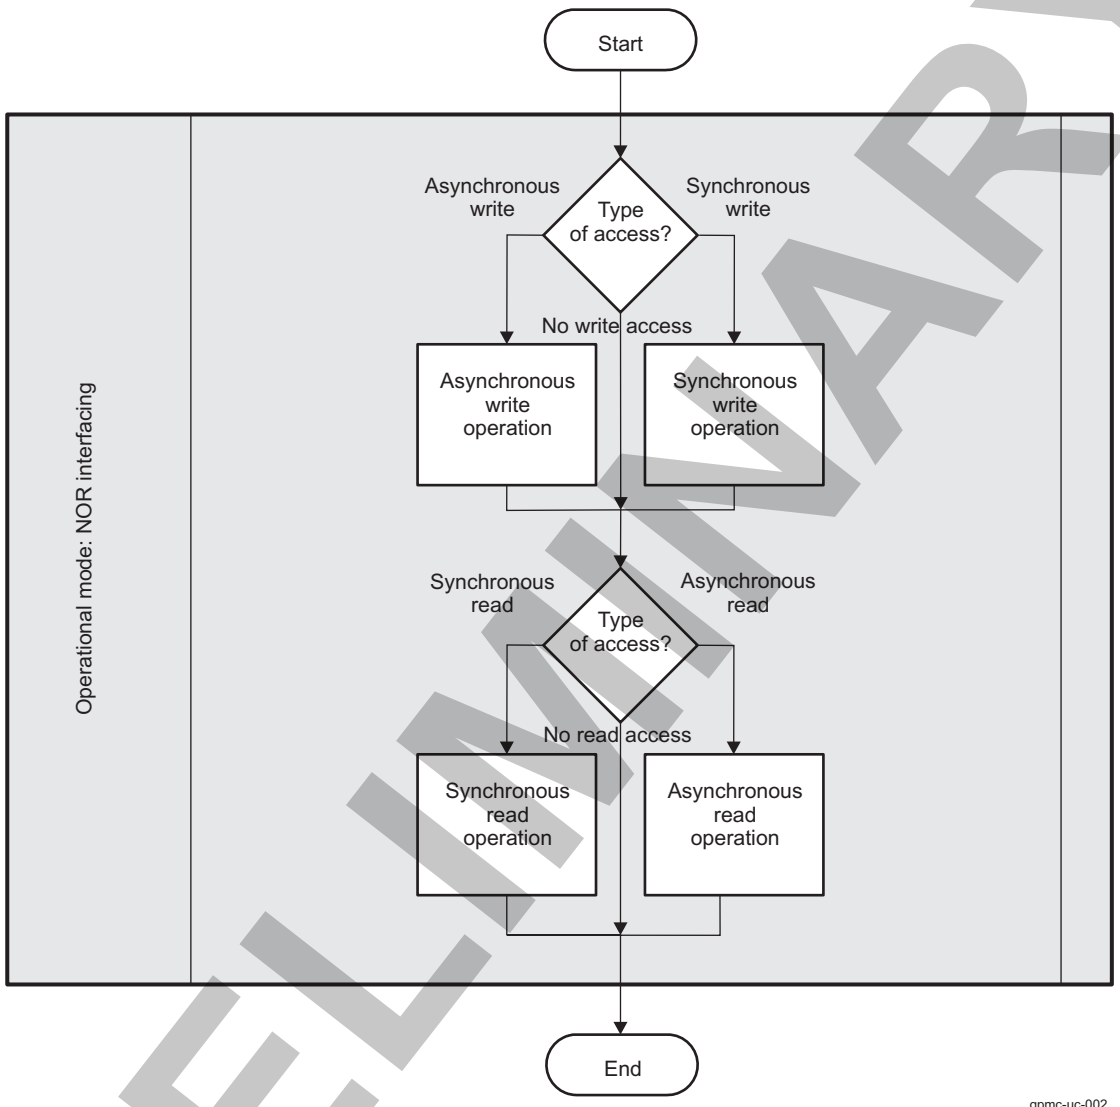

Table 15-374 lists the bit fields to configure adequate timing parameters in various memory modes.

Table 15-374. Timing Parameters

			Asynchronous			Synchronous				Access Type		
Register	Bit	Name	Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address / Data-Multiplexed	AAD Multiplexed
GPMC_CONFIG1_i	9	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y

15.4.5.6.1 GPMC Timing Parameters Formulas

This section is intended to help the user calculate the GPMC timing bit field values. Formulas are not listed exhaustively.

The section describes:

- NAND flash interface timing parameters formulas
- Synchronous NOR flash timing parameters formulas
- Asynchronous NOR flash timing parameters formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to calculate NAND timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x2. Table 15-375 describes the NAND timing parameters.

Table 15-375. NAND Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_nwe valid time
B	ns	Delay time – gpmc_ncs valid to gpmc_nwe valid
C	ns	Delay time – gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid
D	ns	Delay time – gpmc_ad[15:0] valid to gpmc_nwe valid
E	ns	Delay time – gpmc_nwe invalid to gpmc_ad[15:0] invalid
F	ns	Delay time – gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid
G	ns	Delay time – gpmc_nwe invalid to gpmc_ncs invalid
H	ns	Cycle time – Write cycle time
I	ns	Delay time – gpmc_ncs valid to gpmc_noe valid
J	ns	Setup time – gpmc_ad[15:0] valid to gpmc_noe invalid
K	ns	Pulse duration – gpmc_noe valid time
L	ns	Cycle time – Read cycle time
M	ns	Delay time – gpmc_noe invalid to gpmc_ncs invalid

The configuration parameters are calculated through the following formulas.

A = (WEOffTime – WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK period

B = ((WEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

C = ((WEOnTime – ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEExtraDelay - ADVExtraDelay)) * GPMC_FCLK period

D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEExtraDelay) * GPMC_FCLK period

E = (WrCycleTime – WEOffTime * (TimeParaGranularity + 1) – 0.5 * WEExtraDelay) * GPMC_FCLK period

F = (ADVWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay – WEExtraDelay) * GPMC_FCLK period

G = (CSWrOffTime – WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay – WEExtraDelay) * GPMC_FCLK period

H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

I = ((OEOnTime – CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEExtraDelay – CSExtraDelay)) * GPMC_FCLK period

J = ((AccessTime – OEOffTime) * (TimeParaGranularity + 1) – 0.5 * OEExtraDelay)) * GPMC_FCLK period

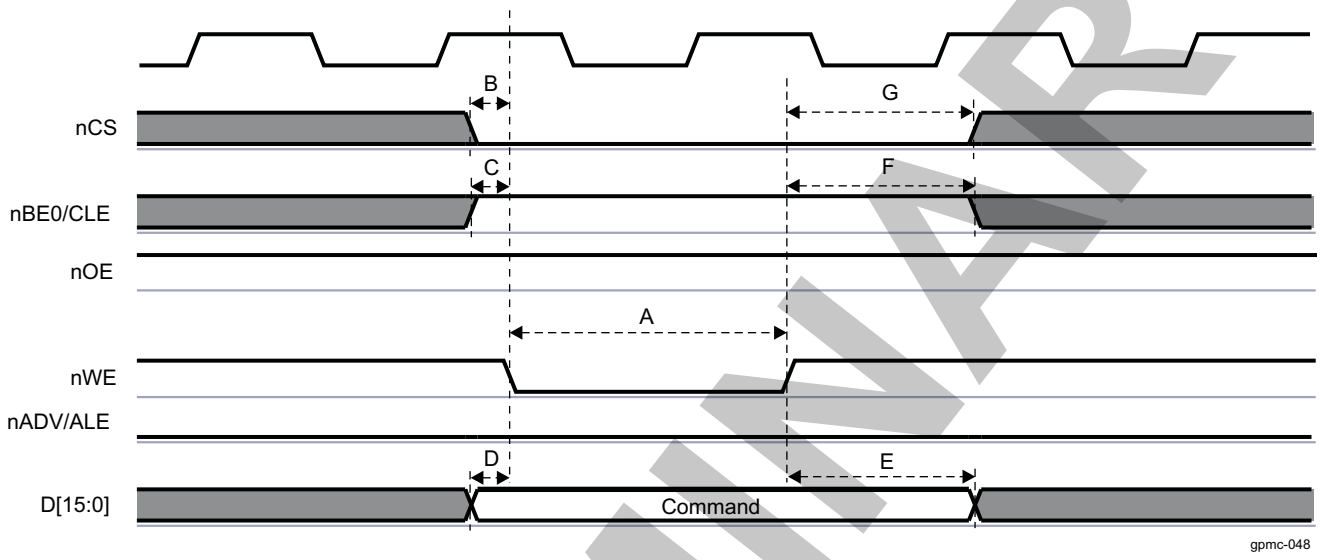
K = (OEOffTime – OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK period

L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK period

M = (CSRdOffTime – OEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSExtraDelay - OEExtraDelay) * GPMC_FCLK period

Figure 15-94 shows a simplified example of command latch cycle timing where formulas are associated with signal waves.

Figure 15-94. NAND Command Latch Cycle Timing Simplified Example



15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to calculate synchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to synchronous mode. Table 15-376 describes the synchronous NOR formulas.

Table 15-376. Synchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_ncs low
B	ns	Delay time – address bus valid to gpmc_clk first edge
		Delay time – gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge
C	ns	Pulse duration – gpmc_nbe0_cle/gpmc_nbe1 low
D	ns	Delay time – gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid
		Delay time – gpmc_clk rising edge to gpmc_nadv_ale invalid
E	ns	Delay time – gpmc_clk rising edge to gpmc_ncs invalid
		Delay time – gpmc_clk rising edge to gpmc_noe invalid
F	ns	Delay time – gpmc_clk rising edge to gpmc_ncs transition
G	ns	Delay time – gpmc_clk rising edge to gpmc_nadv_ale transition
H	ns	Delay time – gpmc_clk rising edge to gpmc_noe transition
I	ns	Delay time – gpmc_clk rising edge to gpmc_nwe transition
J	ns	Delay time – gpmc_clk rising edge to gpmc_ad data bus transition
		Delay time – gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition
K	ns	Pulse duration – gpmc_nadv_ale low
L	ns	Delay time – gpmc_wait invalid to first data latching gpmc_clk edge

The configuration parameters are calculated through the following formulas.

1. For single read accesses:
   A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – ACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – ACCESSTIME) * GPMC_FCLK period
2. For burst read accesses (where n is the page burst access number):
   A = (CSRDOFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (RDCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (RDCYCLETIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSRDOFFTIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
3. For burst write accesses (where n is the page burst access number):
   A = (CSWROFFTIME – CSONTIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   C = (WRCYCLETIME + (n – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
   D = (WRCYCLETIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
   E = (CSWROFFTIME – (ACCESSTIME + (n – 1) * PAGEBURSTACCESSTIME) * GPMC_FCLK period
4. For all accesses:
   For nCS falling edge (chip-select activated):
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in reading mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.
   - Case where GPMCFCLKDIVIDER = 0x2:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
     F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
     F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSRDOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

   For nCS rising edge (chip-select deactivated) in writing mode:
   - Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period
   - Case where GPMCFCLKDIVIDER = 0x1:
     F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and

CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)
F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  F = 0.5 * CSEXTRADELAY * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  F = (1 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  F = (2 + 0.5 * CSEXTRADELAY) * GPMC_FCLK period, when (CSWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV falling edge (nADV activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVONTIME are odd) or (CLKACTIVATIONTIME and ADVONTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in reading mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVRDOFFTIME are odd) or (CLKACTIVATIONTIME and ADVRDOFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nADV rising edge (nADV deactivated) in writing mode:

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and ADVWROFFTIME are odd) or (CLKACTIVATIONTIME and ADVWROFFTIME are even)
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  G = 0.5 * ADVEXTRADELAY * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  G = (1 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  G = (2 + 0.5 * ADVEXTRADELAY) * GPMC_FCLK period, when (ADVWROFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE falling edge (nOE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEONTIME

are odd) or (CLKACTIVATIONTIME and OEONTIME are even)
H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nOE rising edge (nOE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and OEOFFTIME are odd) or (CLKACTIVATIONTIME and OEOFFTIME are even)
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  H = 0.5 * OEEXTRADELAY * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK period, when (OEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE falling edge (nWE activated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEONTIME are odd) or (CLKACTIVATIONTIME and WEONTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEONTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For nWE rising edge (nWE deactivated):

- Case where GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER = 0x0:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period
- Case where GPMCFCLKDIVIDER = 0x1:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (CLKACTIVATIONTIME and WEOFFTIME are odd) or (CLKACTIVATIONTIME and WEOFFTIME are even)
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period otherwise.
- Case where GPMCFCLKDIVIDER = 0x2:
  I = 0.5 * WEEXTRADELAY * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME) is a multiple of 3
  I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 1) is a multiple of 3
  I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK period, when (WEOFFTIME – CLKACTIVATIONTIME – 2) is a multiple of 3

For gpmc_nadv low pulse duration:

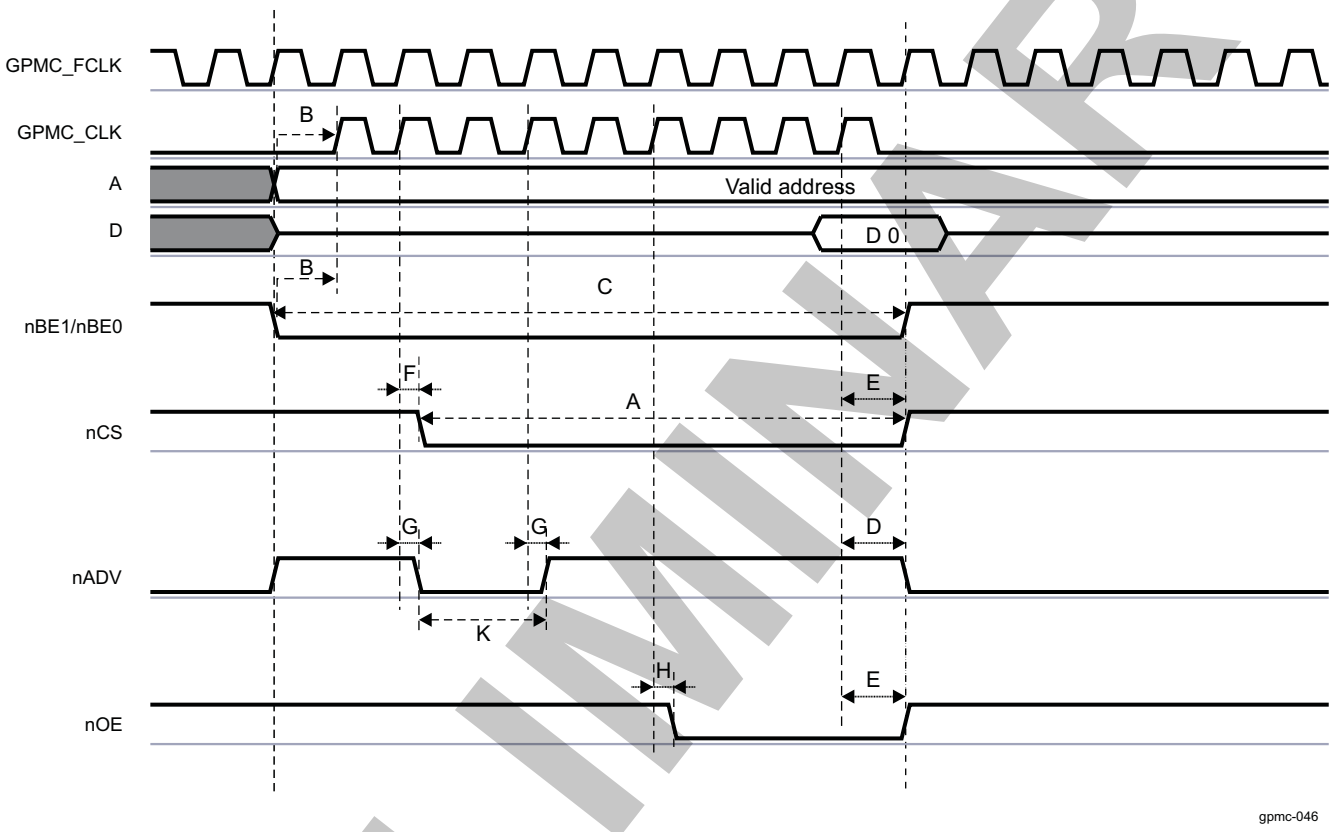
- Read operation:
  K = (ADVRDOFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- Write operation:
  K = (ADVWROFFTIME – ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period

For gpmc_wait invalid to first data latching gpmc_clk edge:

- L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK period + GPMC_CLK period

Figure 15-95 shows a simplified example of a synchronous NOR single read where formulas are associated with signal waves.

Figure 15-95. Synchronous NOR Single Read Simplified Example



15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all the formulas to calculate asynchronous NOR timing parameters. This is the case when GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0 and when READTYPE or WRITETYPE are set to asynchronous mode. Table 15-377 describes the asynchronous NOR formulas.

Table 15-377. Asynchronous NOR Formulas Description

Configuration Parameter	Unit	Description
A	ns	Pulse duration – gpmc_ncs low
B	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale invalid
C	ns	Delay time – gpmc_ncs valid to gpmc_noe invalid (single read)
D	ns	Pulse duration – address bus valid - 2nd, 3rd and 4th accesses
E	ns	Delay time – gpmc_ncs valid to gpmc_nwe valid
F	ns	Delay time – gpmc_ncs valid to gpmc_nwe invalid
G	ns	Address invalid duration between two successive R/W accesses
H	ns	Setup time – read data valid before gpmc_noe high
I	ns	Delay time – gpmc_ncs valid to gpmc_noe invalid (burst read)

Table 15-377. Asynchronous NOR Formulas Description (continued)

Configuration Parameter	Unit	Description
J	ns	Delay time – address bus valid to gpmc_ncs valid
		Delay time – data bus valid to gpmc_ncs valid
		Delay time – gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid
K	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale valid
L	ns	Delay time – gpmc_ncs valid to gpmc_noe valid
M	ns	Delay time – gpmc_ncs valid to first data latching edge
N	ns	Pulse duration – gpmc_nbe0_cle/gpmc_nbe1 valid time
O	ns	Delay time – gpmc_ncs valid to gpmc_nadv_ale valid

The configuration parameters are calculated through the following formulas. These formulas are not exhaustive.

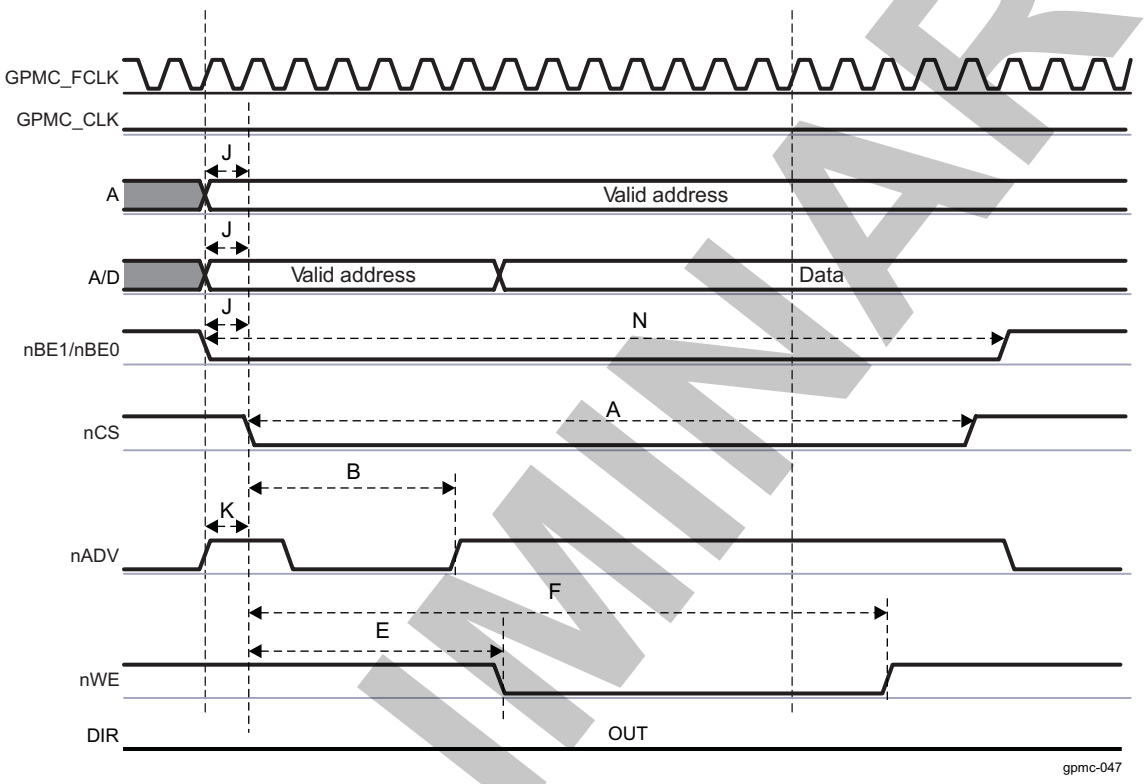
- gpmc_ncs low pulse:
  For single read: A = (CSRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: A = (CSRDOFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For single write: A = (CSWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst write: A = (CSWROFFTIME – CSONTIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
  For reading: B = ((ADVRDOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
  For writing: B = ((ADVWROFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- C = ((OEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- D = PAGEBURSTACCESSTIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
- E = ((WEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- F = ((WEOFFTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (WEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- G = CYCLE2CYCLEDELAY * GPMC_FCLK period * (TIMEPARAGRANULARITY + 1)
- H = ((OEOFFTIME – ACCESSTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * OEEXTRADELAY) * GPMC_FCLK period
- I = ((OEOFFTIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period, where N = page burst access number
- J = (CSONTIME * (TIMEPARAGRANULARITY + 1) + 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- K = ((ADVONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- L = ((OEONTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (OEEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period
- M = ((ACCESSTIME - CSONTIME) * (TIMEPARAGRANULARITY + 1) – 0.5 * CSEXTRADELAY) * GPMC_FCLK period
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
  For single read: N = RDCYCLETIME * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period
  For burst read: N = (RDCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number
  For burst write: N = (WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME) *

(TIMEPARAGRANULARITY + 1) * GPMC_FCLK period, where N = page burst access number

- O = ((WRCYCLETIME + (N – 1) * PAGEBURSTACCESSTIME – CSONTIME) * (TIMEPARAGRANULARITY + 1) + 0.5 * (ADVEXTRADELAY – CSEXTRADELAY)) * GPMC_FCLK period

Figure 15-96 shows a simplified example of an asynchronous NOR single write where formulas are associated with signal waves.

Figure 15-96. Asynchronous NOR Single Write Simplified Example



NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases and Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8- or 16-bit-wide memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples describe how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104-MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

Table 15-378 lists some of the I/Os of the GPMC module.

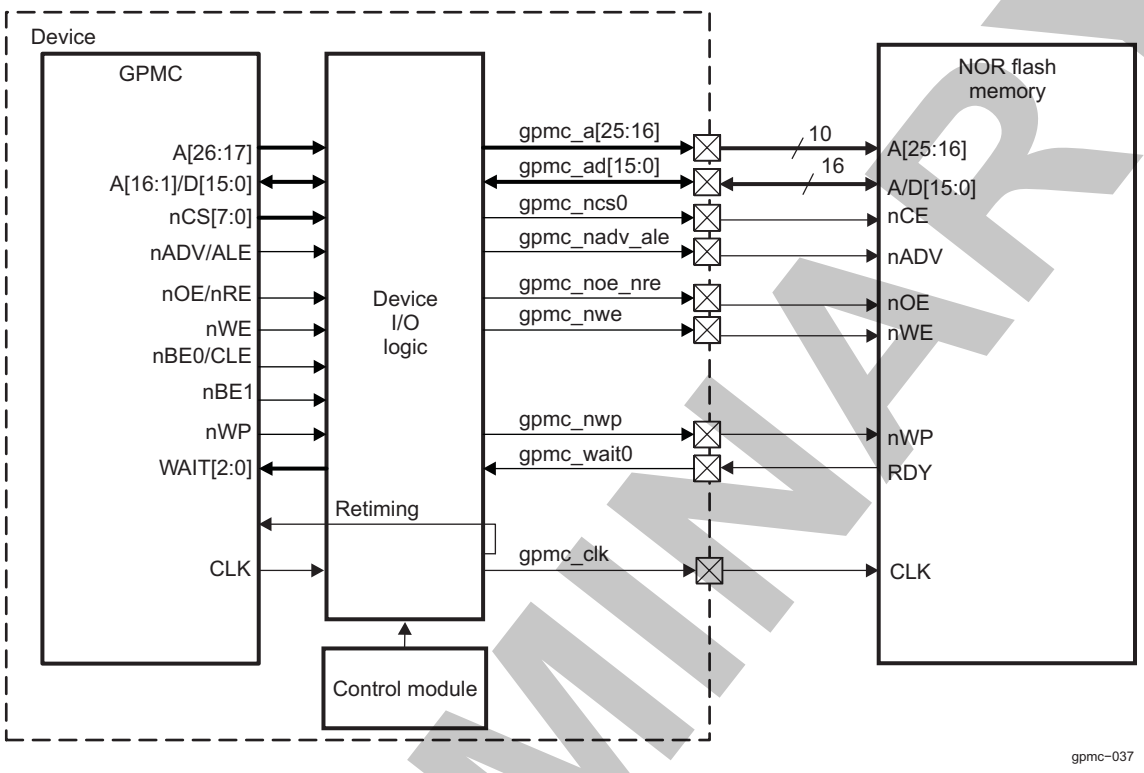
Table 15-378. GPMC Signals

Signal Name	I/0	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
gpmc_clk(1)	O	External clock provided to the external device for synchronous operations
gpmc_a[25:16]	O	Address
gpmc_ad[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
gpmc_ncsx	O	Chip-select (where x = 0, or 1)
gpmc_nadv_ale	O	Address valid enable
gpmc_noe_nre	O	Output enable (read access only)
gpmc_nwe	O	Write enable (write access only)
gpmc_wait[2:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

(1) This output signal is also used as a retiming input. During synchronous operation, the INPUTENABLE bit of the CONTROL_CORE_PAD0_GPMC_NWP_PAD1_GPMC_CLK register must be set to 1.

Figure 15-97 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-97. GPMC Connection to an External NOR Flash Memory



The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-379 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-380 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-98 shows the synchronous burst read access.

Table 15-379. Useful Timing Parameters on the Memory Side

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	nCS setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Z	7
tOEZ	Output enable to High-Z	7
tAVC	nADV setup time	6

Table 15-379. Useful Timing Parameters on the Memory Side (continued)

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tAVD	nAVD pulse	6
tACH	Address hold time from clock	3

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

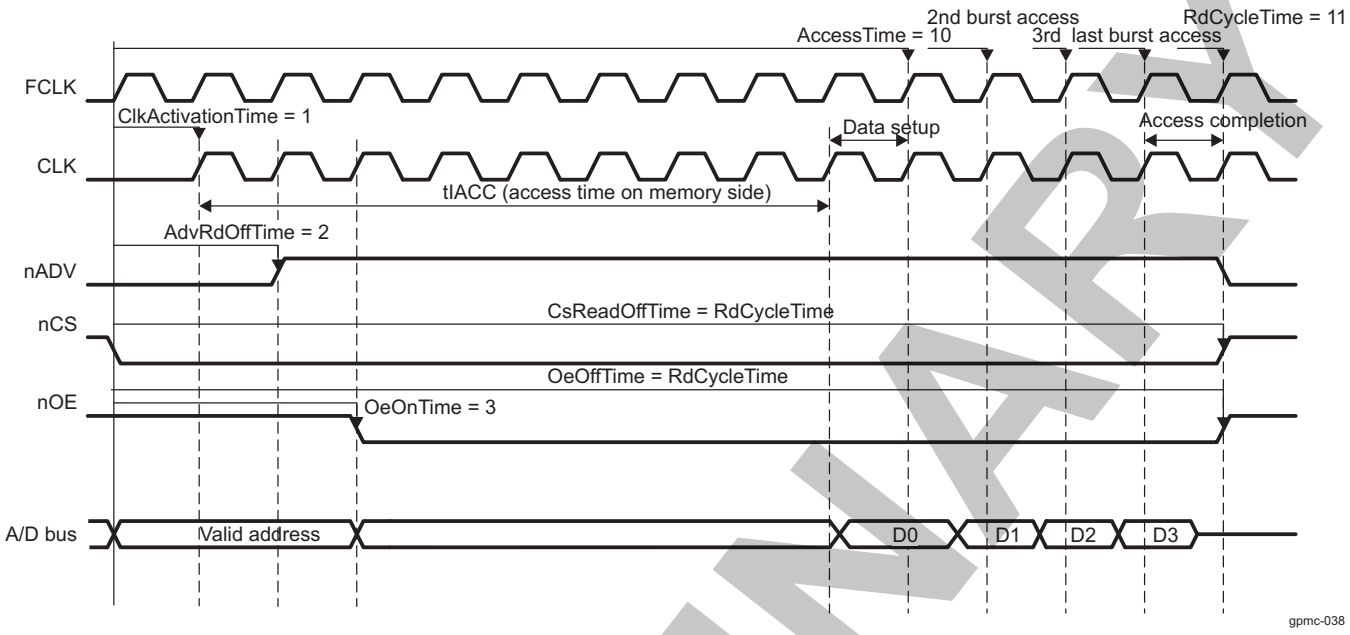
- Read access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle (T = 9,615 ns). The read access time between two bursts of data is tBACC = 5.2 ns. Therefore, data setup time is a clock period – tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 15-380. Calculating GPMC Timing Parameters

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	–	–	–	GPMCFCLKDIVIDER = 0x0
ClkActivation Time	min (tCES, tACS)	3	1	CLKACTIVATIONTIME = 0x1
RdAccessTime	roundmax (ClkActivationTime + tIACC + DataSetupTime)	94.03: (9,615 + 80 + 4,415)	10: roundmax (94.03 / 9,615)	ACCESSTIME = 0x0A
PageBurst AccessTime	roundmax (tBACC)	roundmax (5.2)	1	PAGEBURSTACCESSTIME = 0x1
RdCycleTime	Access time + max (tCEZ, tOEZ)	101.03: (94.03 + 7)	11	RDCYCLETIME = 0x0B
CsOnTime	tCES	0	0	CSONTIME = 0x0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAVC (1)	0	0	ADVONTIME = 0x0
AdvRdOffTime	tAVD + tAVC (2)	12	2	ADVRDOFFTIME = 0x02
OeOnTime (3)	(ClkActivationTime + tACH) < OeOnTime (ClkActivationTime + tIACC)	–	3, for instance	OEONTIME = 0x3
OeOffTime	RdCycleTime	–	11	OEOFFTIME = 0x0B

(1) The external clock provided to the NOR flash is not yet available.
(2) AdvRdOffTime – AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.
(3) OeOnTime must ensure that addresses are available. It must not exceed the availability of the first burst of data.

Figure 15-98. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 15-381 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-382 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-99 shows the asynchronous read access.

Table 15-381. AC Characteristics for Asynchronous Read Access

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from nCS low	80
tAAVDS	Address setup time to rising edge of nADV	3
tAVDP	nADV low time	6
tCAS	nCS setup time to nADV	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Z	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 clock cycle + tOEZ:

1. On the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 15-381: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

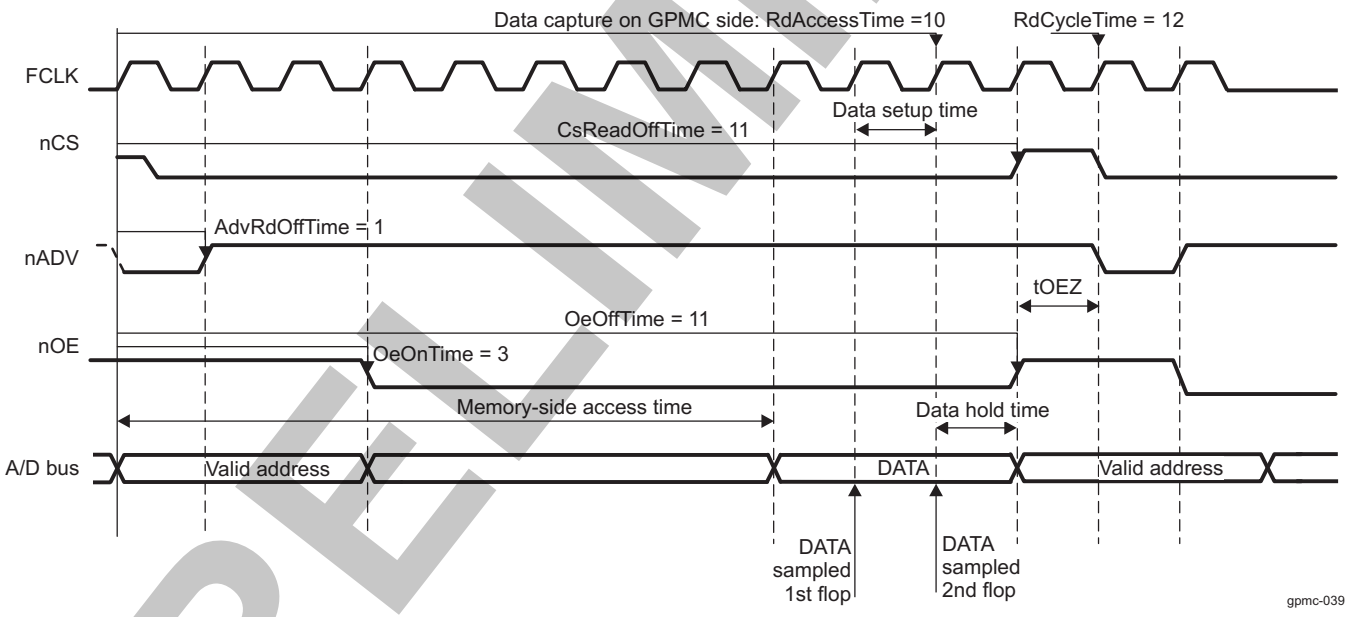
   The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.
2. To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
3. There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is one clock cycle (that is, AccessTime + 1).

4. To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
5. Addresses can now be relatched and a new read cycle begun.

Table 15-382. GPMC Timing Parameters for Asynchronous Read Access

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	10	ACCESSTIME = 0x0A
PageBurstAccess Time	N/A (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	12	RDCYCLETIME = 0x0C
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsReadOffTime	AccessTime + 1 cycle	89, 615	11	CSRDOFFTIME = 0x0B
AdvOnTime	tAAVDS	3	1	ADVONTIME = 0X1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 0x01
OeOnTime	OeOnTime >= AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 0x3
OeOffTime	AccessTime + 1cycle	89, 615	11	OEOFFTIME = 0x0B

Figure 15-99. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)



15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-384 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-383 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-100 shows the synchronous burst write access.

Table 15-383. AC Characteristics for Asynchronous Single Write (Memory Side)

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	nADV low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	nCS setup time to nWE	3
tCAS	nCS setup time to nADV	0
tAVSC	nADV setup time	3

For asynchronous single write access, write cycle time is WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1. For the AccesCompletion, the GPMC requires one cycle of data hold time (nCS deassertion).

Table 15-384. GPMC Timing Parameters for Asynchronous Single Write

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Registers Configuration
ClkActivationTime	N/A (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	N/A (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 0x06
CsOnTime	tCAS	0	0	CSONTIME = 0x0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 0x06
AdvOnTime	tAVSC	3	1	ADVONTIME = 0x1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 0x01
WeOnTime	tCS	3	1	WEONTIME = 0x1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 0x05

15.4.6.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or devices, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit-wide asynchronous or synchronous memory or device (only 8-bit: nonburst device)
- 16-bit address and data-multiplexed NOR flash devices (pSRAM, OneNAND™, etc.)
- 8- and 16-bit NAND flash devices

NOTE: Nonmultiplexed NOR flash devices are supported by the GPMC, but their use is highly limited. Because only 10 address pins are available on the GPMC interface, the maximum device size supported is 2KiB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section describes the interfacing differences of the GPMC supported memories.

Table 15-385. Supported Memories Interfaces

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash [1]	OneNAND	16-Bit NAND	8-Bit NAND
gpmc_a[25]	A26			
gpmc_a[24]	A25			
gpmc_a[23]	A24			
gpmc_a[22]	A23			
gpmc_a[21]	A22			
gpmc_a[20]	A21			
gpmc_a[19]	A20			
gpmc_a[18]	A19			
gpmc_a[17]	A18			
gpmc_a[16]	A17			
gpmc_ad[15]	D15 or A16		IO15	
gpmc_ad[14]	D14 or A15		IO14	
gpmc_ad[13]	D13 or A14		IO13	
gpmc_ad[12]	D12 or A13		IO12	
gpmc_ad[11]	D11 or A12		IO11	
gpmc_ad[10]	D10 or A11		IO10	
gpmc_ad[9]	D9 or A10		IO9	
gpmc_ad[8]	D8 or A9		IO8	
gpmc_ad[7]	D7 or A8		IO7	
gpmc_ad[6]	D6 or A7		IO6	
gpmc_ad[5]	D5 or A6		IO5	
gpmc_ad[4]	D4 or A5		IO4	
gpmc_ad[3]	D3 or A4		IO3	
gpmc_ad[2]	D2 or A3		IO2	
gpmc_ad[1]	D1 or A2		IO1	
gpmc_ad[0]	D0 or A1		IO0	

[1] Addresses seen from the device side. When interfacing to the external device, A1 is connected to the memory A0, A2 to the memory A1, and so on.

Table 15-385. Supported Memories Interfaces (continued)

Function	16-Bit Address/ Data-Multiplexed pSRAM or NOR Flash [1]	OneNAND	16-Bit NAND	8-Bit NAND
gpmc_clk	CLK			
gpmc_ncs0	nCS0 (chip-select)		nCE0 (chip-enable)

gpmc_nwp	nWP (write protect)		nWP (write protect)	
gpmc_wait0	WAIT0		R/nB0 (ready/busy)	
gpmc_wait1	WAIT1		R/nB1	
gpmc_wait2	WAIT2		R/nB2	

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device; that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Because of its high density NAND is best suited to devices that require high capacity data storage, such as pictures, music, and data files. NAND nonvolatility makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-386 summarizes the NAND interface signals level applied to external device or memories.

Table 15-386. NAND Interface Bus Operations Summary

Bus Operation	CLE	ALE	nCE	nWE [1]	nRE [1]	nWP
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H [2]	H [2]	H [2]	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Standby	x	x	H	x	x	H/L [3]

(1) RE stands for rising edge; FE stands for falling edge
(2) Can be nCE high, or WE and nRE high.
(3) nWP must be biased to CMOS high or CMOS low for standby

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; that is, it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities, it also has slow write and erase functions when compared to the NAND architecture.

Table 15-387 summarizes the level of the NOR interface signals applied to external devices or memories.

Table 15-387. NOR Interface Bus Operations Summary

Bus Operation	CLK	nADV	nCS	nOE	nWE	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

15.4.6.2.1.4 Other Technologies

Other supported device types interact with the GPMC through the NOR interface protocol.

OneNAND is a high-density, low-power memory device. OneNAND is based on single- or multilevel-cell NAND core with SRAM and logic. It interfaces as a synchronous NOR flash and has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for mass storage and code storage.

pSRAM (pseudo-static random access memory) is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR flash. It also has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read burst access with wrap capability (4, 8, 16 Word16)

15.4.6.2.2 GPMC Features and Settings

The features and settings of the GPMC are:

- Supported device type: Up to four NAND or NOR protocol external memories or devices
- Operating voltage: 1.8 V
- Maximum GPMC addressing capability: 512MiB divided into eight chip-selects
- Maximum supported memory size: 256MiB (must be a power-of-two)
- Minimum supported memory size: 16MiB (must be a power-of-two). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8, 16 bits wide
- Burst and page access: burst of 4, 8, 16 Word16
- Supports bus keeping
- Supports bus turnaround

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. Table 15-389 provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

Table 15-388. GPMC Instance Summary

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to GPMC_NAND_DATA_i register, are little-endian. If the GPMC_NAND_DATA_i register location is accessed, the endianness is access-dependent.

In this section i corresponds to the chip-select number, where i = 0 to 7.

- GPMC Register Summary: [12]

Table 15-398. GPMC_IRQENABLE

Address Offset	0x0000 001C		
Physical Address	0x5000 001C	**Instance**	GPMC
Description	The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					WAIT2EDGEDETECTIONENABLE	WAIT1EDGEDETECTIONENABLE	WAIT0EDGEDETECTIONENABLE	RESERVED						TERMINALCOUNTEVENTENABLE	FIFOEVENTENABLE

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10	WAIT2EDGEDETECTIONENABLE	Enables the Wait2 Edge Detection interrupt 0x0: Wait2EdgeDetection interrupt is masked. 0x1: Wait2EdgeDetection event generates an interrupt if occurs.	RW	0
9	WAIT1EDGEDETECTIONENABLE	Enables the Wait1 Edge Detection interrupt 0x0: Wait1EdgeDetection interrupt is masked. 0x1: Wait1EdgeDetection event generates an interrupt if occurs.	RW	0x0
8	WAIT0EDGEDETECTIONENABLE	Enables the Wait0 Edge Detection interrupt 0x0: Wait0EdgeDetection interrupt is masked. 0x1: Wait0EdgeDetection event generates an interrupt if occurs.	RW	0x0
7:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00
1	TERMINALCOUNTEVENTENABLE	Enables TerminalCountEvent interrupt issuing in prefetch or write-posting mode 0x0: TerminalCountEvent interrupt is masked. 0x1: TerminalCountEvent interrupt is not masked.	RW	0x0
0	FIFOEVENTENABLE	Enables the FIFOEvent interrupt 0x0: FIFOEvent interrupt is masked. 0x1: FIFOEvent interrupt is not masked.	RW	0x0

Table 15-400. GPMC_TIMEOUT_CONTROL

Address Offset	0x0000 0040		
Physical Address	0x5000 0040	**Instance**	GPMC
Description	The GPMC_TIMEOUT_CONTROL register allows the user to set the start value of the timeout counter.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TIMEOUTSTARTVALUE								RESERVED							TIMEOUTENABLE

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x00000
12:4	TIMEOUTSTARTVALUE	Start value of the time-out counter 0x000: Zero GPMC_FCLK cycle 0x001: One GPMC_FCLK cycle ... 0x1FF: 511 GPMC_FCLK cycles	RW	0x1FF
3:1	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
0	TIMEOUTENABLE	Enable bit of the TimeOut feature 0x0: TimeOut feature is disabled. 0x1: TimeOut feature is enabled.	RW	0x0

Table 15-406. GPMC_CONFIG

Address Offset	0x0000 0050		
Physical Address	0x5000 0050	**Instance**	GPMC
Description	The configuration register allows global configuration of the GPMC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					WAIT2PINPOLARITY	WAIT1PINPOLARITY	WAIT0PINPOLARITY	RESERVED			WRITEPROTECT	RESERVED		LIMITEDADDRESS	NANDFORCEPOSTEDWRITE

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x000000
10	WAIT2PINPOLARITY	Selects the polarity of input pin WAIT2 0x0: WAIT2 active low 0x1: WAIT2 active high	RW	0x0
9	WAIT1PINPOLARITY	Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high	RW	0x1
8	WAIT0PINPOLARITY	Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
4	WRITEPROTECT	Controls the WP output pin level 0x0: WP output pin is low. 0x1: WP output pin is high.	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1	LIMITEDADDRESS	Limited Address device support 0x0: No effect 0x1: A26-A11 are not modified during an external memory access.	RW	0x0
0	NANDFORCEPOSTEDWRITE	Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write	RW	0x0

Bits	Field Name	Description	Type	Reset
31	WRAPBURST	Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported	RW	0x0
30	READMULTIPLE	Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous)	RW	0x0
29	READTYPE	Selects the read mode operation 0x0: Read asynchronous 0x1: Read synchronous	RW	0x0
28	WRITEMULTIPLE	Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous)	RW	0x0
27	WRITETYPE	Selects the write mode operation 0x0: Write asynchronous 0x1: Write synchronous	RW	0x0
26:25	CLKACTIVATIONTIME	Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
24:23	ATTACHEDDEVICEPAGELENGTH	Specifies the attached device page (burst) length 0x0: 4 words 0x1: 8 words 0x2: 16 words 0x3: Reserved (1 word = interface size)	RW	0x0
22	WAITREADMONITORING	Selects the Wait monitoring configuration for Read accesses (Reset value is *bootwaiten* input pin sampled at device reset) 0x0: Wait pin is not monitored for read accesses. 0x1: Wait pin is monitored for read accesses.	RW	0x-
21	WAITWRITEMONITORING	Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses. 0x1: Wait pin is monitored for write accesses.	RW	0x0
20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19:18	WAITMONITORINGTIME	Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data. 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data. 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data. 0x3: Reserved	RW	0x0
17:16	WAITPINSELECT	Selects the input wait pin for this chip-select (Reset value is *bootwaitselect* input pin sampled at device reset for CS0 and 0 for CS1-7) 0x0: Wait input pin is WAIT0. 0x1: Wait input pin is WAIT1. 0x2: Wait input pin is WAIT2. 0x3: Reserved	RW	0x-
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0	RW	0x0
13:12	DEVICESIZE	Selects the device size attached (Reset value is *bootdevicesize* input pin sampled at device reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved	RW	0x-
11:10	DEVICETYPE	Selects the attached device type 0x0: NOR flash-like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND flash-like devices, stream mode 0x3: Reserved	RW	0x0
9:8	MUXADDDATA	Enables the address and data multiplexed protocol (Reset value is *cs0muxdevice* input pin sampled at device reset for CS0 and 0 for CS1-CS7) 0x0: Nonmultiplexed attached device 0x1: AAD-multiplexed protocol device 0x2: Address and data multiplexed attached device 0x3: Reserved	RW	0x-
7:5	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0

Bits	Field Name	Description	Type	Reset
4	TIMEPARAGRANULARITY	Signals timing latencies scalar factor (RD/WRCYCLETIME, RD/WRACCESSTIME, PAGEBURSTACCESSTIME, CSONTIME, CSRD/WROFFTIME, ADVONTIME, ADVRD/WROFFTIME, OEONTIME, OEOFFTIME, WEONTIME, WEOFFTIME, CYCLE2CYCLEDELAY, BUSTURNAROUND, TIMEOUTSTARTVALUE, WRDATAONADMUXBUS) 0x0: x1 latencies 0x1: x2 latencies	RW	0x0
3:2	RESERVED	Write 0s for future compatibility. Read returns 0s.	RW	0x0
1:0	GPMCFCLKDIVIDER	Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency /4	RW	0x0

General-Purpose Memory Controller

- GPMC Register Summary: [0]

15.5 Error Location Module

15.5.1 Error Location Module Overview

Nonmanaged NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the software that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-101 shows the integration of the ELM subsystem in the device.

Figure 15-101. ELM Integration

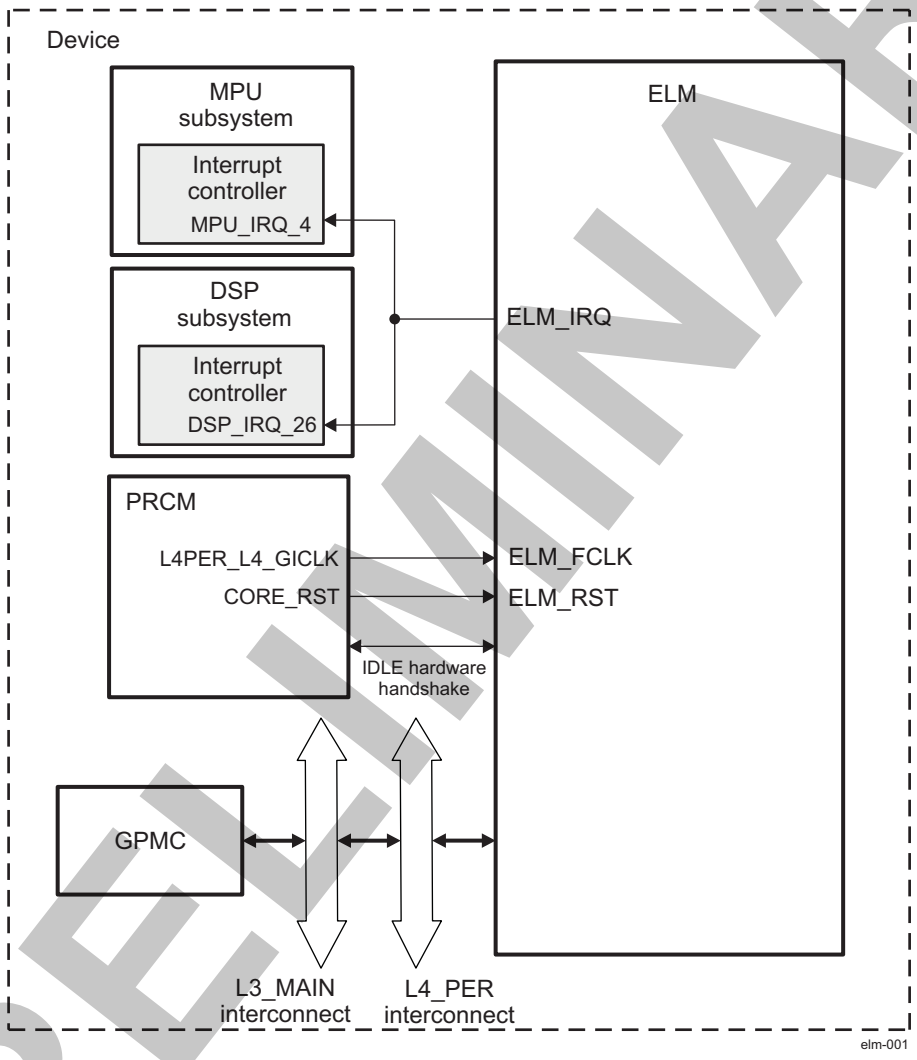

Table 15-462 through Table 15-464 summarize the integration of the module in the device.

Table 15-462. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ELM	PD_L4_PER	No	L4_PER

Table 15-463. Clocks and Resets

Clocks

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
ELM	ELM_RST	L4_PER_RST	PRCM	Module hardware reset For information about PRCM reset sources and distribution, see Section 3.5.4, *Reset Domains*, inSection 3.1.1, *Power, Reset, and Clock Management*.

Table 15-464. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ELM	ELM_IRQ	MPU_IRQ_4	MPU	BCH error-location module interrupt For information about MPU interrupt control, see Section 17.3.2, *Interrupt Requests to INTC_MPU*.
		DSP_IRQ_26	DSP	BCH error-location module interrupt For information about DSP interrupt control, see Section 5.3.2.6, *DSP INTC*.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, set the ELM_SYSCONFIG[1] SOFTRESET bit to 1. The ELM_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM_SYSCONFIG[1] SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

Table 15-465 describes the power-management features available to the ELM.

NOTE:

- For information about source clock gating and a description of the sleep/wake-up transitions, see the Section 3.6.8, *CD_L4_PER Clock Domain*, in Section 3.1.1, *Power, Reset, and Clock Management*.
- For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.6, *Clock Management Functional Description*, in Section 3.1.1, *Power, Reset, and Clock Management*

Table 15-465. Local Power-Management Features

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY	The clock can be switched off or maintained during the wake-up period.
Master standby modes	N/A	
Global wake-up enable	N/A	
Wake-up sources enable	N/A	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1, *Power, Reset, and Clock Management*.

15.5.3.3 ELM Interrupt Requests

Table 15-466 lists the event flags, and their masks, that can cause module interrupts.

Table 15-466. Events

Event Flag	Event Mask	Description
ELM_IRQSTATUS[8] PAGE_VALID	ELM_IRQENABLE[8] PAGE_MASK	Page interrupt
ELM_IRQSTATUS[7] LOC_VALID_7	ELM_IRQENABLE[7] LOCATION_MASK_7	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTATUS[6] LOC_VALID_6	ELM_IRQENABLE[6] LOCATION_MASK_6	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTATUS[5] LOC_VALID_5	ELM_IRQENABLE[5] LOCATION_MASK_5	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTATUS[4] LOC_VALID_4	ELM_IRQENABLE[4] LOCATION_MASK_4	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTATUS[3] LOC_VALID_3	ELM_IRQENABLE[3] LOCATION_MASK_3	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTATUS[2] LOC_VALID_2	ELM_IRQENABLE[2] LOCATION_MASK_2	Error-location interrupt for syndrome polynomial 2
ELM_IRQSTATUS[1] LOC_VALID_1	ELM_IRQENABLE[1] LOCATION_MASK_1	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTATUS[0] LOC_VALID_0	ELM_IRQENABLE[0] LOCATION_MASK_0	Error-location interrupt for syndrome polynomial 0

15.5.3.4 Processing Initialization

ELM_LOCATION_CONFIG global setting parameters must be set before using the error-location engine. The ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL bit field defines the error-correction level used (4-,8-, or 16-bit error correction). The ELM_LOCATION_CONFIG[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

Software can choose to use the ELM in continuous mode or page mode. If all ELM_PAGE_CTRL[i] SECTOR_i bits (i is the syndrome polynomial number, where i = 0 to 7) are reset, continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently. Results for a syndrome can be retrieved and acknowledged at any time, regardless of the status of the other seven processing

contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities: only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM_IRQENABLE[i] LOCATION_MASK_i bits (where i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM_IRQENABLE[8] PAGE_MASK bit must be set to 1 when in page mode.

Software initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM_SYNDROME_FRAGMENT_0_i to ELM_SYNDROME_FRAGMENT_6_i. The first six registers can be written in any order, but ELM_SYNDROME_FRAGMENT_6_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit).

As soon as one validity bit is asserted (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x1, where i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i registers (where i = 0 to 7) are not reset. Software must not consider them until the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 1 and the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE bit is set to 0 while the ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i (where i = 0 to 7) are not updated.

In all other cases, the engine goes through the entire error-location process. Each time an error location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION bit field; the second is logged in the ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION bit field, and so on.

Table 15-467 describes the ELM_LOCATION_STATUS_i value decoding.

Table 15-467. ELM_LOCATION_STATUS_i Value Decoding

ECC_CORRECTABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependent

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, ELM_LOCATION_STATUS_i (where i = 0 to 7) for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit (where i = 0 to 7) is set. The processing exit status is available from the associated ELM_LOCATION_STATUS_i register, and error locations are stored in order in the ECC_ERROR_LOCATION bit fields. Software must read only valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM_PAGE_CTRL are reset), an interrupt is triggered whenever a ELM_IRQSTATUS[i] LOC_VALID_i bit is asserted. Software must read the ELM_IRQSTATUS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM_LOCATION_STATUS_i and ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i). When done, software must clear the corresponding ELM_IRQSTATUS[i] LOC_VALID_i bit by setting it to 1. Other status bits must be set to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM_IRQSTATUS[8] PAGE_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM_IRQENABLE[i] LOCATION_MASK_i bits are cleared. A page is defined using the ELM_PAGE_CTRL register. Each SECTOR_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM_IRQSTATUS[i] LOC_VALID_i bits. The module triggers an ELM_IRQSTATUS[8] PAGE_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM_IRQSTATUS register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the ELM_PAGE_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM_PAGE_CTRL[i] SECTOR_i bits (where i = 0 to 7) are processed as usual, but are essentially ignored. Software must manually poll the ELM_IRQSTATUS bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low-Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-468. ELM Processing Initialization

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value.
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value.
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value.
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value.
If continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQENABLE[i] LOCATION_MASK_i	0x1
else (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (where i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0 and ELM_IRQENABLE[8] PAGE_MASK = 0x1	Set value.
endif		Set value.

Table 15-468. ELM Processing Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value.
	ELM_SYNDROME_FRAGMENT_1_i	Set value.
	ELM_SYNDROME_FRAGMENT_5_i	Set value.
	ELM_SYNDROME_FRAGMENT_6_i	Set value.
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. Table 15-469 and Table 15-470 describe the processing completion for continuous and page modes, respectively.

Table 15-469. ELM Processing Completion for Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. Software must correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
Clear the corresponding i interrupt.	ELM_IRQSTATUS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID = 0x0) and after the exit status register check (ELM_LOCATION_STATUS_i).

Table 15-470. ELM Processing Completion for Page Mode

Step	Register/Bit Field/Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTATUS[8] PAGE_VALID	0x1
Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	
if the process fails (too many errors)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x0
It is software dependent.		
else (process successful, the engine completes)	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS	

Table 15-470. ELM Processing Completion for Page Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
endif		
End Repeat		
Clear the ELM_IRQSTATUS register.	ELM_IRQSTATUS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM is programmed for an 8-bit error-correction capability in continuous mode (see Table 15-471). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a nonzero polynomial syndrome is reported from the GPMC (polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-471. Use Case: Continuous Mode

Step	Register/Bit Field/Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTATUS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1
Defines the maximum buffer length: 528 bytes (2 × 528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQENABLE[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (where i = 0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (where i = 0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (where i = 0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (where i = 0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (where i = 0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STATUS_i[8] ECC_CORRECTABLE (where i = 0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STATUS_i[4:0] ECC_NB_ERRORS (where i = 0)	0x4

Table 15-471. Use Case: Continuous Mode (continued)

Step	Register/Bit Field/Programming Model	Value
Read the error-location bit addresses for syndrome polynomial 0 of the first four registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (where i = 0)	0x1AF
	ELM_ERROR_LOCATION_1_i (where i = 0)	0x426
	ELM_ERROR_LOCATION_2_i (where i = 0)	0x775
	ELM_ERROR_LOCATION_3_i (where i = 0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTATUS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, and then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in Table 15-472 are given in decimal format.

Table 15-472. 16-Bit NAND Sector Buffer Address Map

NAND Memory Address	Message Bit Addresses in Memory Word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464
48	3447	3446	3445	3444	3443	3442	3441	3440	3455	3454	3453	3452	3451	3450	3449	3448
49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode (see Table 15-473). After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189

- P3 = 0x0

Table 15-473. Use Case: Page Mode

15.5.5.2.2 ELM Register Description

through describe the individual ELM registers.

Table 15-476. ELM_REVISION

Address Offset	0x0000 0000		
Physical Address	0x4807 8000	**Instance**	ELM
Description	This register contains the IP revision code. (A write or reset of to this register has no effect.)		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REVISION																															

Bits	Field Name	Description	Type	Reset
31:0	REVISION	IP Revision (TI internal data)	R	0x-

Table 15-477. Register Call Summary for Register ELM_REVISION

Error Location Module

- ELM Register Summary: [0]

Table 15-478. ELM_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4807 8010	**Instance**	ELM
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								CLOCKACTIVITYOCP	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOGATING

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	R	0x000000
8	CLOCKACTIVITYOCP	OCP clock activity when module is in IDLE mode (during wake-up mode period) 0x0: OCP clock can be switched off. 0x1: OCP clock is maintained during wake-up period.	RW	0
7:5	RESERVED	Reserved	R	0x0
4:3	SIDLEMODE	Slave interface power management (IDLE req/ack control) 0x0: Force-idle. IDLE request is acknowledged unconditionally and immediately (Default *Dumb* mode for safety) 0x1: No-idle. IDLE request is never acknowledged. 0x2: Smart-idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use	RW	0x2

Bits	Field Name	Description	Type	Reset
2	RESERVED	Reserved	R	0
1	SOFTRESET	Module software reset This bit is automatically reset by hardware (during reads, it always returns 0). It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence.	RW	0
0	AUTOGATING	Internal OCP clock gating strategy (no module visible effect other than saving power) 0x0: OCP clock is free-running. 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are two on-chip memories in the device.

- 5-KiB SAR random-access memory (RAM)
- 128-KiB level 3 (L3) static random-access memory (L3 OCM_RAM)

There are other on-chip memories inside other subsystems (MPU, DSP, IVA-HD, ABE, IPU) that are not described in the following sections. For more information about these memories, see each subsystem chapter.

15.6.2 OCM Subsystem Integration

Figure 15-102 shows the integration of the OCM subsystem to the device.

Figure 15-102. OCM Subsystem Integration to the Device

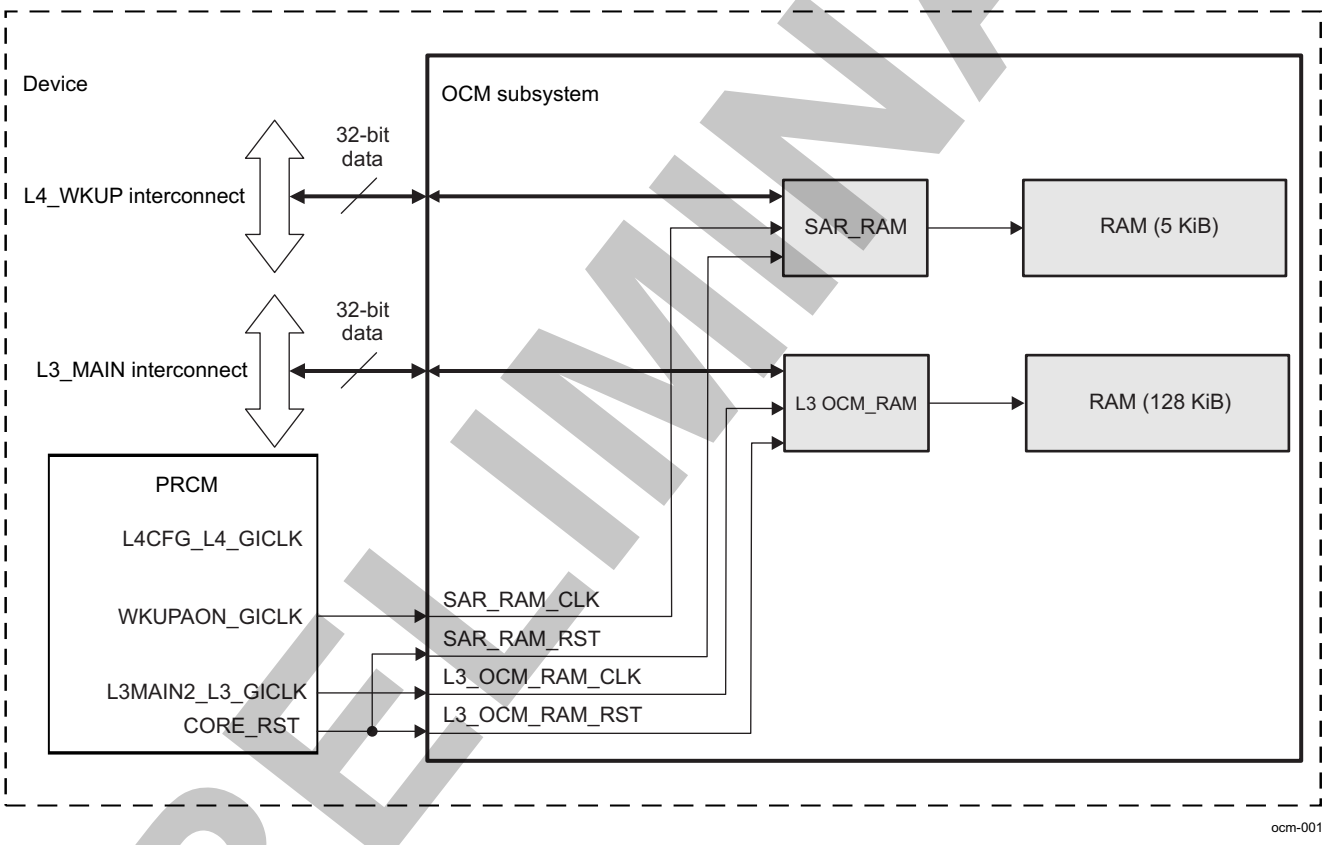

Table 15-538 and Table 15-539 summarize the integration of the module in the device.

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR RAM

The on-chip SAR RAM contains 5 KiB and is mapped as two blocks. The SAR RAM is used by device ROM code to store the software booting configuration: a logical structure that allows the redefinition of the ROM code default settings when booting after a warm reset. The SAR RAM is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
  - Operates at full L4_PER interconnect clock frequency
  - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4 KiB): Starts at 0x4AE2 6000 and ends at 0x4AE2 6FFF
- SAR space 2 (1 KiB): Starts at 0x4AE2 7000 and ends at 0x4AE2 73FF

15.6.3.2 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 128 KiB of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
  - Operates at full L3 interconnect clock frequency
  - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
  - A region-based partitioning (see the L3 firewall description)
  - The module owner of the access, with respect to its read and write permissions to that region
  - The transaction attributes of the access, with respect to the region permission properties. For more information, see Section 14.2.1, *L3 _MAIN Interconnect*.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4031 FFFF.

System DMA

This chapter describes the system direct memory access (DMA_SYSTEM) module.

NOTE: Some of the system DMA features, primarily those concerning the device I/O pads and the system DMA integration, are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

16.1 DMA_SYSTEM Module Overview

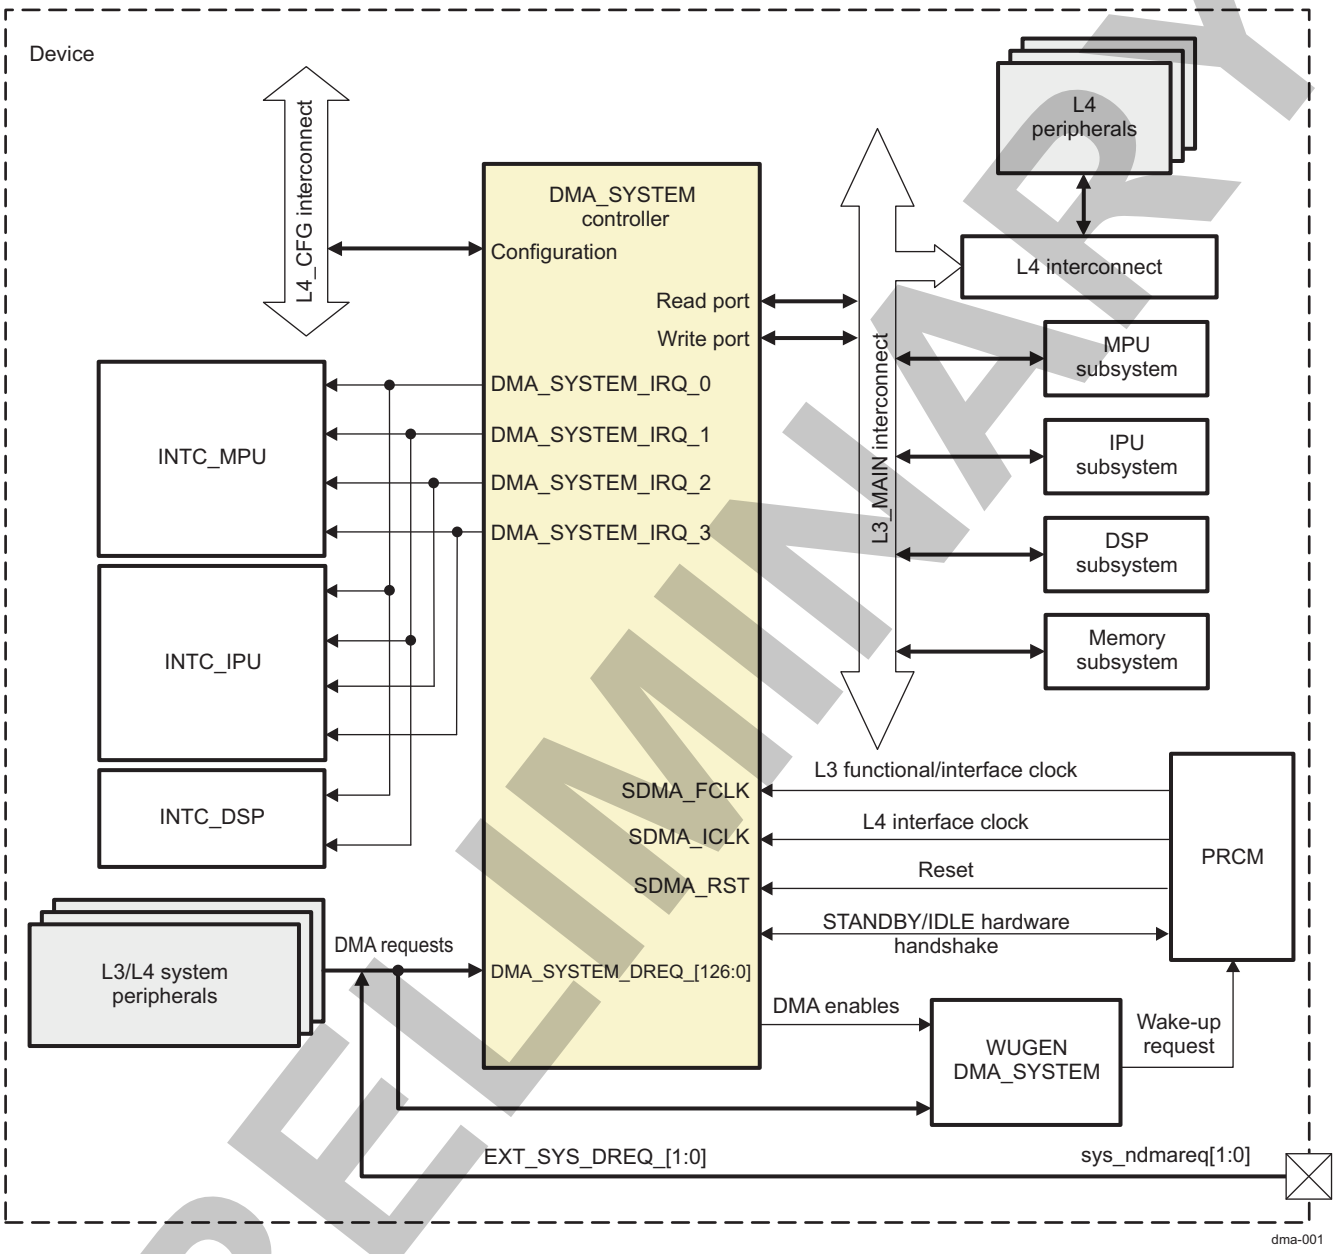
The system direct memory access (DMA_SYSTEM) module, also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
  - Memory and memory
  - Memory and peripheral device
- 32 logical DMA channels supporting:
  - Multiple concurrent transfers
  - Independent transfer profile for each channel
  - 8-bit, 16-bit, or 32-bit data element transfer size
  - Software-triggered or hardware-synchronized transfers
  - Flexible source and destination address generation
  - Burst read and write - max burst size is 16
  - Chained multiple-channel transfers
  - Endianism conversion
  - Draining
  - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see Section 3.1.2.3, *Dynamic Power Switching*, in Chapter 3, *Power, Reset and Clock Management*.

Figure 16-1 shows an overview of the DMA_SYSTEM module.

Figure 16-1. DMA_SYSTEM Overview



The DMA_SYSTEM module has three ports: one read, one write, and one configuration port, and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the DMA_SYSTEM through the L4_CFG interconnect.

16.2 DMA_SYSTEM Controller Environment

The DMA_SYSTEM controller supports external DMA requests through the sys_ndmareq[1:0] pins (see Table 16-1). A logical channel can be configured to respond to an external synchronization request.

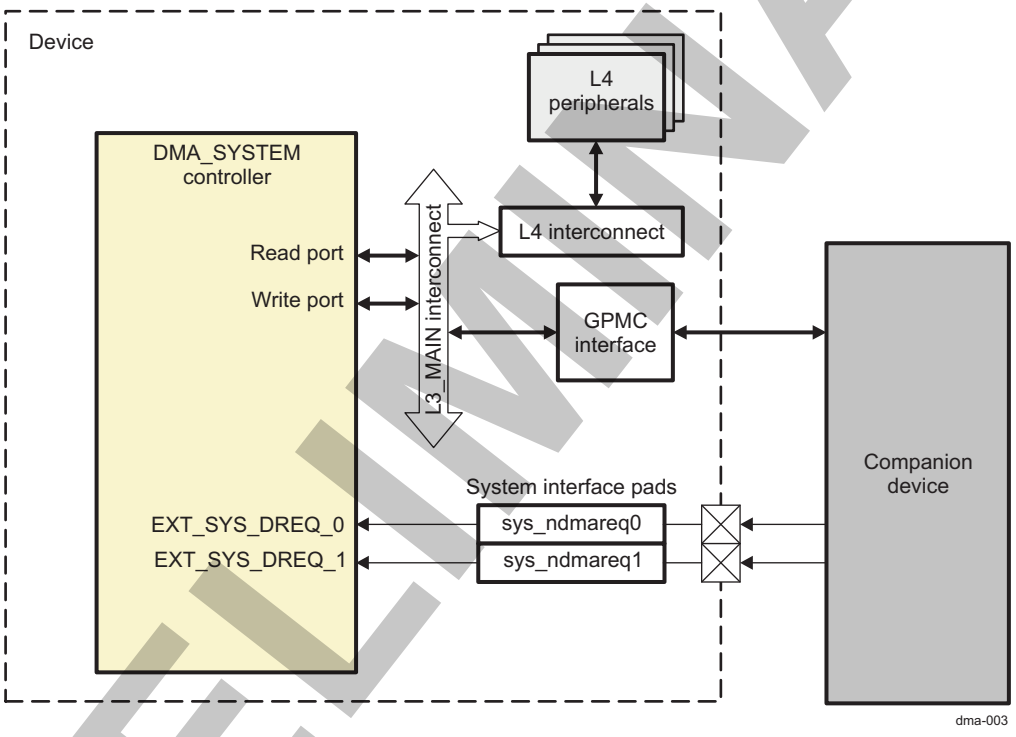
Table 16-1. External DMA_SYSTEM Request Signals

Pin Name	Signal Name	I/O[1]	Description	Module Reset Value
sys_ndmareq0	EXT_SYS_DREQ_0	I	External DMA request 0 (system expansion)	Z
sys_ndmareq1	EXT_SYS_DREQ_1	I	External DMA request 1 (system expansion)	Z

(1) I = Input, O = Output

Figure 16-2 shows an example of how to use the external hardware DMA request pins in the DMA_SYSTEM environment.

Figure 16-2. Example of External DMA Requests Use



An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

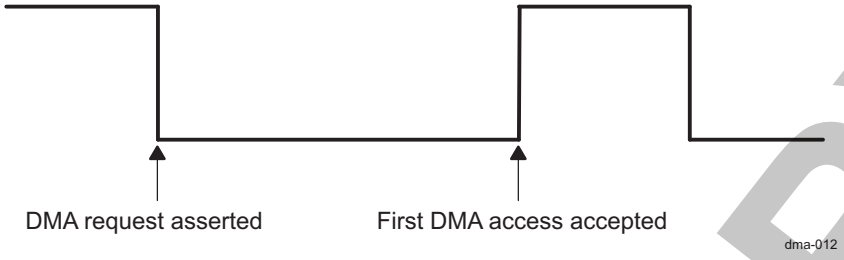
By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the two signal lines to pins, see Chapter 18, *Control Module*.

All 127 DMA request lines are transition sensitive.

For a transition-sensitive DMA request (see Figure 16-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_GICLK):

- When the deassertion time is less than one clock cycle, the DMA_SYSTEM may not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

Figure 16-3. Transition-Sensitive DMA Request Scheme

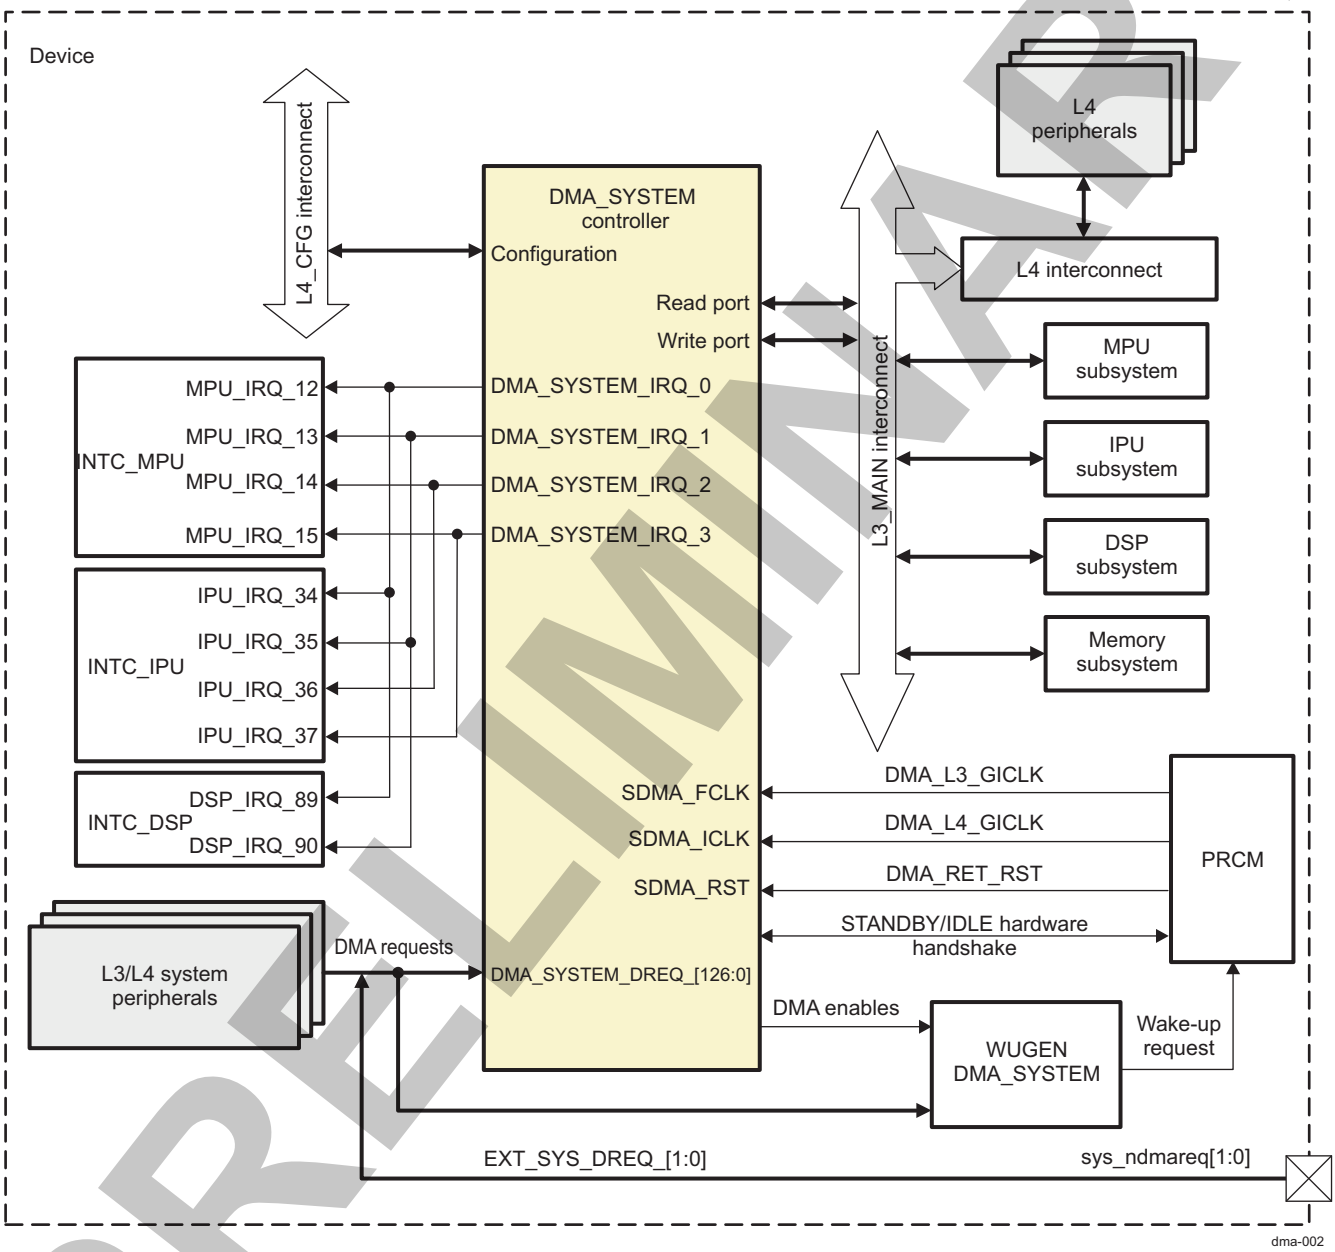


16.3 DMA_SYSTEM Module Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the DMA_SYSTEM controller integration.

Figure 16-4. DMA_SYSTEM Controller Integration



NOTE: For more information about the system DMA wake-up generator (WUGEN_DMA_SYSTEM), the STANDBY/IDLE hardware handshake, and the wake-up request, see Section 3.1.1.1.2, *Clock Management* , in Chapter 3, *Power, Reset, and Clock Management*.

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Clocks

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMA_SYSTEM	SDMA_FCLK	DMA_L3_GICLK	PRCM	Functional clock for all internal logic and for the two master read and write ports. For information about the power, reset, and clock management (PRCM) clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.
	SDMA_ICLK	DMA_L4_GICLK		Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, *Power, Reset, and Clock Management*.

Resets

Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMA_SYSTEM	SDMA_RST	DMA_RET_RST	PRCM	Hardware retention reset. It initializes all internal logic of the DMA_SYSTEM module, all global registers, and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, *Power, Reset, and Clock Management*.

Table 16-4. Hardware Requests

Interrupt Requests

Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
DMA_SYSTEM	DMA_SYSTEM_IRQ_0	MPU_IRQ_12	INTC_MPU	DMA_SYSTEM interrupt request 0. For information about the INTC_MPU, see INTC_MPU Functional Description.
	DMA_SYSTEM_IRQ_1	MPU_IRQ_13	INTC_MPU	DMA_SYSTEM interrupt request 1
	DMA_SYSTEM_IRQ_2	MPU_IRQ_14	INTC_MPU	DMA_SYSTEM interrupt request 2
	DMA_SYSTEM_IRQ_3	MPU_IRQ_15	INTC_MPU	DMA_SYSTEM interrupt request 3
	DMA_SYSTEM_IRQ_0	IPU_IRQ_34	INTC_IPU	DMA_SYSTEM interrupt request 0. For information about the INTC_IPU, see INTC_IPU Functional Description.
	DMA_SYSTEM_IRQ_1	IPU_IRQ_35	INTC_IPU	DMA_SYSTEM interrupt request 1
	DMA_SYSTEM_IRQ_2	IPU_IRQ_36	INTC_IPU	DMA_SYSTEM interrupt request 2
	DMA_SYSTEM_IRQ_3	IPU_IRQ_37	INTC_IPU	DMA_SYSTEM interrupt request 3
	DMA_SYSTEM_IRQ_0	DSP_IRQ_89	INTC_DSP	DMA_SYSTEM interrupt request 0. For information about the INTC_DSP, see Interrupt Controllers Overview.

Table 16-4. Hardware Requests (continued)

DMA_SYSTEM_IRQ_1	DSP_IRQ_90	INTC_DSP	DMA_SYSTEM interrupt request 1

NOTE: For a description of the interrupt source, see Section 16.4.2, *DMA_SYSTEM Controller Interrupt Requests*.

16.3.1 DMA Requests to the DMA_SYSTEM Controller

Table 16-5 lists the DMA_SYSTEM controller request mapping.

Table 16-5. DMA_SYSTEM Controller Request Mapping

DMA Request Line	Source	Description
DMA_SYSTEM_DREQ_0	Reserved	Reserved
DMA_SYSTEM_DREQ_1	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_SYSTEM_DREQ_2	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)
DMA_SYSTEM_DREQ_3	GPMC_DREQ	GPMC data transmit request from prefetch engine
DMA_SYSTEM_DREQ_4	Reserved	Reserved
DMA_SYSTEM_DREQ_5	DISPC_DREQ	Frame update request
DMA_SYSTEM_DREQ_6	CT_TBR_DREQ	DEBUG subsystem CT_TBR request
DMA_SYSTEM_DREQ_7	MCASP_DREQ_AXEVT	MCASP transmit request
DMA_SYSTEM_DREQ_8	ISS_DREQ_1	Imaging subsystem request 1

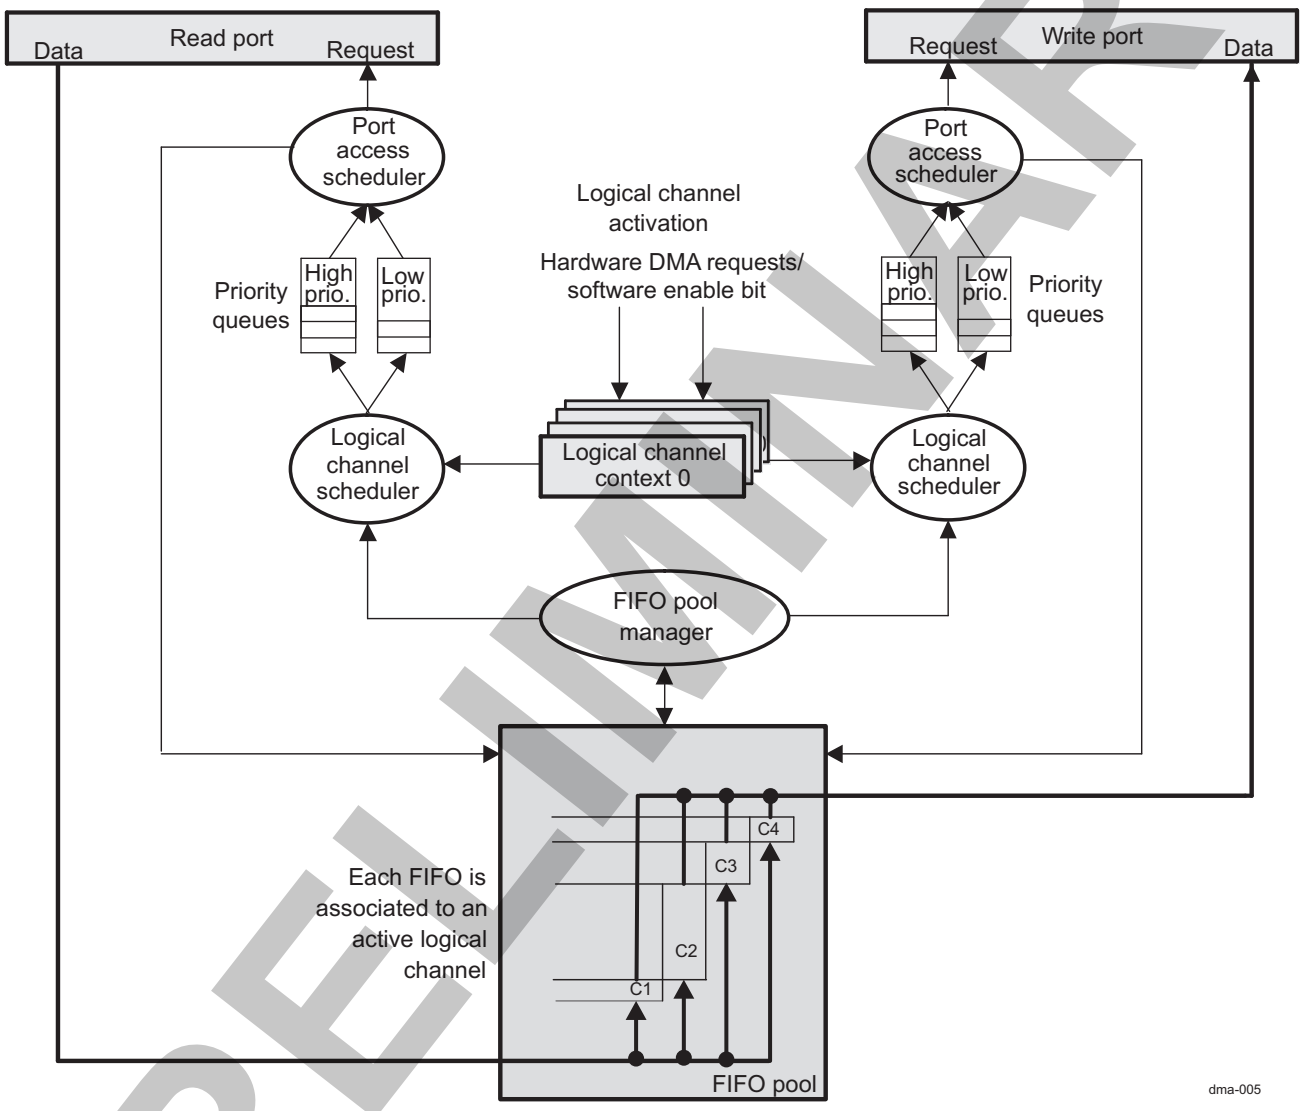
16.4 DMA_SYSTEM Functional Description

The DMA_SYSTEM module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the DMA_SYSTEM controller top-level block diagram.

Figure 16-5. DMA_SYSTEM Controller Top-Level Block Diagram



16.4.1 DMA_SYSTEM Controller Power Management

Table 16-6 describes power-management features available for the DMA_SYSTEM controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1.2, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 16-6. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	DMA4_OCP_SYSCONFIG[0] AUTOIDLE bit	This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity.
Slave idle modes	DMA4_OCP_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	DMA4_OCP_SYSCONFIG[9:8] CLOCKACTIVITY bit field	For configuration details, see Table 16-7.
Master standby modes	DMA4_OCP_SYSCONFIG[13:12] MIDLEMODE bit field	Force-standby, no-standby, and smart-standby modes are available.
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	N/A	Feature not available

Table 16-7. Clock Activity Settings

SDMA_CLOCKACTIVITY Values	Clock State When Module is in IDLE State	
	SDMA_ICLK	SDMA_FCLK
00	Off	Off
10	Off	On
01	On	Off
11	On	On

CAUTION

Because the PRCM module cannot read CLOCKACTIVITY settings through hardware, software must ensure consistent programming between the SDMA_CLOCKACTIVITY and DMA_SYSTEM clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

16.4.2 DMA_SYSTEM Controller Interrupt Requests

DMA4 has four interrupt lines (Lj, where j = 0, 1, 2, 3). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the DMA4_IRQENABLE_Lj bit is 1, channel *i* is the source of interrupt in line *j*. In contrast to the DMA4_CSRi registers, the DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the DMA4_IRQENABLE_Lj registers.
- The DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the DMA4_IRQENABLE_Lj bit is set to 0, channel interrupt *i* of the line *j* is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the DMA4_CICRi register. Each status bit is updated in the DMA4_CSRi register only when the corresponding enable bit is enabled in the DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L*j*:

- Identify the channel (LCH*i*) generating the interrupt.

  Read DMA4_IRQSTATUS_Lj.LCH*i* (LCH0 to LCH31). If LCH*i* = 1, channel *i* is the originator of the interrupt.
- Identify the interrupt event.

  Read the LCH*i* DMA4_CSRi. For example, if the drop event (the DMA4_CSRi[1] DROP bit) is 1, a

request collision will occur.

The interrupt event status bit in the DMA4_CSRi register is immediately reset after it is written to 1.

The interrupt status bit in the DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The DMA_SYSTEM module has four interrupt request output lines, DMA_SYSTEM_IRQ_0 to DMA_SYSTEM_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in Table 16-8 occurs.

Table 16-8. Logical DMA Channel Events

Event	Description
End of packet	A packet transfer completed.
End of block	A block transfer completed.
End of frame	A frame transfer completed.
End of super block	A super block transfer completed.
Half of frame	Half of the current frame transferred.
Start of last frame	The first element of the last frame transferred.
Transaction error	A transaction error is returned by the interconnect in either the read or write port.
Address error	An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3.
Supervisor transaction error	An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer.
Drain end	Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0).
Drop error	A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced.

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the DMA4_IRQENABLE_Lj register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel DMA4_CSRi register.

16.4.3 Logical Channel Transfer Overview

As Figure 16-5 shows, the DMA_SYSTEM module has one read port and one write port operating independently of one another. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

  A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation

  A logical channel becomes active as follows:
  - For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
  - For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

  A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, start address alignment, addressing mode, and

configured maximum burst size, each transaction can be a single access or a burst of accesses.

- Logical channel scheduling

  When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

  In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_ PRIORITY) in the logical channel DMA4_CCRi register determine whether a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the DMA4_GCR[23:16] ARBITRATION_RATE bit field.

  NOTE: The DMA4_GCR[23:16] ARBITRATION_RATE bit field does not depend on the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field. The ARBITRATION_ RATE bit field depends on the DMA4_CCRi[26] WRITE_PRIORITY bit and the DMA4_CCRi[6] READ_PRIORITY bit.

- Read/write port access scheduling policy

  When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

  When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The DMA_SYSTEM module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting
- At least one free thread ID is available

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 × M, 4 × M, 8 × M or 16 × M, where M can be 8, 16, or 32 bits).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see Section 16.4.2.1, *Interrupt Generation*).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the DMA4_GCR[7:0] MAX_CHANNEL_FIFO_DEPTH bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

transfer block size = FN × EN × ES

The FN, EN, and ES are common for the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI must be such that, when added to the logical channel address pointer, it results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see Section 16.4.2.1, *Interrupt Generation*).

The DMA4_CFNi register configures the FN in a block.

The DMA4_CENi register configures the EN.

The DMA4_CSDPi register configures the ES.

The DMA4_CSSAi and DMA4_CDSAi registers configure the source and destination start addresses.

The DMA4_CCRi register configures the source and destination addressing modes.

The DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

NOTE: Constant addressing mode with DMA4 to/from DDR memory is not supported on the device. To fill the DDR memory with a single value, the constant fill feature of the DMA4 must be used, instead of a constant-addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter ≠ 0):

$$A(n + 1) = A(n) + ES + (EI\ 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter ≠ 0):

$$A(n + 1) = A(n) + ES + (FI\ 1)$$

Calculate the element and frame index as follows:

Equation 5. EIement index

$$EI = [(Stride\ EI\ 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride\ FI\ 1) * ES] + 1$$

where:

A(n): Byte address of the element *n* within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element *n* to the start of next element, *n+1*.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, DMA4_CENi.

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, DMA4_CFNi.

Figure 16-6 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in Figure 16-10.) The double-index addressing example shown in Figure 16-6 uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 16-6 through Figure 16-9 show examples of addressing mode configurations. Table 16-9 lists parameter values for the examples.

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

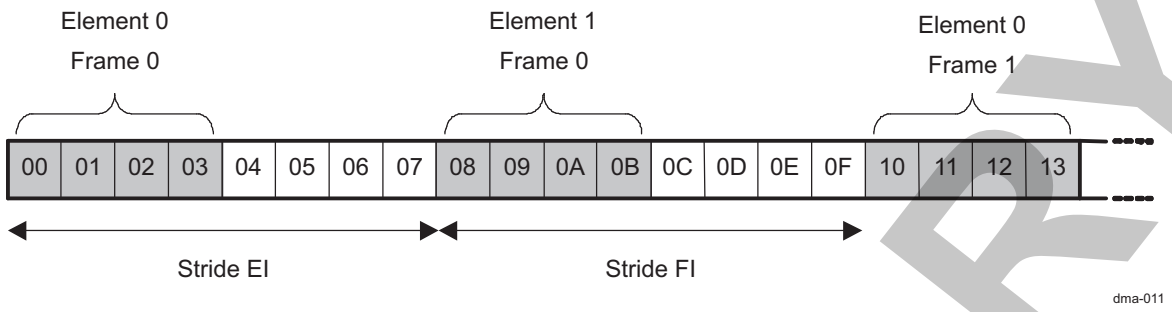


Figure 16-7. Addressing Mode Example (a)

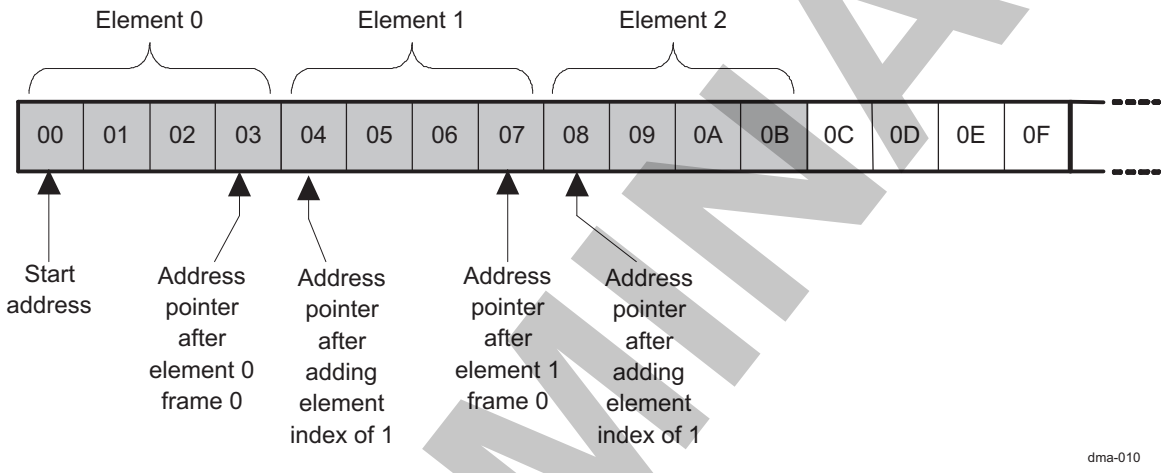

Figure 16-8. Addressing Mode Example (b)

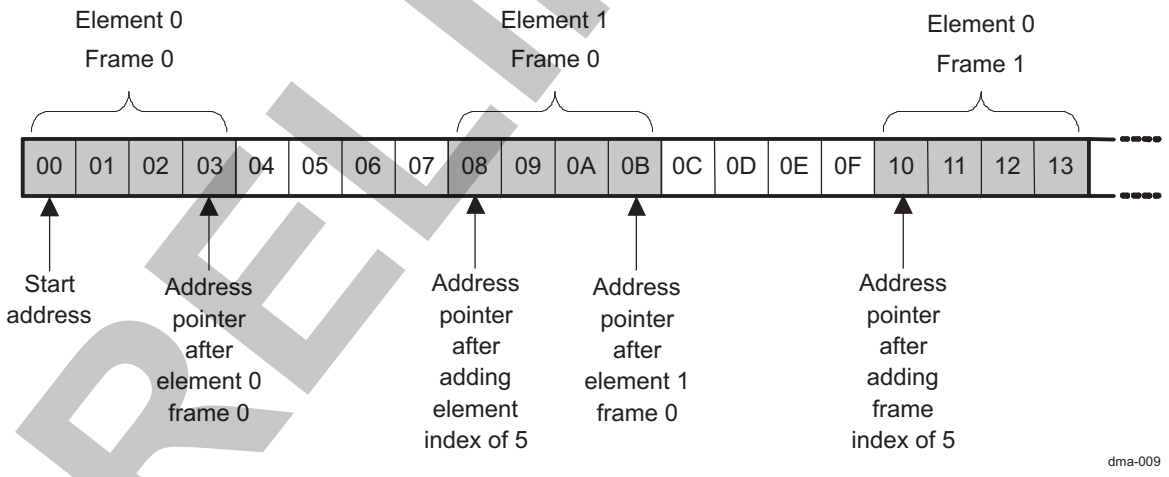

Figure 16-9. Addressing Mode Example (c)

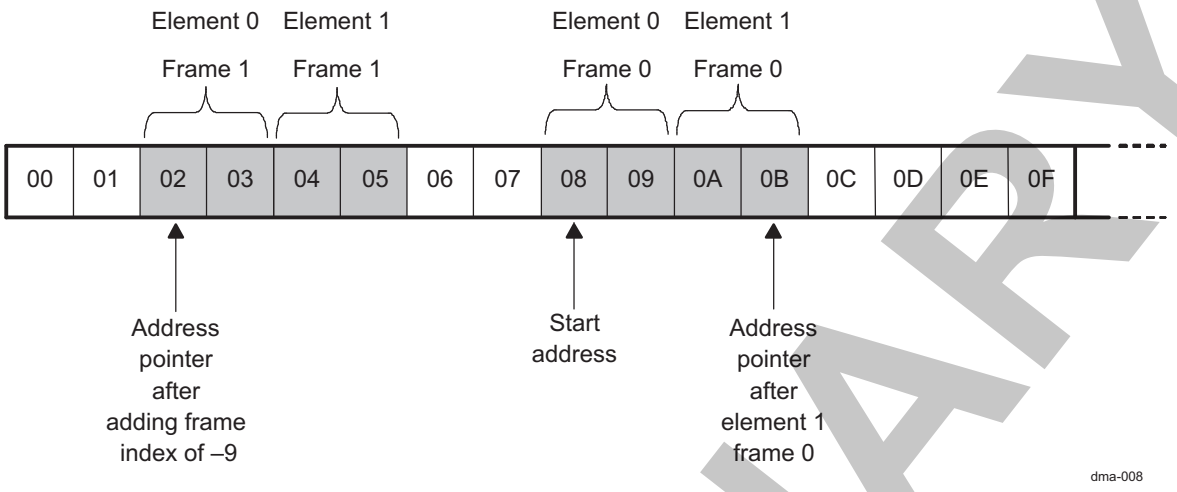

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

Parameter	Example (a)	Example (b)	Example (c)
Addressing mode	Single index (or post-increment)	Double index	Double index
Start address	0	0	8
ES	4 (32-bit)	4 (32-bit)	2 (16-bit)
EN	3	2	2
EI	1	5	1
FN	1	2	2
Frame index	N/A	5	-9

Double indexing can occur on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of (360 – xx) degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

		90° Rotation	180° Rotation	270° Rotation
Double indexing on destination (write)	Base address	ES*(y–1)	ES*(x*y–1)	ES*y*(x–1)
	EI	ES*(y–1) + 1	1–2*ES	1–ES*(y + 1)
	FI	1 ES*[(x–1)*y + 2]	1–2*ES	1+ES*(x–1)*y
Double indexing on source (read)	Base address	ES*x*(y–1)	ES*(x*y–1)	ES*(x–1)
	EI	1–ES*(x + 1)	1–2*ES	ES*(x–1) + 1
	FI	1+ES*(y–1)*x	1–2*ES	1 ES*[(y–1)*x + 2]

Table 16-11 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 × 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line-by-line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

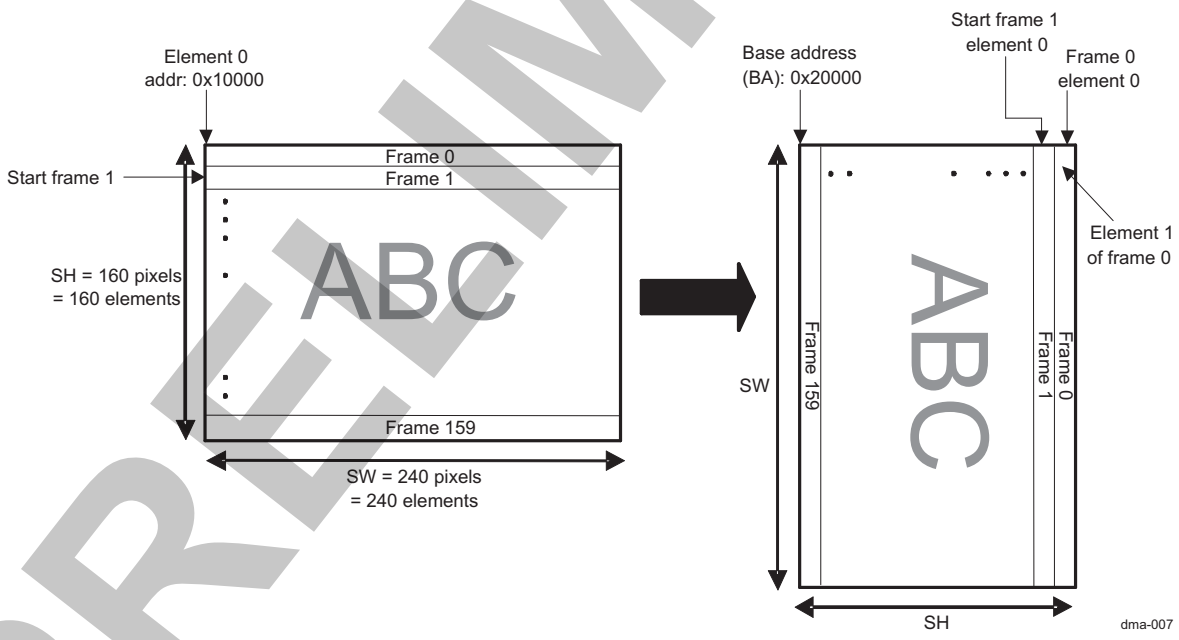
Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

Parameter	Source Value	Destination Value
Bits per pixel	32	32
ES	4	4
Image width	SW	SH
Image height	SH	SW
Stride elements (stride EI)	1 element	SH
Stride frames (stride FI)	1 element	–[(SW-1)*SH + 1] = 38,241 elements
Start address	0x100000	0x200000 + (SH 1) x ES = 0x20027C
EN	SW	SW
EI	[(Stride EI 1) * ES] + 1 = 1	[(Stride EI 1) * ES] + 1 = 637
FN	SH	SH
FI	[(Stride FI 1) * ES] + 1= 1	[(Stride FI 1) * ES] + 1 = 152,967

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation



16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the DMA4_CSDPi register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the DMA4_CSDPi register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the DMA_SYSTEM module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel DMA4_CSDPi register.

NOTE: Because the device is little-endian by construction, the DMA_SYSTEM endianism registers must never be set to big-endian.

If DMA_SYSTEM is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3_MAIN interconnect also executes endian conversion if the DMA_SYSTEM and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA DMA4_CCRi[4:0] and DMA4_CCRi[20:19] bit fields to 0. The transfer starts as soon as the DMA DMA4_CCRi[7] bit is set (when it enters the scheduling process).

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel DMA4_CCRi register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see Table 16-8).

Specify the DMA request number in the DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields. After the DMA4_CCRi[7] ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, the DMA4_CCRi[4:0] SYNCHRO_CONTROL bit field must be set to 0x2 (DMA request number + 1).

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel DMA4_CCRi register and the DMA4_CCRi[5] FS and DMA4_CCRi[18] BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit through either the channel DMA4_CDFIi register (source synchronized) or the DMA4_CSFIi register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

Block_size = Number_of_Frame_in_Block * Number_of_Element_in_Frame * Element_Size

- Synchronized at the source

  The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see Section 16.4.13, *Reprogramming an Active Channel*).

For a source synchronized transfer, buffering can be enabled or disabled by setting the DMA4_CCRi[25] BUFFERING_DISABLE bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

  The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA4_CCRi[23] PREFETCH bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 16.4.4, *FIFO Queue Memory Pool*).

  Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the DMA4_CSDPi[17:16] WRITE_MODE bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The DMA4_CCRi[25] BUFFERING_DISABLE bit must be filled with an allowed value, as specified in Table 16-12.

Table 16-12. Buffering Disable

	BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable)	
Destination synchronized	0	Allowed
	1	Not allowed
Source synchronized	0	Allowed
	1	Allowed

- Synchronized transfer monitoring using CDAC (DMA4_CDACi):

  Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

  The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see Section 16.5.4, *Synchronized Transfer Monitoring Using CDAC*).

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see Section 16.5.5, *Concurrent Software and Hardware Synchronization*):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register DMA4_GCR[13:12] .

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the DMA4_GCR [13:12] value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x1 => Read ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- DMA4_GCR[13:12] = 0x0 => No ThreadID is reserved for high-priority channels
- DMA4_GCR[13:12] = 0x1 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x2 => Write ThreadID 0 is reserved for high-priority channels.
- DMA4_GCR[13:12] = 0x3 => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the DMA4_GCR[13:12] value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (DMA4_CCRi[26]) is added for write priority, and the previous priority bit becomes read priority bit (DMA4_CCRi[6]).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the DMA4_GCR register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the DMA4_GCR[15:14] HI_LO_FIFO_BUDGET field. The maximum channel FIFO depth is limited by the HI_LO_FIFO_BUDGET field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user must perform the following equation:

- For a high-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of High Channel =< High Budget FIFO
- For a low-priority channel: (Per_Channel_Maximum FIFO Depth + 1) x Number of Low Channel =< Low Budget FIFO

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it may be all, none, or simply the first one). The DMA request line number must be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information about the programming model, see Section 16.5, *DMA_SYSTEM Basic Programming Model*.

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the DMA4_CCRi[7] ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the DMA4_CCRi register (DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

maximum_transfer_size =peripheral_FIFO_depth x number_of_frame_in_block

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is $128x2^{16}$ words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = 2^{24} x 2^{16} words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: The Peripheral_element_number_threshold (the number of elements in a packet) shares the DMA4_CSFIi and DMA4_CDFIi configuration registers. If the peripheral is the source target, the addressing mode is constant, and the DMA4_CSFIi[15:0] bit field is used to specify the packet data size in the DMA4_CSFIi register. The user must set the DMA.SDMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the DMA4_CDFIi[15:0], is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the DMA4_CDFIi register, the user must set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0.

  NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting.

  The packet synchronization mode is active when DMA4_CCRi[5] FS = DMA4_CCRi[18] BS = 1. Then:

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 0, the DMA4_CDFIi[15:0] bit field gives the number of elements in the packet and the DMA4_CDFIi[31:16] bit field is unused for the packet size.

  – If DMA4_CCRi[24] SEL_SRC_DST_SYNC = 1, the DMA4_CSFIi[15:0] bit field gives the number of element in the packet and the DMA4_CSFIi[31:16] bit field is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always:

Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.4.15 Graphics Acceleration Support

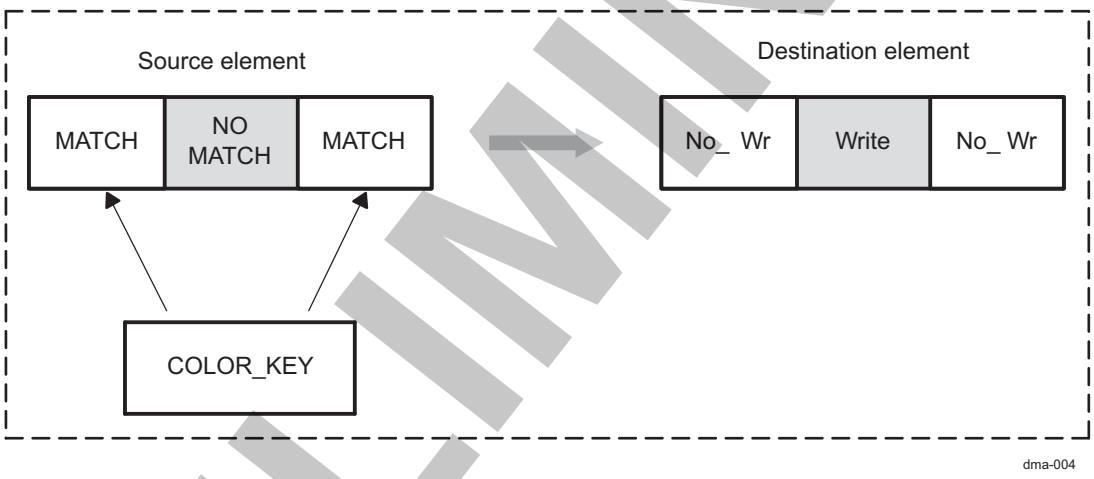
The DMA_SYSTEM supports two graphic acceleration features: transparent copy and constant fill.

Only one of these features can be enabled at a time through the DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the DMA4_COLORi register so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

Figure 16-11. 2-D Graphic Transparent Color Block Diagram



The constant fill feature provides the ability to specify a particular color through the DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8, 16, and 24 bpp, depending on what is specified as the DMA transfer ES through the DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSBs) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the DMA4_CCRi[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its DMA4_CSDPi[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.

- Posted write: Transfer continues without waiting for each write to complete (may improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write completes before transfer can complete.

16.4.18 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware-source-synchronized with buffering enabled (DMA4_CCRi[25] BUFFERING_DISABLE = 0). If this is the case, the FIFO is drained to prevent the loss of data. For more information about this feature, see Section 16.4.19, *FIFO Draining Mechanism*.

16.4.19 FIFO Draining Mechanism

When a source-synchronized channel is disabled during a transfer, the current hardware request (element/packet/frame/block) service completes and the channel DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no longer active on the write port) and if the DMA4_CICRi[12] DRAIN_END_IE is set to 1, the DMA4_CSRi[12] DRAIN_END status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for the DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE bits to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and DMA4_CCRi[25] BUFFERING_DISABLE = 0 and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 Linked List

16.4.20.1 Overview

The DMA_SYSTEM supports the logical transfer-descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter-gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register (DMA4_CNDPi) and a channel-descriptor parameter register (DMA4_CDPi) . The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable, depending on the descriptor type and the Nxt_Dv and Nxt_Sv bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- Src_Element_index and Dst_Element_index are concatenated in the same 32-bit location.
- DMA4_CICRi (interrupt event mask)
- CFN (frame number)
- Bit fields:
  - P: Corresponds to the PAUSE_LINK_LIST bit:
    - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
    - The user must not set the PAUSE_LINK_LIST bit through the configuration port. Otherwise, behavior is undefined.
    - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (descriptor load or data load).
  - B: Corresponds to the end-of-block enable bit (BLOCK_IE) of the DMA4_CICRi register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where DMA4_CICRi is fully specified.
  - Nxt_Dv, Nxt_Sv: Mapped in the DMA4_CDPi register. They indicate one of the following possibilities:
    - Next descriptor contains an updated destination or source address.
    - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
    - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
  - Next_Descriptor_Type: Specifies the next descriptor type that corresponds to the NEXT_DESCRIPTOR_TYPE bit field in the DMA4_CDPi register

16.4.20.3.1 Type 1

A type 1 descriptor includes the overall channel configuration register value to be loaded (global registers are not part of the type 1 descriptor). This descriptor is used primarily when major changes are required:

- Channel read or write access profiles must be modified; for example, bursting and packing (included in the DMA4_CSDPi register)
- Attach a new DMA request to the same channel or change the priority or access privilege (included in the DMA4_CCRi register)
- Enable solid or transparent color fill (included in the DMA4_CCRi and DMA4_COLORi registers)
- Enable a channel link (included in the DMA4_CLNK_CTRLi register)

Table 16-13 shows a type 1 descriptor.

Table 16-13. Type 1

16.4.20.3.2 Type 2

A type 2 descriptor includes the overall logical channel transfer address register and transfer format register to be loaded. This descriptor enables 2D addressing linked-list transfer (for example, a multimedia application where 2D objects are moved in a link). Table 16-14 shows a type 2 descriptor with source and destination address updates. Table 16-15 shows a type 2 descriptor with one source or destination address update.

Table 16-14. Type 2 With Source and Destination Address Updates

16.4.20.3.3 Type 3

A type 3 descriptor is limited to a few logical channel transfer address registers and transfer format registers to be loaded. This descriptor enables simple 1D addressing link transfer (for example, scatter-gather or ping-pong memory movement using a linked list). Table 16-16 shows a type 3 descriptor with source and destination address updates. Table 16-17 shows a type 3 descriptor with one source or address destination update.

16.4.20.4 Linked-List Control and Monitoring

16.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in DMA4_CDPi[9:8] TRANSFER_MODE to distinguish the different transfer modes:

- DMA4_CDPi[9:8] TRANSFER_MODE = 00: The current channel is using normal mode.
- DMA4_CDPi[9:8] TRANSFER_MODE = 01: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (DMA4_CDPi[9:8] TRANSFER_MODE = 0).

16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the DMA4_CCRi[7] ENABLE bit to 1). The DMA4_CDPi[10] FAST bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the DMA4_CCENi (remaining elements) and DMA4_CCFNi (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, DMA4_CCDNi (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the DMA4_CCDNi register to 0 during the initial configuration. When the DMA4_CCDNi register is updated, the DMA4_CCFNi and the DMA4_CCENi registers are updated. The user must also initialize the DMA4_CCFNi and DMA4_CCENi registers to 0xFFFF and to 0xFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in CICR. The DMA4_CICRi register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the DMA4_CICRi and DMA4_CSRi registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update BLOCK_IE (full DMA4_CICRi update), a dedicated BLOCK_IE bit field is also available in a type 3 descriptor.

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the DMA4_CDPi[7] PAUSE_LINK_LIST bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel DMA4_CDPi[7] PAUSE_LINK_LIST bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the DMA4_CDPi[7] PAUSE_LINK_LIST bit through the configuration port; otherwise, transfer behavior is undefined.

  A PAUSE_LINK_LIST bit (P) is set to 1 in the descriptor.

  – The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
  – The linked list can be resumed by resetting the DMA4_CDPi[7] PAUSE_LINK_LIST bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

  A channel is a drain candidate if it is a hardware-source-synchronized transfer with DMA4_CCRi[25] BUFFERING_DISABLE = 0 and should not be doing any of the graphics operation (transparent copy or solid-color fill).
- Drain trigger:

  A drain candidate channel is drained if it is disabled (DMA4_CCRi[7] ENABLE = 0) or if it receives a transaction error on the read port.
- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
  – During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
  – During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a DRAIN_END interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

  A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with DMA4_CCRi[25] BUFFERING_DISABLE = 1.
- Abort trigger:

  A channel is an abort candidate if it is disabled (DMA4_CCRi[7] ENABLE = 0), if it receives a transaction error on the read or write port, or if there is a MISALIGNMENT_ERROR.
- Abort behavior with a type 1, 2, or 3 descriptor:

  If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

  In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the DMA4_CSRi[6] SYNC, DMA4_CCRi[9] RD_ACTIVE and DMA4_CCRi[10] WR_ACTIVE status bits:

- For a hardware-synchronized channel in linked-list mode, the DMA4_CSRi[6] SYNC bit becomes active (DMA4_CSRi[6] SYNC = 1) when the first data load transaction is scheduled and remains active

until the last data load transaction in the block (not super block) is descheduled (DMA4_CSRi[6] SYNC = 0). The SYNC bit is not active during the descriptor load phase.

- The DMA4_CCRi[9] RD_ACTIVE bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
  - When (during the descriptor load phase) the last descriptor write request is descheduled
  - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
  - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The DMA4_CCRi[10] WR_ACTIVE bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
  - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
  - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with DMA4_CCRi[25] BUFFERING_DISABLE = 0) or hardware-destination-synchronized transfer.

16.4.20.4.8 Linked-List Channel Linking

Channel linking for inter- and intra-super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]->CHx[DataN + 1]

CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] -> . -> CHx[DESN]-CHx[DataN+1] -> CHz: CHz[Data1]-> CHz[DES1] -> . -> CHz[DESM]->CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit to 1 and the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1]-> CHx[DES1] ->.-> CHx[DESp]->CHx[Data(p + 1)] -> CHz[Data1]-> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx is disabled after the corresponding data load and enables the channel CHz.

16.5 DMA_SYSTEM Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the DMA4_GCR register, and any required interrupts must be enabled through the DMA4_IRQENABLE_Lj registers and the logical channel DMA4_CICRi registers.

Software clears the DMA4_CSRi register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES (8, 16, or 32 bits) in the DMA DMA4_CSDPi[1:0] bit field.
     - Read and write port access types (single/burst), DMA DMA4_CSDPi[8:7] and DMA4_CSDPi[15:14] bit fields
     - Source and destination endianism, DMA DMA4_CSDPi[21] and DMA4_CSDPi[19] bits
     - Write mode (posted or nonposted) and DMA DMA4_CSDPi[17:16] bit field
     - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA DMA4_CSDPi[6] and DMA4_CSDPi[13] bits
   - DMA4_CENi: EN
   - DMA4_CFNi: FN per transfer block
   - DMA4_CSSAi and DMA4_CDSAi: Source and destination start address (aligned with transfer ES)
   - DMA4_CCRi:
     - Read and write port addressing modes, DMA DMA4_CCRi[13:12] and DMA4_CCRi[15:14] bit field
     - Priority bit for both read and write ports, DMA DMA4_CCRi[6] and DMA4_CCRi[26] bits
     - DMA request number (set to 0 for a software-triggered transfer) and DMA register bit fields DMA4_CCRi[4:0] = 0 and DMA4_CCRi[20:19] = 0
   - DMA4_CSEIi, DMA4_CSFIi, DMA4_CDEIi, and DMA4_CDFIi: Source and destination element and frame indexes (depending on addressing mode)
2. Start the transfer through the enable bit in the channel DMA4_CCRi register and DMA DMA4_CCRi[7] bit

The following example performs a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000):

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t
      *)malloc(sizeof(DMA4_t));

/* Init. parameters
      */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; //
      DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; //
      DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; //
      DMA4_CSDPi[21]
```

```
DMA4->DestinationEndianism = 0; //
      DMA4_CSDPi[19]
DMA4->WriteMode = 0; //
      DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; //
      DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; //
      DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; //
      DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; //
      DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; //
      DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; //
      DMA4_CDSAi
DMA4->SourceElementIndex = 1; //
      DMA4_CSEIi
DMA4->SourceFrameIndex = 1; //
      DMA4_CSFIi
DMA4->DestinationElementIndex = 1; //
      DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; //
      DMA4_CDFIi
DMA4->ReadPortAccessMode = 1; //
      DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; //
      DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; //
      DMA4_CCRi[6]
DMA4->WritePriority = 0; //
      DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; //
      DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; //
      DMA4_CCRi[20:19]

/* 1) Configure the transfer

      index CDEI[15:0]*/
```

```
DMA4_CDEI_CH10 =
      DMA4->DestinationElementIndex;

/* i)- Set the destination
      frame index CDFI[31:0]*/

DMA4_CDFI_CH10 =
      DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by
      Setting the enable bit CCR[7]=1 */

/*----------------------------------------------------------------*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */
```

16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization DMA4_CCRi[5] FS bit and the block synchronization DMA4_CCRi[18] BS bit must be programmed. For all the following synchronized transfers (element, packet, and frame or block-synchronized transfers), the user must first set the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 1 when the source triggers on the DMA request and set it the DMA4_CCRi[24] SEL_SRC_DST_SYNC bit to 0 when the destination triggers on the DMA request.

NOTE: The user must take care when setting the DMA4_CCRi[23] PREFETCH bit it is in conjunction with DMA4_CCRi[24] SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
  1. Set the number of DMA request associated with the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  4. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  5. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  6. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  7. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  8. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  9. Set both FS and BS to 0 in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  10. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one frame per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN

bit field.

5. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
6. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
7. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
8. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
9. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
10. Set FS to 1 and BS to 0, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
11. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

- To configure an LCh to transfer one block per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of element per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  4. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
  5. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  6. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.
  7. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
  8. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
  9. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
  10. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
  11. Set FS to 0 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
  12. Set to 1 the channel enable bit DMA4_CCRi[7] EN.
- To configure an LCh to transfer one packet per DMA request:
  1. Set the number of DMA request associated to the current LCH in the DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and DMA4_CCRi[4:0] SYNCHRO bit field.
  2. Set the data type, also referenced as element size (ES), in the DMA4_CSDPi[1:0] DATA_TYPE bit field.
  3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set DMA4_CCRi [24] SEL_SRC_DST_SYNC to 1 and set the packet element number in the DMA4_CSFIi register and set the addressing mode of source to constant addressing in DMA4_CCRi[13:12] SRC_AMODE bit field; else, if the packet requestor is in the destination, set the DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the DMA4_CDFIi register and set the addressing mode of destination to constant addressing in DMA4_CCRi[15:14] DST_AMODE bit field.
  4. Set the number of elements per frame in the DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
  5. Set in the DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
  6. Set the element number in the packet in the DMA4_CSFIi[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the DMA4_CDFIi[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
  7. Set the Read Port access type (single or burst access) in the DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
  8. Set the Write Port access type (single or burst access) in the DMA4_CSDPi[15:14] DST_BURST_EN bit field.

9. Set the Read Port addressing mode in the DMA4_CCRi[13:12] SRC_AMODE bit field.
10. Set the Write Port addressing mode in the DMA4_CCRi[15:14] DST_AMODE bit field.
11. Set the Read start address in the DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
12. Set the Write start address in the DMA4_CDSAi[31:0] DST_START_ADRS bit field.
13. Set FS to 1 and BS to 1, respectively, in DMA4_CCRi[5] FS and DMA4_CCRi[18] BS.
14. Set to 1 the channel enable bit DMA4_CCRi[7] EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the DMA4_CCRi[7] ENABLE bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the DMA4_CDACi register.
2. Enable the channel.
3. If a time-out occurs, read DMA4_CDACi register.
4. If DMA4_CDACi != 0 (it is the value configured in DMA4_CDACi):

   This indicates that the corresponding transfer has started. The user can then rely on DMA4_CCENi and DMA4_CCFNi element and frame counters.

   Otherwise, if DMA4_CDACi = 0 (it is the value configured in the DMA4_CDACi):

   This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:

   Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the DMA4_GCR[13:12] HI_THREAD_RESERVED bit field to 0x1.
2. Specify channel priority:

   Channel 4 is a write high priority channel: set DMA4_CCRi[26] WRITE_PRIORITY = 1.

   Channel 5 is a read high priority channel: set DMA4_CCRi[6] READ_PRIORITY = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in Section 16.5.5, *Concurrent Software and*

Hardware Synchronization.

2. For each channel in the chain, configure the DMA4_CLNK_CTRLi register as follows:
   - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID bit field.
   - Include the logical channel to the chain and enable link by setting the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit.
   - For a non-looping chain, the last logical channel in the chain must have the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.
3. Enable the transfer through the enable bit in the first logical channel DMA4_CCRi[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the DMA4_CLNK_CTRLi[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 =
      0x0000800A;
```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in Section 16.4.5, *Addressing Modes*, can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
   - DMA4_CSDPi:
     - Transfer ES = 32-bit (32 bpp), DMA4_CSDPi[1:0] DATA_TYPE bit field
     - Read and write port access types = maximum burst size supported by memory device, DMA4_CSDPi[8:7] SRC_BURST_EN and DMA4_CSDPi[15:14] DST_BURST_EN bit fields
     - Source and destination endianism, DMA4_CSDPi[21] SRC_ENDIAN and DMA4_CSDPi[19] DST_ENDIAN bits
     - Write mode = posted with last element nonposted, DMA4_CSDPi[17:16] WRITE_MODE bit field
     - Source and destination packed = Yes (although destination writes do not benefit because EI1), DMA4_CSDPi[6] SRC_PACKED and DMA4_CSDPi[13] DST_PACKED bits
   - DMA4_CENi: EN = 240
   - DMA4_CFNi: FN per transfer block = 160
   - DMA4_CSSAi: Source start address = 0x100000
   - DMA4_CDSAi: destination start address = 0x20013E
   - DMA4_CCRi:
     - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA4_CCRi[13:12] SRC_AMODE and DMA4_CCRi[15:14] DST_AMODE bit fields
     - Low or high priority, DMA4_CCRi[6] READ_PRIORITY bit
     - DMA request number = 0 (for software-triggered transfer), DMA4_CCRi[4:0] SYNCHRO_CONTROL and DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER bit fields
   - DMA4_CSEIi: Source EI = 1
   - DMA4_CSFIi: Source frame index = 1
   - DMA4_CDEIi: destination EI = 637
   - DMA4_CDFIi: destination frame index = 152967

2. Start the transfer through the enable bit in the channel DMA4_CCRi register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*:

```
/* Init. parameters */
DMA4->DataType = 0x2; //
      DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]

DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]

DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]

DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked
      = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; //
      DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi

DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi

DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi

DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi

DMA4->SourceElementIndex = 1; // DMA4_CSEIi

DMA4->SourceFrameIndex = 1; // DMA4_CSFIi

DMA4->DestinationElementIndex = 637; // DMA4_CDEIi

DMA4->DestinationFrameIndex = -152967; // DMA4_CDFIi

DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]

DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority =
      0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]

DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
```

16.5.8 Graphic Operations

- Transparent copy:
  1. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 1
  2. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 0
  3. Set the value of the key color in the DMA4_COLORi[15:0] COLOR_KEY bit field

  To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;

DMA4_COLOR_CH10 = 0x00000003;
```

- Solid Color fill:
  1. Set the DMA4_CCRi[16] CONST_FILL_ENABLE bit to 1
  2. Set the DMA4_CCRi[17] TRANSPARENT_COPY_ENABLE bit to 0

3. Set the value of key the color in the DMA4_CORIRi[15:0] SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of Section 16.5.2, *Software-Triggered (Nonsynchronized) Transfer*.

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;

DMA4_COLOR_CH10 = 0x00000003;
```

16.5.9 Linked-List Programming Guidelines

- With the exception of the DMA4_CCRi[7] ENABLE bit and the DMA4_CDPi[7] PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
  - For type 2, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
  - For type 3, the following registers must be initialized with consistent values:
    - All global registers
    - DMA4_CCRi
    - DMA4_CSDPi
    - DMA4_CLNK_CTRLi
    - DMA4_CICRi
    - DMA4_CFNi
- In case of a linked list with descriptor types 2 and 3, the content of the DMA4_CCRi register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 DMA_SYSTEM Register Manual

16.6.1 DMA_SYSTEM Instance Summary

Table 16-18. DMA_SYSTEM Instance Summary

Module Name	Base Address	Size
DMA_SYSTEM	0x4A05 6000	4 KiB

16.6.2 DMA_SYSTEM Registers

16.6.2.1 DMA_SYSTEM Register Summary

Index *i* represents the logical channel number (where i = 0 to 31). The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_CCR10 (channel 10) register has an offset address of 10 × 0x60 = 0x3C0, and thus a physical address of 0x4A05 6080 + 0x3C0 = 0x4A05 6440.

Index *j* represents the interrupt line number (where j = 0 to 3) The offset address for some registers is calculated from the channel *c* number. For example, the DMA4_IRQSTATUS_L3 (line 3) register has an offset address of 3 × 0x4 = 0xC, and thus a physical address of 0x4A05 6008 + 0xC = 0x4A05 6014.

Table 16-19. DMA_SYSTEM Registers Mapping Summary

16.6.2.2 DMA_SYSTEM Register Description

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

Table 16-20. DMA4_REVISION

Table 16-28. DMA4_OCP_SYSCONFIG

Address Offset	0x0000 002C		
Physical Address	0x4A05 602C	**Instance**	DMA_SYSTEM
Description	DMA system configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		MIDLEMODE		RESERVED		CLOCKACTIVITY		RESERVED		EMUFREE		SIDLEMODE		RESERVED	RESERVED	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0's for future compatibility, Reads return 0	RW	0x00000
13:12	MIDLEMODE	Read write power management, standby/wait control 0x0: Force-standby: MStandby is asserted only when all the DMA channels are disabled 0x1: No-Standby: MStandby is never asserted 0x2: Smart-Standby: MStandby is asserted if at least one of the following two conditions is satisfied: 1. All the channels are disabled, OR 2. There is no non-synchronized channel enabled AND [if hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced]. 0x3: Reserved	RW	0x0
11:10	RESERVED	Reserved for clocks activities extension	RW	0x0
9:8	CLOCKACTIVITY	Clocks activities during wake-up Bit 8: Interface clock 0x0: Interface clock can be switched-off Bit 9: Functional clock 0x0: Functional clock can be switched-off	R	0x0
7:6	RESERVED	Write 0's for future compatibility. Read returns 0	RW	0x0
5	EMUFREE	Enable sensitivity to MSuspend 0x0: DMA4 freezes its internal logic upon MSuspend assertion 0x1: DMA4 ignores the MSuspend input	RW	0
4:3	SIDLEMODE	Configuration port power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Idle acknowledge is given by DMA4 if all of the conditions are true: 1. All the channels are disabled. 2. If hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced. 3. All transactions are completed on all the DMA ports. 4.No interrupts are pending to be serviced. 0x3: Reserved. Do not use	RW	0x0
2	RESERVED	Write 0's for future compatibility, Reads return 0	RW	0
1	RESERVED	Reserved for non-GP devices	RW	0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free running 0x1: Automatic interface clock gating strategy is applied, based on the interface activity.	RW	0

Table 16-38. DMA4_GCR

Address Offset	0x0000 0078		
Physical Address	0x4A05 6078	**Instance**	DMA_SYSTEM
Description	FIFO sharing between high and low priority channel. The Maximum per channel FIFO depth is bounded by the low and high channel FIFO budget. The high respectively low priority channels maximum burst size must be less than the min (high respectively low priority channel FIFO budget , per channel maximum FIFO depth)		
Type	RW		

31 30 29 28 27 26 25	24	23 22 21 20 19 18 17 16	15 14	13 12	11 10 9 8	7 6 5 4 3 2 1 0
RESERVED	CHANNEL_ID_GATE	ARBITRATION_RATE	HI_LO_FIFO_BUDGET	HI_THREAD_RESERVED	RESERVED	MAX_CHANNEL_FIFO_DEPTH

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00
24	CHANNEL_ID_GATE	Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports	RW	0x0
23:16	ARBITRATION_RATE	Arbitration switching rate between prioritized and regular channel queues	RW	0x01
15:14	HI_LO_FIFO_BUDGET	Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels	RW	0x0
13:12	HI_THREAD_RESERVED	Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.	RW	0x0
11:8	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
7:0	MAX_CHANNEL_FIFO_DEPTH	Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.	RW	0x10

Description	Channel Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		RESERVED			WRITE_PRIORITY	BUFFERING_DISABLE	SEL_SRC_DST_SYNC	PREFETCH	SUPERVISOR	RESERVED	SYNCHRO_CONTROL_UPPER		BS	TRANSPARENT_COPY_ENABLE	CONST_FILL_ENABLE	DST_AMODE		SRC_AMODE		RESERVED	WR_ACTIVE	RD_ACTIVE	SUSPEND_SENSITIVE	ENABLE	READ_PRIORITY	FS	SYNCHRO_CONTROL				

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0
29:27	RESERVED	Reserved for non-GP devices	RW	0x0
26	WRITE_PRIORITY	Channel priority on the Write side 0x0: Channel has low priority on the write side during the arbitration process. 0x1: Channel has high priority on write sided during the arbitration process.	RW	0
25	BUFFERING_DISABLE	This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: Buffering is enabled across element/packet when source is synchronized to element, packet, frame or blocks. 0x1: Buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks.	RW	-

Bits	Field Name	Description	Type	Reset
24	SEL_SRC_DST_SYNC	Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register. 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register.	RW	-
23	PREFETCH	Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests. 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is software user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported.	RW	0
22	SUPERVISOR	Enables the supervisor mode 0x0: Supervisor mode is disabled. 0x1: Supervisor mode is enabled.	RW	0
21	RESERVED	Reserved for non-GP devices	RW	0
20:19	SYNCHRO_CONTROL_UPPER	Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as 2 MSB, with the 5 bits of the synchro channel bit field.	RW	0b00
18	BS	Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer.	RW	-
17	TRANSPARENT_COPY_ENABLE	Transparent copy enable 0x0: Transparent copy mode is disabled. 0x1: Transparent copy mode is enabled.	RW	-
16	CONST_FILL_ENABLE	Constant fill enable 0x0: Constant fill mode is disabled. 0x1: Constant fill mode is enabled.	RW	0
15:14	DST_AMODE	Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
13:12	SRC_AMODE	Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode	RW	0bxx
11	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
10	WR_ACTIVE	Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port. Read 0x1: Channel is currently active on the write port.	R	0
9	RD_ACTIVE	Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port. Read 0x1: Channel is currently active on the read port.	R	0

Bits	Field Name	Description	Type	Reset
8	SUSPEND_SENSITIVE	Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions.	RW	0
7	ENABLE	Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled. 0x1: The logical channel is enabled.	RW	0
6	READ_PRIORITY	Channel priority on the read side 0x0: Channel has low priority on the read side during the arbitration process. 0x1: Channel has high priority on read sided during the arbitration process.	RW	0
5	FS	Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS = 0 and BS = 0: An element is transferred once a DMA request is made. FS = 0 and BS = 1: An entire block is transferred once a DMA request is made. FS = 1 and BS = 0: An entire frame is transferred once a DMA request is made. FS = 1 and BS = 1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests.	RW	-
4:0	SYNCHRO_CONTROL	Channel synchronization control This bit field used in conjunction with the second_level_ synchro_control_upper (as 2 MSB) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. **Note:** The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1).	RW	0b00000

Physical Address	0x4A05 6088 + (0x60 * i)	**Instance**	DMA_SYSTEM
Description	Channel Interrupt Control Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	SUPER_BLOCK_IE	RESERVED	DRAIN_IE	MISALIGNED_ERR_IE	SUPERVISOR_ERR_IE	RESERVED	TRANS_ERR_IE	PKT_IE	RESERVED	BLOCK_IE	LAST_IE	FRAME_IE	HALF_IE	DROP_IE	RESERVED

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x00000
14	SUPER_BLOCK_IE	Enables the end of super block interrupt	RW	-
13	RESERVED	Reserved for non-GP devices	RW	1
12	DRAIN_IE	Enables the end of draining interrupt	RW	0
11	MISALIGNED_ERR_IE	Enables the address misaligned error event interrupt 0x0: Disables the misaligned address error event interrupt 0x1: Enables the misaligned address error event interrupt	RW	-
10	SUPERVISOR_ERR_IE	Enables the supervisor transaction error event interrupt 0x0: Disables the supervisor transaction error event interrupt 0x1: Enables the supervisor transaction error event interrupt	RW	1
9	RESERVED	Reserved for non-GP devices	RW	1
8	TRANS_ERR_IE	Enables the transaction error event interrupt 0x0: Disables the transaction error event interrupt 0x1: Enables the transaction error event interrupt	RW	-
7	PKT_IE	Enables the end of Packet interrupt 0x0: Disables the end of Packet transfer interrupt 0x1: Enables the end of Packet transfer interrupt	RW	-
6	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0
5	BLOCK_IE	Enables the end of block interrupt 0x0: Disables the end of block interrupt 0x1: Disables the end of block interrupt	RW	-
4	LAST_IE	Last frame interrupt enable (start of last frame) 0x0: Disables the last frame interrupt 0x1: Enables the last frame interrupt	RW	-
3	FRAME_IE	Frame interrupt enable (end of frame) 0x0: Disables the end of frame interrupt 0x1: Enables the end of frame interrupt	RW	-
2	HALF_IE	Enables or disables the half frame interrupt. 0x0: Disables the half frame interrupt 0x1: Enables the half frame interrupt	RW	-

Bits	Field Name	Description	Type	Reset
1	DROP_IE	Synchronization event drop interrupt enable (request collision) 0x0: Disables the event drop interrupt 0x1: Enables the event drop interrupt	RW	0
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x0000
16:15	RESERVED	Reserved for debug (Monitor descriptor/data load phase), Write 0's for future compatibility, Read returns 0	RW	0x0
14	SUPER_BLOCK	End of Super block event Read 0x0: The current Super block transfer has not been finished Write 0x0: Status bit unchanged Read 0x1: The current Super block has been transferred Write 0x1: Status bit is reset	RW W1toClr	0
13	RESERVED	Reserved for non-GP devices	RW	0

Bits	Field Name	Description	Type	Reset
12	DRAIN_END	End of channel draining Read 0x0: No drain end in the current transfer Write 0x0: Status bit unchanged Read 0x1: The current channel draining is completed Write 0x1: Status bit is reset	RW W1toClr	0
11	MISALIGNED_ADRS_ERR	Misaligned address error event Read 0x0: No address error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: An address error has been occurred	RW W1toClr	0
10	SUPERVISOR_ERR	Supervisor transaction error event Read 0x0: No supervisor transaction error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A supervisor transaction error has been occurred	RW W1toClr	0
9	RESERVED	Reserved for non-GP devices	RW	0
8	TRANS_ERR	Transaction error event Read 0x0: No transaction error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A transaction error has been occurred	RW W1toClr	0
7	PKT	End of Packet transfer Read 0x0: The current packet transfer has not been finished Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The current packet has been transferred	RW W1toClr	0
6	SYNC	Synchronization status of a channel. Read 0x0: Logical channel is not scheduled or servicing a non synchronized DMA request. Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: Logical channel is servicing a synchronized DMA request	RW W1toClr	0
5	BLOCK	End of block event Read 0x0: The current block transfer has not been finished Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The current block has been transferred	RW W1toClr	0
4	LAST	Last frame (start of last frame) Read 0x0: The start of the last frame to transfer is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The start of the last frame to transfer is reached	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
3	FRAME	End of frame event Read 0x0: The end of current transferred frame is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The end of current transferred frame is reached	RW W1toClr	0
2	HALF	Half of frame event. Read 0x0: The half of current transferred frame is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The half of current transferred frame is reached	RW W1toClr	0
1	DROP	Synchronization event drop occured during the transfer Read 0x0: No synchronization collision Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A synchronization collision has been occurred	RW W1toClr	0
0	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0

RESERVED										SRC_ENDIAN	SRC_ENDIAN_LOCK	DST_ENDIAN	DST_ENDIAN_LOCK	WRITE_MODE		DST_BURST_EN		DST_PACKED	RESERVED					SRC_BURST_EN		SRC_PACKED	RESERVED				DATA_TYPE		

Bits	Field Name	Description	Type	Reset
31:22	RESERVED	Write 0's for future compatibility. Read returns 0.	RW	0x000
21	SRC_ENDIAN	Channel source endianness control 0x0: Source has Little Endian type 0x1: Source has Big Endian type	RW	-
20	SRC_ENDIAN_LOCK	Endianness Lock 0x0: Endianness adapt 0x1: Endianness lock	RW	-
19	DST_ENDIAN	Channel Destination endianness control 0x0: Destination has Little Endian type 0x1: Destination has Big Endian type	RW	-
18	DST_ENDIAN_LOCK	Endianness Lock 0x0: Endianness adapt 0x1: Endianness lock	RW	-
17:16	WRITE_MODE	Used to enable writing mode without posting or with posting 0x0: Write None Posted (WRNP) 0x1: Write (Posted) 0x2: All transaction are mapped on the Write command as posted except for the last transaction in the transfer mapped on a Write None Posted 0x3: Undefined	RW	0bxx
15:14	DST_BURST_EN	Used to enable bursting on the Write Port. Smaller burst size than the programmed burst size is also allowed 0x0: single access 0x1: 16 bytes or 4x32-bit / 2x64-bit burst access 0x2: 32 bytes or 8x32-bit / 4x64-bit burst access 0x3: 64 bytes or 16x32-bit / 8x64-bit burst access	RW	0b00
13	DST_PACKED	Destination receives packed data. 0x0: The destination target is non packed 0x1: The destination target is packed	RW	-
12:9	RESERVED	Write the reset value. Read returns reset value	RW	0x-
8:7	SRC_BURST_EN	Used to enable bursting on the Read Port. Smaller burst size than the programmed burst size is also allowed 0x0: single access 0x1: 16 bytes or 4x32-bit / 2x64-bit burst access 0x2: 32 bytes or 8x32-bit / 4x64-bit burst access 0x3: 64 bytes or 16x32-bit / 8x64-bit burst access	RW	0bxx
6	SRC_PACKED	Source provides packed data. 0x0: The source target is non packed 0x1: The source target is packed	RW	-
5:2	RESERVED	Write the reset value. Read returns reset value	RW	0x-
1:0	DATA_TYPE	Defines the type of the data moved in the channel. 0x0: 8 bits scalar 0x1: 16 bits scalar 0x2: 32 bits scalar 0x3: Reserved	RW	0bxx

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

NOTE: Some of the interrupt controllers features, primarily those concerning the device I/O pads and the interrupt controllers integration, are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

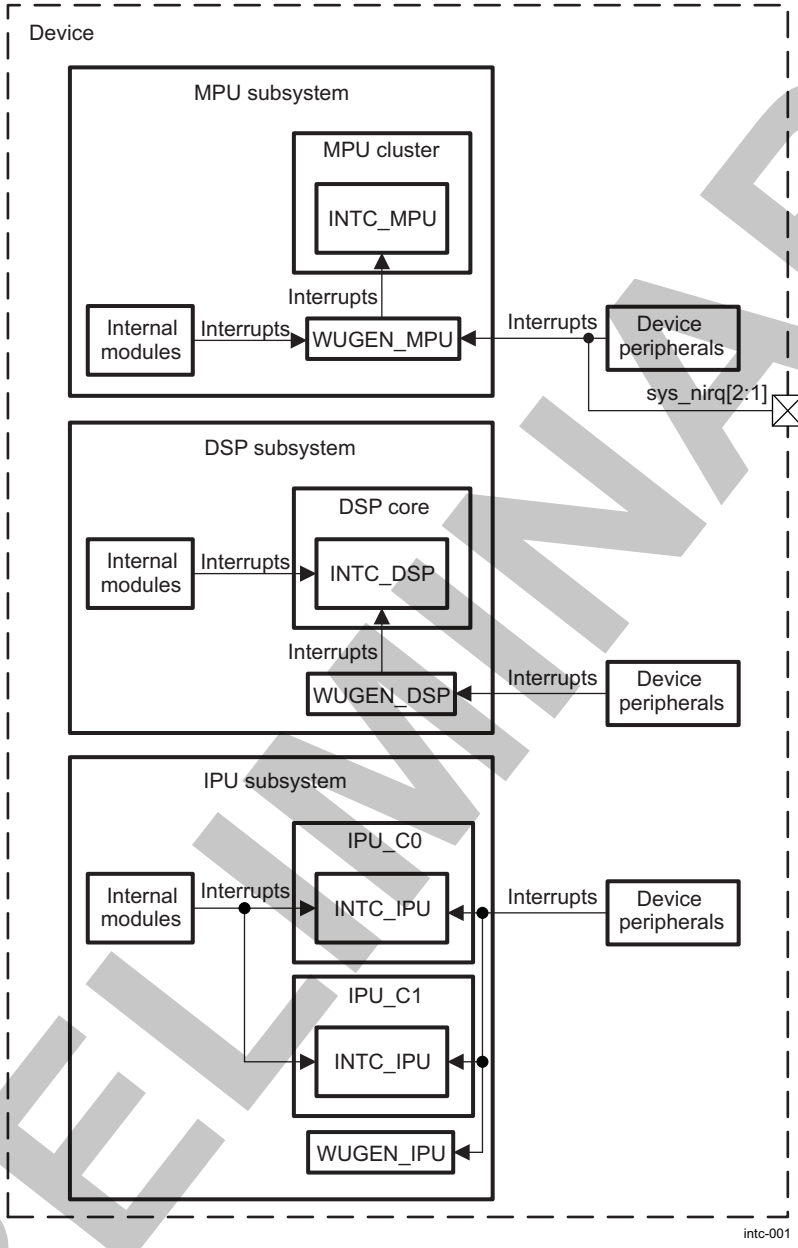
17.1 Interrupt Controllers Overview

The device provides three INTC modules, which handle interrupts at the device level:

- Microprocessor unit (MPU) subsystem (dual Cortex™-A15) interrupt controller (INTC_MPU): This INTC module is a single functional unit that is integrated in the Cortex-A15 multiprocessor core alongside Cortex-A15 processors. It provides:
  - 160 hardware interrupt inputs
  - Generation of interrupts by software
  - Prioritization of interrupts
  - Masking of any interrupts
  - Distribution of the interrupts to the target Cortex-A15 processor(s)
  - Tracking the status of interrupts
  - Support for virtualization extensions
  - Wake-up generator (WUGEN_MPU) module on external and local interrupts
- Digital signal processor (DSP) subsystem interrupt controller (INTC_DSP): This module is a specific combination of wake-up generator (WUGEN_DSP) and the C64x+ INTC_DSP. The INTC_DSP is used in the device but not described in detail in this chapter. For detailed information about this module, see DSP Subsystem.
- Interrupt processor unit (IPU) subsystem (dual Cortex-M4) interrupt controller (INTC_IPU): This module is also called nested vectored interrupt controller (NVIC) and is integrated within each Cortex-M4 core so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. INTC_IPU supports:
  - 64 external interrupts (in addition to 16 Cortex-M4 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
  - Low-latency exception and interrupt handling
  - Prioritization and handling of exceptions
  - Control of the local power management
  - Debug accesses to the processor core
  - Wake-up generator (WUGEN_IPU) module on external interrupts, coming from device peripherals

Figure 17-1 shows an overview of the device interrupt controllers.

Figure 17-1. Interrupt Controllers Overview



NOTE: For more information about the WUGEN_MPU module (including integration, functional and register description), see Dual Cortex-A15 MPU Subsystem.

For more information about the WUGEN_IPU module (including integration, functional and register description), see Dual Cortex-M4 IPU Subsystem.

17.2 Interrupt Controllers Environment

This section describes the environment of the INTC application fields (in other words, external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

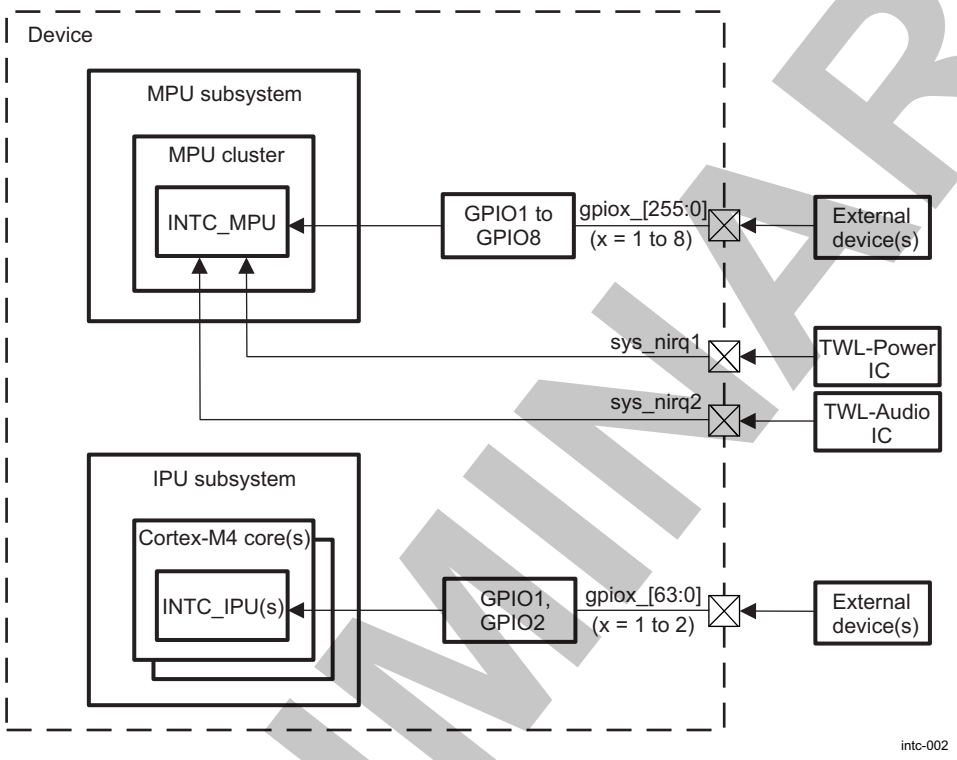


Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the INTC_MPU or INTC_IPU.

Table 17-1. Interrupt Controllers I/O Signals

Signal Name	I/O[1]	Reset Value	Description	INTC_MPU	INTC_IPU
sys_nirq1	I	1	TWL-Power IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–
sys_nirq2	I	1	TWL-Audio IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–

(1) I = Input, O = Output

Table 17-1. Interrupt Controllers I/O Signals (continued)

Signal Name	I/O[1]	Reset Value	Description	INTC_MPU	INTC_IPU
gpio1_[31:0]	I/O	–	External devices can use GPIO modules to generate interrupts to INTC_MPU or INTC_IPU. There are eight dedicated interrupt lines (for GPIO1 to GPIO8) to the INTC_MPU and two dedicated interrupt lines (for GPIO1 and GPIO2) to the INTC_IPU. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see General-Purpose Interface.	✓	✓
gpio2_[63:32]	I/O	–		✓	✓
gpio3_[95:64]	I/O	–		✓	–
gpio4_[127:96]	I/O	–		✓	–
gpio5_[159:128]	I/O	–		✓	–
gpio6_[191:160]	I/O	–		✓	–
gpio7_[223:192]	I/O	–		✓	–
gpio8_[255:224]	I/O	–		✓	–

17.3 Interrupt Controllers Integration

The INTC_MPU is integrated inside the Cortex-A15 MPCore (MPU cluster). For more information about INTC_MPU integration, see Section 4.2, *Dual Cortex-A15 MPU Subsystem Integration*, in Chapter 4, *Dual Cortex-A15 MPU Subsystem*.

The INTC_IPU is integrated inside each Cortex-M4 core. For more information about INTC_IPU integration, see Section 7.2, *Dual Cortex-M4 IPU Subsystem Integration*, in *Chapter 7, Dual Cortex-M4 IPU Subsystem*.

17.3.1 Interrupts Mapping

NOTE: All device peripherals interrupts (external to the MPU, DSP, and IPU subsystems) are active-high, level sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (MPU, DSP, and IPU subsystems). With multiple-mapped interrupts, TI strongly recommendeds unmasking each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to INTC_MPU

Table 17-2 shows the INTC_MPU interrupt mapping.

Table 17-2. INTC_MPU Interrupt Mapping

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
MPU_IRQ_0	MPU_CLUSTER_IRQ_INTERR	MPU_CLUSTER	Illegal writes to interrupt controller memory map region[1]
MPU_IRQ_1	CS_CTI_MPU_C0_IRQ	CS_CTI_MPU_C0	TRIGOUT[6] of Cross Trigger Interface 0 (CTI0)[1]
MPU_IRQ_2	CS_CTI_MPU_C1_IRQ	CS_CTI_MPU_C1	TRIGOUT[6] of Cross Trigger Interface 1 (CTI1)[1]
MPU_IRQ_3	MPU_CLUSTER_IRQ_AXIERR	MPU_CLUSTER	Error indication for AXI write transactions with a BRESP error condition[1]
MPU_IRQ_4	ELM_IRQ	ELM	Error location process completion[2]
MPU_IRQ_5	WD_TIMER_MPU_C0_IRQ_WARN	WD_TIMER_MPU_C0	WD_TIMER_MPU_C0 warning interrupt
MPU_IRQ_6	WD_TIMER_MPU_C1_IRQ_WARN	WD_TIMER_MPU_C1	WD_TIMER_MPU_C1 warning interrupt
MPU_IRQ_7	EXT_SYS_IRQ_1	EXT_SYS	External interrupt (active low)
MPU_IRQ_8	Reserved	Reserved	Reserved
MPU_IRQ_9	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	Reports debug errors on L3
MPU_IRQ_10	L3_MAIN_IRQ_APP_ERR	L3_MAIN	Reports application or nonattributable errors on L3

(2) Internally generated within IPU subsystem
(3) Shared with INTC_DSP
(4) Shared with INTC_MPU
(5) Shared with INTC_DSP and INTC_MPU

NOTE: All IPU subsystem internal interrupts are edge interrupts, except the one generated from the MMU (XLATE_MMU_FAULT_IRQ), which is level interrupt.

17.4 Interrupt Controllers Functional Description

17.4.1 INTC_MPU Functional Description

INTC_MPU is configured to have the following interrupt sources:

- 16 software-generated interrupts (SGIs): ID[15:0]
- 7 private peripheral interrupts (PPIs): ID[31:25]
- 160 shared peripheral interrupts (SPIs): ID[191:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is presented in Table 17-2.

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the INTC_MPU, see ARM *Cortex-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.4.2 INTC_IPU Functional Description

The INTC_IPU has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M4 core. The interrupt mapping of these interrupts (IPU_IRQ_[79:16]) is presented in Table 17-3.
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M4 core within the IPU subsystem. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M4 processor level. Writing to this bit has no effect.

For more information about the functionality of the INTC_IPU, see *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5 Interrupt Controllers Register Manual

17.5.1 Interrupt Controllers Instance Summary

For information about the INTC_MPU and INTC_IPU instances, see Dual Cortex-A15 MPU Subsystem and Dual Cortex-M4 IPU Subsystem, respectively.

17.5.2 INTC_MPU Registers

For information about the INTC_MPU registers and their description, see *ARM Cortex-A15 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5.3 INTC_IPU Registers

For information about the INTC_IPU (NVIC) registers and their description, see *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Control Module

This chapter describes the system control module for the device.

NOTE: Some of the control module features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

For details, see Section 1.5, *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (pad configuration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

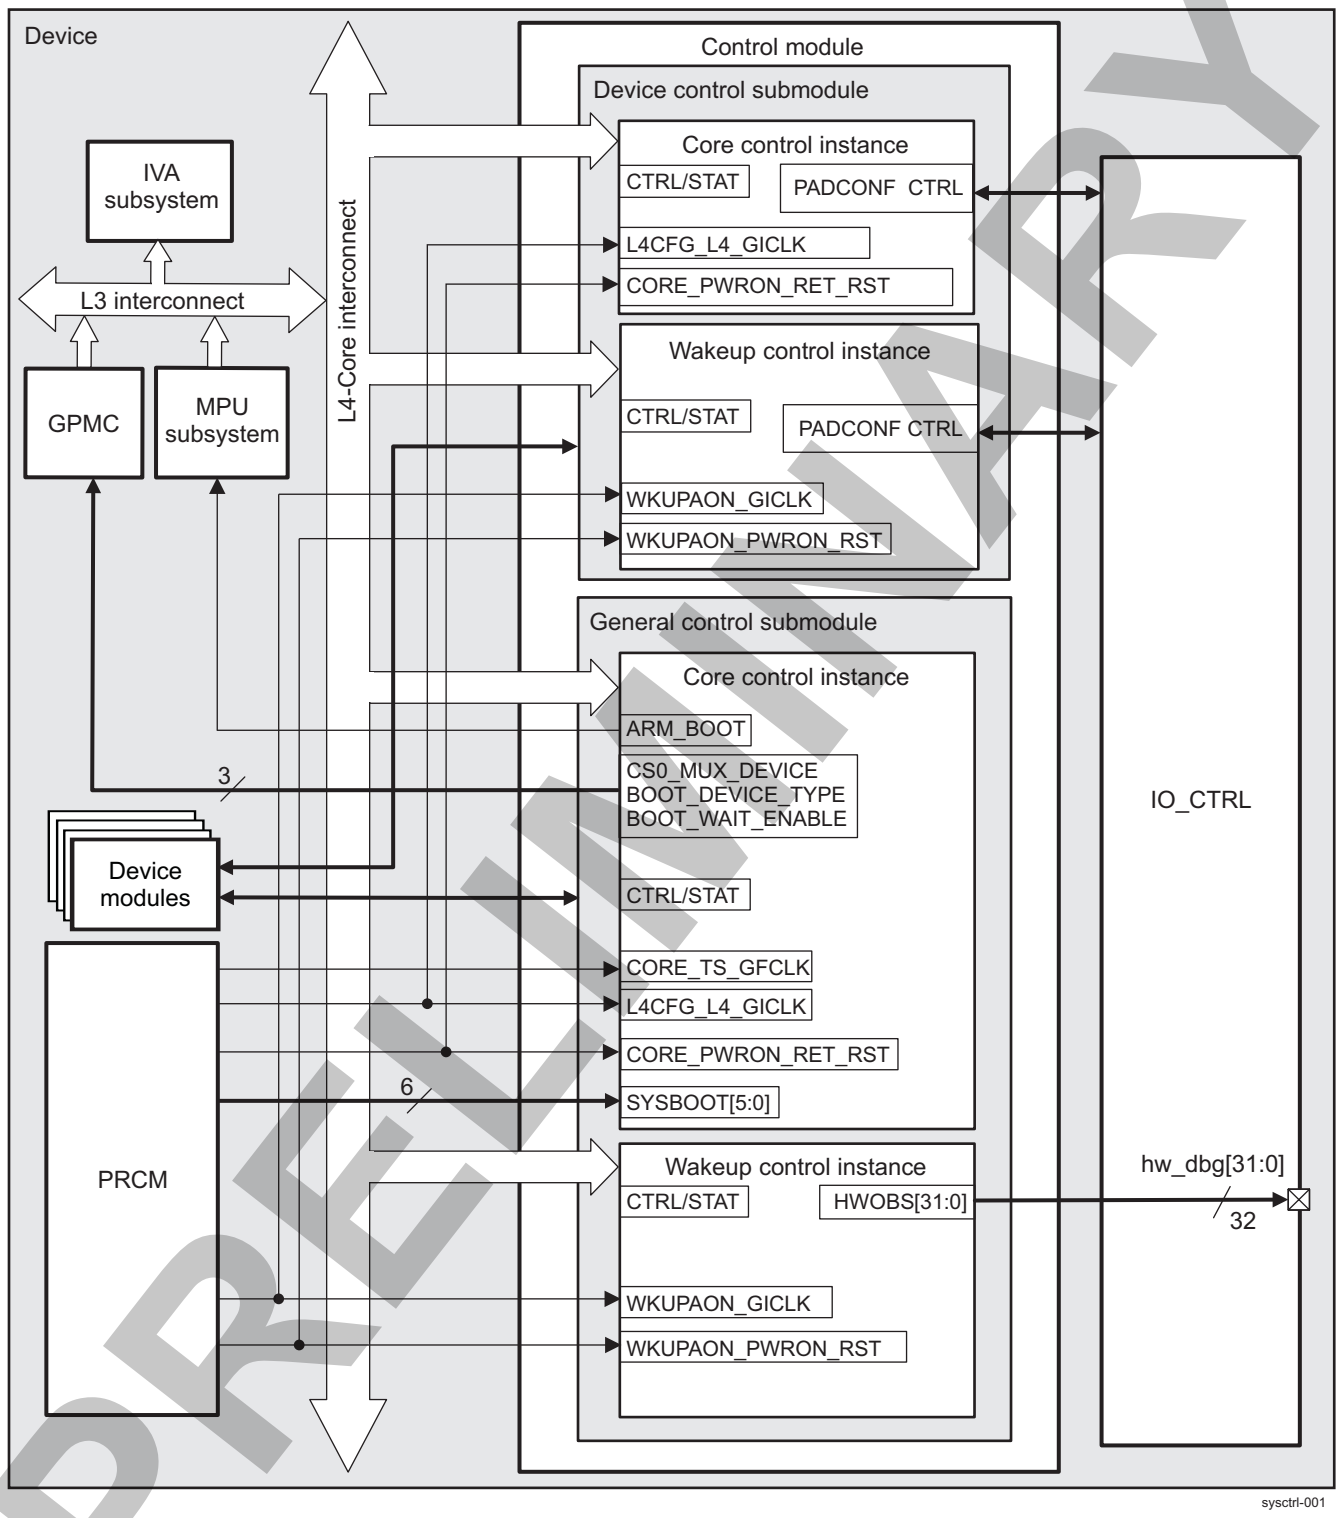
The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup and pulldown configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four control module instances, see Section 18.3, *Control Module Integration*.

Figure 18-1 is an overview of the control module.

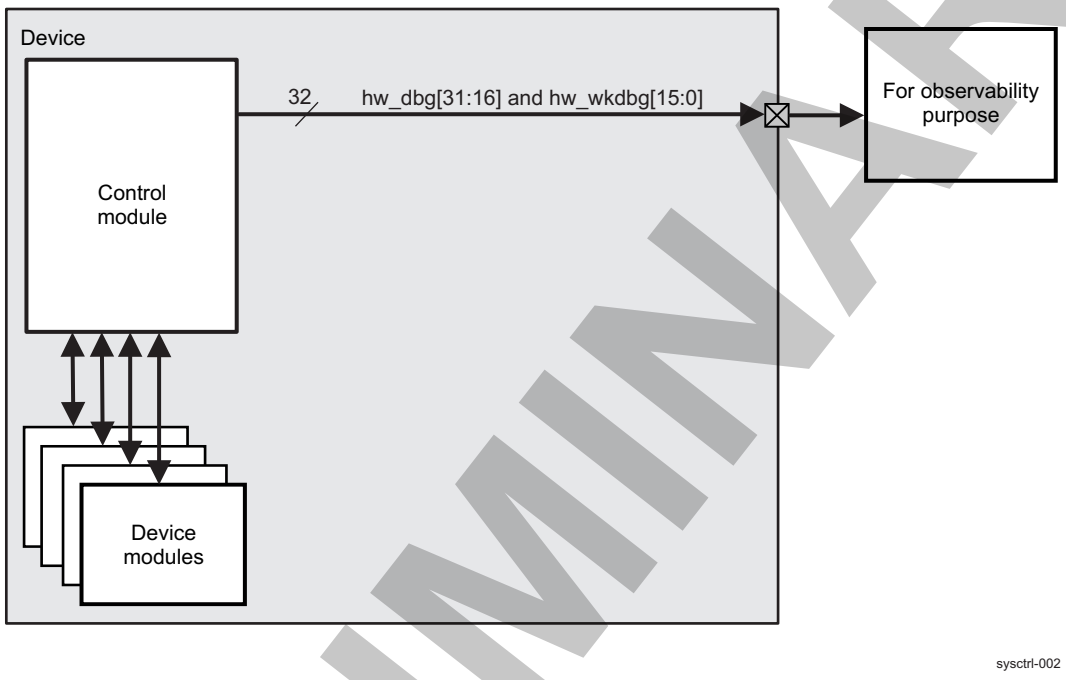
Figure 18-1. Control Module Overview



18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *PAD Functional Multiplexing and Configuration*. Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module, direct memory access (DMA) requests, and interrupts. Figure 18-2 is an overview of the control module environment.

Figure 18-2. Control Module Environment



18.2.1 Control Module Signals

Table 18-1 lists the control module hardware observability outputs configured to observe the debug signals of the device module. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

Signal	I/O[1]	Description	Reset Value[2]
hw_dbg[31:16] and hw_wkdbg[15:0]	O	32 internal hardware observability signals. hw_dbg[31:16] are mapped to pads in the CORE power domain and hw_wkdbg[15:0] are mapped to pads in the WKUP power domain.	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional

(2) Hi-Z = High impedance

18.3 Control Module Integration

The control module of the device is on the L4_CORE interconnect. It consists of four module instances:

- General core control module (CTRL_MODULE_CORE)
- General wakeup control module (CTRL_MODULE_WKUP)
- Device core control module (CTRL_MODULE_CORE_PAD)
- Device wakeup control module (CTRL_MODULE_WKUP_PAD)

For more information about the different control module instances, see Table 18-4.

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. The exception is the general core control module (CTRL_MODULE_CORE), which also receives a secondary functional clock, L3INSTR_TS_GCLK. Table 18-2 describes the signals.

Table 18-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
CTRL_MODULE_WKUP	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	L4_WKUP interface/functional clock propagated to the general wkup control module
CTRL_MODULE_WKUP_PAD	WKUPAON_GICLK	WKUPAON_GICLK	PRCM	L4_WKUP interface/functional clock propagated to the device wkup control module
CTRL_MODULE_CORE	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	L4_CFG interface/functional clock propagated to the general core control module
	L3INSTR_TS_GCLK	L3INSTR_TS_GCLK	PRCM	Functional clock for the three bandgap state-machines instantiated in the general core control module
CTRL_MODULE_CORE_PAD	L4CFG_L4_GICLK	L4CFG_L4_GICLK	PRCM	L4_CFG interface/functional clock propagated to the device core control module
Resets				
CTRL_MODULE_WKUP	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal power-on reset (POR) affecting the general wakeup control module
CTRL_MODULE_CORE	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the general core control module
CTRL_MODULE_WKUP_PAD	WKUPAON_PWRON_RST	WKUPAON_PWRON_RST	PRCM	Internal POR affecting the device wakeup control module
CTRL_MODULE_CORE_PAD	CORE_PWRON_RET_RST	CORE_PWRON_RET_RST	PRCM	Internal POR affecting the device core control module

Table 18-3. Hardware Requests

Interrupt Requests				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Destination**	**Description**
CTRL_MODULE_CORE	MPU_IRQ_126	THERMAL_ALERT	MPU	Interrupt generated by general core control module to the MPU
CTRL_MODULE_CORE	MPU_IRQ_75	PBIAS_IRQ	MPU	Interrupt generated by the PBIAS cell to the MPU

NOTE: For a description of the interrupt sources, see Section 17.3.2, *Interrupt Requests to INTC_MPU*, in Chapter 17, *Interrupt Controllers*.

The control module is reset by the internal POR, which is active low. The PRCM module provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to both of the core control module instances, and a nonretention POR signal (WKUPAON_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*. The control module does not respond to a warm reset or to an L4_CORE reset.

The main sequential logic within the system control module is accessible in a register file through the L4_CORE interconnect. The PRCM module provides the L4CFG_L4_GICLK functional clock signal (CD_L4_CFG clock domain) separately to each of the two core control submodules. In addition, the bandgap state-machine, instantiated inside the CTRL_MODULE_CORE receives its functional clock (L3INSTR_TS_GCLK) from the PRCM module. For more information about this signal, see Section 3.6.3.1 , *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module also supplies the WKUPAON_GICLK functional clock signal (CD_WKUPAON clock domain) to each of the two wake-up control module instances. For more information about this signal, see Section 3.6.3.1 , *PRM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.

The PRCM module latches the sys_boot[5:0] pad signals at POR and exports them as vector to the SYS_BOOT[5:0] input of the CTRL_MODULE_CORE. It is scanned in the CONTROL_STATUS[5:0] SYS_BOOT bit field.

The thermal management subsystem inside the general core control module delivers one interrupt request (THERMAL_ALERT) to line MPU_IRQ_126 of the MPU subsystem interrupt controller (INTC), and delivers three thermal protection output signals (TSHUT) to the PRCM module, used as warm resets. For more information about the functional outputs of the thermal management control module, see Section 18.4.10.

The PBIAS cell delivers an interrupt request (PBIAS_IRQ) to the MPU_IRQ_75 line of the MPU subsystem INTC. This line is activated when a PBIAS error occurs.

The signal integration of the control module features:

- No IDLE hardware handshake
- No STANDBY hardware handshake
- No wake-up request generation
- No DMA request generation
- Two interrupt requests to the MPU subsystem - THERMAL_ALERT and PBIAS_IRQ
- Three TSHUT used as PRCM warm-reset sources
- Three functional clocks: two clocks in the CFG and one in the WKUP clock domains
- One retention and one nonretention internal power-on-based resets

Figure 18-3 shows the integration of the module in the device.

Figure 18-3. Control Module Integration

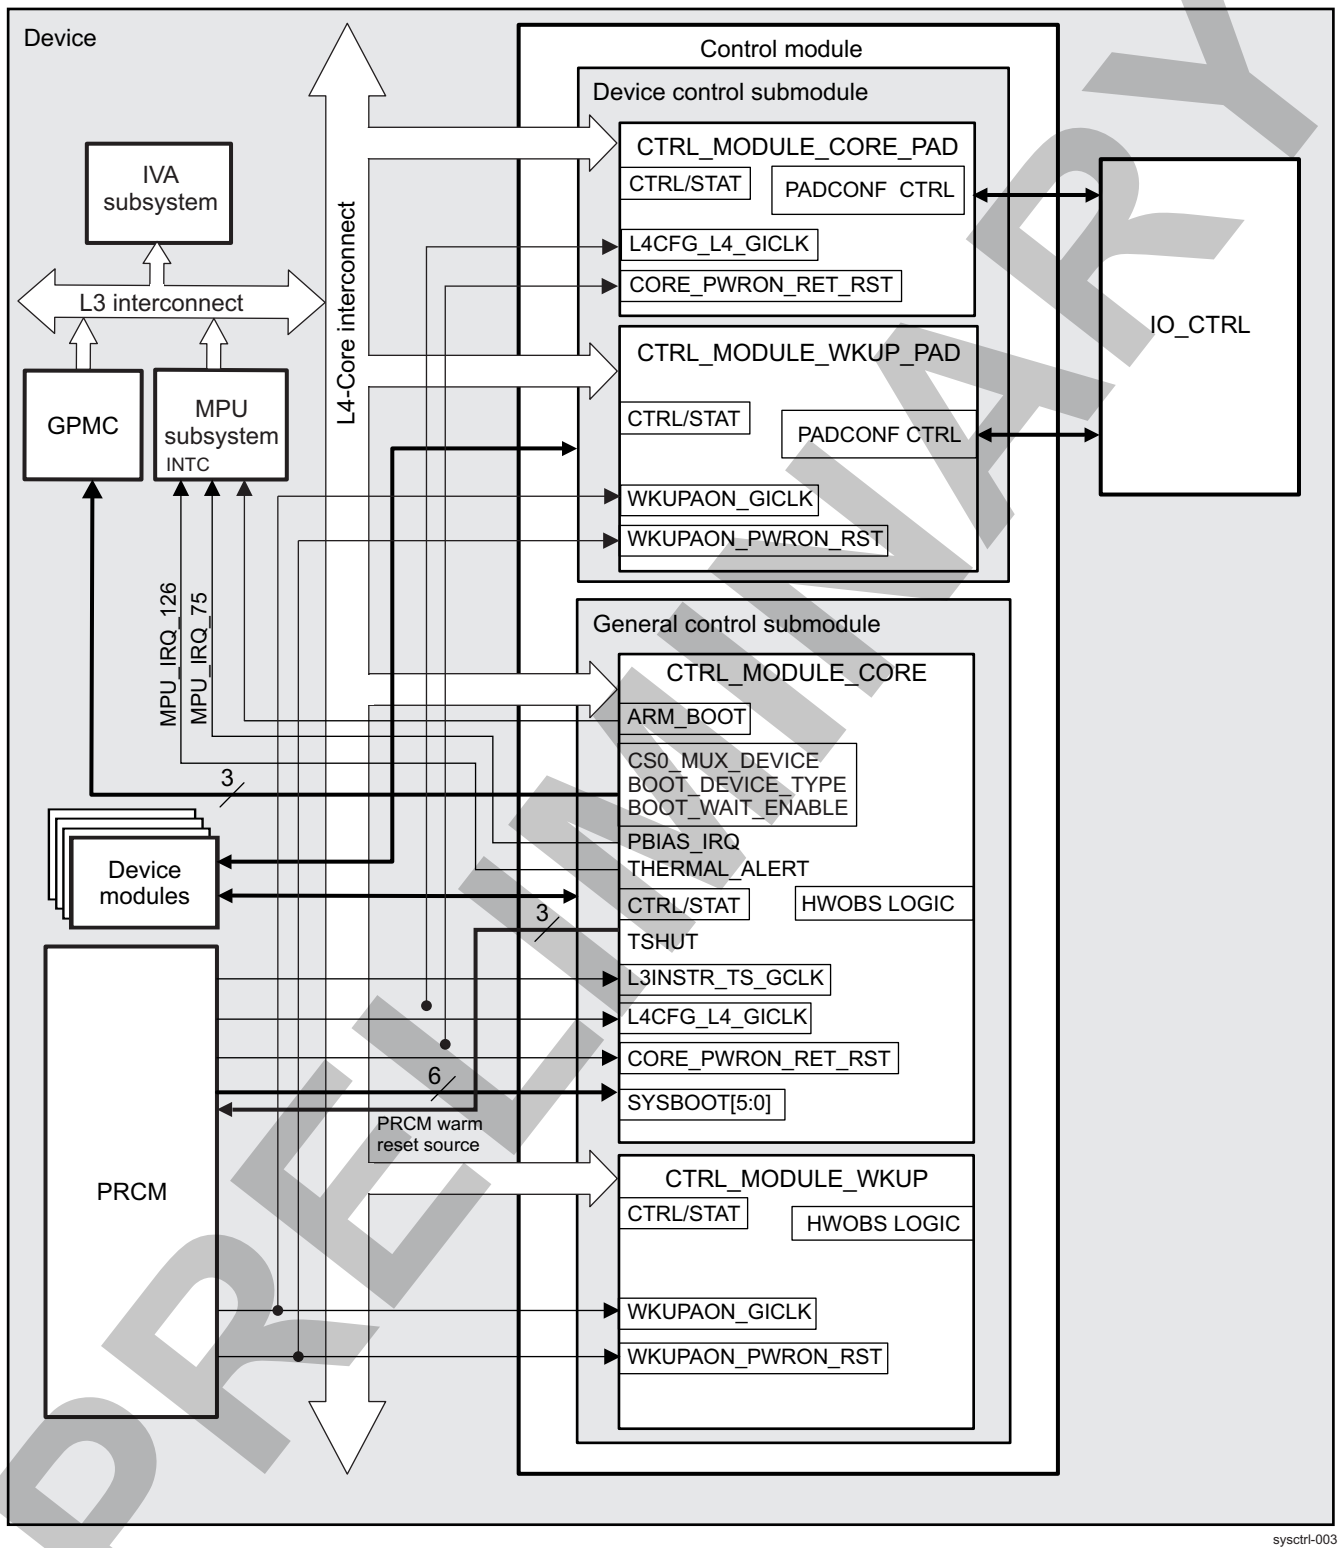


Table 18-4 lists the integration attributes.

Table 18-4. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
CTRL_MODULE_WKUP	PD_WKUPAON	L4_WKUP
CTRL_MODULE_CORE	PD_CORE	L4_CFG
CTRL_MODULE_WKUP_PAD	PD_WKUPAON	L4_WKUP
CTRL_MODULE_CORE_PAD	PD_CORE	L4_CFG

Software sets the configuration registers to the desired values depending on the configuration of the requested device. Software can set static device configuration registers any time, and the settings are effective immediately.

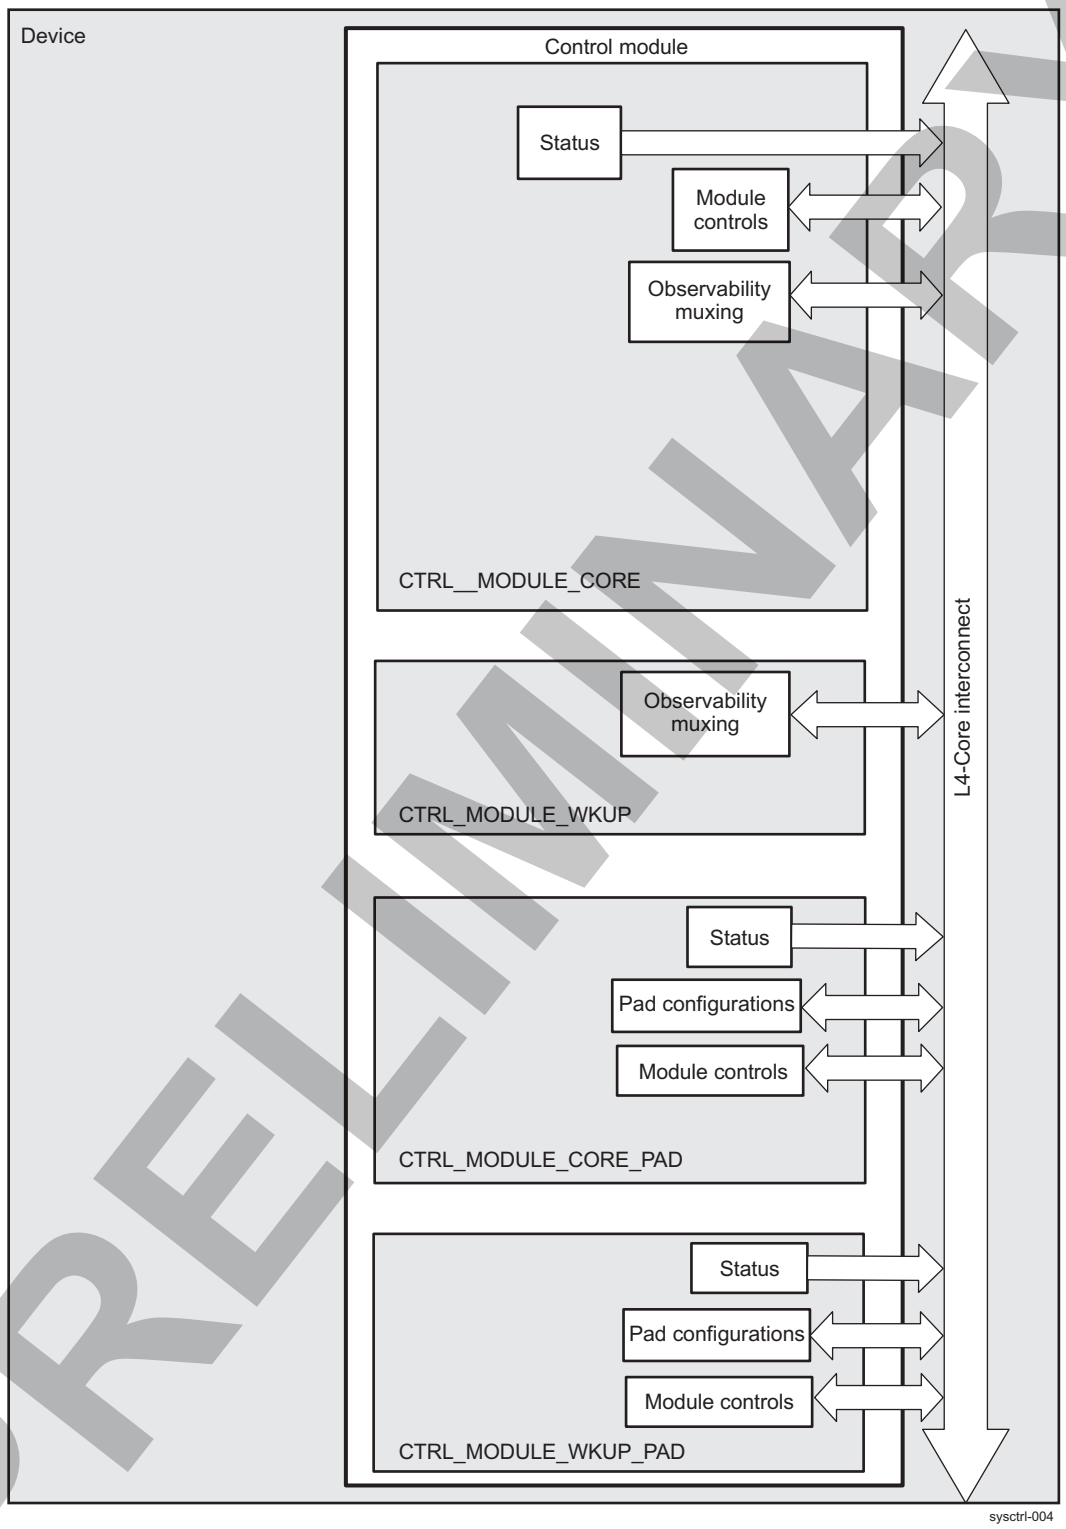
18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

The control module controls the settings of various device modules through the register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pads configured for hardware observability.

Figure 18-4 is the control module block diagram.

Figure 18-4. Control Module Block Diagram



The control submodules primarily implement a bank of registers accessible (read and write) by software and some read-only registers that provide status information.

The 32-bit read and write registers in the general control module (CTRL_MODULE_CORE and CTRL_MODULE_WKUP) can be divided into the following classes:

- Hardware observability registers
- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

The 32-bit read/write registers in the device control module (CTRL_MODULE_CORE_PAD and CTRL_MODULE_WKUP_PAD) can be divided into the following classes:

- Pad configuration registers
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

The L4CFG_L4_GICLK and WKUPAON_GICLK source clocks are internally distributed into two clock paths: the first path directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path is automatically gated when there is no access to the control module through the L4 interconnect.

There are no PRCM software controls for the L4CFG_L4_GICLK and WKUPAON_GICLK clocks in the control module. There are, however, clock activity status bits in the PRCM module.

The L3INSTR_TS_GCLK has the following software controls located in the PRCM module:

- Status: see in Chapter 3, *Power, Reset, and Clock Management*
- Divider ratio: see in Chapter 3, *Power, Reset, and Clock Management*

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The control module CORE instances are fully built with retention flip-flops (RFFs) and are powered in the CORE power domain; thus, they can be in active or retention mode. In contrast to the core control instances, the control wake-up instances are always powered and active. For more information about the device low-power states, see Section 3.1.1, *Device Power-Management Architecture Building Blocks*, in Chapter 3*, Power, Reset, and Clock Management*.

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.5 Hardware Requests

The control module does not generate DMA or wake-up requests. The general core control module generates one IRQ (THERMAL_ALERT) to the MPU (MPU_IRQ_126 line). For more information, see Section 17.3.2, *Interrupt Requests to INTC_MPU*.

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power on, reset values for the registers define the safe state for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and outputs pads are turned off. After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see Section 28.1, *Initialization overview*.

The CONTROL_STATUS[5:0] SYS_BOOT bit field reflects the state of the sys_boot pads captured at POR in the PRCM module.

18.4.7 Control Module Instances

18.4.7.1 General Core Control Module Instance

The CTRL_MODULE_CORE instance contains most of the control logic that provides the hardware observability features for different digital phase-locked loop (DPLL) clockout and DPLL-specific signals, DMA requests, IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, and some peripheral control and status registers are also mapped there.

The following register sets are available within the CTRL_MODULE_CORE:

- Observability control registers:
  - CONTROL_HWOBS_CONTROL
  - CONTROL_DEBOBS_FINAL_MUX_SEL
  - CONTROL_CONF_SDMA_REQ_SELx
  - CONTROL_CONF_CLK_SELx (where x = 0 to 2)
  - CONTROL_CONF_DPLL_X_SEL (where X = FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
  - CONTROL_CONF_DPLLCTRL_X_SEL (where X = PLLLOCK, PLLRECAL, STOPCLOCK, STOPCLOCKACKZ)
  - CONTROL_CONF_MMCX_X_SEL (where X = ADPIDLE, OCPL4IDLEREQ, OCPL3MWAIT, PIRFFRET, OCPL4SIDLEACKO1, OCPL4SIDLEACKO0, OCPL3MSTANDBYO, SWAKEUP)
- Part of the debug view channel selection registers: CONTROL_CORE_CONF_DEBUG_SEL_TST_X
- MMU address translation-related registers: CONTROL_CORTEX_M4_MMUADDRTRANSLTR and CONTROL_CORTEX_M4_MMUADDRLOGICTR
- Standard fuse registers: CONTROL_STD_FUSE_X
- Control status register: CONTROL_STATUS
- Different peripheral control registers.

18.4.7.2 General Wake-Up Control Module Instance

The following registers are associated with the CTRL_MODULE_WKUP instance:

- Register with spare bits: CONTROL_OCPREG_SPARE
- Part of the debug view channel selection registers: CONTROL_CONF_DEBUG_SEL_TST_X

18.4.7.3 Device Core Control Module Instance

The CTRL_MODULE_CORE_PAD instance provides the device-specific pad control features, such as pullup and pulldown I/O configuration and pad functional multiplexing. Wake-up control and status features are also subjects of the device core control.

The following registers are associated with this module:

- Different peripheral pad mode configuration and wake-up status and configuration registers, such as:
  - CONTROL_CORE_PAD0_X_PAD1_Y

  - CONTROL_PADCONF_WAKEUPEVENTx
  - CONTROL_SMARTxIO
- Peripheral pad voltage-level control register: CONTROL_PADCONF_MODE
- Miscellaneous controls for different device interface modules: CONTROL_X registers, such as the CONTROL_EMIF register (including the CONTROL_EFUSE registers)

18.4.7.4 Device Wake-Up Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the CTRL_MODULE_WKUP instance. The registers instantiated are:

- CONTROL_WKUP_PAD0_X_PAD1_Y registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations
- Peripheral pad voltage-level control register: CONTROL_WKUP_PADCONF_MODE

Section 18.6.1, *Control Module Instance Summary*, shows the memory size and base addresses assigned to the different control module instances.

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or a group of pads. Each configurable pad has its own configuration register for pullup and pulldown control and for assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers (CONTROL_CORE_PAD0_X_PAD1_Y) configures the pads in the CORE power domain. The second set of registers (CONTROL_WKUP_PAD0_X_PAD1_Y) configures the pads in the WKUP power domain.

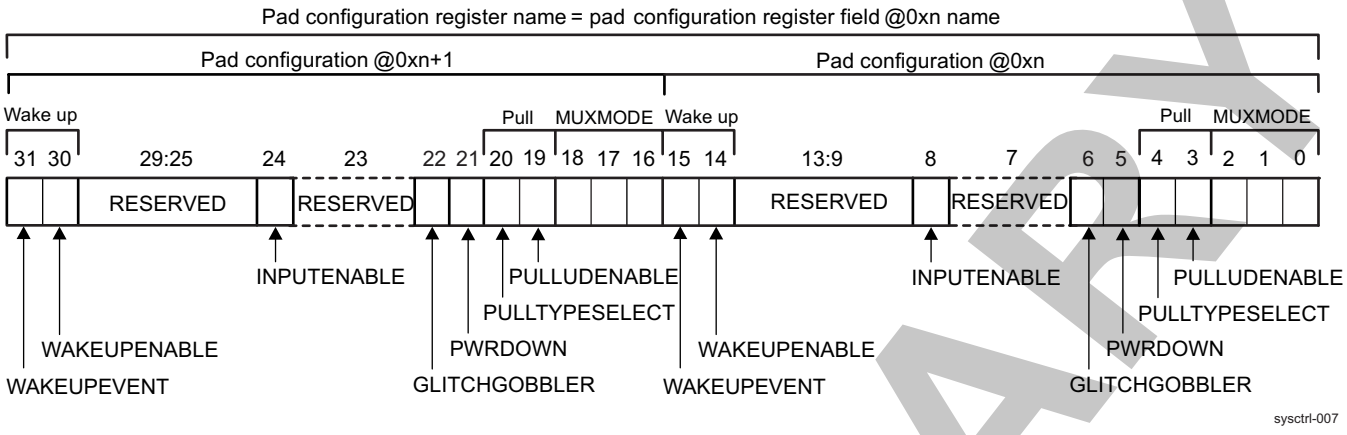
The pad configuration as defined in this module is used in the IO_CTRL logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO_CTRL logic and driven by the state and/or logic of the internal device.

The gating feature allows forcing an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state or value to be set on the pad when the logic equation is True.

The protection feature provides control on each input line of the control module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad_x.MuxMod selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16 least-significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); thus, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. Figure 18-5 shows the 16-bit-wide pad configuration register field associated with each pin.

Figure 18-5. Pad Configuration Register Functionality



NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

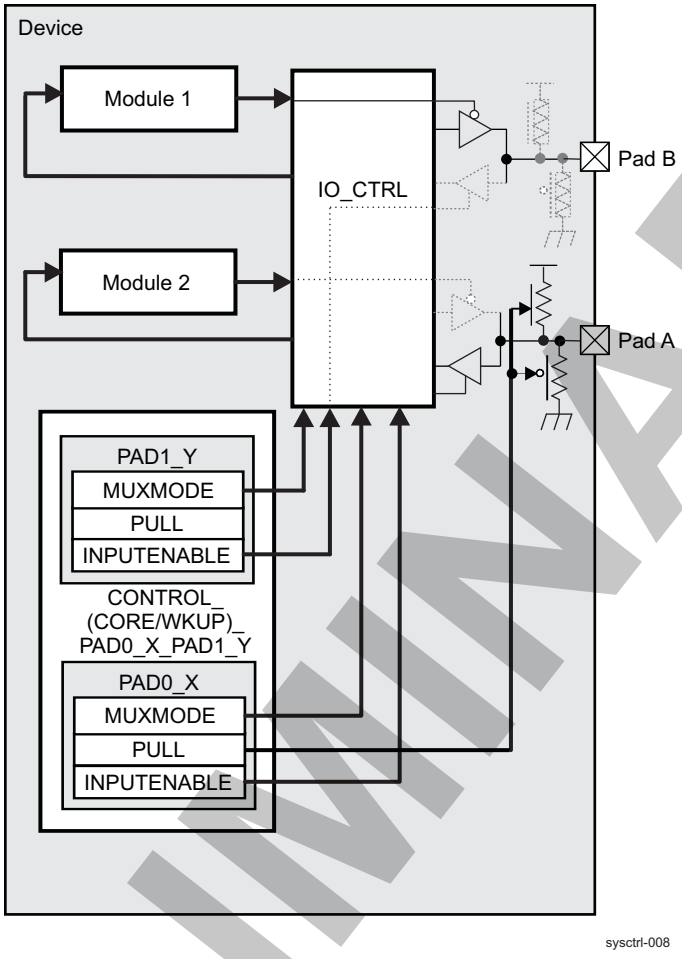
The functional bits of a pad configuration register field are divided into the following seven fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pad. A mode corresponds to the selection of the function mapped on the pad with seven (0 to 6) possible functional modes for each pad.
- PULL (2 bits) for combinational pullup and pulldown configuration:
  - PULLTYPESELECT: Pullup and pulldown type selection for the pad
  - PULLUDENABLE: Enables pullup and pulldown feature for the pad
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
  - INPUTENABLE = 0: Input disable. Pad is configured only in output mode.
  - INPUTENABLE = 1: Input enable. Pad is configured in bidirectional mode.
- Wake-up bits (2 bits):
  - WAKEUPENABLE: Enable wake-up detection on input.
  - WAKEUPEVENT: Wake-up event status for the pad
- PWRDOWN (1 bit): The Power Down setting for the corresponding pad
  - PWRDOWN = 0: The I/O cell is powered.
  - PWRDOWN = 1: The I/O cell is not powered.
- GLITCHGOBBLER (1 bit): Enables/Disables glitch filtering
  - GLITCHGOBBLER = 0: The I/O cell does not filter outside glitches.
  - GLITCHGOBBLER = 1: The I/O cell filters outside glitches.

NOTE: The GLITCHGOBBLER bit is available only in several pad configuration registers at bit positions [22] or [6].

Figure 18-6 shows the pad configuration functionality.

Figure 18-6. Pad Configuration Diagram



The I/O pads are controlled by software by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup and pulldown configuration
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration

For more information about the GPIO module, see Section 25.4.8, *General-Purpose Interface Data Input/Output Capabilities*.

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- USB_HOST_HS
- MCPDM

The output clock is driven back and used for retiming of the modules.

NOTE: For a correct configuration of each pad direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and GPIOi.GPIO_OE registers must be written.

Table 18-5 lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-5. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

Pad Configuration Bit	Bit Meaning	
	0	1
PULLUDENABLE	Not activated	Activated
PULLTYPESELECT	Pulldown	Pullup
INPUTENABLE	Input enable signal is inactive.	Input enable signal is active.
WAKEUPENABLE	Disable I/O wake-up function.	Enable I/O wake-up function.
WAKEUPEVENT	Wake-up event is not detected.	Wake-up event is detected.
MUXMODE bits	See Table 18-6	See Table 18-6
PWRDOWN	The I/O cell is powered.	The I/O cell is not powered.
GLITCHGOBBLER	Glitch filter disable	Glitch filter enable

18.4.8.1 Mode Selection

Table 18-6 lists the multiplexing modes and settings.

Table 18-6. Mode Selection

MUXMODE	Selected Mode
0b000	Primary mode = Mode 0
0b001	Mode 1
0b010	Mode 2
0b011	Mode 3
0b100	Mode 4
0b101	Mode 5
0b110	Mode 6
0b111	Safe mode = Mode 7

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pad corresponds to the name of the pad.

Modes 1–6 are possible modes for alternate functions. On each pad, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

Safe mode (mode 7) avoids any risk of electrical contention by configuring the pad as an input with no functional interface mapped to it. Safe mode is used mainly as the default mode for all pads containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pad multiplexing, the pad is actually set undriven (Hi-Z) with potential pullup or pulldown.

For more information about the configurable mode on each pad, see Table 18-8 and Table 18-9.

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown or pullup resistors on a pad are disconnected whenever pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-7 describes the software controls available for pad internal pullup and pulldown resistors in the control module padconfiguration registers.

Table 18-7. Pull Selection

PULL		Pin Behavior
PULLTYPESELECT	PULLUDENABLE	
0b0	0b0	Pulldown selected but not activated
0b0	0b1	Pulldown selected and activated
0b1	0b0	Pullup selected but not activated
0b1	0b1	Pullup selected and activated

For more information about the pull available on each pad, see Table 18-8 and Table 18-9.

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the CONTROL_LPDDR2CH1_0 and CONTROL_LPDDR2CH1_1 registers, respectively.

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x, usbb2_hsic_x, and usbb3_hsic_x pads are available in the CONTROL_SMART3IO_PADCONF_1 register.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-8 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default pad configuration settings (POR values) for pads in the CORE power domain, see Section 18.6.3, *CTRL_MODULE_CORE_PAD Registers.* For pads in the WKUP power domain, see Section 18.6.5, *CTRL_MODULE_WKUP_PAD Registers*.

NOTE:

- Table 18-8 lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. Table 18-9 lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
- In Table 18-8 and Table 18-9, an empty cell indicates that the mode or pull is not available for this pad.

Table 18-8. Device Wake-Up Control Module Pad Configuration Register Fields

CTRL_MODULE_WKUP_PAD [Register name]	Address Offset	Mode 0[1]	Mode 1	Mode 2	Mode 3	Mode 4	Mode 5	Mode 6	Mode 7

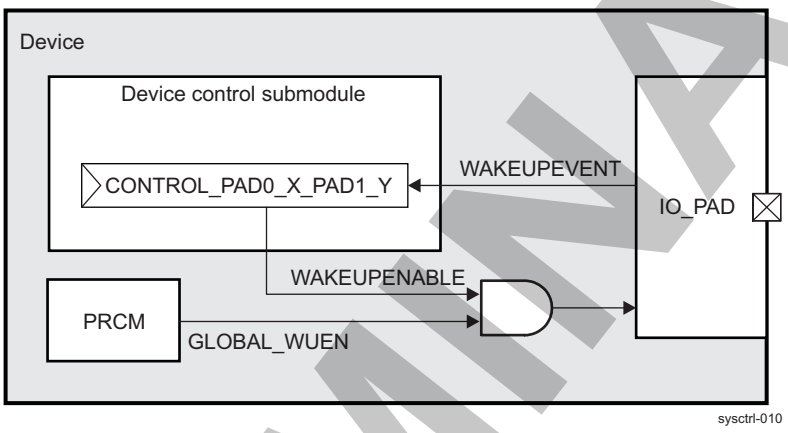
18.4.8.4 Wake-Up Event Detection

In low power mode, wake-up event detection can also be enabled on an input pad. The pad wake-up event is latched in the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] WAKEUPEVENT bits.

The wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from the PRCM module. The status of the wake-up scheme is transmitted by the WKUP_ENABLE signal. The capability of each I/O pad to detect wake-up events in the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-7 is an overview of wake-up event detection in the device.

Figure 18-7. Wake-Up Event Detection Overview



NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver.

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup and pulldown resistors at the pad to avoid spurious wake-up detection.

The CONTROL_PADCONF_WAKEUPEVENT_0 through CONTROL_PADCONF_WAKEUPEVENT_6 registers are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these additional registers helps to reduce the software latency when identifying which pad has triggered a wake-up event.

For unconnected device pads, safe_mode pad configuration is recommended if available. Table 18-10 summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where safe_mode configuration is not available.

Table 18-10. Recommended Configuration For Unconnected Device Pads

Pad MuxMode Set Features	Power-on reset default configuration		Recommended Unconnected Device Pad Configuration				
Safe Mode Available?	Multiplexed Signal Direction at Pad	Pad State[1]	Multiplexed Signal Direction at Pad	Pad State	Input Buffer Disabled? [2]	Output Buffer Disabled? [3]	MUX Function Selected [4]
Yes	Input	PU	Safe mode	PU	Yes	N/A	Safe mode
Yes	Input	PD	Safe mode	PD	Yes	N/A	Safe mode
Yes	Output	1	Safe mode	PD	Yes	N/A	Safe mode
Yes	Output	0	Safe mode	PD	Yes	N/A	Safe mode
Yes	–	Hi-Z	Safe mode	PD	Yes	N/A	Safe mode
No	Input	PU	Input	PU	Yes	N/A	N/A (default)
No	Input	PD	Input	PD	Yes	N/A	N/A (default)
No	Output	1	Output	1	Yes	N/A	N/A (default)
No	Output	0	Output	0	Yes	N/A	N/A (default)
No	–	Hi-Z	Input	PD	Yes	N/A	N/A (default)

(1) PU = Pullup; PD = Pulldown; Hi-Z = High impedance

(2) Yes: If a certain device pad is left unconnected, its associated pad configuration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

(3) N/A: There is no software control over the pad associated output buffer in the control module.

(4) SAFE MODE: If a certain pad has a defined safe_mode and is left unconnected in an application, it is recommended to keep its padconfiguration MUXMODE value at 0x7 (that is, safe_mode).
N/A (default): The pad does not have a defined safe_mode. Keeping the default value is recommended.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device primarily supports 1.8-V I/O voltage on its interfaces, with the exception of the MMC/SD/SDIO1 interface, which supports 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on the MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell SDCARD_PBIAS to provide a 1.8-V or 3.0-V reference.

The SDCARD_PBIAS cell and its associated extended-drain I/O cell are software-controlled by bits in the CONTROL_PBIAS and CONTROL_HYST_1 registers of the device core control module.

Figure 18-8 shows the functional block diagram with the connections between the PBIAS cell and the extended-drain I/O cell.

Figure 18-8. Functional Block Diagram

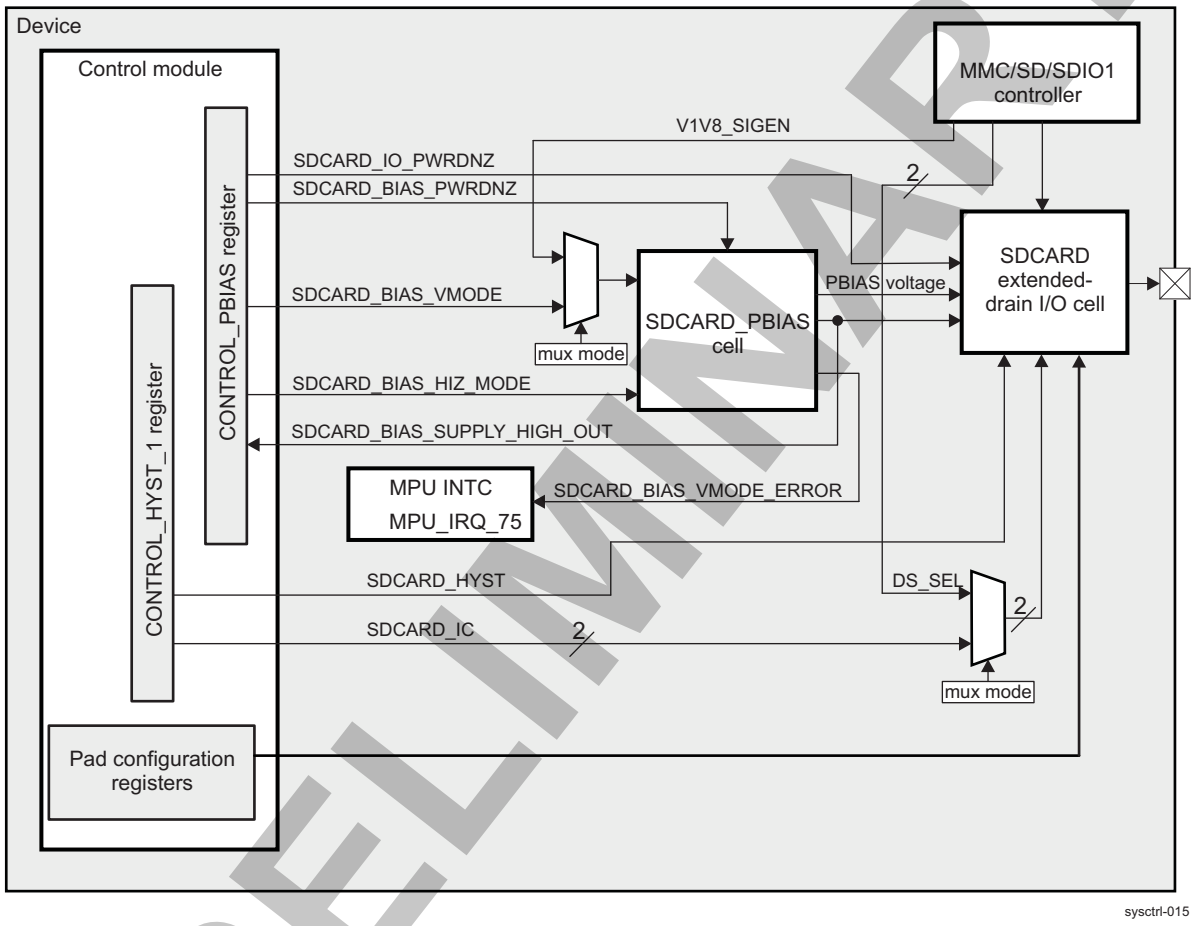


Table 18-11 describes PBIAS cell and extended-drain I/O cell control signals.

Table 18-11. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS Bit Control

Control Signals for PBIAS Cell and Extended-Drain I/O Cell	Description
SDCARD_BIAS_PWRDNZ	Protects the SDCARD_PBIAS cell when the SDCARD_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is set to 0, the PBIAS output voltage is equal to the SDCARD_VDDS voltage and the PBIAS supply detector is disabled.
SDCARD_IO_PWRDNZ	Protects the SDCARD extended-drain I/O cell when the SDCARD_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDCARD_VDDS supply voltage ramps up/down or changes. When this bit is set to 0, the pad is floating.
SDCARD_BIAS_VMODE	Controls the SDCARD_VDDS voltage level. The default state of this bit is HIGH, indicating that the voltage level SDCARD_VDDS is 3.0 V.
SDCARD_BIAS_HIZ_MODE	When SDCARD_BIAS_HIZ_MODE is set to 1, the PBIAS output is in high impedance. SDCARD_BIAS_ERROR is automatically set to 1 when SDCARD_BIAS_HIZ_MODE is set to 1. When SDCARD_BIAS_HIZ_MODE is set to 0, SDCARD_PBIAS cell is in normal operation mode.
SDCARD_BIAS_SUPPLY_HI_OUT	Output from the internal SDCARD_PBIAS voltage supply detector, which indicates whether the SDCARD_VDDS supply is 3.0 V or 1.8 V
SDCARD_BIAS_VMODE_ERROR	Indicates whether the software-programmed voltage level of the SDCARD_PBIAS cell matches the SDCARD_BIAS_SUPPLY_HI_OUT output signal during normal operation
SDCARD_HYST	Hysteresis enabling/disabling for the extended-drain I/O cell input buffer.
SDCARD_IC	Impedance control for the extended-drain I/O cell output buffer.
V1V8_SIGEN	Controls the SDCARD_VDDS voltage level. The default state of this bit is LOW, indicating that the voltage level SDCARD_VDDS is 3.0 V.
DS_SEL	Drive strength (impedance) control for extended-drain I/O cell output buffer

NOTE: When MUXMODE is set to 0 (sdcard_i signals are selected), then the CONTROL_PBIAS[21] SDCARD_BIAS_VMODE and CONTROL_HYST_1[30:29] SDCARD_IC bits do not apply. In this case the voltage level and drive strength are controlled through the MMC1.MMCHS_AC12[19] V1V8_SIGEN and MMC1.MMCHS_AC12[21:20] DS_SEL bits, respectively.

Table 18-12 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-12. Power Supplies

Power Supply Name	Description
VDD2	Core voltage supply
SDCARD_VDDS	SDCARD I/O cell supply voltage nominal 1.8 V/3.0 V
VDDS	1.8-V supply for the input buffer

18.4.9.1 PBIAS Cell

The SDCARD_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended drain in the MMC/SD/SDIO1 cell. In addition to generate the bias voltage, the cell can detect the supply voltage (SDCARD_VDDS) value (1.8 V or 3.0 V) and update, with its status, the CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT bit. However, this is possible when the voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the SDCARD_BIAS_PWRDNZ signal is set to 0b1).

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not part of a peripheral, but part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os.

18.4.9.2 Extended-Drain I/O

The following MMC1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the SDCARD extended-drain I/O cell:

- sdcard_clk
- sdcard_cmd
- sdcard_datai (where i = 0 to 3)

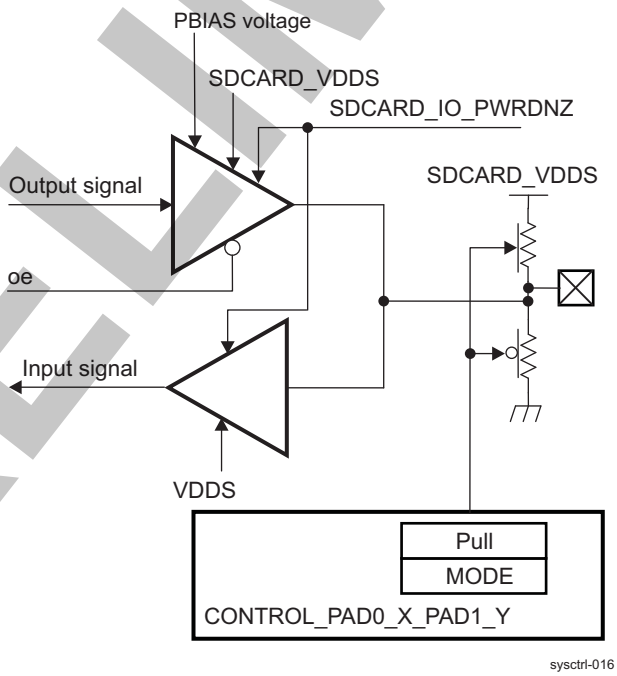
The SDCARD I/O cell is powered externally through the vdds_sdcard pad.

NOTE: The device pads associated with SDCARD I/O cells are also shared with other signals. jtag_tdo, jtag_tdi, uart6_rx, and so forth. are available when MuxMode is different than 0x0. If signals other than sdcard_x are selected, the SDCARD I/O cell must also be configured.

For more information about signal multiplexing, see Table 18-9.

Figure 18-9 shows the extended-drain I/O cells.

Figure 18-9. Extended-Drain I/O



The extended-drain I/O cells have the following I/O signals:

- The output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup and pulldown configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the SDCARD cell.
- The SDCARD_IO_PWRDNZ signal is used to protect the extended-drain I/O cell when the SDCARD_VDDS voltage is not stable.

NOTE: Software must keep the SDCARD_IO_PWRDNZ signal set to 0b0 whenever the SDCARD_VDDS signal ramps up/down or changes. When SDCARD_IO_PWRDNZ is set to 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT is a status bit for the SDCARD_VDDS value and is used to inform the SDCARD I/O cell about the value of the SDCARD_VDDS signal.

For more information about the software configurations of the extended drain I/Os and PBIAS cells, see Section 18.5.1.2.1, *Extended-Drain I/Os and PBIAS Cells Programming Guide.*

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable SDCARD_VDDS (for the MMC/SD/SDIO1 or muxed I/O modules) and the LDO to provide 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I^2C™) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage, generated from the companion power IC and applied on the vdds_sdcard device pad, must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, for 1.8-V activity software must either assert the SDCARD_BIAS_VMODE signal to low or the V1V8_SIGEN signal to high depending on the selected muxmode: in this case, the PBIAS is connected to ground.

Table 18-13 lists the control signals with the corresponding control bits from the CONTROL_PBIAS, CONTROL_HYST_1, and MMC1.MMCHS_AC12 registers to configure the PBIAS and the extended-drain I/O cells. Software can control these signals.

Table 18-13. PBIAS and Extended-Drain I/O Cells Control Signals

Control Signals for PBIAS Cell and Extended-Drain I/O Cell	Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules	Reset Value
SDCARD_BIAS_PWRDNZ	CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ	0
SDCARD_IO_PWRDNZ	CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ	0
SDCARD_BIAS_VMODE	CONTROL_PBIAS[21] SDCARD_BIAS_VMODE	1
SDCARD_BIAS_HIZ_MODE	CONTROL_PBIAS[25] SDCARD_BIAS_HIZ_MODE	0
SDCARD_BIAS_SUPPLY_HI_OUT	CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT	0
SDCARD_BIAS_VMODE_ERROR	CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR	0
SDCARD_HYST	CONTROL_HYST_1[31] SDCARD_HYST	1
SDCARD_IC	CONTROL_HYST_1[30:29] SDCARD_IC	0x0
DS_SEL	MMC1. MMCHS_AC12[21:20] DS_SEL	0x0
V1V8_SIGEN	MMC1. MMCHS_AC12[19] V1V8_SIGEN	0

The PBIAS cell supports two ranges of SDCARD_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the PBIAS cell generates suitable bias voltage (PBIAS) for the extended-drain I/O cell.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See Table 18-14.

Table 18-14. Voltage Configuration(1)

PBIASVMODE Configuration	SDCARD_VDDS Voltage	Type of Operation
1.8 V	1.8 V	Normal 1.8-V operation
1.8 V	3.0 V	Damaging configuration(2)
3.0 V	1.8 V	Degraded functionality(2)
3.0 V	3.0 V	Normal 3.0-V operation

(1) For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

(2) These modes must not be used.

Once the SDCARD_VDDS supply is stable, software can release SDCARD_BIAS_PWRNDZ and SDCARD_IO_PWRDNZ bits setting them high. Setting SDCARD_BIAS_PWRNDZ to 0b1 powers-up the PBIAS cell and it starts to generate the bias voltage. During the completion process the corresponding I/Os cannot be used to transmit data. If the voltage level is set correctly (compared with supply detector output and found to be the same), then bias voltage is generated based on this value.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The SDCARD_BIAS_VMODE or V1V8_SIGEN bit must be defined before the SDCARD_IO_PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of SDCARD_BIAS_VMODE bit is high (indicates 3.0-V operation).
- The default state of the MMC1.MMCHS_AC12[19] V1V8_SIGEN bit is low (indicates 3.0-V operation).
- The SDCARD_IO_PWRNDZ bit must be kept low whenever the SDCARD_VDDS supply ramps up/down or changes. This can be damaging.

18.4.9.3 PBIAS Error Generation

If the programmed PBIAS voltage and supply detector output are unequal, it takes 4 µs for the comparator to process the inputs and generate the SDCARD_BIAS_VMODE_ERROR flag.

Table 18-15 summarizes the generation of the PBIAS error signal (SDCARD_BIAS_VMODE_ERROR of the SDCARD_PBIAS cell), which depends on the various CONTROL_PBIAS bit combinations. The shaded row in the table indicates a condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDCARD_VDDS when the PBIAS error signal is high. This condition disables the I/Os.

NOTE: Although asserting SDCARD_BIAS_VMODE_ERROR to 1 ensures that PBIAS voltage is equal to SDCARD_VDDS, this does not completely protect the I/O cells. It is recommended that all the I/Os are powered down, thus setting the CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ bit to 0b0 by software as soon as CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR = 0b1.

Table 18-15. PBIAS Error Signal Truth Table

Programmed voltage level		PWRDNZ Bits	SDCARD_BIAS_HIZ_MODE	SDCARD_BIAS_SUPPLY_HI_OUT	SDCARD_BIAS_VMODE_ERROR
SDCARD_BIAS_VMODE (MUXMODE ≠ 0)	V1V8_SIGEN (MUXMODE = 0)				
0	1	0	X	0	0
0	1	1	0	0	0
0	1	1	0	1	1
X	X	1	1	X	1
1	0	0	X	0	0
1	0	1	0	0	1
1	0	1	0	1	0

NOTE: SDCARD_BIAS_VMODE_ERROR = 0b1: The programmed voltage level is not the same as SDCARD_BIAS_SUPPLY_HI_OUT, or Hi-Z mode is selected.

SDCARD_BIAS_VMODE_ERROR = 0b0: The programmed voltage level is the same as SDCARD_BIAS_SUPPLY_HI_OUT, or it is not considered (SDCARD_PWRDNZ = 0b0).

The SDCARD_BIAS_VMODE_ERROR signal output is mapped to the MPU subsystem INTC. The interrupt line MPU_IRQ_75 is activated when an error occurs. For more information about the MPU INTC registers and their description, see the *ARM Cortex-A15 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

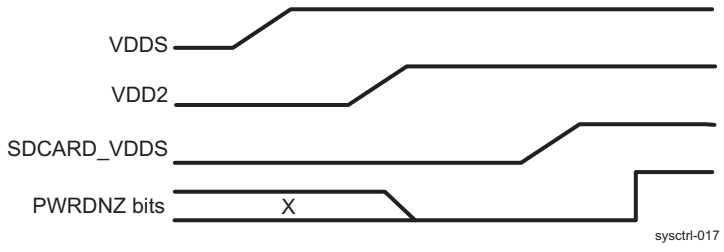
The CONTROL_PBIAS[23] SDCARD_BIAS_VMODE_ERROR bit also indicates whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is critical that SDCARD_BIAS_PWRDNZ and SDCARD_IO_PWRDNZ bits are deasserted (changed from 0 to 1) only after SDCARD_VDDS power supply voltage is stable in the device. The cells support only the case where the 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon POR by hardware in the device. Take care to ensure that the externally provided SDCARD_VDDS voltage (1.8 V/ 3 V) is powered up only after VDD2 and VDDS reach their steady state.

Figure 18-10 shows the only possible power-up sequence, as well as the expected behavior of PWRNDZ mode-related bit with regard to supplying voltage ramp up.

Figure 18-10. VDDS Ramps Up Before VDD2



18.4.10 Bandgap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the bandgap voltage and temperature sensor (VBGAPTS) module. The bandgap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature. There are three bandgaps: one for MPU, one for GPU and one for device die center.

The main features of the VBGAPTS modules are:

- A constant voltage reference output
- Five constant current reference outputs
- Nominal analog supply
- Small ADC with 10-bit digital output

Three small finite state-machines (FSMs) (bandgap FSMs) are instantiated inside the general core control module to help the three VBGAPTS cells accomplish different measurement modes (see Section 18.4.10.2, *Temperature Sensor*). In addition, three sets of two programmable comparator blocks inside the general core control module post-process the converted data and provide the following outputs:

- Thermal alert programmable comparator outputs
- Thermal shutdown nonprogrammable comparator outputs

Figure 18-11 shows the functional block diagram of the bandgap and the temperature sensor module.

Figure 18-11. Functional Block Diagram

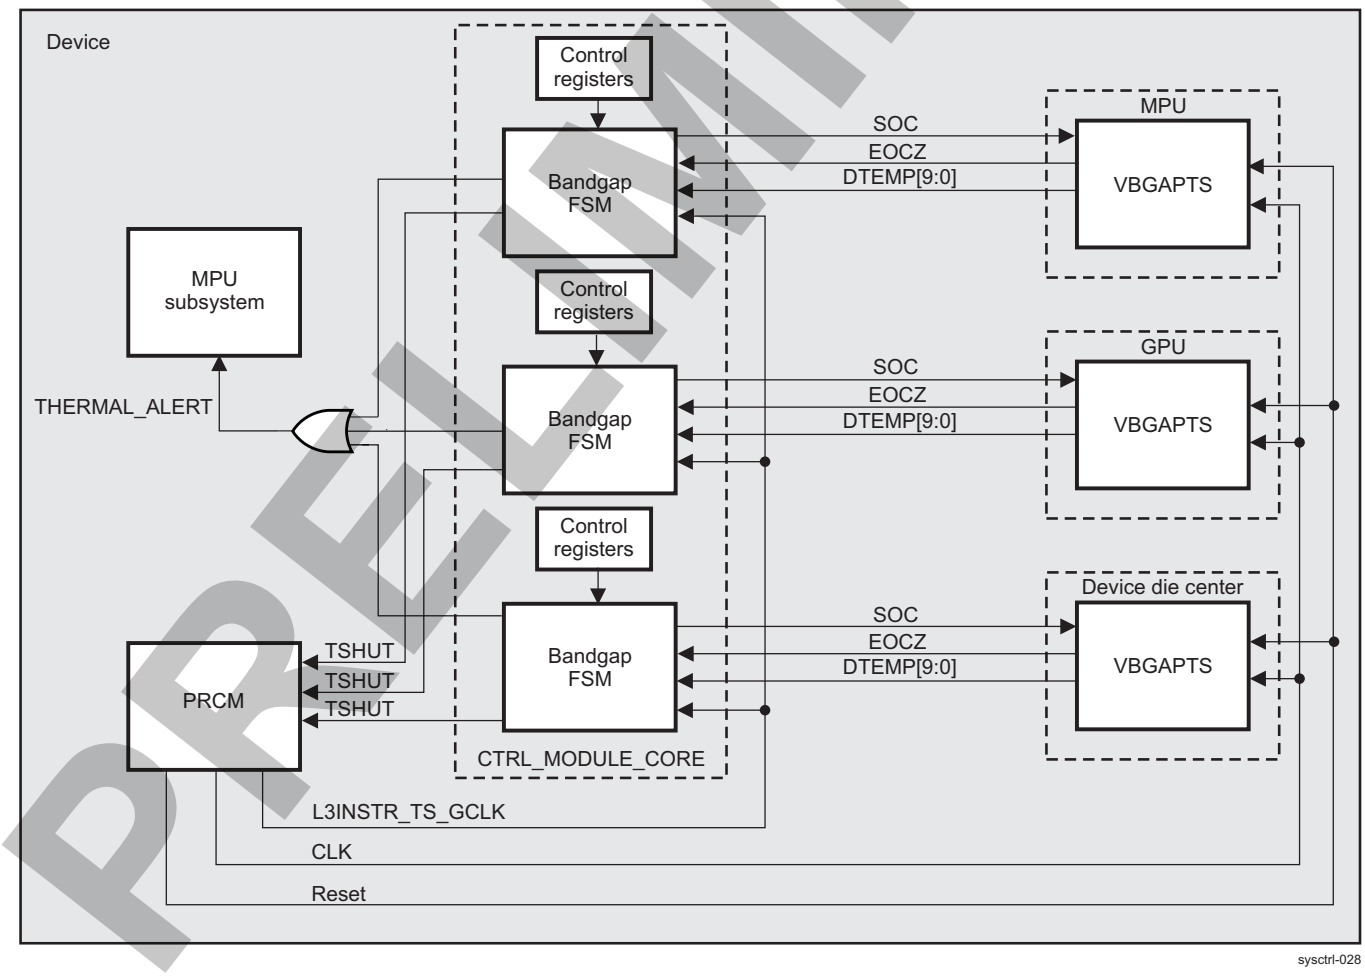


Table 18-16 describes the I/O signals, some of which (SOC, EOCZ, DTEMP[9:0]) build the interface between the VBGAPTS modules and the bandgap state-machines of the general core control module.

Table 18-16. Bandgap Voltage and Temperature Sensor Signal Description

Pin	I/O[1]	Description
SOC	I	Start of Conversion signal. A transition to high starts a new ADC conversion cycle. This signal is automatically generated by the bandgap FSM.
EOCZ	O	End of Conversion signal. When low, the signal indicates that the value of DTEMP[9:0] is valid.
DTEMP[9:0]	O	Temperature data from the temperature sensor. This value is valid when EOCZ is low.
CLK	I	Functional clock in the range (500 kHz - 5 MHz) from the WKUP power domain used by the temperature sensor during temperature conversion

(1) I = Input; O = Output; I/O = Bidirectional

All the configuration signals of the VBGAPTS temperature conversion logic are available through the CONTROL_TEMP_SENSOR_MPU, CONTROL_TEMP_SENSOR_MM, and CONTROL_TEMP_SENSOR_CORE registers.

NOTE: For more information about all of the configuration registers related to temperature sensor control, see Table 18-63.

The bandgap state-machines of the general core control module are driven by a dedicated clock (L3INSTR_TS_GCLK) that shares a common PRCM clock source with the VBGAPTS CLK. For more information about the thermal management clocks, see Section 3.1.1, *Device Power-Management Architecture Building Blocks*.

Table 18-17 describes the functional outputs of the two post-processing comparator blocks integrated in the general core control module.

Table 18-17. General Core Control Thermal Logic Outputs Description

Functional Output	Description
THERMAL_ALERT	The three thermal alert outputs from each bandgap FSM are ORed and then mapped as an interrupt in the MPU subsystem. Software uses this interrupt to implement a thermal management policy of the device.
TSHUT	Each of the three general core control module thermal shutdown comparator outputs is mapped as a source of PRCM warm reset signals. These overheat protection signals are high during normal operation and go low during a thermal shutdown event.

The configuration bits of the thermal post-processing logic are in several registers of the general core control module. For more information, see Section 18.4.10.2.2, *Thermal Data Post-Processing Logic*.

18.4.10.1 Bandgap Voltage Reference

The bandgap voltage reference feature provides several constant voltage and current references for its internal circuits and for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or tests.

The current reference signals consist of five lines, each of which generates a 1-µA current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 10 bits. An internal ADC, which is part of the device embedded bandgap cell, is used for conversion.

For more information on the thermal sensor operating parameters–temperature range, accuracy, and so on, see the *Temperature Sensor* section of the device data manual.

For more details on the device operating junction temperature ranges under different conditions, see the *Recommended Operating Conditions* section of the device data manual.

NOTE: The temperature measured at the three temperature sensor locations is lower than the temperature of the hottest spot on the device die. This difference, defined also as the temperature offset between the on-die hottest spot temperature and the temperature registered by the on-die thermal sensors, depends on a number of factors, such as the current system power dissipation, device cooling conditions, etc. For more information regarding the temperature sensor offset values under different conditions, contact your TI representative.

CAUTION

User software must always take care to program thermal alert thresholds at levels which do not exceed the device hottest spot maximum-allowed temperature minus the device temperature sensor offset estimated at current conditions.

The TSHUT signals are connected internally to PRCM pins. The three bandgap state-machines operate in continuous conversion mode.

18.4.10.2.1 Continuous Conversion Mode

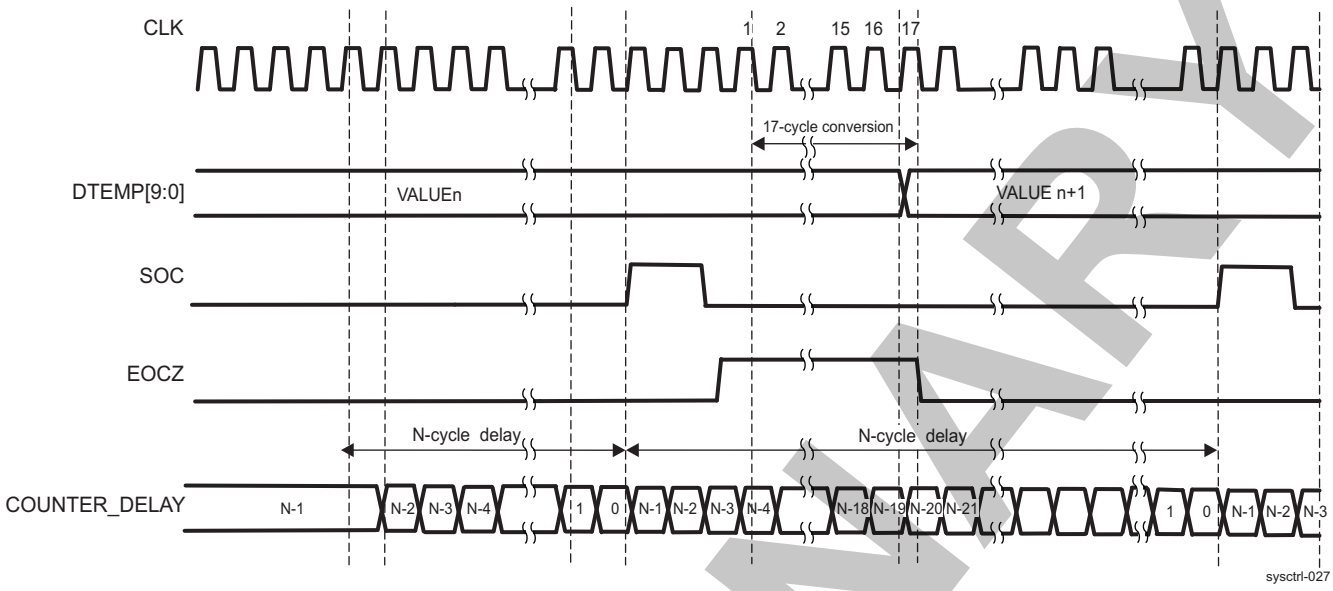
The continuous conversion mode follows this sequence:

After reset, each FSM produces a programmable delay which is also used as a main delay between two temperature measurements. After this delay the three FSMs automatically generate SOC pulses which start a temperature conversion. Software can control the main delay between two measurements through the dedicated bit field CONTROL_BANDGAP_MASK[29:28] COUNTER_DELAY. The conversion is complete when the CONTROL_TEMP_SENSOR_MPU[10] BGAP_EOCZ_MPU, CONTROL_TEMP_SENSOR_MM[10] BGAP_EOCZ_MM, and CONTROL_TEMP_SENSOR_CORE[10] BGAP_EOCZ_CORE status bits are set to 0b0. After this stage the valid temperature is written automatically by each FSM in the CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU, CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM, and CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE bit fields, and then software is able to read the valid temperature value from each register. After writing the valid temperature values the three FSMs wait one clock cycle and start another conversion cycle.

NOTE: The main delay between two measurements is controlled by the CONTROL_BANDGAP_MASK[29:28] COUNTER_DELAY bit field. After this delay there is an additional 5µs delay before a new temperature conversion starts. This is managed automatically by each FSM.

Figure 18-12 shows the timing sequence for a programmable-delay continuous conversion mode. The continuous temperature measurement is performed as a sequence of single ADC conversions automatically initiated at regular time intervals. As show in Figure 18-12, the duration of a single temperature conversion is 17 bandgap clock cycles regardless of the CLK frequency.

Figure 18-12. Programmable-Delay Continuous Conversion Mode



18.4.10.2.2 Thermal Data Post-Processing Logic

A thermal data post-processing logic with dedicated registers is implemented in the general core control module. The registered ADC value from each of the three temperature sensors is passed in parallel to the inputs of four comparators (two blocks of two comparators). In each block, the temperature data is compared to high- and low-temperature thresholds, to handle the hysteresis effect when temperature decreases. Three sets of two comparator blocks provide different thermal management functions.

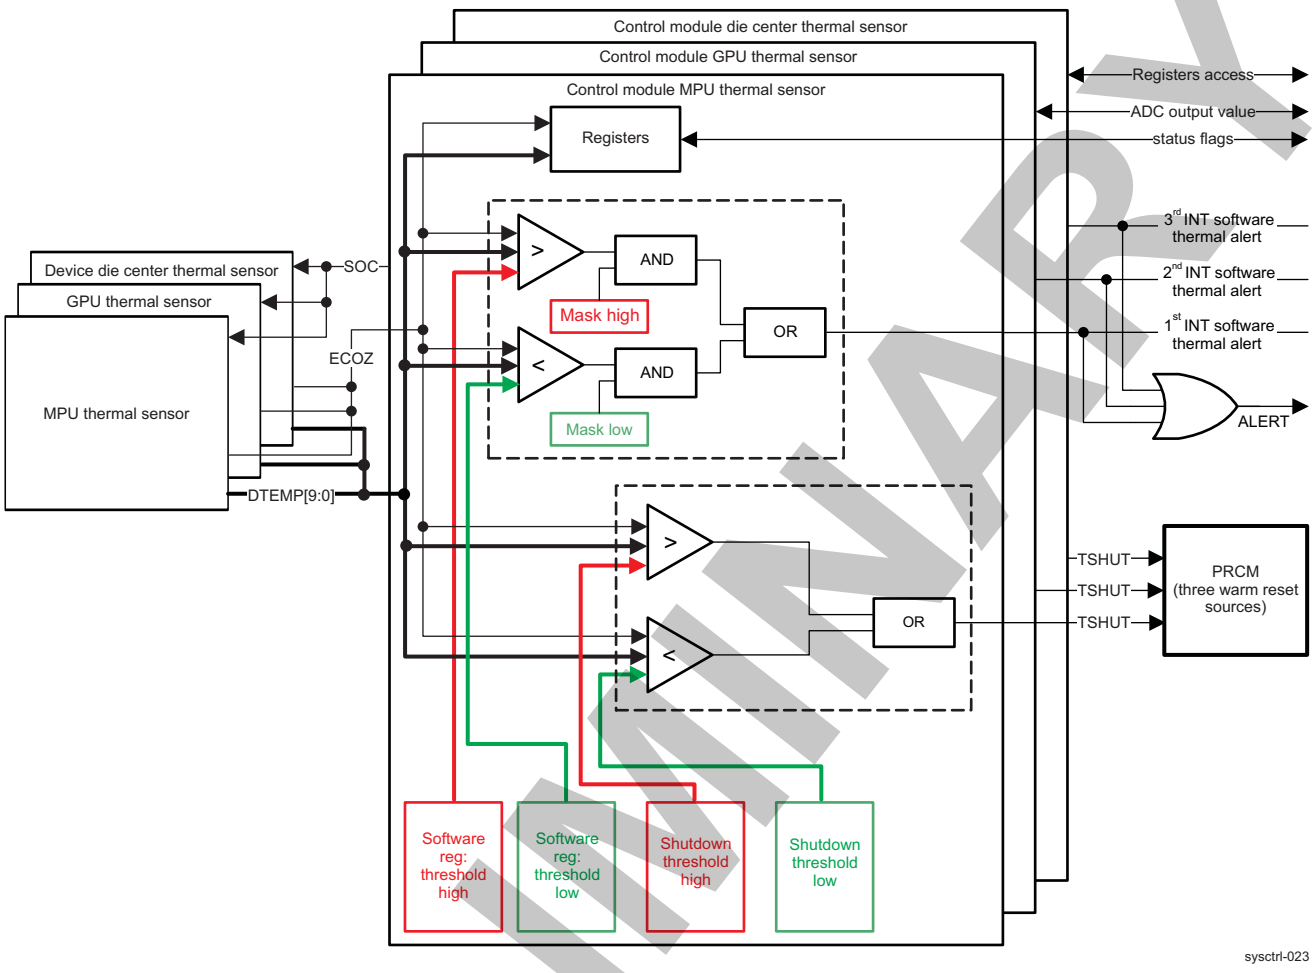
Figure 18-13 shows the thermal management schema in the device.

There are three register sets

- CONTROL_TEMP_SENSOR_MPU, CONTROL_BANDGAP_TSHUT_MPU, CONTROL_BANDGAP_THRESHOLD_MPU, CONTROL_BANDGAP_CUMUL_DTEMP_MPU, and CONTROL_DTEMP_MPU_x (where x = 0 to 4) for the MPU thermal sensor
- CONTROL_TEMP_SENSOR_MM, CONTROL_BANDGAP_TSHUT_MM, CONTROL_BANDGAP_THRESHOLD_MM, CONTROL_BANDGAP_CUMUL_DTEMP_MM, and CONTROL_DTEMP_MM_x (where x = 0 to 4) for the GPU thermal sensor
- CONTROL_TEMP_SENSOR_CORE, CONTROL_BANDGAP_TSHUT_CORE, CONTROL_BANDGAP_THRESHOLD_CORE, CONTROL_BANDGAP_CUMUL_DTEMP_CORE, and CONTROL_DTEMP_CORE_x (where x = 0 to 4) for the device die center thermal sensor.

For more information, see Table 18-63 *Temperature Sensor Registers*.

Figure 18-13. Thermal Management Schema



18.4.10.2.3 Thermal Alert Functionality Comparators

There are three sets (for MPU, for GPU, and for the device die center) of two comparator blocks inside the general core control module. The first three comparator blocks are programmable and provide a thermal alert function output. The high-temperature threshold for this function is configurable through the follwoing 10-bit fields:

- CONTROL_BANDGAP_THRESHOLD_MPU[25:16] THOLD_HOT_MPU for the MPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_MM[25:16] THOLD_HOT_MM for the GPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_CORE[25:16] THOLD_HOT_CORE for the device die center temperature sensor

The low-temperature threshold for this function is configurable through the following 10-bit fields:

- CONTROL_BANDGAP_THRESHOLD_MPU[9:0] THOLD_COLD_MPU for the MPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_MM[9:0] THOLD_COLD_MM for the GPU temperature sensor
- CONTROL_BANDGAP_THRESHOLD_CORE[9:0] THOLD_COLD_CORE for the device die center temperature sensor

Thermal alert logic in the general core control module provides the capability to mask (active low) comparator outputs for hot events through the CONTROL_BANDGAP_MASK[1] MASK_HOT_MPU, CONTROL_BANDGAP_MASK[3] MASK_HOT_MM and CONTROL_BANDGAP_MASK[5] MASK_HOT_CORE bits, and for cold events through the CONTROL_BANDGAP_MASK[0] MASK_COLD_MPU, CONTROL_BANDGAP_MASK[2] MASK_COLD_MM, and CONTROL_BANDGAP_MASK[4] MASK_COLD_CORE bits. The masked HOT and COLD point-monitoring signals from each of the three comparator blocks are ORed in three thermal alert signals (first, second, third INT software thermal alert) (for details, see Figure 18-13). These three signals are then ORed in the THERMAL_ALERT signal, which delivers an interrupt to the MPU subsystem on the MPU_IRQ_126 input (see Section 18.3, *Control Module Integration*). Software can use this interrupt to implement the thermal management policy of the device. For more information about this interrupt, see Section 17.3.2, *Interrupt Requests to INTC_MPU*, in Chapter 17, *Interrupt Controllers*.

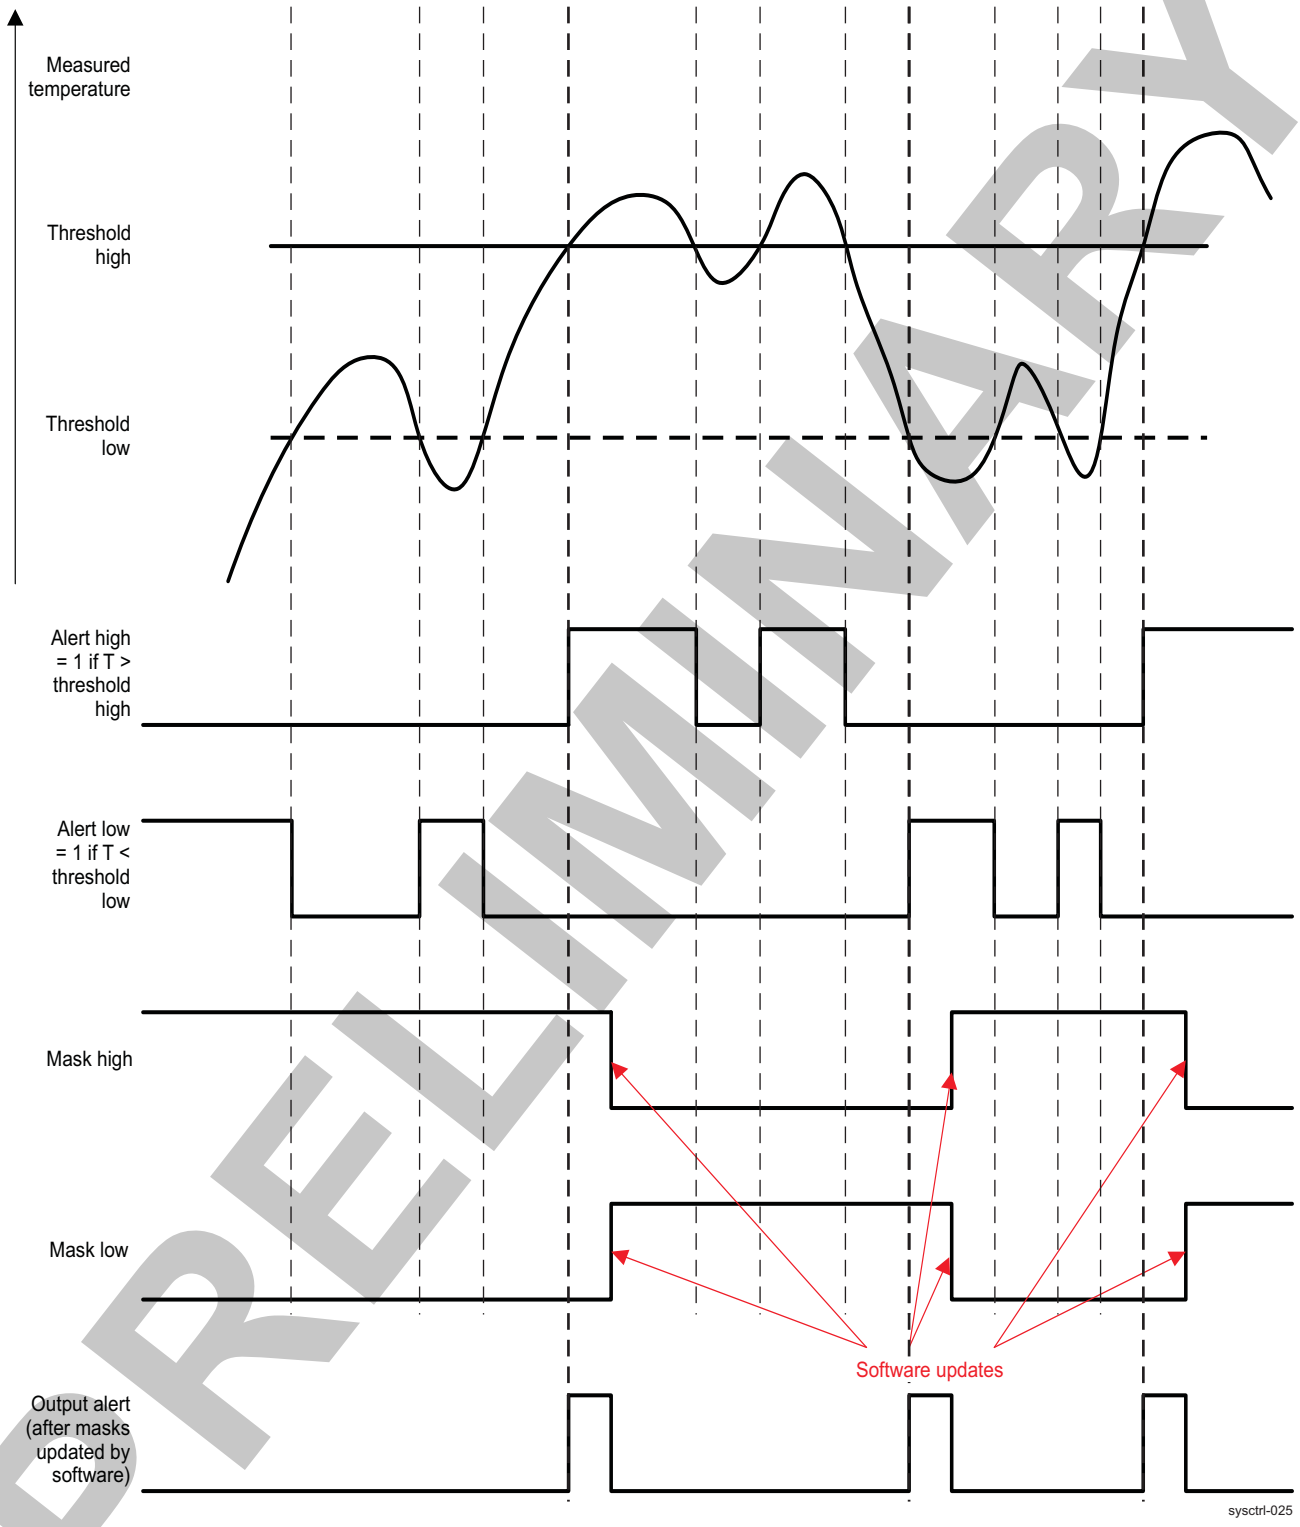
The nonmasked outputs of the thermal alert logic comparators are individually registered in the following read-only (RO) bits:

- CONTROL_BANDGAP_STATUS[1] HOT_MPU
- CONTROL_BANDGAP_STATUS[3] HOT_MM
- CONTROL_BANDGAP_STATUS[5] HOT_CORE
- CONTROL_BANDGAP_STATUS[0] COLD_MPU
- CONTROL_BANDGAP_STATUS[2] COLD_MM
- CONTROL_BANDGAP_STATUS[4] COLD_CORE

The THERMAL_ALERT signal is mapped to the CONTROL_BANDGAP_STATUS[31] ALERT RO bit.

Figure 18-14 shows the behavior of the thermal alert logic.

Figure 18-14. Thermal Alert Generation Signals



18.4.10.2.4 Thermal Shutdown Functionality Comparators

There are three sets (for MPU, for GPU, and for the device die center) of two comparator blocks inside the general core control module. The second set of three comparator blocks cannot be programmed and are responsible for the thermal shutdown protection of the device. The values of the three high and low TSHUT thresholds are set by default and connot be overriden by software.

High thresholds can be read through the following bit fields:

- CONTROL_BANDGAP_TSHUT_MPU[25:16] TSHUT_HOT_MPU
- CONTROL_BANDGAP_TSHUT_MM[25:16] TSHUT_HOT_MM
- CONTROL_BANDGAP_TSHUT_CORE[25:16] TSHUT_HOT_CORE

Low thresholds can be read through the following bit fields:

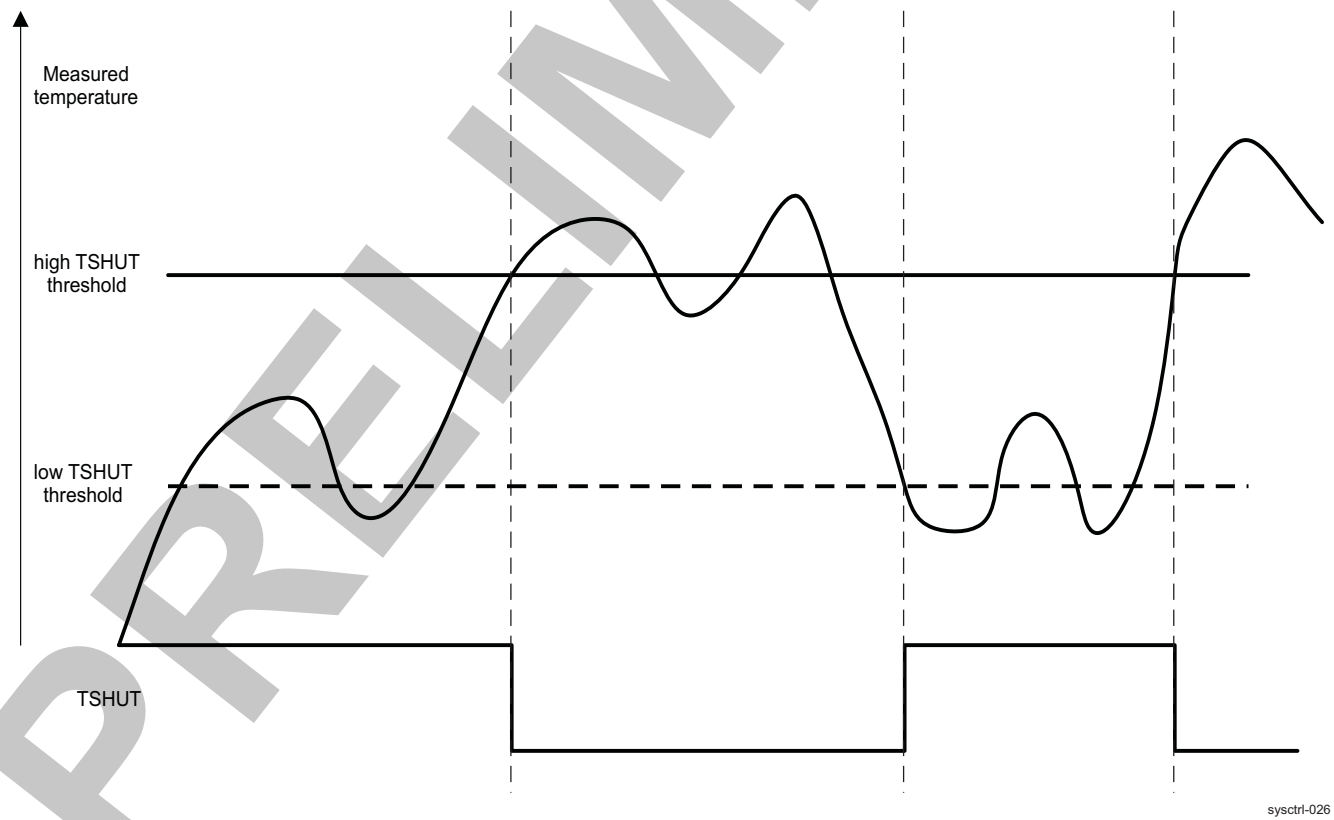
- CONTROL_BANDGAP_TSHUT_MPU[9:0] TSHUT_COLD_MPU
- CONTROL_BANDGAP_TSHUT_MM[9:0] TSHUT_COLD_MM
- CONTROL_BANDGAP_TSHUT_CORE[9:0] TSHUT_COLD_CORE

When the maximum allowed MPU, GPU, or device die center temperature is reached, one of the three TSHUT outputs is activated, respectively (see Figure 18-13). Each of these TSHUT outputs is tied internally to the PRCM module, and is used as a warm reset signal. It flags that the maximum MPU, GPU, or device die center junction temperature is reached.

To deactivate each TSHUT output, the temperature must go below the value of each low TSHUT threshold.

Figure 18-15 shows the behavior of the TSHUT logic.

Figure 18-15. Thermal Shutdown Generation Signals



18.4.10.2.5 Temperature Timestamping

Each time one of the three bit fields (CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU, CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM, and CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE) is updated with new temperature value, this value is also automatically stored into a 5-level deep FIFO and a timestamp is also registered. The FIFO registers are in CTRL_MODULE_CORE.

There are three (one for MPU, one for GPU, and one for the device die center) 5-level FIFOs which store a brief history for the last few temperature measurements and are also dedicated to temperature timestamping feature.

The MPU FIFO consists of the following registers:

- CONTROL_DTEMP_MPU_0
- CONTROL_DTEMP_MPU_1
- CONTROL_DTEMP_MPU_2
- CONTROL_DTEMP_MPU_3
- CONTROL_DTEMP_MPU_4

The GPU FIFO consists of the following registers:

- CONTROL_DTEMP_MM_0
- CONTROL_DTEMP_MM_1
- CONTROL_DTEMP_MM_2
- CONTROL_DTEMP_MM_3
- CONTROL_DTEMP_MM_4

The device die center FIFO consists of the following registers:

- CONTROL_DTEMP_CORE_0
- CONTROL_DTEMP_CORE_1
- CONTROL_DTEMP_CORE_2
- CONTROL_DTEMP_CORE_3
- CONTROL_DTEMP_CORE_4

Table 18-18 shows a generic description of FIFOs.

Each FIFO has two fields. The first one is 10 bits wide, 5 levels deep, and is intended to store the temperature values for the last five measurements. The second field is 22 bits wide, 5 levels deep, and acts like a counter for the number of temperature measurements.

Table 18-18. FIFOs Generic Description

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10] (x=MPU,MM and CORE)	Description	First FIFO field (10 Bits) – Temperature Bits [9:0] (x=MPU,MM and CORE)	Description
Level 1	DTEMP_TAG_x_0	Indicates the number of temperature measurements	DTEMP_TEMPERATURE_x_0	Indicates the last measured temperature value (the most recent sample)
Level 2	DTEMP_TAG_x_1	Indicates the number of temperature measurements minus one (DTEMP_TEMPERATURE_x_0 – 1)	DTEMP_TEMPERATURE_x_1	Indicates the penultimate measured temperature value
Level 3	DTEMP_TAG_x_2	Indicates the number of temperature measurements minus two (DTEMP_TEMPERATURE_x_0 – 2)	DTEMP_TEMPERATURE_x_2	Indicates temperature value measured before DTEMP_TEMPERATURE_x_1

Table 18-18. FIFOs Generic Description (continued)

FIFO Levels	Second FIFO Field (22 Bits) – Timestamp Bits [31:10] (x=MPU,MM and CORE)	Description	First FIFO field (10 Bits) – Temperature Bits [9:0] (x=MPU,MM and CORE)	Description
Level 4	DTEMP_TAG_x_3	Indicates the number of temperature measurements minus three (DTEMP_TEMPERATURE_x_0 – 3)	DTEMP_TEMPERATURE_x_3	Indicates temperature value measured before DTEMP_TEMPERATURE_x_2
Level 5	DTEMP_TAG_x_4	Indicates the number of temperature measurements minus four (DTEMP_TEMPERATURE_x_0 – 4)	DTEMP_TEMPERATURE_x_4	Indicates temperature value measured before DTEMP_TEMPERATURE_x_3 (the oldest sample)

NOTE: DTEMP_TAG_x_4 (where x=MPU,MM and CORE) increments its value with one after each fifth temperature measurement.

DTEMP_TAG_x_3 (where x=MPU,MM and CORE) increments its value with one after each forth temperature measurement.

DTEMP_TAG_x_2 (where x=MPU,MM and CORE) increments its value with one after each third temperature measurement.

DTEMP_TAG_x_1 (where x=MPU,MM and CORE) increments its value with one after each second temperature measurement.

DTEMP_TAG_x_0 (where x=MPU,MM and CORE) increments its value with one after each temperature measurement.

Software can stop a certain FIFO to update with new temperature and timestamp values when setting one of the following bits to 0x1:

- CONTROL_BANDGAP_MASK[21] FREEZE_MPU for the MPU FIFO.
- CONTROL_BANDGAP_MASK[22] FREEZE_MM for the GPU FIFO.
- CONTROL_BANDGAP_MASK[23] FREEZE_CORE for the device die center FIFO.

These 3 bits are automatically cleared by hardware after FIFOs are reset.

Each FIFO can also be cleared setting the following bits to 0x1:

- CONTROL_BANDGAP_MASK[18] CLEAR_MPU for the MPU FIFO.
- CONTROL_BANDGAP_MASK[19] CLEAR_MM for the GPU FIFO.
- CONTROL_BANDGAP_MASK[20] CLEAR_CORE for the device die center FIFO.

These 3 bits are automatically cleared by hardware after FIFOs are reset.

18.4.10.2.6 Temperature Accumulators

Three registers are intended to accumulate the temperature after each measurement. The value of every next temperature measurement is added to the previous value and then stored in the following bit fields:

- CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU
- CONTROL_BANDGAP_CUMUL_DTEMP_MM[31:0] CUMUL_DTEMP_MM
- CONTROL_BANDGAP_CUMUL_DTEMP_CORE[31:0] CUMUL_DTEMP_CORE

Software can divide the accumulated in each register value to the number of measurements and thus get the average temperature. For example, the MPU average temperature for a given time period is:

MPU Average Temperature = CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU / CONTROL_DTEMP_MPU_0[31:10] DTEMP_TAG_MPU_0

Software can reset CONTROL_BANDGAP_CUMUL_DTEMP_MPU[31:0] CUMUL_DTEMP_MPU, CONTROL_BANDGAP_CUMUL_DTEMP_MM[31:0] CUMUL_DTEMP_MM, and CONTROL_BANDGAP_CUMUL_DTEMP_CORE[31:0] CUMUL_DTEMP_CORE temperature accumulators through bits CONTROL_BANDGAP_MASK[15] CLEAR_ACCUM_MPU, CONTROL_BANDGAP_MASK[16] CLEAR_ACCUM_MM, and CONTROL_BANDGAP_MASK[17] CLEAR_ACCUM_CORE, respectively, setting each one of them to 0x1. These bits also reset the three FIFOs and are automatically cleared by hardware when the reset procedure completes.

18.4.10.2.7 Bandgap FSMs Power Management

Each one of the three bandgap FSMs comply with the PRCM power-management protocol. They share common functional clock (L3INSTR_TS_GCLK), which is automatically gated by PRCM depending on the value of the CONTROL_BANDGAP_MASK[31:30] SIDLEMODE bit field. L3INSTR_TS_GCLK clock is also enabled automatically by the PRCM module.

18.4.10.2.8 ADC Codes Versus Temperature

Table 18-19 gives the temperature range that corresponds to each value of the following bit fields:

- CONTROL_TEMP_SENSOR_MPU[9:0] BGAP_DTEMP_MPU
- CONTROL_TEMP_SENSOR_MM[9:0] BGAP_DTEMP_MM
- CONTROL_TEMP_SENSOR_CORE[9:0] BGAP_DTEMP_CORE

Table 18-19. ADC Code Versus Temperature

ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature		ADC Code	Temperature	
	From	To		From	To		From	To		From	To
0-539	Outside region of operation										
540	-40	-40	586	-22.4	-22	632	-2.8	-2.4	678	16.4	16.8

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

The general control module provides observability features covering different module internal signals related to:

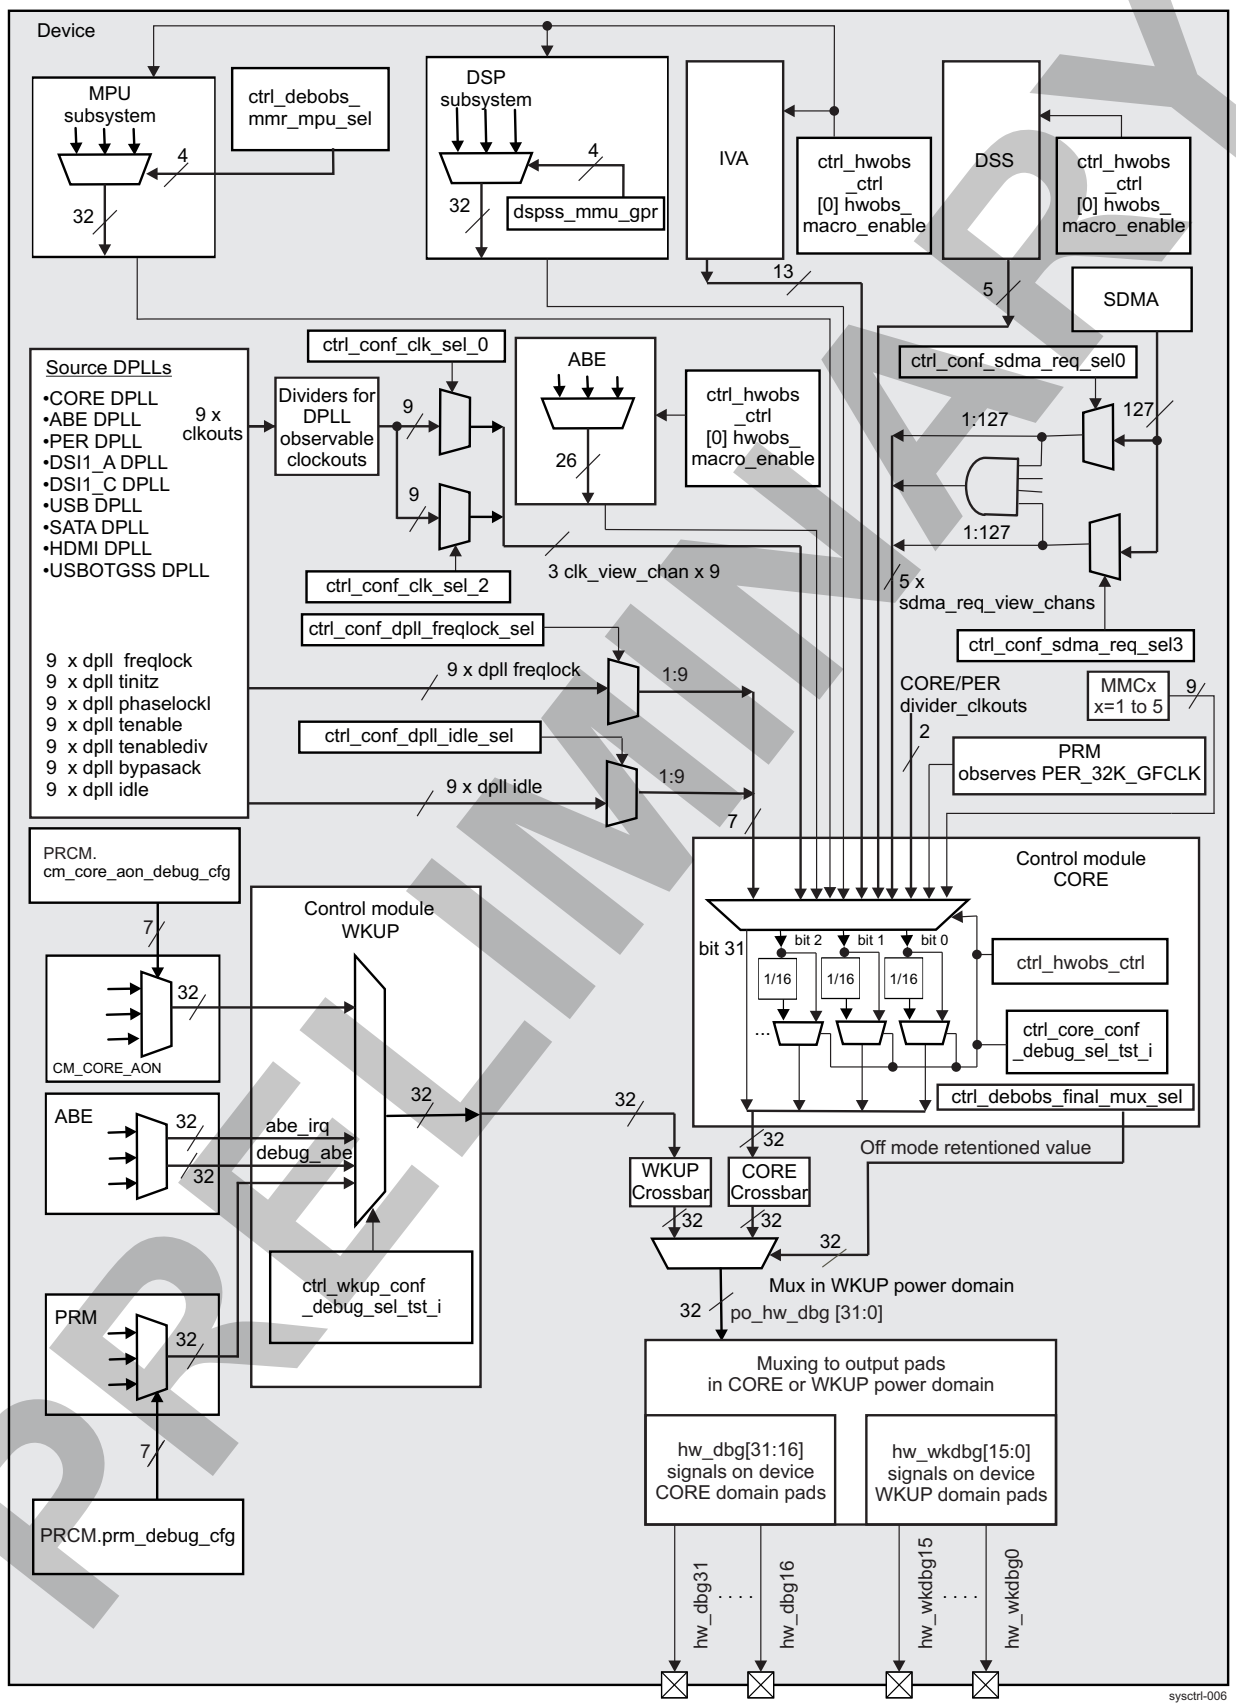
- Power and reset management protocol inside different power domains
- Power domain states and transition indication

- IRQs by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals reside in the CORE or WKUP power domain and are mapped on the po_hw_dbg[31:0] observability bus, which is in the WKUP power domain. The po_hw_dbg[31:16] and po_hw_dbg[15:0] observability outputs are then further multiplexed as their corresponding hw_dbg[31:16] and hw_wkdbg[15:0] signals on the different pads of the CORE and WKUP power domain, respectively.

Figure 18-16 is an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

Figure 18-16. Overview of the Hardware Observability Functionality



18.4.11.2 Observability Gating Capabilities

The programmer has the option to gate all 32 signals of the observability bus simultaneously at the observability paths of the CORE and WKUP power domains, keeping them tied to 1 (CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE = 0b1) or keeping them tied to 0 (CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE = 0b1). This can be useful to check the path from hardware observability to external pads. These 2 bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- MPU subsystem
- DSP subsystem
- IVA
- Display subsystem
- CM_CORE
- ABE

When the CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit is set to 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE and CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE simultaneously to 1 to avoid undefined states of the observability bus.

In the CORE power domain, the frequency of the signals which are mapped on po_hw_dbg[2:0] lines can be optionally divided by 1, 2, 4, 8, or 16 through programming dedicated bit fields in the CONTROL_HWOBS_CONTROL register.

Assignment of the dividers is as follows:

- CONTROL_HWOBS_CONTROL[7:3] HWOBS_CLKDIV_SEL for po_hw_dbg0
- CONTROL_HWOBS_CONTROL[13:9] HWOBS_CLKDIV_SEL_1 for po_hw_dbg1
- CONTROL_HWOBS_CONTROL[18:14] HWOBS_CLKDIV_SEL_2 for po_hw_dbg2

NOTE: To enable observability over the po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus lines, the respective bit fields in the CONTROL_HWOBS_CONTROL register (HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, and HWOBS_CLKDIV_SEL_2) must be set different than 0. The default value (0) is not sufficient to see an observability value.

NOTE: The frequency division and ability to gate the MACRO group observability signals (configurable in the CONTROL_HWOBS_CONTROL register) are limited only to hardware observability signals multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1).

These options do not apply to hardware observability signals muxed and propagated in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b0).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group modules/DPLLs/sDMA associated) are configurable in CTRL_MODULE_CORE, which is part of the switchable CORE power domain. Signal multiplexers are also instantiated in CTRL_MODULE_WKUP (CM1/PRM/ABE dedicated), which is part of the WKUP power domain. The CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field, instantiated in the CORE power domain, selects a signal to be observed between the outputs at the CORE and WKUP multiplexing levels. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain po_hw_dbgn (where n = 0 to 31) line; when the bit is set to 0, selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to the pad configuration muxing I/O level within device control module boundaries.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 5-bit field MODE in the 32 × 32-bit registers CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31. The following modules can be selected as source of observability signals: Cortex-A15 MPU subsystem, DSP subsystem, IVA, display subsystem, CM2, and ABE (MACRO signal sources).

Some of the CONTROL_CONF_DEBUG_SEL_TST registers are responsible for selection of sDMA view channels, different DPLL clock view channels, and other signal view channels.

- 3 x DPLL clkout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clkout view channels monitoring the hwobs_coredivider_clkout3, hwobs_perdivider_clkout4, and hwobs_pd_l4_per_per32k_gfclk signals

Table 18-20 summarizes the internal signals multiplexing schema for each of the 32 CONTROL_CORE_CONF_DEBUG_SEL_TST registers.

A third 1:N selection layer is applied over several signals to route them one-at-a-time to a certain view channel output:

- The CONTROL_CONF_CLK_SEL0[3:0] MULT through CONTROL_CONF_CLK_SEL2[3:0] MULT bit fields control the multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of the following DPLLs in the device:
  - CORE DPLL
  - ABE DPLL
  - PER DPLL

  - DSI1_A DPLL
  - DSI1_C DPLL
  - USB DPLL
  - HDMI DPLL
  - SATA DPLL
  - USBOTGSS DPLL
- The register bit fields associated with the seven different DPLL signal view channels are summarized in Table 18-21. Again, the 4-bit MULT bit field in each of the seven registers makes it possible to choose the source of the DPLL signal to be one of the following DPLLs in the device:
  - CORE DPLL
  - ABE DPLL
  - PER DPLL
  - DSI1_A DPLL
  - DSI1_C DPLL
  - USB DPLL
  - HDMI DPLL
  - SATA DPLL
  - USBOTGSS DPLL
- Nine registers are associated with the power-management observable signals of MMCx (where x = 1 to 5) modules. These registers are summarized in Table 18-22.
- There are four independent sDMA request view channels, each of which has a dedicated register (CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3) with a 7-bit MULT bit field to select 1 from 127 possible DMA_SYSTEM request signals for observation purposes. For more information, see Section 16.1, *DMA_SYSTEM Module Overview*. The fifth channel, sdma_req_view_all, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.
- The General Core observability logic input (hwobs_pd_l4_per_per32k_gfclk) is tied to a PRM output observability signal. This PRM signal corresponds to the hardware gated in the CD_L4_PER clock domain clock (PER_32K_GFCLK), which is directly sourced by the SCRM clock (SYS_32K).
- The General Core observability logic input, hwobs_coredivider_clkout3, is tied to the Core DPLL observability output, CLK_FUNC_1_0_3, which is a direct (nongated, nondivided) version of the CORE DPLL clock output, CLKOUTX2_M3.
- The General Core observability logic input, hwobs_perdivider_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see Section 3.6.3.4, *DPLL_PER Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-21 lists the DPLL signal observability controls.

Table 18-21. DPLL Signal Observability Controls

Feature	Type	Register/Bit Field/Observability Control	Description
Different domain DPLL freqlock observability	Control	CONTROL_CONF_DPLL_FREQLOCK_SEL[3:0] MULT	Selects DPLL freqlock view channel
Different domain DPLL phaselock observability	Control	CONTROL_CONF_DPLL_PHASELOCK_SEL[3:0] MULT	Selects DPLL phaselock view channel
Different domain DPLL tinitz observability	Control	CONTROL_CONF_DPLL_TINITZ_SEL[3:0] MULT	Selects to observe DPLL tinitzview channel
Different domain DPLL tenable observability	Control	CONTROL_CONF_DPLL_TENABLE_SEL[3:0] MULT	Selects to observe DPLL tenableview channel
Different domain DPLL tenablediv observability	Control	CONTROL_CONF_DPLL_TENABLEDIV_SEL[3:0] MULT	Selects to observe DPLL tenabledivview channel
Different domain DPLL bypassack observability	Control	CONTROL_CONF_DPLL_BYPASSACK_SEL[3:0] MULT	Selects to observe DPLL bypassackview channel
Different domain DPLL idle observability	Control	CONTROL_CONF_DPLL_IDLE_SEL[3:0] MULT	Selects to observe DPLL idleview channel

Table 18-22. MMCx Signal Observability Controls

Register/Bit Field/Observability Control	Description
CONTROL_CONF_MMCX_ADPIDLE_SEL[2:0] MULT	Selects to observe hwobs_mmcx_adpidle (where x = 1 to 5)
CONTROL_CONF_MMCX_ADPDAT1PADEN_SEL[2:0] MULT	Selects to observe hwobs_mmcx_adpdat1paden (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4IDLEREQ_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4idlereq (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL3MWAIT_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl3mwait (where x = 1 to 5)
CONTROL_CONF_MMCX_PIRFFRET_SEL[2:0] MULT	Selects to observe hwobs_mmcx_pirffret (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4SIDLEACKO1_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4sidleacko_1 (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL4SIDLEACKO0_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl4sidleacko_0 (where x = 1 to 5)
CONTROL_CONF_MMCX_OCPL3MSTANDBYO_SEL[2:0] MULT	Selects to observe hwobs_mmcx_ocpl3mstandbyo (where x = 1 to 5)
CONTROL_CONF_MMCX_SWAKEUP_SEL[2:0] MULT	Selects to observe hwobs_mmcx_swakeup (where x = 1 to 5)

NOTE: Features configured in the following registers are limited to hardware observability signals multiplexed and propagated in the CORE power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b1):

- CONTROL_CORE_CONF_DEBUG_SEL_TST_0 through CONTROL_CORE_CONF_DEBUG_SEL_TST_31
- CONTROL_CONF_CLK_SEL0[3:0] MULT through CONTROL_CONF_CLK_SEL2[3:0] MULT
- CONTROL_CONF_SDMA_REQ_SEL0 through CONTROL_CONF_SDMA_REQ_SEL3
- CONTROL_CONF_MMCX_ADPIDLE_SEL through CONTROL_CONF_MMCX_SWAKEUP_SEL
- CONTROL_CONF_DPLL_FREQLOCK_SEL
- CONTROL_CONF_DPLL_TINITZ_SEL
- CONTROL_CONF_DPLL_PHASELOCK_SEL
- CONTROL_CONF_DPLL_TENABLE_SEL
- CONTROL_CONF_DPLL_TENABLEDIV_SEL
- CONTROL_CONF_DPLL_BYPASSACK_SEL
- CONTROL_CONF_DPLL_IDLE_SEL

These options do not apply to hardware observability signals muxed and propagated in the WKUP power domain (CONTROL_DEBOBS_FINAL_MUX_SEL[i] SELECT = 0b0).

The CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[1:0] MODE bit (where i = 0 to 31) provides the option to choose between observation of power and reset manager signals in the device or observation of signals related to CM1. If CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[1:0] = 0b1, the hwobs_int_prm_i signal is selected. Otherwise, the hwobs_int_cm1_i signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn/hw_wkdbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in the CORE Power Domain

To map the hw_dbg16 through hw_dbg31 signals to their associated external device pads in the CORE power domain, set the related MUXMODE bit fields within the CONTROL_CORE_PAD0_C2C_DATAOUT0_PAD1_C2C_DATAOUT1 through CONTROL_CORE_PAD0_C2C_DATA14_PAD1_C2C_DATA15 pad configuration registers to 0b101 (mode 5). These signals can also be mapped on the external device pads in the CORE power domain through the following registers (MUXMODE = 0x5):

- CONTROL_CORE_PAD0_UART2_RTS_PAD1_UART2_CTS through CONTROL_CORE_PAD0_UART2_RX_PAD1_UART2_TX to map hw_dbg16 through hw_dbg19 signals on the uart2_rts – uart2_tx pads, respectively
- CONTROL_CORE_PAD0_MCSPI2_CLK_PAD1_MCSPI2_SIMO[31:16] to map the hw_dbg20 signal on the mcspi2_simo pad
- CONTROL_CORE_PAD0_MCSPI2_SOMI_PAD1_MCSPI2_CS0[15:0] to map the hw_dbg21 signal on the mcspi2_somi pad
- CONTROL_CORE_PAD0_GPIO6_184_PAD1_GPIO6_185 through CONTROL_CORE_PAD0_GPIO6_186_PAD1_GPIO6_187 to map hw_dbg22 through hw_dbg25 signals on the gpio6_184 – gpio6_187 pads, respectively
- CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_TIMER11_PWM_EVT[31:16] to map the hw_dbg26 signal on the timer11_pwm_evt pad
- CONTROL_CORE_PAD0_TIMER8_PWM_EVT_PAD1_I2C3_SCL to map the hw_dbg27signal on the timer8_pwm_evt pad

- CONTROL_CORE_PAD0_UART5_RX_PAD1_UART5_TX through CONTROL_CORE_PAD0_UART5_CTS_PAD1_UART5_RTS to map hw_dbg28 through hw_dbg31 signals on the uart5_rx – uart5_rts pads, respectively

For more information, see Table 18-9.

18.4.11.4.2 Observability Signals Muxed on Pads in the WKUP Power Domain

To map the hw_wkdbg0 through hw_wkdbg15 signals to their associated external device pads in the WKUP power domain, set the MUXMODE bit field to 0x5 in the following CTRL_MODULE_WKUP_PAD registers:

- CONTROL_WKUP_PAD0_LLIA_WAKEREQIN_PAD1_LLIB_WAKEREQIN to map the hw_wkdbg14 and hw_wkdbg13 signals on the llia_wakereqin and llib_wakereqin pads, respectively.
- CONTROL_WKUP_PAD0_DRM_EMU0_PAD1_DRM_EMU1 to map the hw_wkdbg6 and hw_wkdbg7 signals on the drm_emu0 and drm_emu1 pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK0_OUT_PAD1_FREF_CLK1_OUT to map the hw_wkdbg9 and hw_wkdbg5 signals on the fref_clk0_out and fref_clk1_out pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK2_OUT_PAD1_FREF_CLK2_REQ to map the hw_wkdbg10 and hw_wkdbg11 signals on the fref_clk2_out and fref_clk2_req pads, respectively.
- CONTROL_WKUP_PAD0_FREF_CLK1_REQ_PAD1_SYS_NRESPWRON[15:0] to map the hw_wkdbg12 signal on the fref_clk1_req pad.
- CONTROL_WKUP_PAD0_SYS_NRESWARM_PAD1_SYS_PWR_REQ[31:16] to map the hw_wkdbg15 signal on the sys_pwr_req pad.
- CONTROL_WKUP_PAD0_SYS_BOOT0_PAD1_SYS_BOOT1 through CONTROL_WKUP_PAD0_SYS_BOOT4_PAD1_SYS_BOOT5 to map the hw_wkdbg0 – hw_wkdbg4 and hw_wkdbg8 signals on the sys_boot0 – sys_boot5 pads, respectively.

For more information, see Table 18-8.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (see Figure 18-16).

18.4.11.5.1 MPU Subsystem Observable Signals

Table 18-23 through Table 18-38 list the MPU subsystem observable signals available in 16 functional multiplexing modes. The mode is selected at the general core control module level by programming the CONTROL_DEBOBS_MMR_MPU[3:0] SELECT bit field.

Table 18-23. Observability Signals Multiplexing at MPU Subsystem Level – Mode 0

18.4.11.5.2 IVA Subsystem Observable Signals

Table 18-39 lists the full set of 13 IVA observable signals from inside the IVA subsystem. No observability signal multiplexing is implemented at the IVA level. POHWDBGOUT[31:0] outputs are internal signals exported at IVA boundary to provide support during platform debug. They are enabled when PIHWDBGEN is high. They are always low when PIHWDBGEN is low

Table 18-39. Observability Signals at IVA Subsystem Level

CTRL_MODULE_CORE Observability Inputs Tied to Signals Inside IVA Subsystem	IVA Subsystem Observable Signals Mapped to CTRL_MODULE_CORE Observability Inputs	Signal Description	Logical Value Meaning

18.4.11.5.3 Display Subsystem Observable Signals

The display subsystem observable signals described in Table 18-40 are directly mapped to the display subsystem observability inputs of the CTRL_MODULE_CORE module, and no additional multiplexing is performed inside the display subsystem wrapper.

Table 18-40. Observability Signals at Display Subsystem Level

CTRL_MODULE_CORE Observability Inputs Tied to Signals Inside Display Subsystem	Display Subsystem Observable Signals Mapped to CTRL_MODULE_CORE Observability Inputs	Signal Description	Logical Value Meaning
hwobs_dsshdmiphypwrcmdtxon	HDMI_PHYPWRCMD_TXON	Command for TX ON	–
hwobs_dsshdmiphypwrcmdoff	HDMI_PHYPWRCMD_OFF	Command to go off state	
hwobs_dsshdmiphypwrack	HDMI_PHYPWRACK	Acknowledge	
hwobs_dsshdmihpd	HDMI_HPD	Hot plug detect	

18.4.11.5.4 DSP Subsystem Observable Signals

Table 18-41 through Table 18-47 show DSP subsystem observable signals available in sixteen multiplexing modes. The mode is selected at the general control module level through writing in the bit field DSPSS_MMU_GPR[3:0] HWDEBUG_MUX.

The DSPSS.DSPSS_MMU_GPR register provides mux control for hardware observability signals exported at the DSPSS boundary to the general control module. Interrupts, DMA requests, and other events can be seen on the PO_HW_DBG_OUT bus. The DSPSS.DSPSS_MMU_GPR register provides mux controls for selecting the appropriate 32-bit value to be output on the PO_HW_DBG_OUT signal bus. The mux values and associated signals that can be observed on the PO_HW_DBG_OUT bus are described in Chapter 20, *Memory Management Units*. Setting the DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit initiates IDLE request/acknowledgment protocol with various blocks; the acknowledge information can be observed when HWDEBUG_MUX = 4'b1110.

All interrupts into DSPSS can be observed by setting the DSPSS.DSPSS_MMU_GPR[3:0] HWDEBUG_MUX bit field to 0x6, 0x7, 0x8, and 0x9. All interrupts to the INTC, which includes external and internal interrupts, can be seen by setting the HWDEBUG_MUX values to 0x2, 0x3, 0x4, and 0x5. DMA requests can be seen when the HWDEBUG_MUX values are set to 0xA and 0xB.

DPLL_IVA and the associated HSDIVIDER values can be seen by values of 0x0, the default reset value. DSPSS raw CD0 clock is sent out without any division. Other clocks are divided by 32.

The DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit must be used only for observability purposes, not in functional mode. When set, the FORCE_IDLE_REQ bit causes IDLE requests to be sent to various components inside the DSPSS, and idle acknowledgment is displayed when the value of the HWDEBUG_MUX[3:0] bit field is 4'b1110; the signals listed can then be checked to determine which component is not idle.

NOTE: Once this feature is used, FORCE_IDLE_REQ must be set to 0 before continuing the observability process.

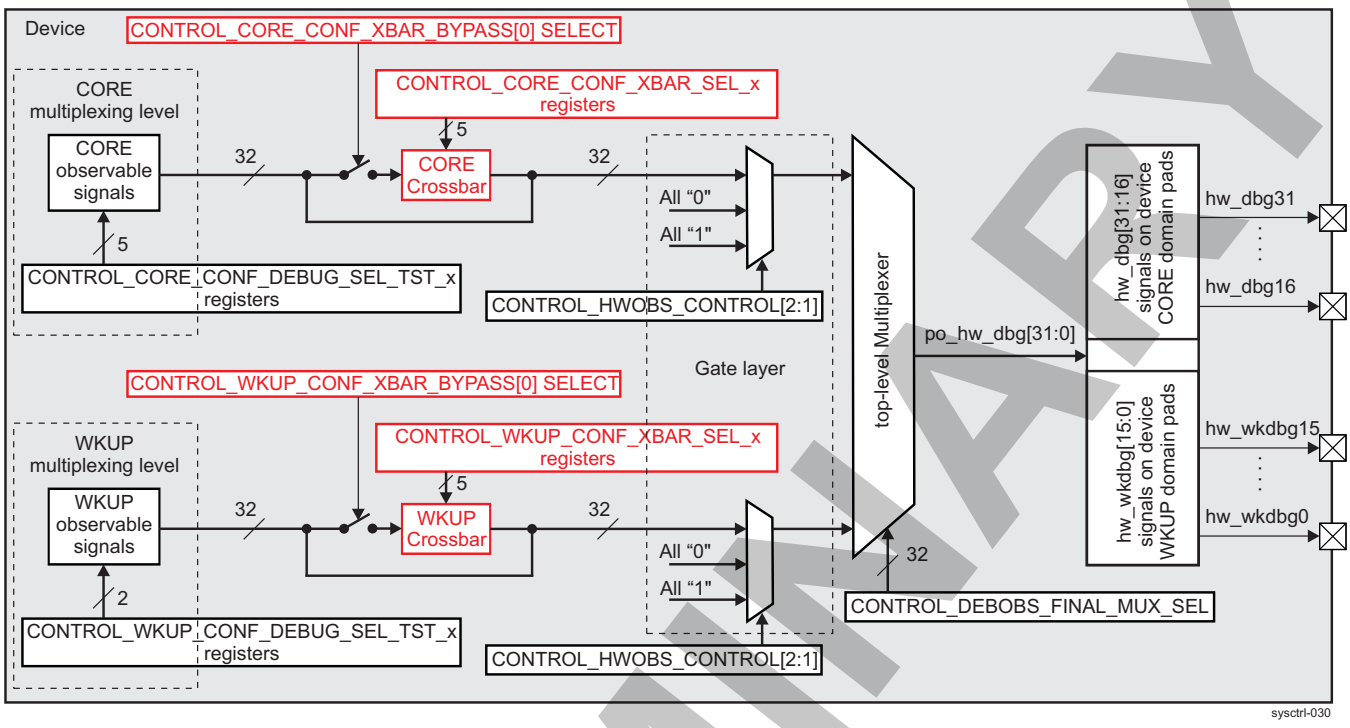
18.4.11.6 Cross-bar

The cross-bar is part of the device observability logic. The purpose of the cross-bar is to shuffle any input observable signal to any output observable signal. There are two identical cross-bars, one for CORE observability signals and one for WKUP observability signals. Each cross-bar has 32 inputs and 32 outputs and can be seen as a 32-to-32 multiplexer. The cross-bar resides between the CORE/WKUP multiplexing level and the gate layer before the top-level multiplexer, which selects an observable signal between the CORE and WKUP power domains.

Figure 18-17 shows the location of the cross-bar in device observability logic.

Figure 18-17. Cross-bar Location



The cross-bars in the CORE and in WKUP power domains can be bypassed by setting the CONTROL_CORE_CONF_XBAR_BYPASS[0] SELECT and CONTROL_WKUP_CONF_XBAR_BYPASS[0] SELECT bits to 0x1, respectively. By default both the cross-bars are bypassed.

Figure 18-18 represents the way in which the cross-bar works. The selection of an input signal to remap is made through the CONTROL_CORE_CONF_XBAR_SEL_x and CONTROL_WKUP_CONF_XBAR_SEL_x registers. Each of these registers has a structure described in Table 18-59. Each of the 5-bit fields (CONF_XBAR_SEL) selects one of the 32 observable input signals to be mapped on a certain cross-bar output. The number of each cross-bar output corresponds to the suffix number of each one of these 5-bit fields. For example:

- The CONTROL_CORE_CONF_XBAR_SEL_0[4:0] CONF_XBAR_SEL_0 bit field selects one of 32 observable signals to be mapped on cross-bar output 0.
- The CONTROL_CORE_CONF_XBAR_SEL_0[12:8] CONF_XBAR_SEL_1 bit field selects one of 32 observable signals to be mapped on cross-bar output 1.
- The CONTROL_CORE_CONF_XBAR_SEL_28[28:24] CONF_XBAR_SEL_31 bit field selects one of 32 observable signals to be mapped on cross-bar output 31.

The same logic is applied for cross-bar control registers in the WKUP power domain.

Table 18-60 shows all the cross-bar control registers.

Figure 18-18. CORE/WKUP Cross-bar Functional Diagram

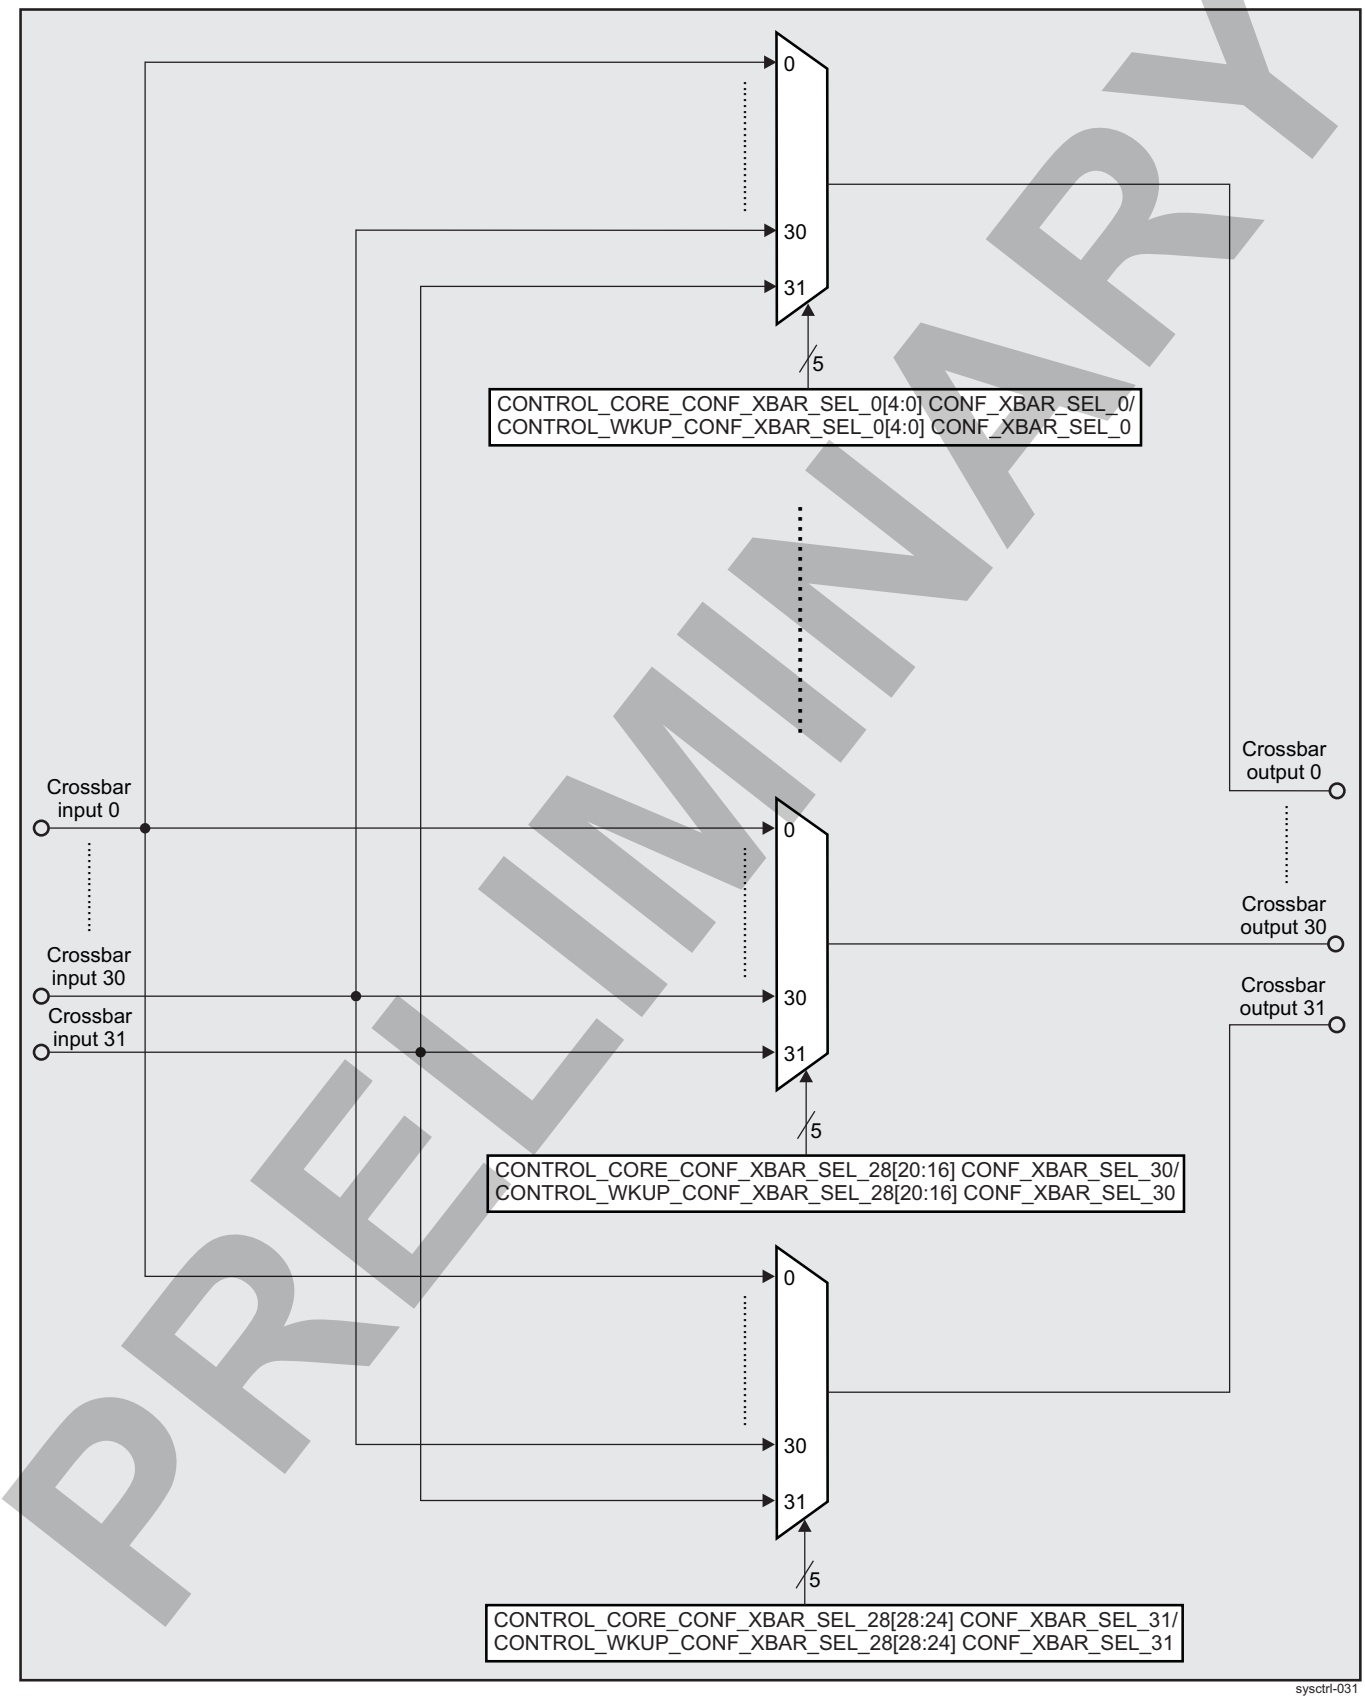


Table 18-59. Generic Description of CONTROL_CORE_CONF_XBAR_SEL_x and CONTROL_WKUP_CONF_XBAR_SEL_x Registers (where x = 0, 4, 8, 12, 16, 20, 24, and 28)

18.4.12.1 DSP Boot Register

Table 18-61 describes the DSP boot address register.

Table 18-61. DSP Boot Address Register

Physical Address	Register Name	Description	Access
0x4A00 2304	CONTROL_DSP_BOOTADDR	DSP boot loader address register	R/W

The CONTROL_DSP_BOOTADDR register defines the physical address for the DSP boot loader and drives the DSP_BOOTADDR[31:10] signals from the control block to the DSP subsystem.

18.4.12.1.1 PBIAS Control Register

Table 18-62 describes the CONTROL_PBIAS register, which controls some settings of PBIASLITE cells for the SDCARD I/O interface.

Table 18-62. PBIAS Control Register

Physical Address	Register Name	Description	Access
0x4A00 2E00	CONTROL_PBIAS	Control settings for PBIAS cell	RW

18.4.12.2 Temperature Sensor Control Registers

Table 18-63 describes the thermal management registers of the general core control module, which control the temperature sensor, bandgap state-machine, thermal post-processing logic, temperature accumulation, and temperature time stamping features.

Table 18-63. Temperature Sensor Registers

Physical Address	Register Name	Description	Access
0x4A00 232C	CONTROL_TEMP_SENSOR_MPU	Temperature sensor control registers	R/W
0x4A00 2330	CONTROL_TEMP_SENSOR_MM		
0x4A00 2334	CONTROL_TEMP_SENSOR_CORE		
0x4A00 239C	CONTROL_BANDGAP_CUMUL_DTEMP_MPU	Temperature accumulator registers	RO
0x4A00 23A0	CONTROL_BANDGAP_CUMUL_DTEMP_MM		
0x4A00 23A4	CONTROL_BANDGAP_CUMUL_DTEMP_CORE		
0x4A00 2390	CONTROL_BANDGAP_TSHUT_MPU	Bandgap thermal shutdown threshold registers	RO
0x4A00 2394	CONTROL_BANDGAP_TSHUT_MM		
0x4A00 2398	CONTROL_BANDGAP_TSHUT_CORE		

Table 18-63. Temperature Sensor Registers (continued)

Physical Address	Register Name	Description	Access
0x4A00 2384	CONTROL_BANDGAP_THRESHOLD_MPU	Bandgap thermal alert threshold registers	R/W
0x4A00 2388	CONTROL_BANDGAP_THRESHOLD_MM		
0x4A00 238C	CONTROL_BANDGAP_THRESHOLD_CORE		
0x4A00 23A8	CONTROL_BANDGAP_STATUS	Thermal alert and bandgap idle events status register	RO
0x4A00 2380	CONTROL_BANDGAP_MASK	Hot and cold bandgap events mask register. This register is also used to control the FIFOs and temperature accumulators.	R/W
0x4A00 23C0	CONTROL_DTEMP_MPU_0	Temperature timestamping registers	RO
0x4A00 23C4	CONTROL_DTEMP_MPU_1		
0x4A00 23C8	CONTROL_DTEMP_MPU_2		
0x4A00 23CC	CONTROL_DTEMP_MPU_3		
0x4A00 23D0	CONTROL_DTEMP_MPU_4		
0x4A00 23D4	CONTROL_DTEMP_MM_0		
0x4A00 23D8	CONTROL_DTEMP_MM_1		
0x4A00 23DC	CONTROL_DTEMP_MM_2		
0x4A00 23E0	CONTROL_DTEMP_MM_3		
0x4A00 23E4	CONTROL_DTEMP_MM_4		
0x4A00 23E8	CONTROL_DTEMP_CORE_0		
0x4A00 23EC	CONTROL_DTEMP_CORE_1		
0x4A00 23F0	CONTROL_DTEMP_CORE_2		
0x4A00 23F4	CONTROL_DTEMP_CORE_3		
0x4A00 23F8	CONTROL_DTEMP_CORE_4		

18.4.12.2.1 CSI Receiver Control Register

To enable the physical layer of the camera receiver, the programmer manipulates the bits within the CONTROL_CAMERA_RX register as described in Table 18-64.

Table 18-64. CSI Receiver Control Register

Physical Address	Register Name	Description	Access
0x4A00 2E08	CONTROL_CAMERA_RX	Module dedicated configurations	RW

18.4.12.3 Protection Status Registers

Table 18-65 lists the protection status registers.

Table 18-65. Protection Status Registers

Physical Address	Register Name	Description	Access
0x4A00 2148	CONTROL_SEC_ERR_STATUS_FUNC	Protection firewall error status register	Public (R)
0x4A00 2150	CONTROL_SEC_ERR_STATUS_DEBUG	Protection firewall error status register debug	Public (RW)

These registers do not depend on the device type.

The CONTROL_SEC_ERR_STATUS_FUNC can be read in public mode, but cannot be written.

The CONTROL_SEC_ERR_STATUS_DEBUG register is both read and write accessible in GP devices.

These bits are cleared when the L3 and L4 firewall embedded-error log registers are cleared. All bits in these registers reflect internal events in the device related to the device protection.

On a specific event (signal rising edge), the corresponding bit is set. On a rising edge, the input signal must stay high for at least two interface clock periods to be recognized. Software must clear each bit after reviewing the events.

When a protection violation occurs, the following bits are set:

- In application mode:
  - CONTROL_SEC_ERR_STATUS_FUNC[1] = L3RAM protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[2] = GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[3] = EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[4] = IVA-HD protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[5] = Dual Cortex-M4 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[6] = IVAHD SL2 protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[8] = SYSTEMDMA protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[10] = DISPDMA protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[13] = GPU protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[14] = DSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[15] = ISS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[16] = L4_PER protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[17] = L4_CFG protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[18] = DebugSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[19] = AUDIOSS protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[22] = L4 wakeup protection violation
  - CONTROL_SEC_ERR_STATUS_FUNC[23] = BB2D protection violation
- In debug mode:
  - CONTROL_SEC_ERR_STATUS_DEBUG[1] = L3RAM protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[2] = GPMC protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[3] = EMIF protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[4] = IVA-HD protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[5] = Dual Cortex-M4 protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[6] = IVAHD SL2 protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[13] = GPU protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[14] = DSS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[15] = ISS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[16] = L4_PER protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[17] = L4_CFG protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[18] = DebugSS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[19] = AUDIOSS protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[22] = L4 wakeup protection violation
  - CONTROL_SEC_ERR_STATUS_DEBUG[23] = BB2D protection violation

18.4.12.4 Protection SDRAM Configuration Registers

Table 18-66 lists the protection SDRAM configuration registers for EMIF1 and EMIF2 that are part of the general wakeup control module (CTRL_MODULE_WKUP). Upon POR, their values are exported as reset values of the EMIF1 and EMIF2 registers (EMIF_SDRAM_CONFIG and EMIF_SDRAM_CONFIG_2, respectively).

Table 18-66. Protection SDRAM Configuration Registers for EMIF1 and EMIF2

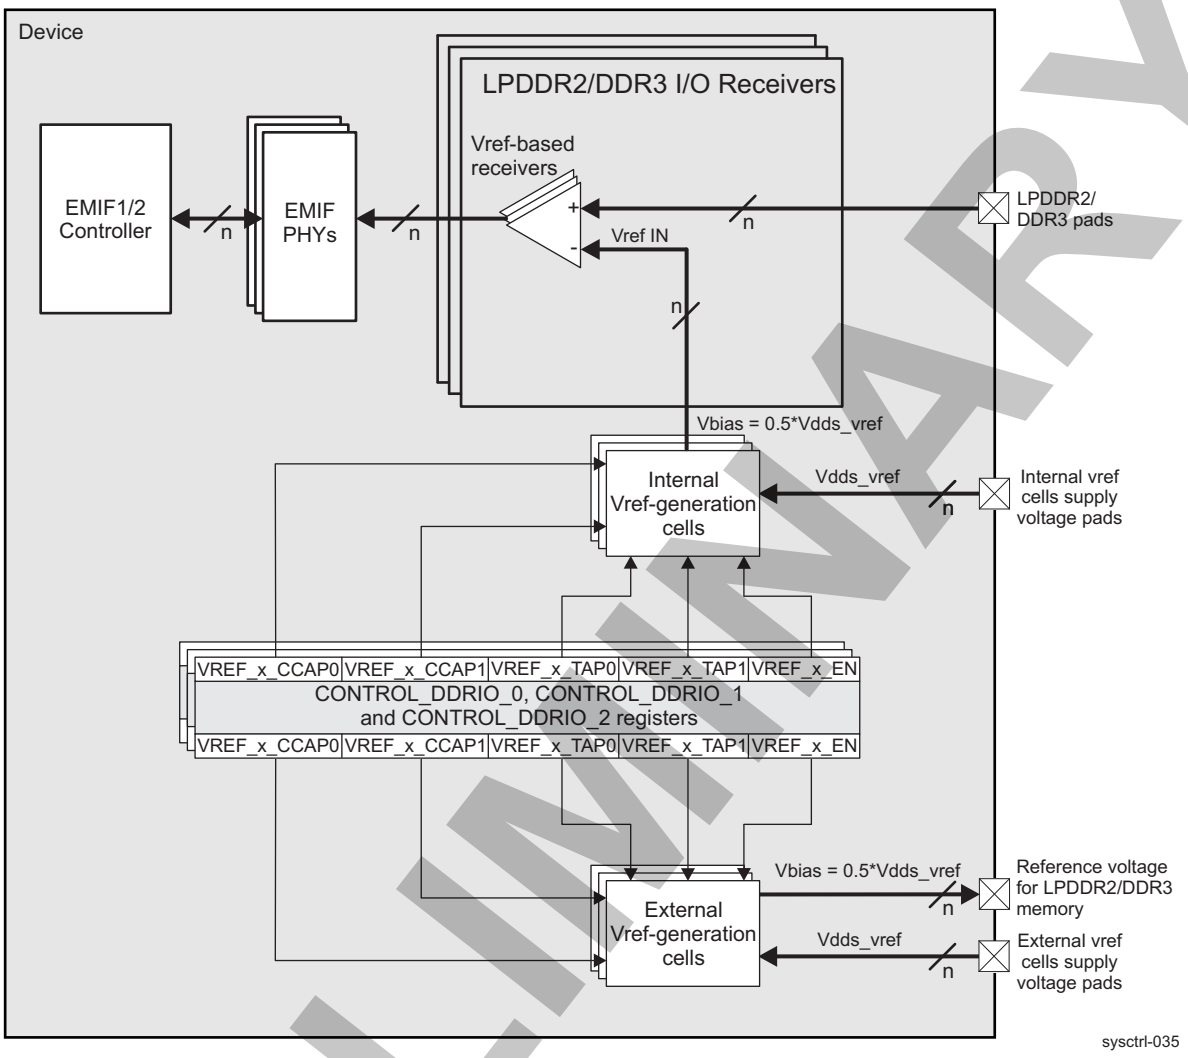
Physical Address	Register Name	Description	Access
0x4AE0 C110	CONTROL_PROT_EMIF1_SDRAM_CONFIG	Protection SDRAM configuration register 1. This register defines the bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG register	RW
0x4AE0 C114	CONTROL_PROT_EMIF1_LPDDR2_NVM_CONFIG	Protection SDRAM configuration register 2. This register defines the bit field reset values of the EMIF1.EMIF_SDRAM_CONFIG_2 register	RW
0x4AE0 C118	CONTROL_PROT_EMIF2_SDRAM_CONFIG	Protection SDRAM configuration register 1. This register defines the bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG register	RW
0x4AE0 C11C	CONTROL_PROT_EMIF2_LPDDR2_NVM_CONFIG2	Protection SDRAM configuration register 2. This register defines the bit field reset values of the EMIF2.EMIF_SDRAM_CONFIG_2 register	RW

18.4.12.5 Reference Voltage for Device LPDDR2/DDR3 I/O Buffers and LPDDR2/DDR3 Memory

The device LPDDR2/DDR3 I/O buffers work in so-called Vref-based receiver mode. In this mode, the buffers act like differential comparators with positive terminal connected to a device pad which receives signals from LPDDR2/DDR3 memory and negative terminal connected to a source of reference voltage. To work properly, a reference voltage must be provided to the device LPDDR2/DDR3 I/O buffers. Several Vref-generation cells are integrated in the device to supply this internal reference voltage. They are referred to as internal Vref-generation cells. There are also external Vref-generation cells which provide reference voltage to the externally connected LPDDR2/DDR3 memory.

Figure 18-19 shows the internal and external Vref-generation cells for the device.

Figure 18-19. Internal and External Vref-Generation Cells and Their Controls



The Vref-generation cells reference voltage (Vbias) is equal to 0.5 × Vdds_vref, where Vdds_vref is the power supply voltage of the Vref cell. The Vref-based receiver allows improvement of speed performance when the LPDDR2/DDR3 I/Os are supplied by 1.2 V. A reference voltage is also provided to externally attached LPDDR2/DDR3 memory. The same type of Vref-generation cells are used for these external reference voltages.

The control bits for these internal and external Vref-generation cells reside in the CONTROL_DDRIO_0, CONTROL_DDRIO_1 and CONTROL_DDRIO_2 registers. Individual VREF_x_TAP[1:0] control bits set the output drive capability of the Vref cells. Table 18-67 lists the possible options for selection of load current sourced from the output of the Vref-generation cell.

Table 18-67. Vref Cell Load Current Selection

VREF_x_TAP1	VREF_x_TAP0	Description
0	0	2-µA load current
0	1	4-µA load current
1	0	8-µA load current
1	1	32-µA load current

According to the noise environment, the user can choose to filter the supplied reference voltage. Two coupling capacitors internal to the Vref-generation cell are available and configurable through the individual VREF_x_CCAP[1:0] control bits in the CONTROL_DDRIO_0, CONTROL_DDRIO_1 and CONTROL_DDRIO_2 registers, as specified in Table 18-68.

Table 18-68. Vref Cell Coupling Capacitor Selection

VREF_x_CCAP1	VREF_x_CCAP0	Capacitor
0	0	No capacitor connected.
0	1	One capacitor connected between Vbias and ground.(1)
1	0	One capacitor connected between Vbias and Vdds_vref.(2)
1	1	One capacitor connected between Vbias and ground and one capacitor connected between Vbias and Vdds_vref.

(1) Vbias is the output of the Vref-generation cell which provides the reference voltage.
(2) Vdds_vref is the power supply voltage of the Vref-generation cell.

The Vref-gereration cells can be enabled by setting the VREF_x_EN bits in the CONTROL_DDRIO_0, CONTROL_DDRIO_1, and CONTROL_DDRIO_2 registers to 0x1; these cells can be disabled (for leakage improvement and when not in use) by clearing the same VREF_x_EN bits.

There are the following internal and external Vref-generation cells per memory channel:

- Four internal Vref-generation cells providing reference voltage for the device LPDDR2/DDR3 DQ line I/Os (one Vref cell per data byte);
- One external Vref-generation cell that is intended to provide reference voltage to CA line receivers of the LPDDR2 memory;
- One external Vref-generation cell that provides reference voltage simultaneously to the four DQ lines of the LPDDR2/DDR3 memory;
- Two external Vref-generation cells intended to provide reference voltage to the command and address line receivers of the DDR3 memory.

NOTE: For leakage improvement software must set the CONTROL_DDRIO_2[27] LPDDR2CH1_VREF_CA_INT_EN and CONTROL_DDRIO_2[17] LPDDR2CH2_VREF_CA_INT_EN bits to 0x0.

Table 18-69 shows the internal Vref-generation cells control bits and the LPDDR2/DDR3 IOs pads used as receivers to which the corresponding Vref cell supplies reference voltage.

Table 18-69. Internal Vref-Generation Cells Controls Versus LPDDR2/DDR3 Receiver Pads

18.4.12.6 Force MPU Write Nonposted Transactions Control Register

At the top level, software can force all writes from the MPU subsystem to the L3 interconnect to be nonposted, regardless of the attributes of the transactions coming from the MPU. When active-high bit FORCEWRNP = 1, only nonposted write commands are sent to the L3 interconnect. This bit must remain stable for the entire transfer and must not change during the transfer.

Table 18-71 describes the general core control module register with FORCEWRNP control.

Table 18-71. Force MPU Write Nonposted Transactions Control Register

Physical Address	Register Name	Description	Access
0x4A00 215C	CONTROL_FORCEWRNP	Forces only nonposted write commands from the MPU subsystem to the L3 interconnect	R/W

18.4.12.7 Signal Integrity Parameter Control Registers With Pad Group Assignment

18.4.12.7.1 Signal Integrity Parameter Controls Overview

Most of the I/O cells associated with the device pads can be configured to deliver their carried signals to the targeted input with maximum signal integrity. Configuration of these I/Os is done by pad group assignment, and not individually per pad.

The different I/O-specific requirements determine the use of different types of I/O cells for the device I/Os. Software controls associated with the signal integrity parameters are implemented at the CTRL_MODULE_CORE_PAD and CTRL_MODULE_WKUP_PAD level.

The following types of I/O cells associated with pad groups can be identified:

- LPDDR2/DDR3 high-speed I/O cells with impedance (I), slew rate (SR), and weak driver (WD) settings
- SMART I/O cells for most of the pads with slew rate control (SC) and drive strength (DS) control settings
- I2Cx I/O cells with pullup resistance versus capacitance load (LB), glitch free operation (GLFENB) and PULLUPRESX settings
- Extended drain I/O cells for sdcard pads. For more information, see Section 18.4.9, *Extended-Drain I/O and PBIAS Cell*
- Glitch Free I/O cells only for pads sys_nrespwron and sys_nreswarm

NOTE: Unlike most of the I/O cells, the glitch free I/O cell does not have signal integrity or dual voltage group control settings.

NOTE: C_{LOAD} is the total capacitance seen at the far end of the transmission line.

NOTE: I/Os are non-failsafe, meaning one must never apply voltage at a pad before the internal I/O supply voltage VDDS is powered.

The pad group-assigned signal integrity controls are provided through the registers described in Table 18-72.

Table 18-72. Signal Integrity Parameter Control Registers

Physical Address	Register Name	Description	Access

18.4.12.7.2 High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings

The LPDDR2/DDR3 buffers are based on 1.2-V high-speed unterminated logic and require excellent driver impedance control to achieve optimal timing-EMI trade-offs. A specific type of device I/O cells with programmable features are used to meet this requirement. These I/O cells support 1.2-V operation. These cells are also provided with additional features to support the high-speed inter-chip (HSIC) interface.

Two types of software-configurable I/O cells are integrated to support high-speed unterminated logic:

- Single-ended I/O cells
- Two-pad differential I/O cells

Two-pad differential I/O cells are provided with a differential receiver and complementary transmitter. They are used to support the LPDDR2/DDR3 clock pads and LPDDR2/DDR3 strobe pads.

The LPDDR2/DDR3 I/O cells are integrated with the following controls in the CTRL_MODULE_CORE_PAD module:

- Driver output impedance (I) controls
- SR controls
- WD controls to support LPDDR2/DDR3/HSIC interface and avoid floating pad
- Process-only impedance compensation using 5-bit binary coded schema separately for pullup p<1:5> and pulldown n<1:5> impedance

Programmable bits for impedance and SR control are provided when the I/Os are set to operate in driver mode (outputs).

The bits I[2:0] are used to program the desired impedance value of the driver. Table 18-73 describes the driver impedance settings.

Table 18-73. Driver Impedance Output Settings

I[2]	I[1]	I[0]	Drive Setting Name
0	0	0	Drv5
0	0	1	Drv6
0	1	0	Drv7
0	1	1	Drv8
1	0	0	Drv9
1	0	1	Drv10
1	1	0	Drv11
1	1	1	Drv12

NOTE:

- Table 18-73 is valid for pullup and pulldown outputs.
- For all electrical characteristics please see the Electrical Characteristics / DC Electrical Characteristics section of the device Data Manual.

To achieve optimal noise/speed trade off, the slew rate of the output signal can also be programmed using the slew rate (turn-on time) control bits SR[2:0]. The SR settings in Table 18-74 do not affect the driver DC drive strength. They control only the driver turn-on time.

Table 18-74. Driver Slew Rate Settings

SR[2]	SR[1]	SR[0]	Turn-On Time Level	Note
0	0	0	fastest	All 8 values are valid.
...	...	...		
...	...	...		
1	1	1	slowest	

Weak pullup or pulldown or a keeper on pad is enabled through the WD[0] and WD[1] bits. The weak pullup or pulldown option is used to define the pad state (high or low) when no signal is driving the pad. The weak keeper option is used to maintain the previous output value when nothing is driving the pad. Table 18-75 describes the WD controls.

NOTE: The WD[1:0] bit field controls play the role of the PULLTYPESELECT and PULLUDENABLE bits within the standard pad configuration registers, and provides the keeper function to the I/Os with the state WD = 0b11.

Similar to the ddr1_x, ddr2_x and ddr3_x pads, the usbb1_hsic_data/strobe, usbb2_hsic_data/strobe, and usbb3_hsic_data/strobe pads also have weak driver software controls. They are in the CONTROL_SMART3IO_PADCONF_1 register.

Table 18-75. Weak Driver PUPD/Latch Mode

WD[1]	WD[0]	Operation
0	0	Pull logic disabled
0	1	Weak pullup enabled
1	0	Weak pulldown enabled
1	1	Weak keeper enabled

NOTE: To avoid unnecessary power consumption, software must overwrite the Weak Driver (WD) reset values by setting them to 0x0.

NOTE: There is no software control (INPUTENABLE) for the input buffer of the high-speed unterminated logic I/Os associated with the ddr, usbb_hsic_data/strobe pads. If the CMOS buffer is enabled, it is always bidirectional (that is, the input buffer is always enabled).

18.4.12.7.3 SMART I/O Buffers with Slew Rate and Drive Strength Control Settings

Most of the device pads are associated with SMART I/O cells. The SMART I/O cell includes an output buffer which has programmable slew rate and drive strength controls (SC and DS bits, respectively).

There are three programmable slew rate levels for these I/Os. Based on the required AC performance, the slew rate selection is done for a given group of I/Os through the CONTROL_SMART2IO_PADCONF_0, CONTROL_SMART2IO_PADCONF_1 and CONTROL_SMART2IO_PADCONF_2 registers in the CORE power domain and the CONTROL_SMART1NOPMIO_PADCONF_1 registers located in the WKUP power domain. For the different groups of pads and corresponding signal integrity control registers, see Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Table 18-76 provides the slew rate control settings that are selectable through the SC[1:0] bit field.

Table 18-76. Slew Rate Control Settings

SC1 Bit	SC0 Bit	Slew Rate Control Mode
0	0	slow
0	1	medium
1	0	high
1	1	Not applicable

The SMART I/O output buffer has four programmable drive strength levels. The drive strength selection is done for a given group of I/Os through the CONTROL_SMART1IO_PADCONF_0, CONTROL_SMART1IO_PADCONF_1, and CONTROL_SMART1IO_PADCONF_2 registers in the CORE power domain, and the CONTROL_SMART1NOPMIO_PADCONF_0 registers in the WKUP power domain. For the different groups of pads and corresponding signal integrity control registers, see Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Table 18-77 provides the drive strength control settings selectable through the DS[1:0] bit fields.

Table 18-77. Drive Strength Control Settings

DS1	DS0	Drive Strength Control Mode
0	0	Maximum output buffer resistance
0	1	
1	0	
1	1	Minimum output buffer resistance

NOTE: For all electrical characteristics please see the device Data Manual.

18.4.12.7.4 I2Cx I/Os Group PULLUPRESX Controls and Load Range Settings

The I2Cx buffer contains internal pullup resistors for FS and HS modes. The I2Cx_LB (where x = 1 to 5) bit fields in the CONTROL_SMART3IO_PADCONF_0 register are used to select an appropriate pullup resistor for a given load range. These pullup resistors can be enabled or disabled through the I2Cx_SDA_PULLUPRESx and I2Cx_SCL_PULLUPRESx (where x = 1 to 5) bits, which reside in the CONTROL_I2C_0 register. In the same register, the active high I2Cx_SDA_GLFENB and I2Cx_SCL_GLFENB bits are implemented for I^2C receivers to enable glitch-free operation.

The CONTROL_SMART1NOPMIO_PADCONF_0[7:6] SR_LB bit field is used to select an appropriate pullup resistor value for SR PMIC I2C. The SR PMIC associated internal pullup resistors can be enabled and disabled through the CONTROL_I2C_2[30] SR_PMIC_SDA_PULLUPRESX and CONTROL_I2C_2[28] SR_PMIC_SCL_PULLUPRESX bits. Setting the CONTROL_I2C_2[31] SR_PMIC_SDA_GLFENB and CONTROL_I2C_2[29] SR_PMIC_SCL_GLFENB bits enables glitch-free operation.

NOTE: The pullup-versus-load settings applicable to I2Cx FS mode also apply to I2Cx standard speed mode.

NOTE: PULLUDENABLE must be set to 0b0 in the I2Cx pad configuration registers (disable internal weak pullup resistors on I2Cx pads) to ensure the full I/O cell performance capabilities of the I^2C.

NOTE: For all electrical characteristics and different modes settings, see the device Data Manual.

18.4.12.7.5 Device Interfaces Signal Group Controls Mapping

Table 18-78 through Table 18-96 describe the mapping of the signal integrity control bit fields in the different signal integrity control registers described in Table 18-72.

NOTE: The same I/O cell and I/O cell controls assigned to a pad signal available when MUXMODE = 0 are shared between signals available on the same pad when MUXMODE is selected different than 0. For more information, see Section 18.4.8.3, *Pad Multiplexing Register Fields*.

18.4.12.8 Dual Voltage-Supplied Peripheral Controls

Some of the peripheral I/Os have the option to be supplied with a 1.2-V or 1.8-V power supply (VDDS through device external pads). The power supply level to the dual-voltage I/Os of different peripherals is configurable through bit fields in the CONTROL_PADCONF_MODE register in the CORE domain (Camera TCTRL i/f, GPIO, I2C2, I2C3, I2C4, I2C5, Timers, ABE modules i/f, SDIO/MMC2, SDIO/MMC3, MCSPI1, MCSPI2, DSI, UART1, UART2, UART3, UART5, UART6, HSI1, HSI2, HDMI) and the CONTROL_WKUP_PADCONF_MODE register in the WKUP domain (I2C1 i/f, Power management IC i/f, system i/f). One control bit in these registers is dedicated to set dual-voltage per group of pads.

Table 18-97 describes dual-voltage controls versus the mapping of different pads.

Table 18-97. Dual-Voltage Peripheral Control Bits vs Pad Mapping

Dual-Voltage VDDS = 1.2-V/1.8-V Control Bits	Pads With Dual-Voltage Settings

18.5 Control Module Programming Guide

18.5.1 Control Module Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the control module.

18.5.1.1 Global Initialization

18.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the control module is used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the control module. For more information, see *Section 18.2, Control Module Environment*, and Section 18.3, *Control Module Integration*.

Table 18-98. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The three clocks coming from the PRCM module (L4CFG_L4_GICLK, WKUPAON_GICLK, and L3INSTR_TS_GCLK) are not software-controlled by PRCM. For more information about the three clocks, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 interconnect	For information about the L4_CFG interconnect configuration, see Section 14.3, *L4 Interconnects*.

18.5.1.1.2 Control Module Global Initialization

18.5.1.1.2.1 Software Reset

The control module is not sensitive to a software reset.

18.5.1.2 Operational Modes Configuration

18.5.1.2.1 Extended-Drain I/Os and PBIAS Cells Programming Guide

This section describes the programming flow from 3.0 V to 1.8 V, and vice versa, when operating with the extended-drain I/Os and PBIAS cells. Figure 18-20 shows the interrup-method configuration of the PBIAS cell for operation in different modes. Table 18-99 lists the registration settings for configuring the SDCARD_PBIAS cell and SDCARD extended-drain I/O cell.

Figure 18-20. Configuring PBIAS Cell to Operate in Different Modes, Interrupt Method

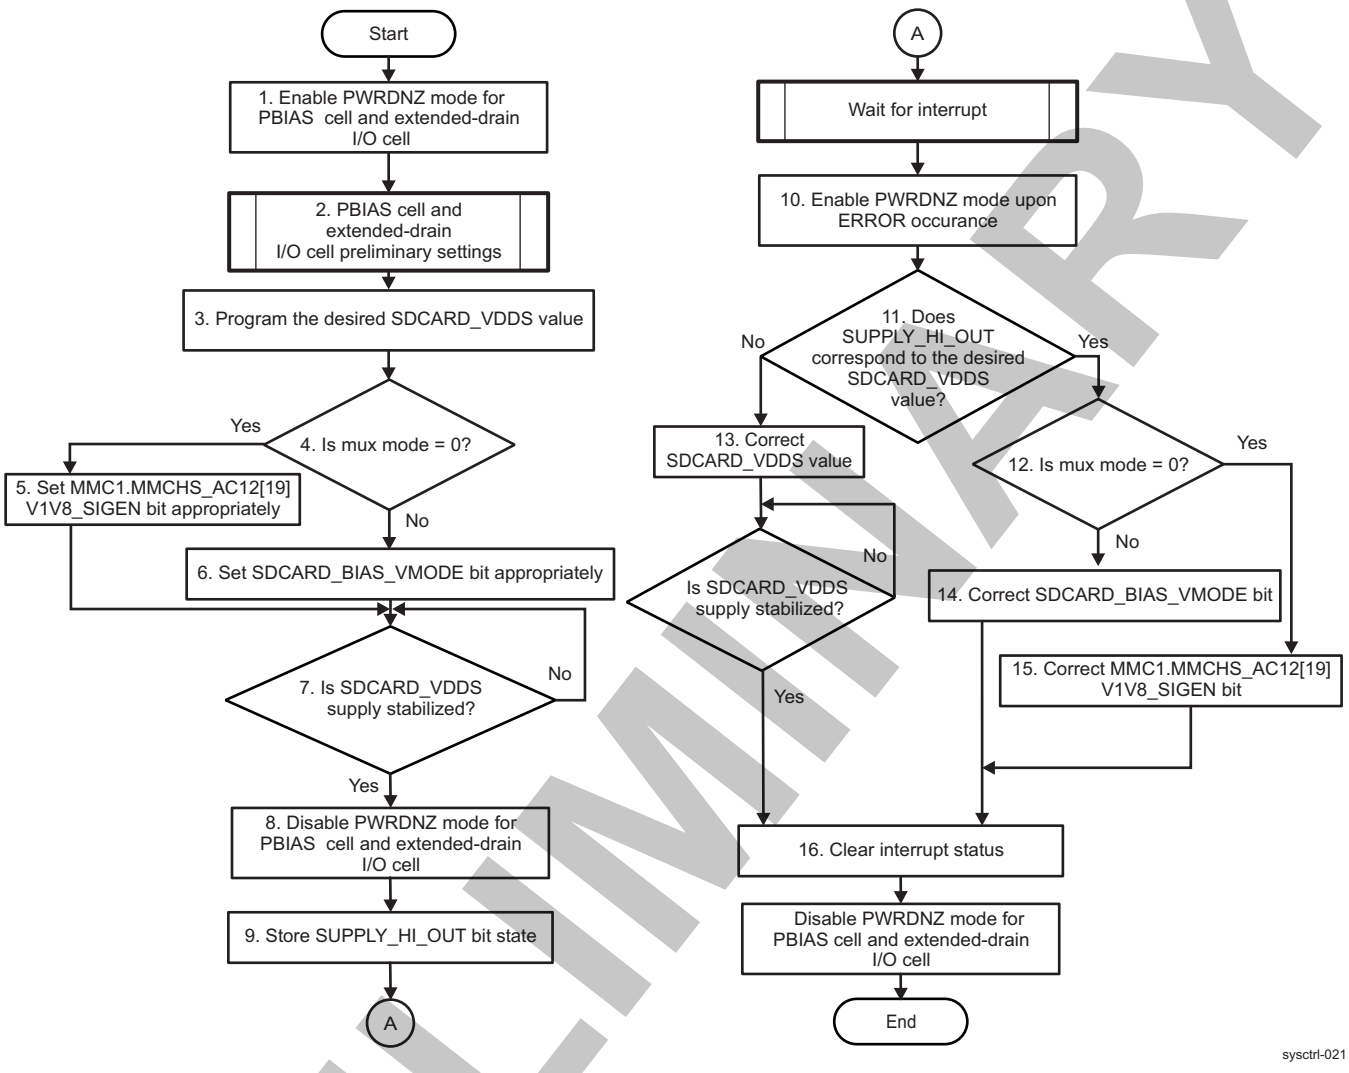

Table 18-99. Register Settings for Configuring the SDCARD_PBIAS Cell and SDCARD Extended-Drain I/O Cell

Procedure Name	Description	Register Settings
1. Enable PWRDNZ mode for PBIAS cell and extended-drain I/O cell.	Software must keep SDCARD_PBIAS cell and SDCARD extended-drain I/O cell PWRDNZ signals low whenever SDCARD_VDDS ramps up/down or changes. This is for cell protection purposes.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b0. 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b0.
2. Preliminary SDCARD_PBIAS cell and SDCARD extended-drain I/O cell settings.	Enable SDCARD_PBIAS cell output and SDCARD_PBIAS error associated interrupt. Select desired I/Os within the SDCARD I/O cell and set the corresponding pad configuration fields appropriately.	1. Set CONTROL_PBIAS[25]SDCARD_BIAS_HIZ_MODE = 0b0. 2. For more information about setting MPU_IRQ_75 line-associated interrupt request PBIAS_IRQ, see Chapter 17, *Interrupt Controllers*. 3. For I/O multiplexing and pad configuration settings, see Section 18.5.1.2.3, *Pad Configuration Programming Points*.
3. Program the desired SDCARD_VDDS voltage for MMC/SD/SDIO1 I/Os.	Program external power supply IC to generate appropriate SDCARD_VDDS voltage (3.0 V or 1.8 V).	For more information about I^2C interface operation, see Section 23.1.1, *HS I2C Overview*.

Table 18-99. Register Settings for Configuring the SDCARD_PBIAS Cell and SDCARD Extended-Drain I/O Cell (continued)

Procedure Name	Description	Register Settings
4. Check whether MUXMODE is set to 0 or not.	When mux mode is set to 0 sdcard_i signals are muxed on the pads and SDCARD_BIAS_VMODE does not apply. In this case MMC1.MMCHS_AC12[19] V1V8_SIGEN applies.	CONTROL_CORE_PAD0_X_PAD1_Y.MUXMODE = 0x-
5. Set V1V8_SIGEN bit appropriately.	PBIAS voltage generation is based on the value of V1V8_SIGEN, set according to externally applied SDCARD_VDDS voltage.	MMC1.MMCHS_AC12[19] V1V8_SIGEN = 0b- (1)
6. Set SDCARD_BIAS_VMODE bit appropriately.	PBIAS voltage generation is based on the value of SDCARD_BIAS_VMODE, set according to externally applied SDCARD_VDDS voltage.	Set CONTROL_PBIAS[21] SDCARD_BIAS_VMODE = 0b- (2).
7. Check whether the SDCARD_VDDS supply is stabilized.	Check the state of the externally generated SDCARD_VDDS voltage, which is provided through communication between the device and external power supply device over the I^2C interface.	For more information about I^2C interface settings, see Section 23.1.1, *HS I2C Overview*.
8. Disable PWRDNZ mode for SDCARD_PBIAS cell and extended-drain I/O cell	This starts the SDCARD_PBIAS cell work to generate the PBIAS voltage.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b1. 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b1.
9. Store the state of the SUPPLY_HI_OUT bit.	Done as a preliminary step for error-handling analysis. (Whenever PWRDNZ = 0b0, SUPPLY_HI_OUT is unconditionally set to 0b0.)	Store the CONTROL_PBIAS[24] SDCARD_BIAS_SUPPLY_HI_OUT bit in memory.
10.Enable PWRDNZ mode upon error occurrence.	It is recommended that all the I/Os are powered down (PWRDNZ = 0) as soon as VMODE_ERROR is high.	1. Set CONTROL_PBIAS[26] SDCARD_IO_PWRDNZ = 0b0 2. Set CONTROL_PBIAS[27] SDCARD_BIAS_PWRDNZ = 0b0.
11. Does SUPPLY_HI_OUT correspond to the desired SDCARD_VDDS?	Test whether the error comes from incorrectly set value of SDCARD_VDDS or incorrectly set VMODE bit.	Check the SUPPLY_HI_OUT bit stored in memory.
12. Check whether MUXMODE is set to 0 or not.	When muxmode is set to 0, sdcard_i signals are muxed on the pads and SDCARD_BIAS_VMODE does not apply. In this case MMC1.MMCHS_AC12[19] V1V8_SIGEN applies.	CONTROL_CORE_PAD0_X_PAD1_Y.MUXMODE = 0x-
13. Correct SDCARD_VDDS value.	If SUPPLY_HI_OUT is different from expected, correct and set SDCARD_VDDS value over I^2C again.	For more information about I^2C interface settings, see Section 23.1.1, *HS I2C Overview*.
14. Correct SDCARD_BIAS_VMODE bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDCARD_VDDS, correct the value of the SDCARD_BIAS_VMODE bit.	Modify the value of the CONTROL_PBIAS[21] SDCARD_BIAS_VMODE bit.
15. Correct V1V8_SIGEN bit.	If the level of SUPPLY_HI_OUT corresponds to the desired value of SDCARD_VDDS, correct the value of the V1V8_SIGEN bit.	Modify the value of the MMC1.MMCHS_AC12[19] V1V8_SIGEN bit.
16. Clear interrupt status.	Clear the MPU_IRQ_75 interrupt status flag.	For more information about setting the MPU_IRQ_75 line associated interrupt request PBIAS_IRQ, see Section 17.1, *Interrupt Controllers Overview*.

(1) Must be set low when the external SDCARD_VDDS source is programmed to be 3.0 V, or set to high when the external SDCARD_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

(2) Must be set high when external SDCARD_VDDS source is programmed to be 3.0 V, or low when the external SDCARD_VDDS source is programmed to be 1.8 V. The reset default value corresponds to 3.0 V.

18.5.1.2.2 Hardware Observability Settings

This section describes the procedures to control the hardware observability features of the device. To configure these features, the programmer must perform the steps listed in Table 18-100.

Table 18-100. Configure Hardware Observability Features

	Step	Register/Bit Field/Programming Model	Value
1.	Select the hwobs(0)/hwobs(1)/hwobs(2) signal frequency divider value (applies only to po_hw_dbg0, po_hw_dbg1, and po_hw_dbg2 bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[7:3] HWOBS_CLKDIV_SEL CONTROL_HWOBS_CONTROL[13:9] HWOBS_CLKDIV_SEL_1 CONTROL_HWOBS_CONTROL[18:14] HWOBS_CLKDIV_SEL_2	0x- (1)
2.	Enable/disable gating of hwobs and alternatively set all hwobs ports to 0 or 1.	.CONTROL_HWOBS_CONTROL[2] HWOBS_ALL_ZERO_MODE CONTROL_HWOBS_CONTROL[1] HWOBS_ALL_ONE_MODE	0x- (2)
3.	Enable/disable hwobs port gating only for signals coming from IPs identified in the MACRO group (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE	0x- (3)
4.	Associate a certain hwobs channel to the CORE or WKUP power domain.	Configure each bit from the CONTROL_DEBOBS_FINAL_MUX_SEL[31:0] SELECT bit field appropriately for its corresponding hw_dbg channel.	0x-

10.	Choose to associate a certain clockout signal to a given clockview channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_CLK_SEL0[3:0] MULT through CONTROL_CONF_CLK_SEL2[3:0] MULT	0x-
11.	Choose to associate an sDMA signal to a given sDMA view channel (applies only to po_hw_dbg bus signals propagated in the CORE power domain).	CONTROL_CONF_SDMA_REQ_SEL0[6:0] MULT through CONTROL_CONF_SDMA_REQ_SEL3[6:0] MULT	0x-

(1) To configure the hwobs(0) channel to operate normally, the value of the HWOBS_CLKDIV_SEL, HWOBS_CLKDIV_SEL_1, or HWOBS_CLKDIV_SEL_2 bit must be set different than 0.

(2) Set both bits to 0 to enable hardware observability. Set only one bit to 1 to gate hwobs ports according to the output state required.

(3) The following subsystems belong to this group: MPU subsystem, IVA and ABE.

Table 18-100. Configure Hardware Observability Features (continued)

	Step	Register/Bit Field/Programming Model	Value
12.	Set the appropriate pad configuration bit fields to associate the hw_dbgn pad function to output pins and configure additional output pad features.	For more information, see Section 18.4.11, *Hardware Observability*, and Section 18.4.8, *Pad Functional Multiplexing and Configuration*.	For more information, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*.

For more information about the different functions and registers associated with the hardware observability features, see Section 18.4.11, *Hardware Observability*.

18.5.1.2.3 Pad Configuration Programming Points

This section uses an example to describe the configurations of pads necessary for working in active mode.

Perform the follwing steps to configure the pad:

1. Identify interface signals required from the target application.

   Example: Configure the UART3 interface with the required signals: uart3_rx_irrx, uart3_tx_irtx, uart3_cts_rctx, and uart3_rts_irsd.

2. Choose the pads used for those signals. Some signals may be available on several pads and/or may be multiplexed with other signals needed for another application. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.

   Example: Unlike the uart3_rx_irrx and uart3_tx_irtx signals, each of which is available on three pads, the uart3_cts_rctx and uart3_rts_irsd signals are available only on one pad each (MUXMODE = 0x0).

   However, on pad uart3_rx_irrx, the uart3_rx_irrx signal is multiplexed with the sdio4_cmd signal (MUXMODE = 0x4), and on pad uart3_tx_irtx, the uart3_tx_irtx signal is multiplexed with the sdio4_clk signal. The uart3_rx_irrx and uart3_tx_irtx pads are the only pads on which the sdio4_cmd and sdio4_clk signals are available in the device, respectively. Assuming that the SDIO4 interface is required in the system along with UART3 interface, the only way is to choose to multiplex uart3_tx_irtx and uart3_rx_irrx on other pads.

   To preserve SDIO4 capability, the uart3_rx_irrx and uart3_tx_irtx signals can be remapped on alternative pads of the device (for example, the rfbi_data1 and rfbi_data2 pads [with MUXMODE set to 0x4 in the corresponding padconfiguration registers]).

3. Identify the signal integrity parameter settings (drive strength, impedance, slew rate, pullup and pulldown strength, and so forth) necessary for the pads associated with I/O cells, listed in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*).

   For the register settings of the signal integrity parameters for the uart3_cts_rctx and uart3_rts_irsd pads, see Table 18-85. According to the table, the assigned to uart3_cts_rctx and uart3_rts_irsd pads, software signal parameter controls are:

- CONTROL_SMART1IO_PADCONF_1[7:6] UART3_PART1_DS
- CONTROL_SMART2IO_PADCONF_1[5:4] UART3_PART1_SC

   According to Table 18-85, for the sdio4_clk and sdio4_cmd (available on pads uart3_tx_irtx and uart3_rx_irrx when corresponding padconfiguration MUXMODE bit field is set to 0x4), the following bit fields should be set to tune signal performance:

  - CONTROL_SMART1IO_PADCONF_1[5:4] UART3_PART2_DS
  - CONTROL_SMART2IO_PADCONF_2[31:30] UART3_PART2_SC

   Assuming the uart3_rx_irrx and uart3_tx_irtx signals are mapped on the rfbi_data1 and rfbi_data2 pads (MUXMODE set to 0x4), the following signal integrity parameter control bit fields must be set appropriately:

- CONTROL_SMART1IO_PADCONF_2[19:18] DSS_PART2_DS

- CONTROL_SMART2IO_PADCONF_0[3:2] DSS_PART2_SC.

NOTE: To identify the signal-associated I/O cell signal parameter settings in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, the user must search for the device pad name on which the desired signal is muxed, because the I/O cell settings are designated and listed on a per-pad basis. This means that a signal name does not appear (unless MUXMODE = 0x0) in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, but only the name of the pad on which the signal is muxed. Pads that do not have software I/O cell signal integrity parameter controls are not listed in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.

Assume the user application configures the kpd_row6 and kpd_row7 signals on the c2c_datain6 and c2c_datain7 pads (MUXMODE = 0x3). The I/O cell signal parameter control bit fields CONTROL_SMART1IO_PADCONF_0[19:18] C2C_PART1_DS and CONTROL_SMART2IO_PADCONF_0[19:18] C2C_PART1_SC listed in Table 18-79 also apply to the kpd_row6 and kpd_row7 signals.

For recommendations about the mentioned pad group signal integrity parameter settings, see the device data manual.

4. Identify and program the peripheral dual-voltage settings, if they apply to the chosen pads. Table 18-97 lists the corresponding control bits of the pads in the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE and CTRL_MODULE_WKUP_PAD.CONTROL_WKUP_PADCONF_MODE registers.

The identification of the I/O dual-voltage domains control bits for a signal must be made on a per-pad basis.

The I/O supply voltage (1.2 V/1.8 V) for pads uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx (signal sdio4_cmd), and uart3_tx_irtx (signal sdio4_clk) is configured by setting the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[23] VDDS_21_MODE bit. Because the uart3_rx_irrx and uart3_tx_irtx signals are multiplexed on the rfbi_data1 and rfbi_data2 pads in MUXMODE = 0x4, the dual-voltage control for these uart3 signals is the dual-voltage control corresponding to the pads – CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[18] VDDS_9_MODE.

For more information about pad performance dependencies from I/O dual-voltage supply settings, see the device data manual.

5. Identify the pad configuration registers associated with the pads to be used in the application. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.

Example: Under the previous hypothesis, the pad configuration registers to program are:

- uart3_cts_rctx (MUXMODE = 0x0): CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[31:16]
- uart3_rts_irsd (MUXMODE = 0x0): CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[15:0]
- uart3_rx_irrx (MUXMODE = 0x4): CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[15:0]
- uart3_tx_irtx (MUXMODE = 0x4): CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2 [31:16]
- sdio4_clk (MUXMODE = 0x4): CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[31:16]
- sdio4_cmd (MUXMODE = 0x4): CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[15:0]

Table 18-101. Active Pads Configuration Points

Step	Register/Bit Field/Programming Model	Value
1. Identify the interface signals and map them to the appropriate pads according to the application requirements and the device-specific pad I/O muxing capabilities. See Section 18.4.8.3, *Pad Multiplexing Register Fields*.	Define the list of I/O signal names: uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx, uart3_tx_irtx, sdio4_clk and sdio4_cmd. Define the list of corresponding pads used by application: uart3_cts_rctx, uart3_rts_irsd, rfbi_data1, rfbi_data2, uart3_tx_irtx, and uart3_rx_irrx, respectively	–
2. Identify the corresponding I/O cell signal integrity parameter controls for the pad (on a per-pad basis). See Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*.	(uart3_cts_rctx, uart3_rts_irsd pads) CONTROL_SMART1IO_PADCONF_1[7:6] UART3_PART1_DS CONTROL_SMART2IO_PADCONF_1[5:4] UART3_PART1_SC (uart3_rx_irrx, uart3_tx_irtx pads) CONTROL_SMART1IO_PADCONF_1[5:4] UART3_PART2_DS CONTROL_SMART2IO_PADCONF_2[31:30] UART3_PART2_SC (rfbi_data1, rfbi_data2 pads) CONTROL_SMART1IO_PADCONF_2[19:18] DSS_PART2_DS CONTROL_SMART2IO_PADCONF_0[3:2] DSS_PART2_SC	For more information about the recommended I/O settings, see the device data manual
3. Determine whether the pad is associated with a peripheral dual-voltage domain (see the device data manual). Identify its corresponding 1.2-V/1.8-V dual-voltage control bit in the CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE or CTRL_MODULE_WKUP_PAD.CONTROL_PADCONF_MODE registers. For more information, see Table 18-97.	(uart3_cts_rctx, uart3_rts_irsd, uart3_rx_irrx, uart3_tx_irtx) CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[23] VDDS_21_MODE (rfbi_data1, rfbi_data2) CTRL_MODULE_CORE_PAD.CONTROL_PADCONF_MODE[18] VDDS_9_MODE	For more information about the I/O performance dependency on dual-voltage settings, see the device data manual.
4. Configure MUXMODE field in pad configuration registers associated with the pads used.	(signal uart3_cts_rctx) CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[18:16] UART3_CTS_RCTX_MUXMODE	0x0
	(signal uart3_rts_irsd) CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[2:0] UART3_RTS_IRSD_MUXMODE	0x0
	(signal sdio4_clk) CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[18:16] UART3_TX_IRTX_MUXMODE	0x4
	(signal sdio4_cmd) CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[2:0] UART3_RX_IRRX_MUXMODE	0x4
	(signal uart3_rx_irrx) CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[2:0] RFBI_DATA1_MUXMODE	0x4
	(signal uart3_tx_irtx) CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[18:16] RFBI_DATA2_MUXMODE	0x4

Table 18-101. Active Pads Configuration Points (continued)

Step	Register/Bit Field/Programming Model	Value
5. Select the type of the internal pullup/down resistor.(1)	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[20] UART3_CTS_RCTX_PULLTYPESELECT	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[4] UART3_RTS_IRSD_ PULLTYPESELECT	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[20] UART3_TX_IRTX_ PULLTYPESELECT	0x-
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[4] UART3_RX_IRRX_ PULLTYPESELECT	0x-
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[4] RFBI_DATA1_PULLTYPESELECT	0x-
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[20] RFBI_DATA2_PULLTYPESELECT	0x-
6. Enable/disable pullup/down feature of the pad. (2)	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[19] UART3_CTS_RCTX_PULLUDENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[3] UART3_RTS_IRSD_PULLUDENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[19] UART3_TX_IRTX_PULLUDENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[3] UART3_RX_IRRX_PULLUDENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[3] RFBI_DATA1_PULLUDENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[19] RFBI_DATA2_PULLUDENABLE	0x-
7. Set the direction of the pin signal.(2)	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[24] UART3_CTS_RCTX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[8] UART3_RTS_IRSD_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[24] UART3_TX_IRTX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[8] UART3_RX_IRRX_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[8] RFBI_DATA1_INPUTENABLE	0x-
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[24] RFBI_DATA2_INPUTENABLE	0x-
8. Glitch filter enable/disable	The GLITCHGOBBLER bit setting applies to several device pads only (bit is available in several padconfiguration registers, at positions [22] or [6]). It enables/disables I/O cell to filter glitches from outside. The example pads listed in this table do NOT have such setting.	0x-
9. Enable/disable the I/O cell power	CONTROL_CORE_PAD0_UART6_RTS_PAD1_UART3_CTS_RCTX[21] UART3_CTS_RCTX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[5] UART3_RTS_IRSD_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RTS_IRSD_PAD1_UART3_TX_IRTX[21] UART3_TX_IRTX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_UART3_RX_IRRX_PAD1_USBB3_HSIC_STROBE[5] UART3_RX_IRRX_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_RFBI_DATA1_PAD1_RFBI_DATA0[5] RFBI_DATA1_PWRDOWN	0x-(3)
	CONTROL_CORE_PAD0_RFBI_DATA3_PAD1_RFBI_DATA2[21] RFBI_DATA2_PWRDOWN	0x-(3)

(1) It is recommended to use internal pullup/down resistor if pad is used as input and external pullup/down is not used.
(2) If the pad is configured in output mode, the hardware automatically disables the internal weak pullup/down resistors.
(3) Default (power-on reset) value is 0, which corresponds to I/O cell powered on.

NOTE: The order for setting the previous pad configuration bits is not important.

NOTE: If a device pad is left unconnected but power is supplied to the I/O cell, it is recommended to keep the corresponding pad configuration bit, CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE, set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

NOTE: I/Os are non-failsafe, which means that voltage must never be applied at a pad before the internal I/O supply voltage VDDS is powered.

Description	PHY register for EMIF1 Access conditions. Read: unrestricted, Write: unrestricted		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																EMIF1_REG_PHY_NUM_OF_SAMPLES		EMIF1_REG_PHY_SEL_LOGIC	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT			RESERVED	EMIF1_SDRAM_DISABLE_RESET	EMIF1_PHY_RD_LOCAL_ODT		RESERVED	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF1_EN_SLICE_2	EMIF1_EN_SLICE_1	EMIF1_EN_SLICE_0	

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15:14	EMIF1_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples) and for incremental leveling is 0x0 (4 samples). 0x0: 4 samples. 0x1: 8 samples. 0x2: 16 samples. 0x3: 128 samples.	RW	0x2
13	EMIF1_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0: Algorithm 1 is used. 0x1: Algorithm 2 is used.	RW	0
12	EMIF1_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit. This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0
11:9	EMIF1_REG_PHY_OUTPUT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through CONTROL_EMIF1_SDRAM_CONFIG_EXT_1 register. 0x0: selects phy_reg_rdlvl_start_ratio[7:0] 0x1: selects phy_reg_rdlvl_start_ratio[15:8] 0x2: selects phy_reg_rdlvl_end_ratio[7:0] 0x3: selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0
8	RESERVED	Reserved	R	1
7	EMIF1_SDRAM_DISABLE_RESET	ddr3ch1_nreset signal disable. Keep this bit set to 0x1 during normal operations and to 0x0 at boot time and when a memory reset is necessary. 0x0: ddr3ch1_nreset is enabled. It can be asserted by EMIF. 0x1: ddr3ch1_nreset is disabled. It is forbidden to EMIF to assert it.	RW	0

Bits	Field Name	Description	Type	Reset
6:5	EMIF1_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0: ODT disabled. 0x1: 60 Ohms. 0x2: 80 Ohms. 0x3: 120 Ohms.	RW	0x0
4	RESERVED	Reserved	R	0
3	EMIF1_DFI_CLOCK_PHASE_CTRL	EMIF_CORE1 clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0
2	EMIF1_EN_SLICE_2	Enable command PHY 2. 0x1 is the mandatory setting if LPDDR2 is used. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	1
1	EMIF1_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. When using LPDDR2 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	1
0	EMIF1_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. When using LPDDR2 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used. EMIF1_EN_SLICE_0 and EMIF1_EN_SLICE_1 have to be programmed with the same value.	RW	1

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:14	EMIF2_REG_PHY_NUM_OF_SAMPLES	Controls the number of DQ samples required for read leveling. The recommended setting for full leveling is 0x3 (128 samples) and for incremental leveling is 0x0 (4 samples). 0x0: 4 samples. 0x1: 8 samples. 0x2: 16 samples. 0x3: 128 samples.	RW	0x2
13	EMIF2_REG_PHY_SEL_LOGIC	Selects an algorithm for read leveling. The use of algorithm 1 (set by default) is recommended. 0x0: Algorithm 1 is used. 0x1: Algorithm 2 is used.	RW	0
12	EMIF2_REG_PHY_ALL_DQ_MPR_RD_RESP	Analysis method of DQ bits during read leveling. 0x0: if the DRAM provides a read response on only one DQ bit. This is the default setting and works with all memory types (memories send responses on all DQ bits or on a single DQ bit). 0x1: if the DRAM provides a read response on all DQ bits.	RW	0
11:9	EMIF2_REG_PHY_OUTPUT_STATUS_SELECT	Selects the status to be observed on the outputs of the DDR PHYs through CONTROL_EMIF2_SDRAM_CONFIG_EXT_2 register. 0x0: selects phy_reg_rdlvl_start_ratio[7:0] 0x1: selects phy_reg_rdlvl_start_ratio[15:8] 0x2: selects phy_reg_rdlvl_end_ratio[7:0] 0x3: selects phy_reg_rdlvl_end_ratio[15:8]	RW	0x0
8	RESERVED	Reserved	R	1
7	EMIF2_SDRAM_DISABLE_RESET	ddr3ch2_nreset signal disable. Keep this bit set to 0x1 during normal operations and to 0x0 at boot time and when a memory reset is necessary. 0x0: ddr3ch2_nreset is enabled. It can be asserted by EMIF. 0x1: ddr3ch2_nreset is disabled. It is forbidden to EMIF to assert it.	RW	0
6:5	EMIF2_PHY_RD_LOCAL_ODT	Control of ODT (on – die termination) settings for the device DDR I/Os. ODT is enabled only during read operations when termination is required. 0x0: ODT disabled. 0x1: 60 Ohms. 0x2: 80 Ohms. 0x3: 120 Ohms.	RW	0x0
4	RESERVED	Reserved	R	0
3	EMIF2_DFI_CLOCK_PHASE_CTRL	EMIF_CORE2 clock phase control (shifting by 180°). For normal operation this bit must always be set to 0x0 (disabled).	RW	0
2	EMIF2_EN_SLICE_2	Enable command PHY 2. 0x1 is the mandatory setting if LPDDR2 is used. When using DDR3 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used.	RW	1
1	EMIF2_EN_SLICE_1	Enable command PHY 1. 0x1 is the mandatory setting if DDR3 is used. When using LPDDR2 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used. EMIF2_EN_SLICE_0 and EMIF2_EN_SLICE_1 have to be programmed with the same value.	RW	1

Bits	Field Name	Description	Type	Reset
0	EMIF2_EN_SLICE_0	Enable command PHY 0. 0x1 is the mandatory setting if DDR3 is used. When using LPDDR2 this bit can be set to 0x0 or 0x1. For lower power consumption 0x0 is used. EMIF2_EN_SLICE_0 and EMIF2_EN_SLICE_1 have to be programmed with the same value.	RW	1

Mailbox

This chapter describes the mailbox module in the device.

Topic **Page**

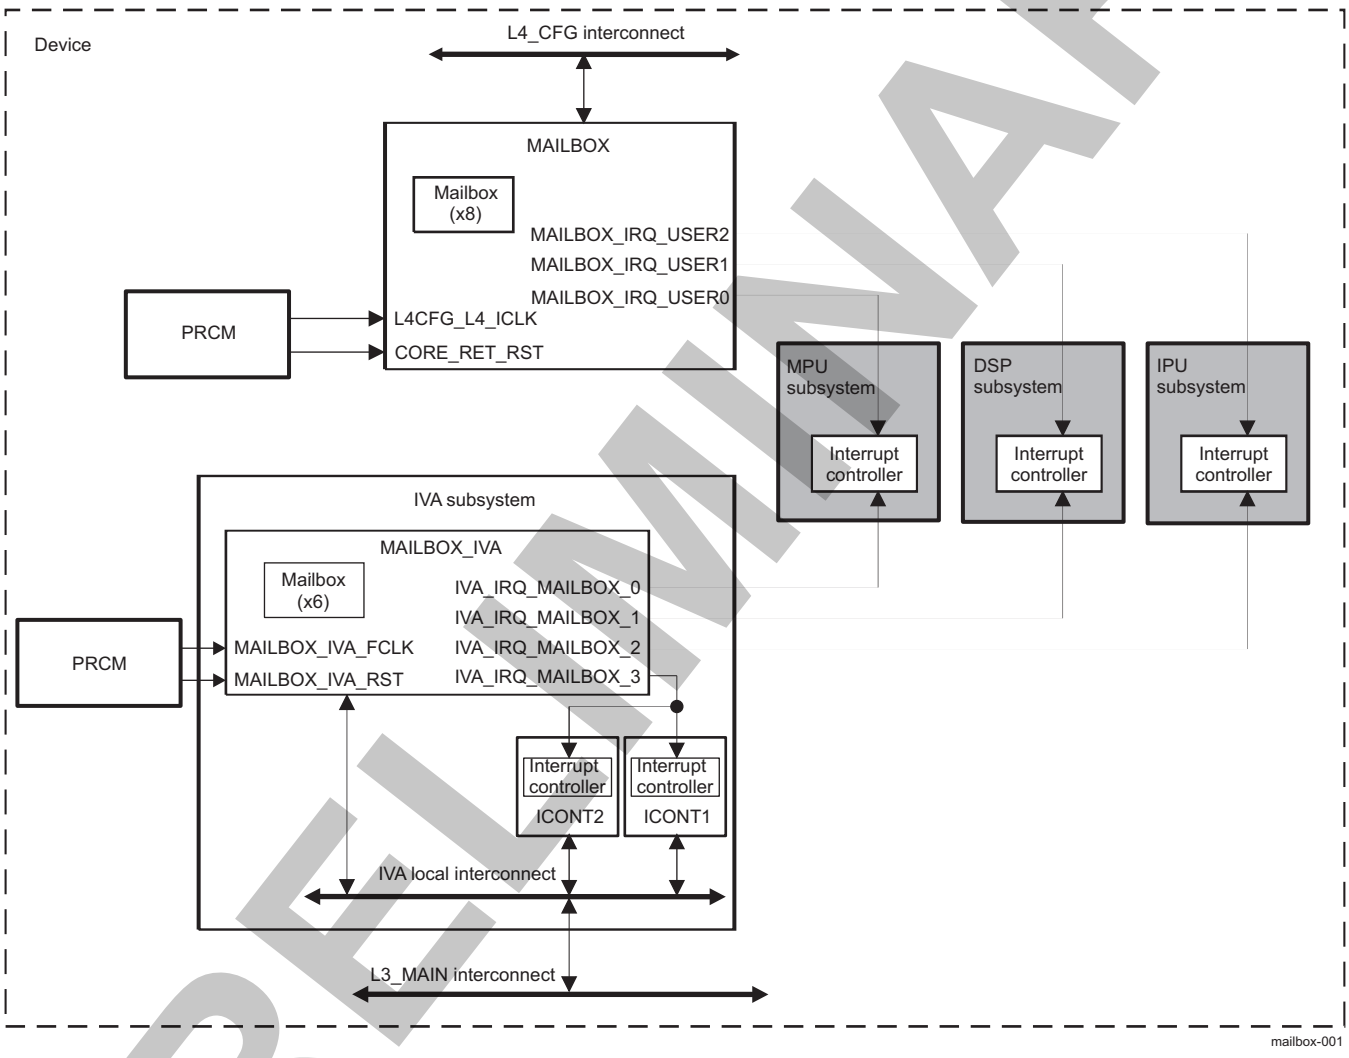
19.1 Mailbox Overview

Communication between the on-chip processors of the device uses a queued mailbox-interrupt mechanism.

The queued mailbox-interrupt mechanism allows the software to establish a communication channel between two processors through a set of registers and associated interrupt signals by sending and receiving messages (mailboxes).

Figure 19-1 shows an overview of the mailbox module.

Figure 19-1. Mailbox Overview



There are two mailbox module instances in the device:

- "System" mailbox (MAILBOX) - used for communication between microprocessor unit (MPU), digital signal processor (DSP), and image processing unit (IPU).
- IVA mailbox (MAILBOX_IVA) - used for communication between one internal to the IVA subsystem user (ICONT1, or ICONT2) and three external to the IVA subsystem users (MPU, DSP and IPU). This communication is insured through three pairs of mailboxes.

The mailbox module includes the following features:

- Three users for the MAILBOX instance (MPU, DSP, and IPU); four users for the MAILBOX_IVA instance (ICONT1/ICONT2, MPU, DSP and IPU)
- Eight mailbox message queues for the MAILBOX instance; six mailbox message queues for the MAILBOX_IVA instance

- Flexible assignment of receiver and sender for each mailbox through interrupt configuration
- Four interrupts (one per user) for the MAILBOX instance; four interrupts (one per user) for the MAILBOX_IVA instance
- 32-bit message width
- Four-message FIFO depth for each message queue
- Message reception and queue-not-full notification using interrupts
- Support of 16-/32-bit addressing scheme
- Power management support

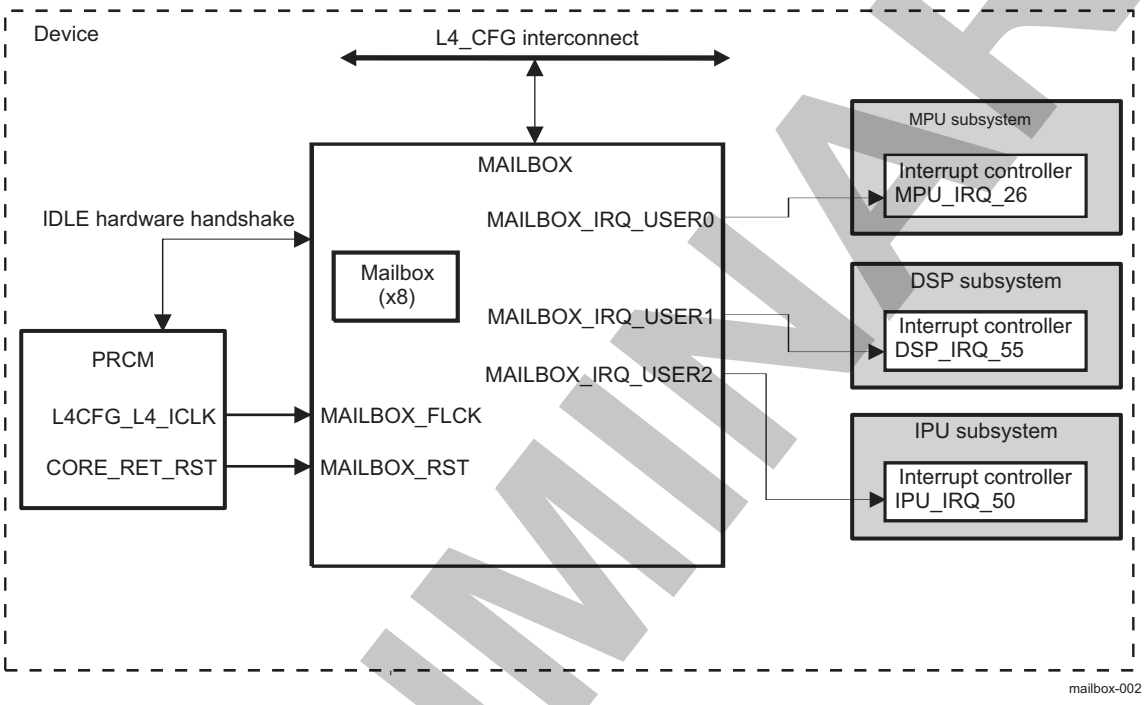
19.2 Mailbox Integration

This section describes the mailbox integration in the device, including information about clocks, resets, and hardware requests.

19.2.1 MAILBOX Integration

Figure 19-2 shows the MAILBOX integration.

Figure 19-2. MAILBOX Integration



NOTE: For more information about the IDLE hardware handshake, see Module-Level Clock Management, in Chapter 3, *Power, Reset, and Clock Management* chapter.

Table 19-1 through Table 19-3 summarize the MAILBOX integration in the device.

Table 19-1. Integration Attributes

Module Instance	Attributes

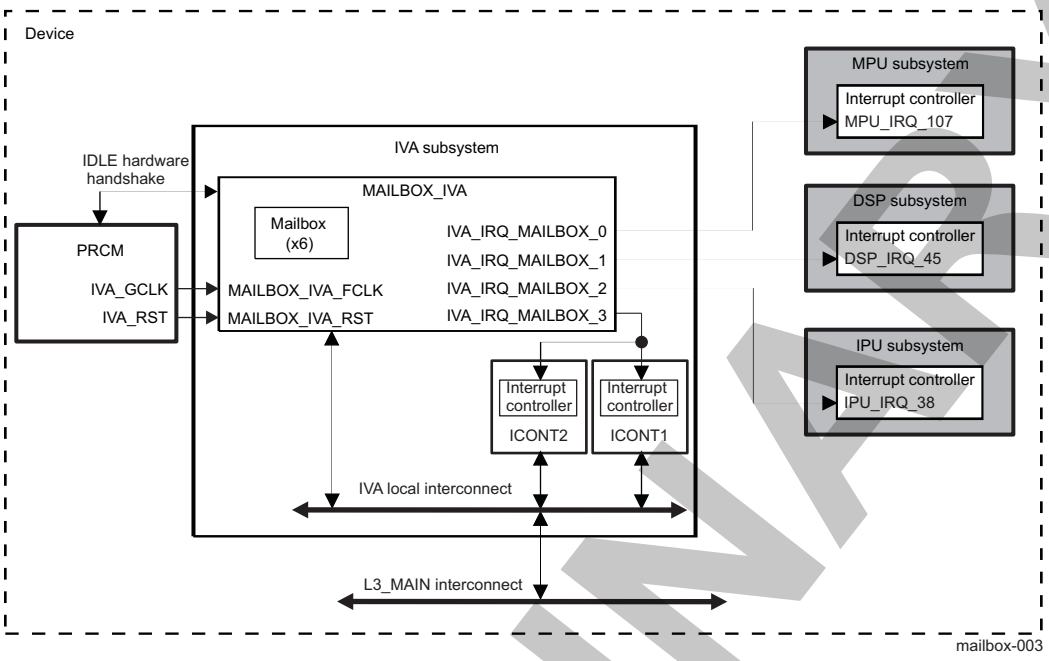
	MAILBOX_IRQ_USER1	DSP_IRQ_55	DSP	MAILBOX user 1 interrupt request. For information about DSP interrupt mapping, see Interrupt Requests, in *DSP Subsystem* chapter.
	MAILBOX_IRQ_USER2	IPU_IRQ_50	IPU	MAILBOX user 2 interrupt request. For information about IPU interrupt mapping, see Interrupt Requests to INTC_IPU, in *Interrupt Controllers* chapter.
No DMA Requests				

NOTE: For information about interrupt source description, see Section 19.3.4, *Interrupt Requests*.

19.2.2 MAILBOX_IVA Integration

Figure 19-3 shows the MAILBOX_IVA integration.

Figure 19-3. MAILBOX_IVA Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The two imaging controllers - ICONT1 and ICONT2, are mapped on a shared interrupt line. The choice between them is done by masking mailbox interrupt on ICONT1 or ICONT2.

Table 19-4 through Table 19-6 summarize the MAILBOX_IVA integration in the device.

	IVA_IRQ_MAILBOX_2	IPU_IRQ_38	IPU	MAILBOX_IVA user 2 interrupt request
	IVA_IRQ_MAILBOX_3	IRQ#11	ICONT1/ICONT2	MAILBOX_IVA user 3 interrupt request.
	No DMA Requests			

NOTE: For information about interrupt source description, see Section 19.3.4, *Interrupt Requests*.

19.3 Mailbox Functional Description

NOTE: In the mailbox functional description, *u* is the user number and *m* is the mailbox number as follows:

- for the MAILBOX module instance, *u*=0 to 2 and *m*=0 to 7
- for the MAILBOX_IVA module instance, *u*=0 to 3 and *m*=0 to 5

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the MAILBOX instance, 6 for the MAILBOX_IVA instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

CAUTION

For the MAILBOX_IVA instance, communication is possible only if one of the users is ICONT1 or ICONT2.

The mailbox module includes the following user subsystems:

- User 0: MPU subsystem (u = 0)
- User 1: DSP subsystem (u = 1)
- User 2: IPU subsystem (u = 2)
- User 3:
  - For the MAILBOX_IVA instance - IVA subsystem (ICONT1 or ICONT2)

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers.
Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the MAILBOX instance, a user can query its interrupt status register through the L4_CFG interconnect.

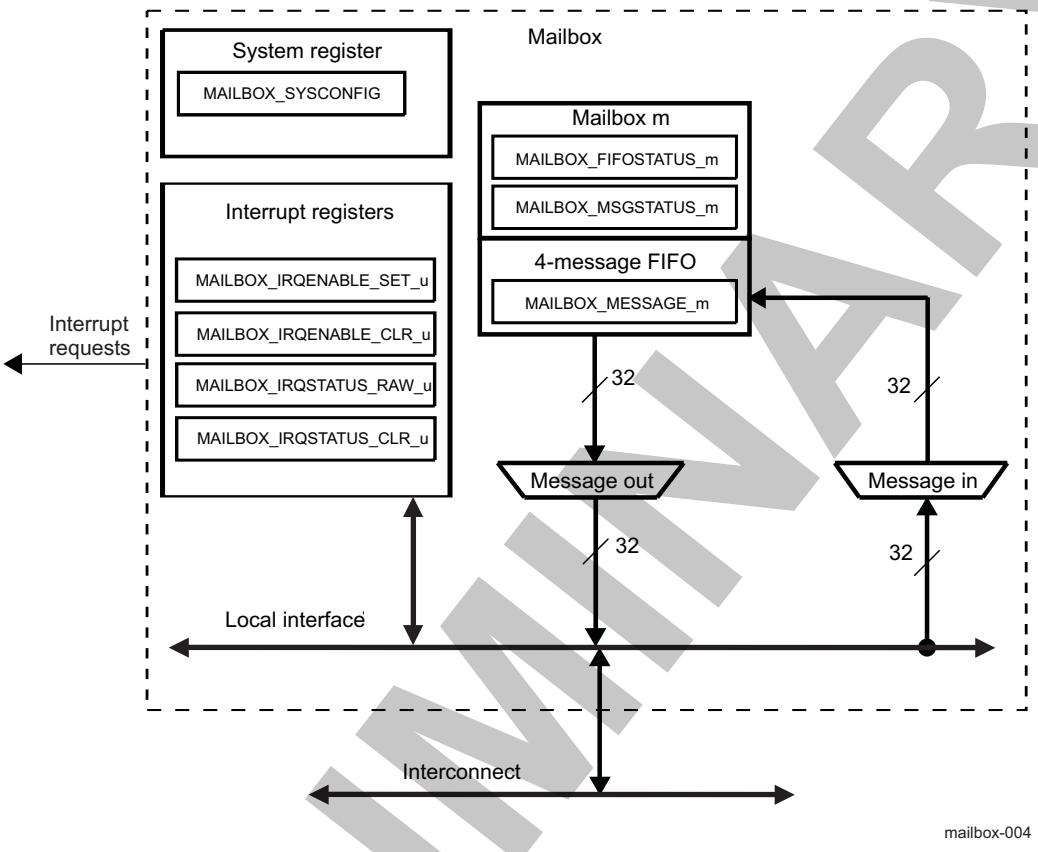
For the MAILBOX_IVA instance, a user can query its interrupt status register as follows:

- MPU and IPU - through the L3_MAIN interconnect
- ICONT1/ICONT2 and DSP - private access (directly through the IVA local interconnect)

19.3.1 Mailbox Block Diagram

Figure 19-4 shows the mailbox block diagram.

Figure 19-4. Mailbox Block Diagram



NOTE: The interrupt requests and the interconnect depend on the mailbox module instance. For more information, see Section 19.2, *Mailbox Integration*.

19.3.2 Mailbox Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going.
- Read 0: the software reset is complete.

The software must ensure that the software reset completes before doing mailbox operations.

19.3.3 Mailbox Power Management

Table 19-7 describes power-management features available for the mailbox module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Clock Domain-Level Clock Management, in *Power, Reset, and Clock Management* chapter.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Module-Level Clock Management, in *Power, Reset, and Clock Management* chapter.

Table 19-7. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

19.3.4 Mailbox Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user.

NOTE: For more information about interrupt requests, see Section 19.2, *Mailbox Integration*.

Table 19-8 lists the event flags, and their mask, that can cause module interrupts.

Table 19-8. Interrupt Events

Non-Maskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2] NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2] NEWMSGSTATUSUUMBm	Mailbox *m* receives a new message.
MAILBOX_IRQSTATUS_RAW_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2] NOTFULLSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2] NOTFULLSTATUSUUMBm	Mailbox *m* message queue is not full.

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register.

Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

19.3.5 Mailbox Assignment

19.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where *u* is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available.

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

19.3.6 Sending and Receiving Messages

19.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded.

Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it.

Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned.

The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

19.3.7 16-Bit Register Access

19.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02).

All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

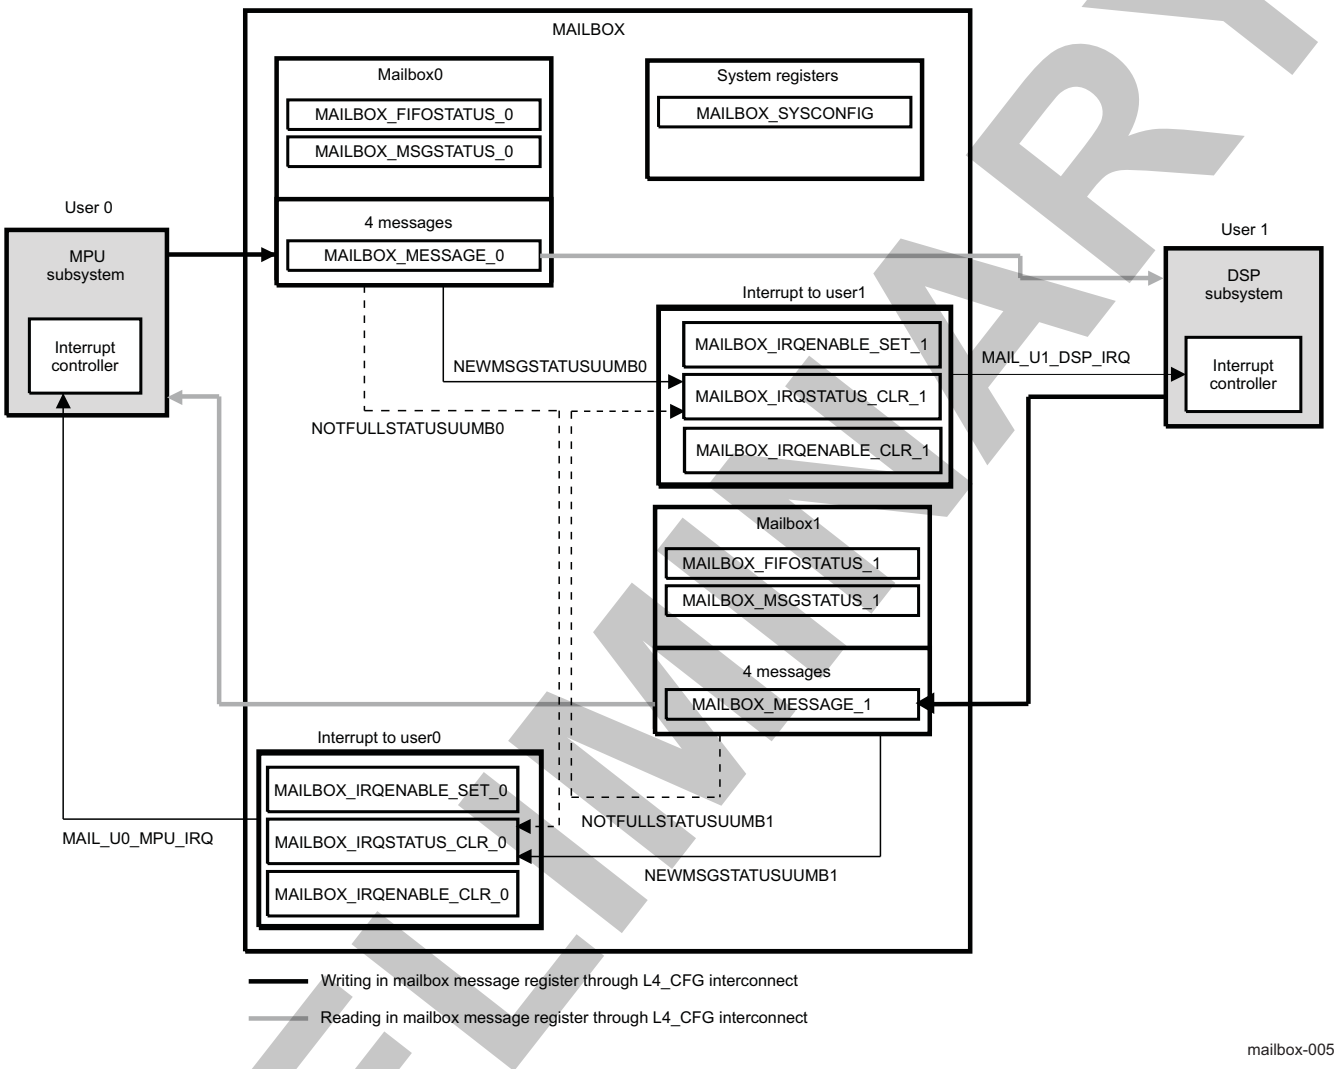
When using 16-bit accesses, it is critical to ensure that the mailbox used has only one assigned receiver and only one assigned sender.

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

19.3.8 Example of Communication

Figure 19-5 shows an example of communication between MPU and DSP subsystems.

Figure 19-5. Example of Communication



19.4 Mailbox Programming Guide

19.4.1 Mailbox Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

19.4.1.1 Global Initialization

19.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 19.2, *Mailbox Integration*, for further information.

Table 19-9. Global Initialization of Surrounding Modules for MAILBOX

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see CD_L4_CFG Clock Domain , in *Power, Reset, and Clock Management* chapter.
Interrupt Controllers	MPU, or IPU, or DSP interrupt controller must be configured to enable the interrupt request generation to the MPU, or IPU, or DSP subsystem. For information about enabling interrupts in INTC_MPU, see the *ARM Cortex™-A15 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in INTC_IPU, see the *ARM Cortex™-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp). For information about enabling interrupts in INTC_DSP, see DSP Subsystem chapter.
Interconnect	For information about L4_CFG interconnect configuration, see L4 Interconnects, in *Interconnect* chapter.

Table 19-10. Global Initialization of Surrounding Modules for MAILBOX_IVA

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled. For more information, see Power, Reset, and Clock Management chapter.
Interrupt Controllers	MPU, or IPU, or DSP, or ICONT1/ICONT2 interrupt controller must be configured to enable the interrupt request generation to the MPU, or IPU, or DSP, or IVA subsystem. For information about enabling interrupts in INTC_MPU, or INTC_IPU, or INTC_DSP, see Table 19-9, *Global Initialization of Surrounding Modules for MAILBOX*.
Interconnect	For information about L3_MAIN interconnect configuration, see L3 Interconnect, in *Interconnect* chapter.

19.4.1.1.2 Mailbox Global Initialization

19.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 19-11. Mailbox Global Initialization

Step	Register/ Bit Field / Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is complete	MAILBOX_SYSCONFIG[0] SOFTRESET	= 0x0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2] SIDLEMODE	0x-

19.4.1.2 Mailbox Operational Modes Configuration

19.4.1.2.1 Mailbox Processing modes

19.4.1.2.1.1 Main Sequence - Sending a Message (Polling Method)

Table 19-12. Sending a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x0
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.2 Main Sequence - Sending a Message (Interupt Method)

Table 19-13. Sending a Message (Interupt Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0] FIFOFULLMB	= 0x1
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.1 for interrupt handling in sending mode		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.3 Main Sequence - Receiving a Message (Polling Method)

Table 19-14. Receiving a Message (Polling Method)

Step	Register/ Bit Field / Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ENDIF		

19.4.1.2.1.4 Main Sequence - Receiving a Message (Interupt Method)

Table 19-15. Receiving a Message (Interupt Method)

Step	Register/ Bit Field / Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	0x1
User (processor) can perform another task until interrupt occurs See Section 19.4.1.3.2 for interrupt handling in receiving mode		

19.4.1.3 Mailbox Events Servicing

19.4.1.3.1 Events Servicing in Sending Mode

Table 19-16 describes the events servicing in sending mode.

Table 19-16. Events Servicing in Sending Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1
Write message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	0x1

19.4.1.3.2 Events Servicing in Receiving Mode

Table 19-17 describes the events servicing in receiving mode.

Table 19-17. Events Servicing in Receiving Mode

Step	Register/ Bit Field / Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0] NBOFMSGMB	!= 0x0
Read message	MAILBOX_MESSAGE_m[31:0] MESSAGEVALUEMBM	0x----
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	0x1
ENDIF

Mailbox Register Manual • Mailbox Register Summary: [4] [5] • Mailbox Register Description: [6]

NOTE: For each interrupt status and enable register (MAILBOX_IRQSTATUS_RAW_u, MAILBOX_IRQSTATUS_CLR_u, MAILBOX_IRQENABLE_SET_u and MAILBOX_IRQENABLE_CLR_u), bits [15:12] have the given meaning only for the MAILBOX instance. For the MAILBOX_IVA instance, these bits are considered as Reserved.

Memory Management Units

This chapter describes the memory management units (MMUs).

Topic **Page**

20.1 MMU Overview

A memory management unit (MMU) is a hardware component responsible for handling accesses to memory requested by a processing unit. MMU functions include translation of virtual addresses to physical addresses (that is, virtual memory management) and cache control.

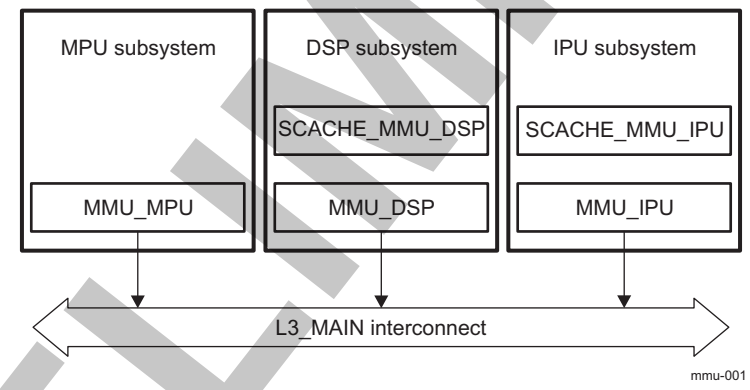
The device contains the following MMUs:

- One MMU inside the MPU (dual Cortex™-A15) subsystem – MMU_MPU. This MMU is integrated in the Cortex-A15 processor. For more information about this MMU, see the ARM® *Cortex™-A15 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).
- Two MMUs inside each of the DSP and IPU (dual Cortex-M4) subsystems:
  - One that manages the memory attribute and mapping at the L1/L2 shared cache level – SCACHE_MMU_DSP and SCACHE_MMU_IPU, respectively. For more information about these MMUs, see DSP Subsystem, and Dual Cortex-M4 IPU Subsystem.
  - One that manages all external accesses to the L3_MAIN interconnect (shared device memory space) – MMU_DSP and MMU_IPU, respectively. The functionality of these MMUs is described in this chapter.

NOTE: There is Physical Address Translator (PAT) module in the Dynamic Memory Manager (DMM), which has similar to the MMU functionality. For more information about this module, see Dynamic Memory Manager.

Figure 20-1 shows the MMU instances in the device.

Figure 20-1. Device MMU Instances



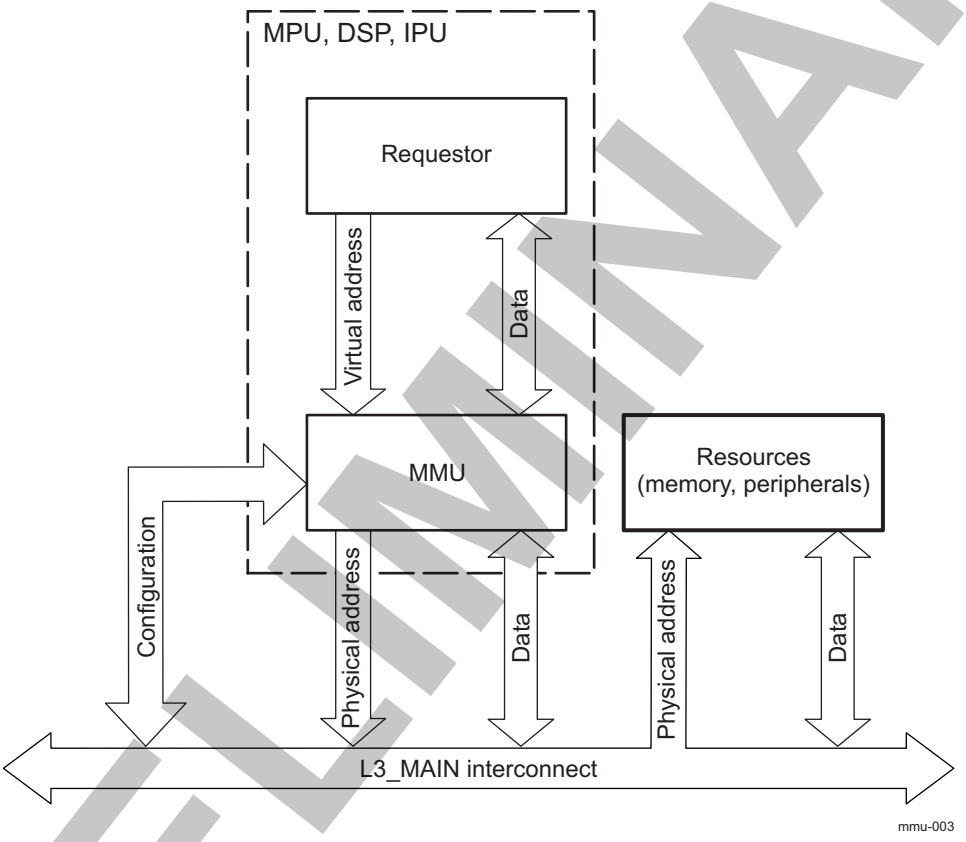
20.2 MMU Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The MMU communicates accesses from the requestor (MPU, DSP, or IPU) to the L3_MAIN interconnect, performing virtual to physical address translation. Although all MMUs are programmed (configured) through the L3_MAIN interconnect, the MMU_DSP can be programmed both through the L3_MAIN interconnect or through the DSP local interconnect. MMU_DSP and MMU_IPU error conditions are signaled as interrupts to the system main processor Cortex-A15 MPU.

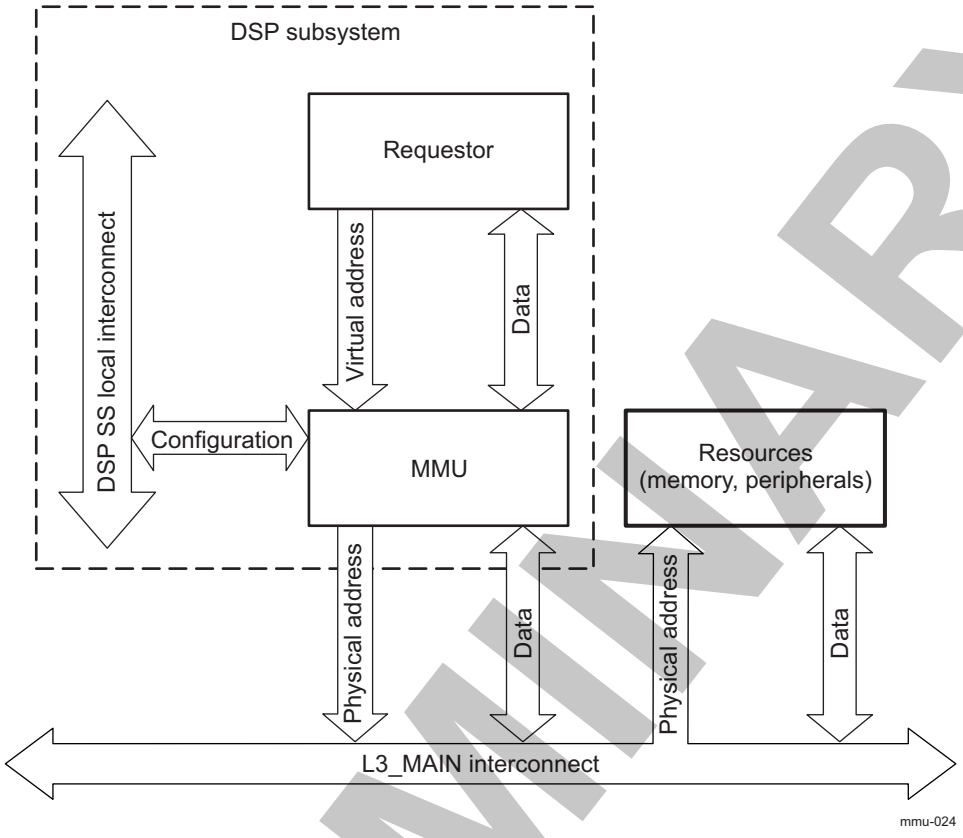
Figure 20-2 shows typical MMU integration.

Figure 20-2. MMU Integration



NOTE: All MMUs are programmed through the L3_MAIN interconnect.

Figure 20-3. MMU_DSP Integration



NOTE: The MMU_DSP can be programmed from both the DSP local interconnect and from the L3_MAIN interconnect.

Table 20-1 through Table 20-3 summarize the MMU integration in the various modules of the device.

Table 20-1. Integration Attributes

Module Instance	Power Domain
MMU_IPU and SCACHE_MMU_IPU	PD_CORE
MMU_MPU	PD_MPU

Table 20-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
MMU_MPU	MPU_CORE_CLK	MPU_DPLL_CLK	DPLL_MPU	Internal clock in the MPU subsystem; supplies the MMU in Cortex-A15.
MMU_IPU and SCACHE_MMU_IPU	IPU_GCLK	IPU_GCLK	PRCM	External clock from the power, reset, and clock management (PRCM) module; supplies the SCACHE_MMU_IPU and MMU_IPU.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
MMU_IPU	IPU_PWRON_RST	IPU_PWRON_RST	PRCM	Power-on reset signal for the IPU subsystem
	IPU_MMU_SCACHE_RST	IPU_MMU_SCACHE_RST	PRCM	Reset signal to the MMU_IPU

Table 20-2. Clocks and Resets (continued)

SCACHE_MMU_IPU	IPU_MMU_SCACHE_RST	IPU_MMU_SCACHE_RST	PRCM	Reset signal for the SCACHE_MMU_IPU
	IPU_RET_RST	IPU_RET_RST	PRCM	Retention reset signal for the IPU subsystem
MMU_MPU	MPU_PWRON_RST	MPU_PWRON_RST	PRCM	Power-on reset signal to the MMU_MPU and the rest of the MPU subsystem
	MPU_RST	MPU_RST	PRCM	Reset signal to the MMU_MPU and the rest of the MPU subsystem

Table 20-3. Hardware Requests

		Interrupt Requests		
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
MMU_IPU	IPU_IRQ_MPU	MPU_IRQ_100	INTC_MPU	MMU_IPU interrupt to the MPU interrupt controller (INTC_MPU)
	XLATE_MMU_FAULT_IRQ	IPU_IRQ_16	INTC_IPU	Internal interrupt from the MMU_IPU to the IPU interrupt controller (INTC_IPU)
SCACHE_MMU_IPU	SCACHE_MMU_IRQ	IPU_IRQ_17	INTC_IPU	Internal interrupt from the SCACHE_MMU_IPU to the INTC_IPU

NOTE:

- For a description of the interrupt source, see Section 20.3.5, *Interrupt Requests*.

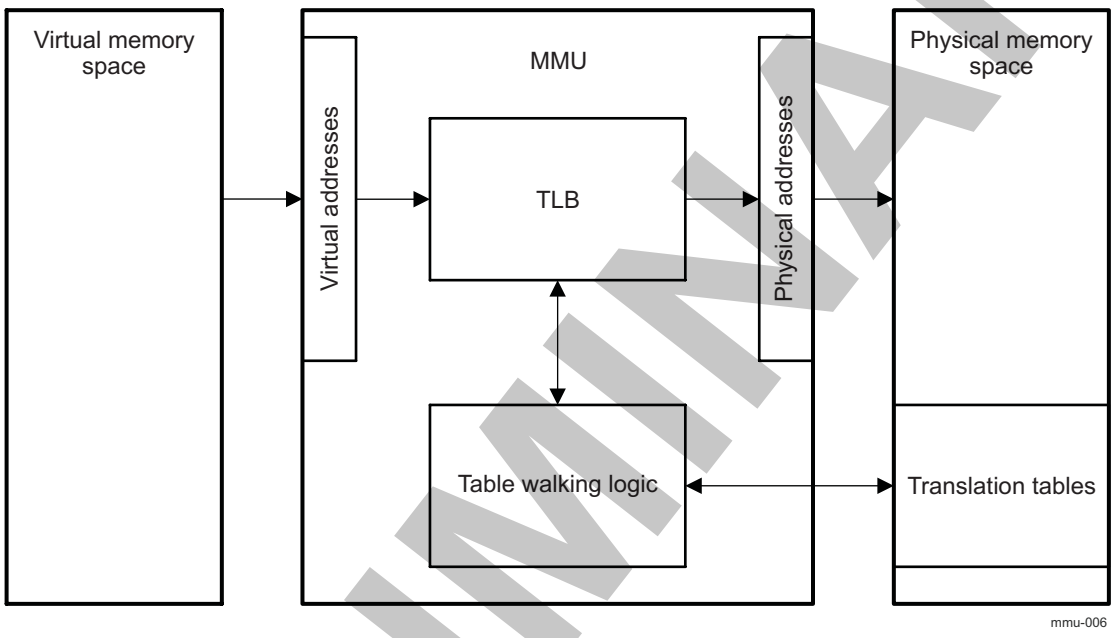
20.3 MMU Functional Description

20.3.1 MMU Block Diagram

The MMU manages the virtual to physical address translation for external addresses, as well as endianness conversion. The MMU can be programmed through the L3_MAIN interconnect. MMU programming is expected to be accomplished by the Cortex-A15 MPU, except for the MMU_DSP, of which the configuration can be accomplished through the DSP local interconnect.

Figure 20-4 is the MMU block diagram.

Figure 20-4. MMU Block Diagram



Each table entry describes the translation of one contiguous memory region. For a description of the structure of these tables, see Section 20.3.1.2, *Translation Tables*.

Two major functional units exist in the MMU to provide address translation automatically based on the table entries:

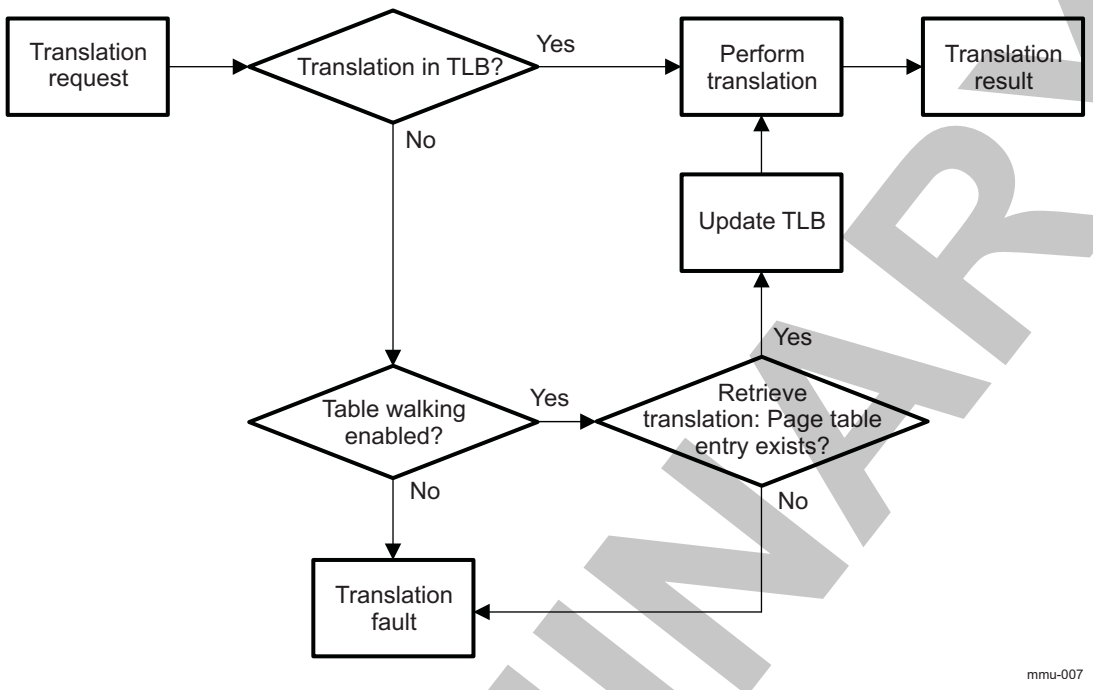
- The table walker automatically retrieves the correct translation table entry for a requested translation. If two-level translation is used (for the translation of small memory pages), the table walker also automatically reads the required second-level translation table entry. The two-level translation is described later in the chapter.
- The translation look-aside buffer (TLB) stores recently used translation entries, acting like a cache of the translation table.

20.3.1.1 MMU Address Translation Process

Whenever an address translation is requested (that is, for every access with the MMU enabled), the MMU first checks whether the translation is contained in the TLB, which acts like a cache storing recent translations. The TLB can also be programmed manually to ensure that time-critical data can be translated without delay.

If the requested translation is not in the TLB, the table-walking logic retrieves this translation from the translation table(s), and then updates the TLB. The address translation is then performed. Figure 20-5 summarizes the process.

Figure 20-5. Translation Process



20.3.1.2 Translation Tables

The translation of virtual to physical addresses is based on entries in translation tables that define the following properties:

- Address translation, that is, the correspondence between virtual and physical addresses
- Size of the memory region the entry translates
- Endianness, data access size, and the mixed property of this memory region

The virtual addresses index the translation tables. Each virtual address corresponds to exactly one entry in the translation table.

20.3.1.2.1 Translation Table Hierarchy

When developing a table-based address translation scheme, one of the most important design parameters is the memory page size described by each translation table entry. MMU instances support 4-KiB and 64-KiB pages, a 1-MiB section, and a 16-MiB supersection. Using bigger page sizes means a smaller translation table.

Using a smaller page size greatly increases the efficiency of dynamic memory allocation and defragmentation. That is why many operating systems (OSs) can operate on memory blocks as small as 4 KiB; however, the smaller size implies a more complex table structure.

A quick calculation shows that using 4 KiB memory pages with one translation table would require one million entries to span the entire 4-GiB address range. The table itself would be 32 MiB, a size that is not feasible.

However, using bigger pages greatly reduces the functionality of the OS memory management. Implementing a two-level hierarchy reconciles these two requirements. Within this hierarchy, one first-level translation table describes the translation properties based on 1 MiB memory regions.

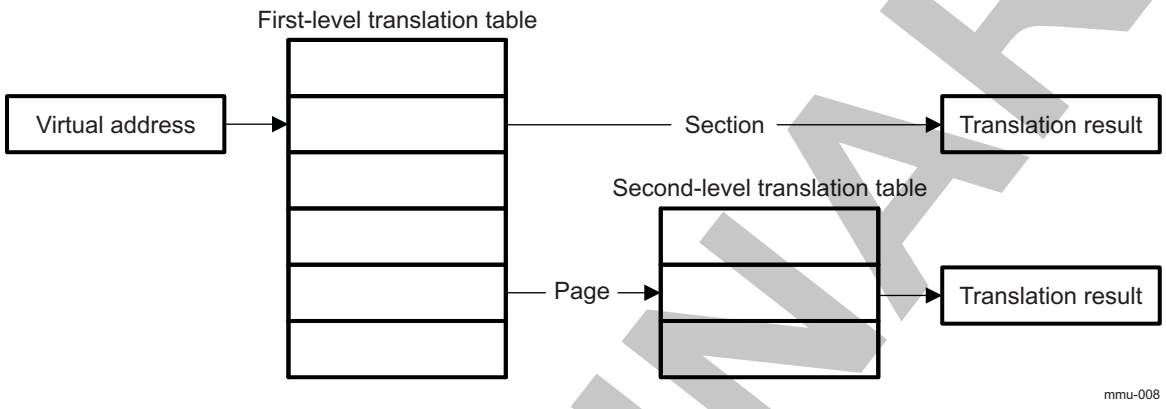
Each of the entries in this first-level translation table can specify the following:

- The translation properties for a big memory section. This memory section can be either 1 MiB (section) or 16 MiB (supersection). In this case, all translation parameters are specified in the first-level translation table entry.

- A pointer to a second-level translation table that specifies individual translation properties based on smaller pages within the 1-MiB page of memory. These pages can be either 64 KiB (large page) or 4 KiB (small page). In this case, the actual translation parameters are specified in the second-level translation table entry. The first-level translation table entry specifies only the base address of the second-level translation table.

This hierarchical approach means that additional translation information for smaller pages must be provided only when the pages are actually used. Figure 20-6 shows the hierarchy.

Figure 20-6. Translation Hierarchy



The structure of the first and second-level translation tables and their entries are described in more detail in Section 20.3.1.2.2, *First-Level Translation Table*, and Section 20.3.1.2.3, *Two-Level Translation*.

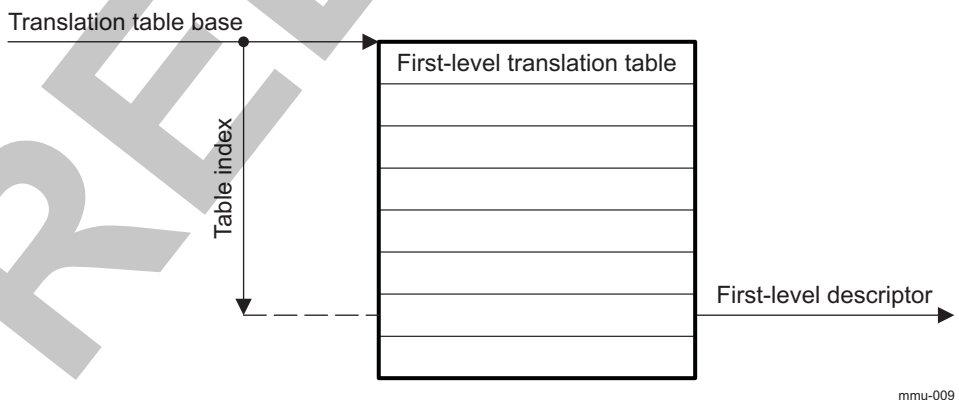
20.3.1.2.2 First-Level Translation Table

The first-level translation table describes the translation properties for 1-MiB sections. To describe a 4-GiB address range requires 4096 32-bit entries (so-called first-level descriptors).

The first-level translation table start address must be aligned on a multiple of the table size with a 128-byte minimum. Consequently, an alignment of at least 16K bytes is required for a complete 4096-entry table; that is, at least the last fourteen address bits must be zero.

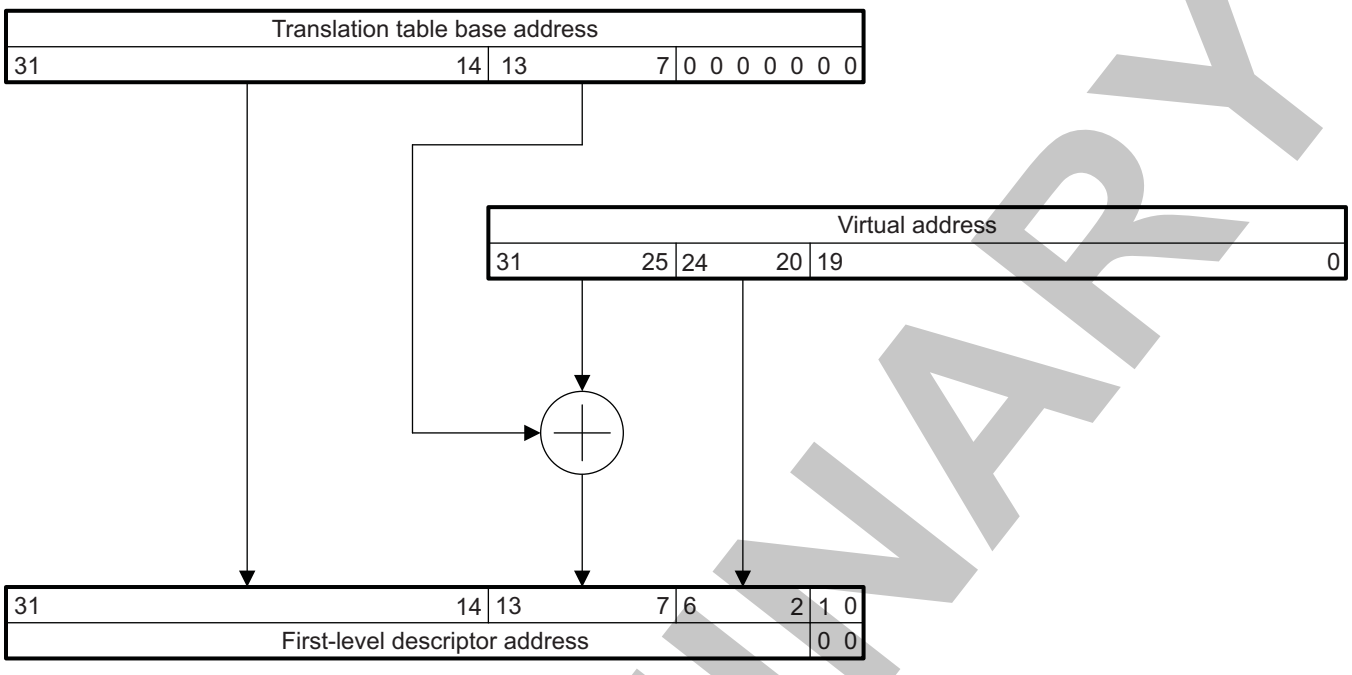
The start address of the first-level translation table is specified by the so-called translation table base. The table is indexed by the upper 12-bits of the virtual address. Figure 20-7 shows this mechanism.

Figure 20-7. First-level Descriptor Address Calculation



To summarize, the translation table base and the translation table index together define the first-level descriptor address. Figure 20-8 outlines the precise mechanism used to calculate this address.

Figure 20-8. Detailed First-Level Descriptor Address Calculation



As an example of this mechanism, consider a translation table base address of 0x8000:0000 and a virtual address of 0x1234:5678. In this case, the first-level descriptor address is 0x8000:0000 + (0x123 << 2) = 0x8000:048C.

20.3.1.2.2.1 First-Level Descriptor Format

Each first-level descriptor provides either the complete address translation for 1-MiB or 16-MiB sections or provides a pointer to a second-level translation table for 4 KiB or 64 KiB pages. Table 20-4 shows the first-level descriptor format.

Table 20-4. First-Level Descriptor Format

First-Level Descriptor Format												
31:24	23:20	19	18	17	16	15	14:12	11:10	9:2	1	0	
X										0	0	Fault
Second-Level Translation Table Base Address									X	0	1	Page
Section Base Address		X	0	M	X	E (1)	X	ES	X	1	0	Section
Supersection Base Address	X		1	M	X	E	X	ES	X	1	0	Supersection
X										1	1	Fault

(1) See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little endian, 1 = Big endian (endianness is locked on little endian)

ES = Element Size: 00 = 8-bit, 01= 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

20.3.1.2.2.2 First-Level Page Descriptor Format

If a translation granularity smaller than 1 MiB is required, a two-level translation process is used. In this case, the first-level block descriptor specifies only the start address of a second-level translation table. The second-level translation table entries specify the actual translation properties.

20.3.1.2.2.3 First-Level Section Descriptor Format

Each section descriptor in the first-level translation table specifies the complete translation properties for a 1-MiB section or a 16-MiB supersection.

NOTE: Supersection descriptors must be repeated 16 times, because each descriptor in the first-level translation table describes 1 MiB of memory. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

In addition to the address translation itself, three parameters are specified in the section descriptors:

- Endianness

  The *endianness* parameter specifies whether the memory section uses a big- or little-endian data format. This parameter is locked to little endian. See Table 20-42 for more information.

- Element size

  The *element size* parameter can optionally specify the data access size (8, 16, or 32 bits) for all data items in the defined section.

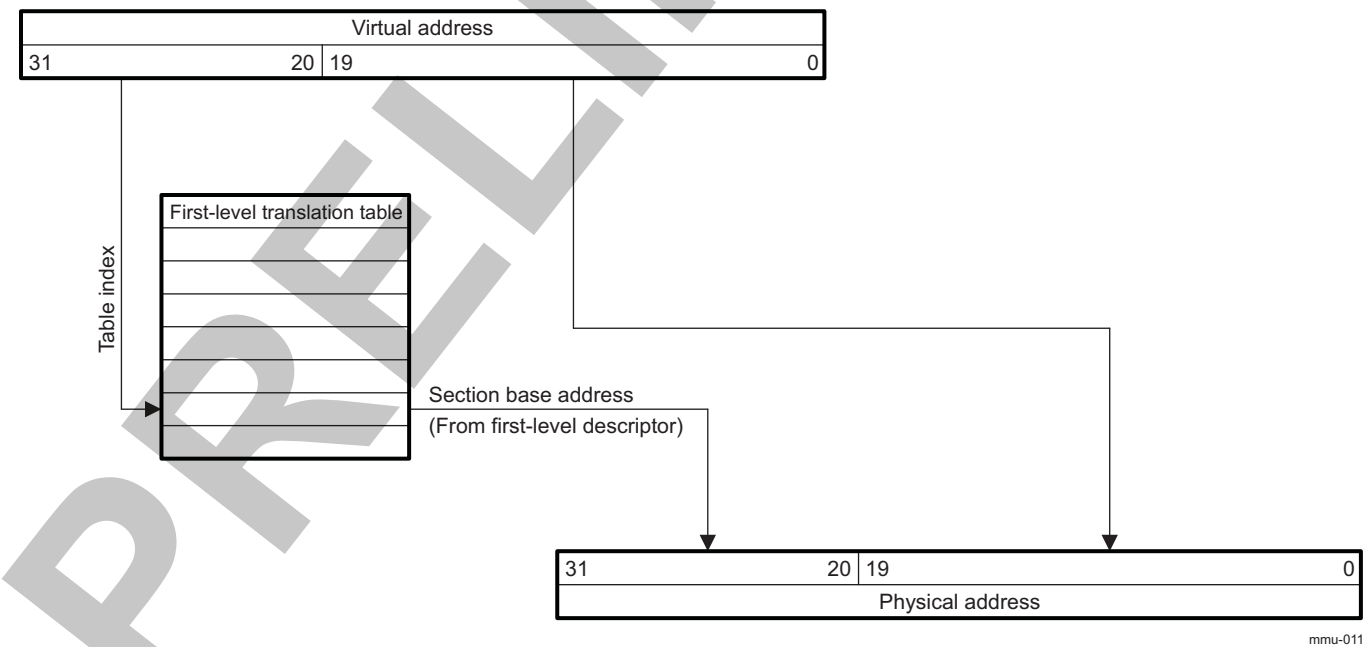
- Mixed region

  The *mixed region* parameter specifies whether the information about the data access size is detected from the access itself (access-based detection) or if the specified element size parameter is used (page-based detection). For example, the specified element size parameter can be used when several smaller sized accesses are packed into a bigger sized access, such as two 16-bit accesses packed into one 32-bit access. In this case, with no specified data access size, 32 bits would be the access size detected, leading to an incorrect result. To avoid this problem, specify the data access size for the memory section.

20.3.1.2.2.4 Section Translation Summary

Sections and supersections can be translated based solely on the information in the first-level translation table. Figure 20-9 summarizes the address translation process for a section.

Figure 20-9. Section Translation Summary

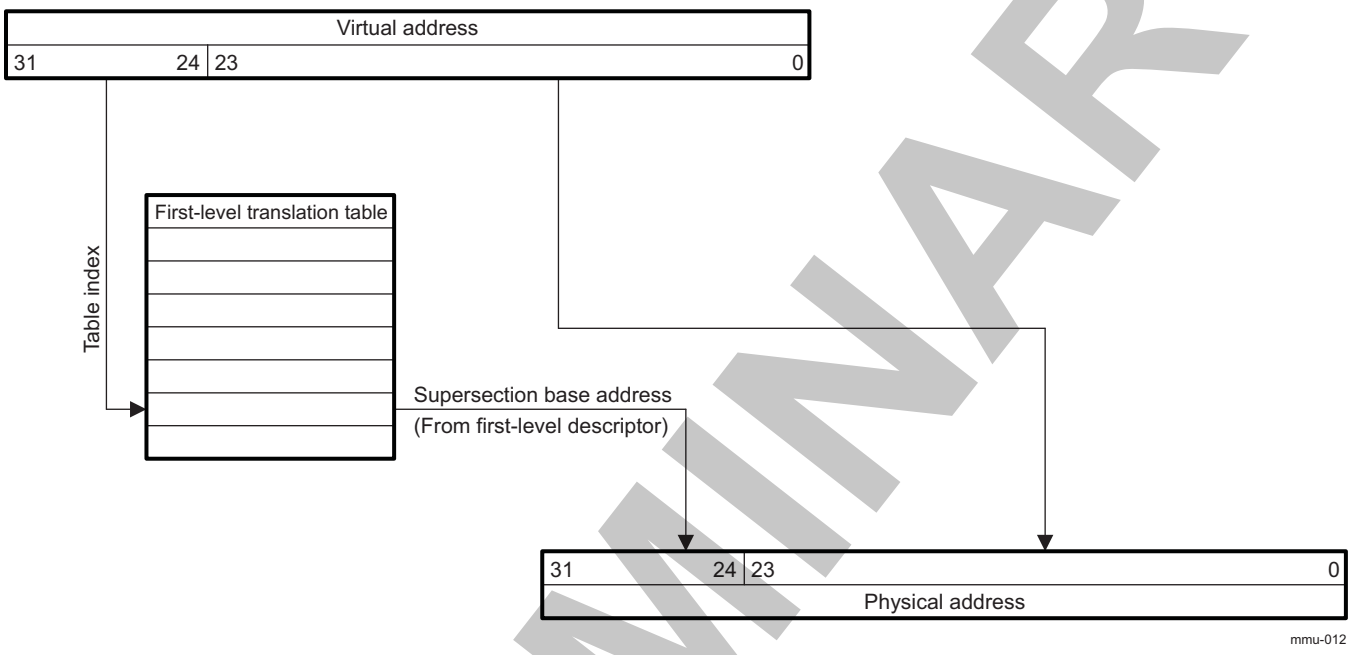


20.3.1.2.2.5 Supersection Translation Summary

The translation of a supersection is similar to the translation of a section. The difference is that for a supersection only bits 31 to 24 index into the first-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a supersection.

Figure 20-10 shows the translation mechanism for a supersection.

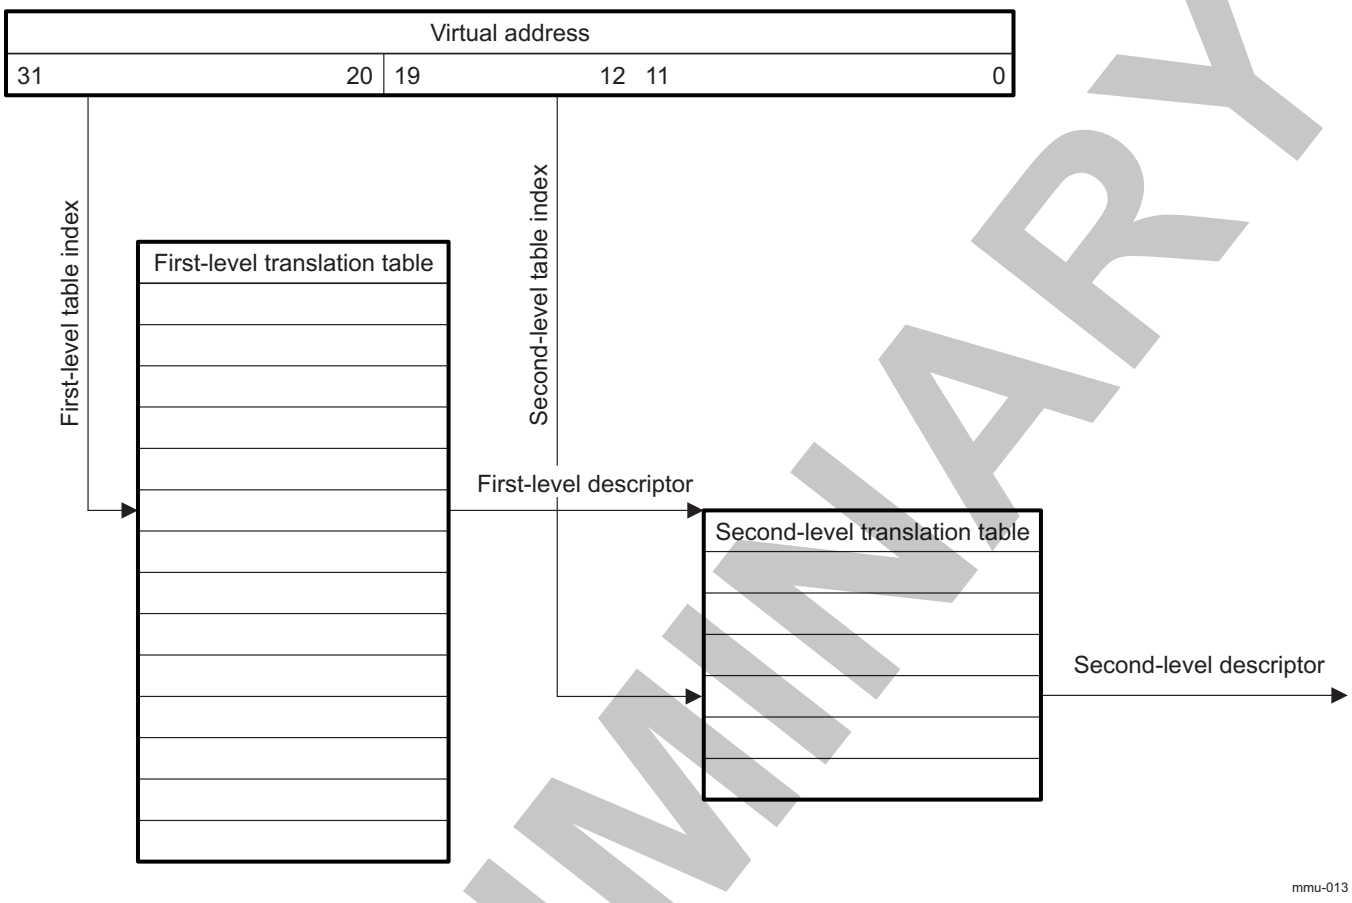
Figure 20-10. Supersection Translation Summary



20.3.1.2.3 Two-Level Translation

Two-level translation is used when fine-grain granularity is required, that is, when memory sections smaller than 1 MiB are needed. In this case, the first-level descriptor provides a pointer to the base address of a second-level translation table. This second-level table is indexed by bits 19 to 12 of the virtual address. Figure 20-11 shows this indexing mechanism.

Figure 20-11. Two-Level Translation



Each second-level translation table describes the translation of 1 MiB of address space in pages of 64 KiB (large page) or 4 KiB (small page). It consists of 256 second-level descriptors describing 4 KiB each.

NOTE: In the case of a large page, the same descriptor must be repeated 16 times. If an access points to a descriptor that is not initialized, the MMU will behave in an unpredictable way.

20.3.1.2.3.1 Second-Level Descriptor Format

Similar to first-level section descriptors, second-level descriptors provide all of the necessary information for the translation of a large or small page. Table 20-5 shows the format of second-level descriptors. The translation parameters (endianness, element size, and mixed region) have the same meaning as those for sections.

Table 20-5. Second-Level Descriptor Format

Second-Level Descriptor Format										
31:16	15:12	11	10	9	8:6	5:4	3:2	1	0	
X								0	0	Fault
Large Page Base Address	X	M	X	E (1)	X	ES	X	0	1	Large Page
Small Page Base Address		M	X	E	X	ES	X	1	X	Small Page

(1) See for endianness limitations.

M = Mixed region: 0 = Page-based endianness, 1 = Access-based endianness

E = Endianness: 0 = Little-endian, 1 = Big-endian (endianness is locked on little endian)

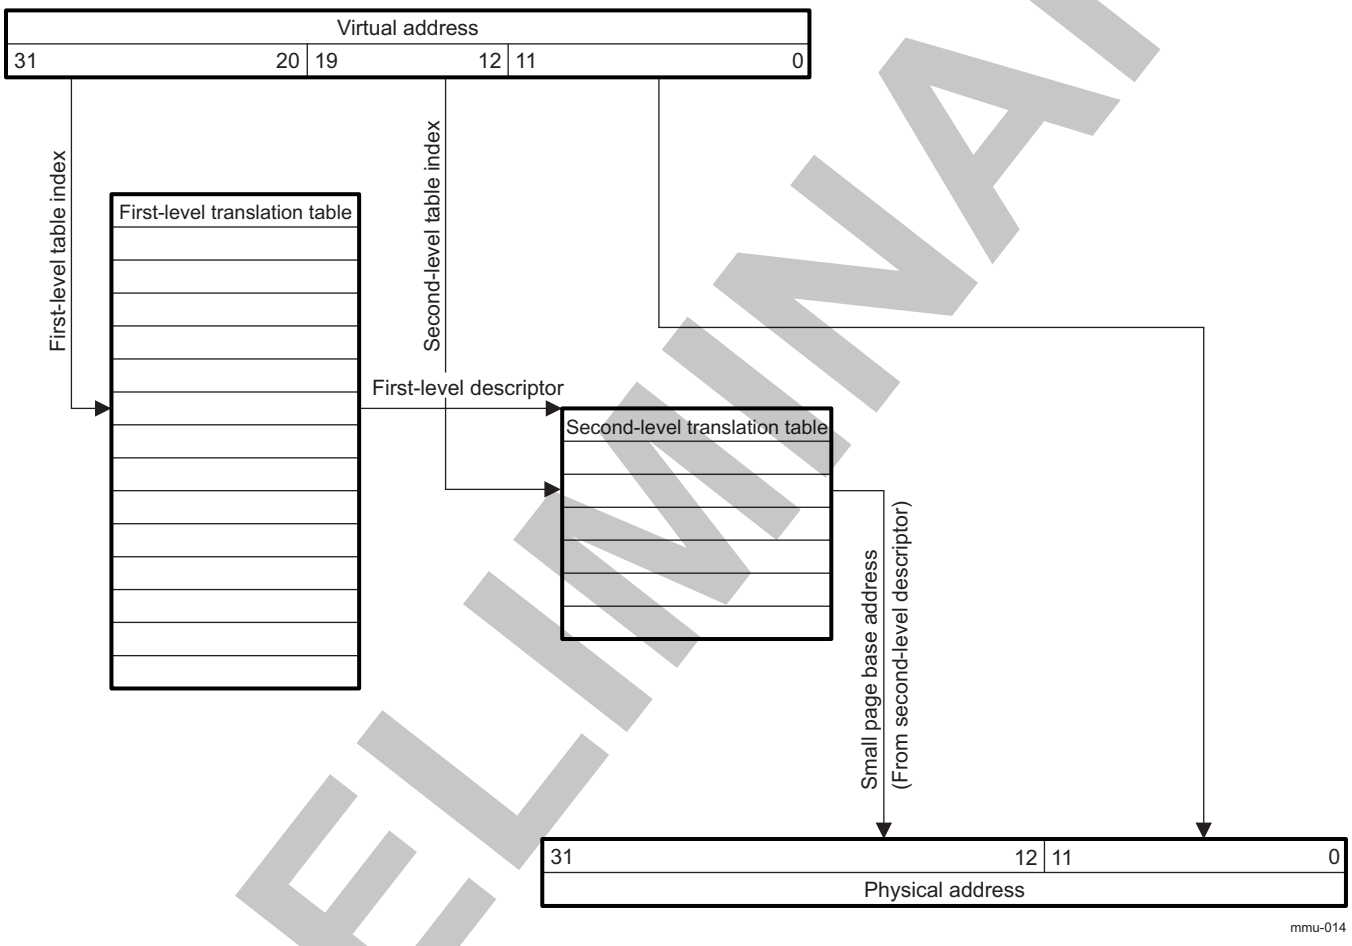
ES = Element Size: 00 = 8-bit, 01= 16-bit, 10 = 32-bit, 11 = No endianness conversion

X = Don't care

20.3.1.2.3.2 Small Page Translation Summary

Figure 20-12 summarizes the translation process for small pages.

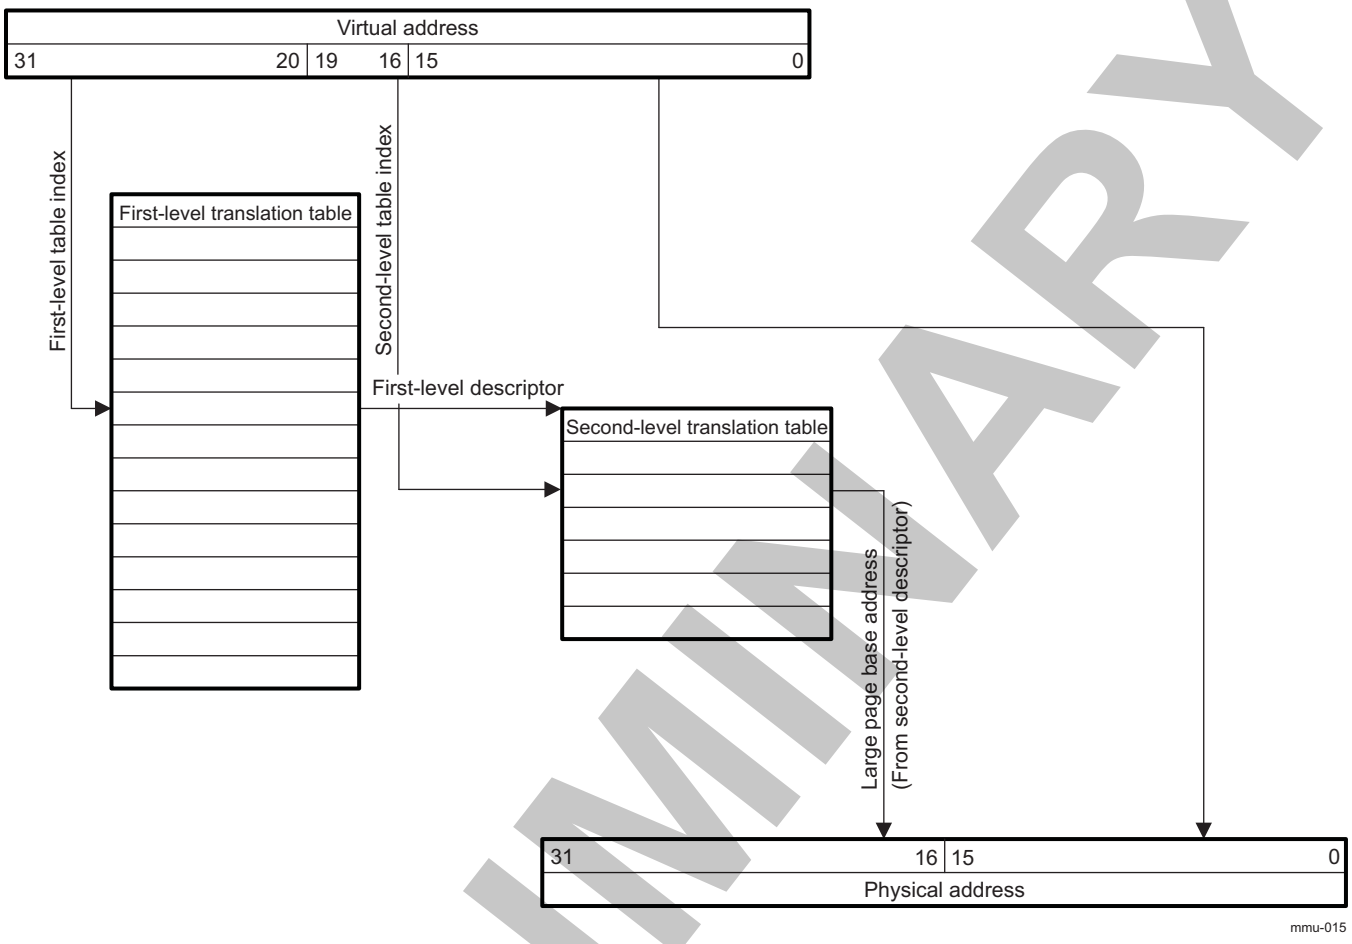
Figure 20-12. Small Page Translation Summary



20.3.1.2.3.3 Large Page Translation Summary

The translation of a large page is similar to the translation of a small page. The difference is that, for a large page, only bits 19 to 16 index into the second-level translation table. The last four bits of the table index are implicitly assumed to be zero as there are 16 identical consecutive entries for a large page. This is shown in Figure 20-13.

Figure 20-13. Large Page Translation Summary



20.3.1.3 Translation Lookaside Buffer

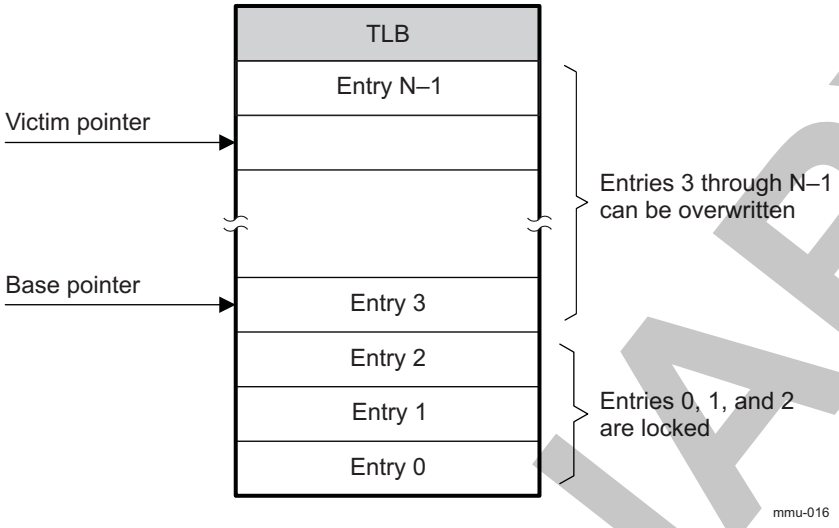
Translating virtual addresses to physical addresses is required for each memory access in systems using an MMU. To accelerate this translation process, a cache, or TLB, holds the result of recent translations.

For every translation, the MMU internal logic first checks whether the requested translation is already cached in the TLB. If the translation is cached, this translation is used; otherwise the translation is retrieved from the translation tables and the TLB is updated. If the TLB is full, one of its entries must be replaced. This entry is selected on a random basis.

The first *n* TLB entries, where *n* < *Total Number N of TLB Entries*, can be protected (locked) against being overwritten by setting the TLB base pointer to *n*. When this mechanism is used, only unprotected entries can be overwritten. The victim pointer indicates the next TLB entry to be written. Figure 20-14 shows an example of the TLB with N TLB entries (ranging from 0 to N-1). The base pointer contains the value "3" protecting Entry 0, Entry 1, and Entry 2 and the victim pointer points to the next TLB entry to be updated.

NOTE: The last TLB entry (Entry N-1) always remains unprotected.

Figure 20-14. TLB Entry Lock Mechanism



The table walking logic automatically writes the TLB entries. The entries can also be manually written, which is done typically to ensure that the translation of time-critical data accesses is already present in the TLB so that they execute as fast as possible. The entries must be locked to prevent them from being overwritten.

20.3.1.3.1 TLB Entry Format

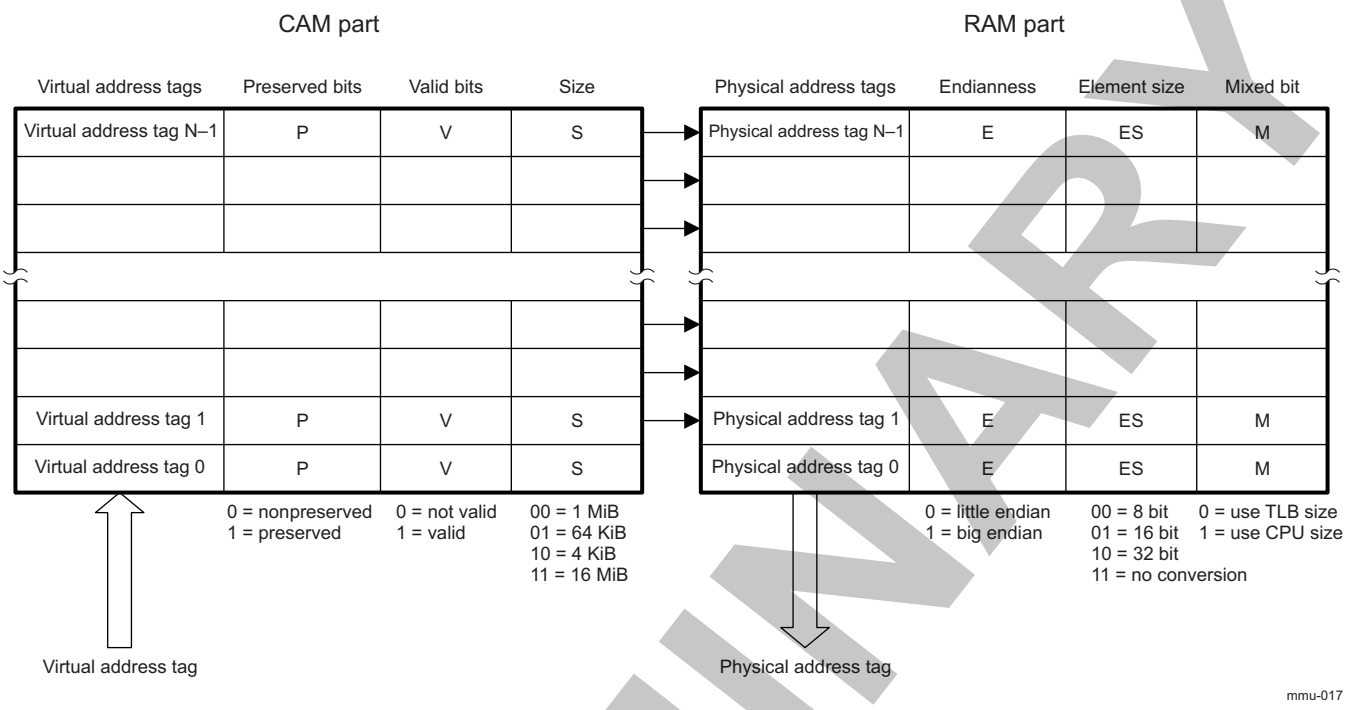
TLB entries consist of two parts:

- The CAM part contains the virtual address tag used to determine if a virtual address translation is in the TLB. The TLB acts like a fully associative cache addressed by the virtual address tag. The CAM part also contains the section/page size, as well as the preserved and the valid parameters. See the MMU_CAM register table for more details.
- The RAM part contains the address translation that belongs to the virtual address tag as well as the endianness, element size, and mixed parameters described in Section 20.3.1.2.2, *First-Level Translation Table*. See the MMU_RAM register table for more details.

The valid parameter specifies whether an entry is valid or not. The preserved parameter determines the behavior of an entry in the event of a TLB flush. If an entry is set as preserved, it is not deleted when a TLB is flushed, that is, when MMU_GFLUSH[0] GLOBALFLUSH is set to 1. Preserved entries must be deleted manually. Section 20.3.1.2.2 describes the procedure to delete TLB entries.

Figure 20-16 shows the TLB entry structure.

Figure 20-15. TLB Entry Structure



20.3.2 MMU Clock Configuration

There are two clock domains: The functional clock domain for the MMU, which is synchronous to the clock for the interconnect slave and master access ports; and the clock domain for the interconnect slave configuration port. As these clocks are matched, there is a single input clock with enables for each of the clock domains. If a clock domain should run at the same frequency as the input clock, that enable can be tied high.

Two clock enable signals exist, one to enable the interconnect data master and slave ports, and the other to enable the clock on the configuration L3_MAIN interconnect port. The clock signals are configured through the MMU_SYSCONFIG register. This is a system configuration register that controls the various parameters of the L3_MAIN interface.

20.3.3 MMU Software Reset

This section describes the software reset feature of the module. The MMU instances are reset together with their respective reset domains. See Table 20-2 for information about the reset domains of the different MMU instances.

To perform a software reset, write 1 in the MMU_SYSCONFIG[1] SOFTRESET bit. The MMU_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the MMU_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before doing MMU operations. When an MMU instance is released from reset, its TLB is empty and the MMU is disabled.

20.3.4 MMU Power Management

As part of the device system-wide power management scheme, each MMU instance supports a communication protocol with the PRCM module that allows the PRCM module to request an MMU instance to enter a low-power state. When the MMU instance acknowledges a low-power mode request from the PRCM module, the clock to the instance is gated off at the PRCM clock generator. Because the clock is disabled at the source, the low-power mode offers lower power consumption than the internal clock gating method in the local power management.

Table 20-6 describes the power-management features available for the MMU modules.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Clock Management, in *Power, Reset, and Clock Management* chapter.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Module-Level Clock Management, in *Power, Reset, and Clock Management* chapter.

Table 20-6. MMU Local Power Management Features

Feature	Register
Idle modes	MMU_SYSCONFIG[4:3] IDLEMODE
Clock activity	MMU_SYSCONFIG[9:8] CLOCKACTIVITY
Clock autogating	MMU_SYSCONFIG[0] AUTOIDLE

NOTE: The MMU_SYSCONFIG[9:8] CLOCKACTIVITY bits are read only.

20.3.5 MMU Interrupt Requests

Table 20-7 lists the event flags and their masks that can cause module interrupts.

Table 20-7. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
MMU_IRQSTATUS[4] MULTIHITFAULT	MMU_IRQENABLE[4] MULTIHITFAULT	Yes	Level	IPU_IRQ_16	Error in the L2 MMU due to multiple matches in the TLB
MMU_IRQSTATUS[3] TABLEWALKFAULT	MMU_IRQENABLE[3] TABLEWALKFAULT	Yes	Level	IPU_IRQ_16	Error in the L2 MMU due to error response received during a Table Walk
MMU_IRQSTATUS[2] EMUMISS	MMU_IRQENABLE[2] EMUMISS				For more information about emulation and debug features, see Chapter 29, *On-Chip Debug Support*.
MMU_IRQSTATUS[1] TRANSLATIONFAULT	MMU_IRQENABLE[1] TRANSLATIONFAULT	Yes	Level	IPU_IRQ_16	Error in the L2 MMU due to invalid descriptor in the translation tables (translation fault)
MMU_IRQSTATUS[0] TLBMISS	MMU_IRQENABLE[0] TLBMISS	Yes	Level	IPU_IRQ_16	Error in L2 MMU due to unrecoverable TLB miss (hardware TWL disabled)

20.3.6 MMU Error Handling

Table 20-8 summarizes the intended operation for real and potential error conditions.

Table 20-8. Error Handling

Item	Condition	Action
1	Table-walk read has an error response.	Treat generally the same as a translation fault, but set the TableWalkFault interrupt status bit to aid in diagnosis
2	MMU is disabled during table-walk.	Not permitted; can result in loss of the current transaction but must not deadlock the MMU.
		Avoid this condition by first disabling the table-walk logic and then polling the TWLRunning bit to ensure that no table walk is pending
3	MMU is disabled during an address translation.	Not permitted; can result in access to an unintended location, but must not deadlock MMU.
		This condition should be avoided by ensuring that no accesses are pending.
4	TLB is accessed during an address translation or a table walk.	Reading permitted; write should be done with care to ensure that the TLB is self-consistent at all times that a translation can occur.

Table 20-8. Error Handling (continued)

Item	Condition	Action
5	TLB is flushed during address translation or a table walk.	Permitted; the flush is processed first, followed by the TWL update.
6	MMU is disabled while an interrupt is pending.	Not permitted; all pending interrupts should be processed before disabling the MMU.

L3_MAIN Interconnect configuration port: Accesses to undecoded register addresses must not give an error response.

To protect against changes to the address translation between a READEX and the corresponding write or during a burst the following configuration operations are protected against writes during these processes:

- TLB update
- Global flush
- Flush entry
- MMU disable

The protection is implemented by stalling the configuration interconnect transaction until the write can proceed safely.

20.4 MMU Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

20.4.1 Global Initialization

20.4.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the MMU module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMU. For more information, see Section Section 20.2, *MMU Module Integration* .

Table 20-9. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Power, Reset, and Clock Management chapter.
(optional) INTC_MPU or INTC_DSP or INTC_IPU	MPU, DSP, and IPU interrupt controller configuration must be done to enable the interrupts from module.
Interconnect	For more information about the L3_MAIN interconnect configuration, see L3 Interconnect.

NOTE: If the interrupt-based communication mode is used, the MPU, DSP, and IPU interrupt controllers configurations are required.

20.4.1.2 MMU Global Initialization

20.4.1.2.1 Main Sequence - MMU Global Initialization

Figure 20-16 shows the procedure to initialize the MMU after a power-on or software reset.

Figure 20-16. MMU Global Initialization

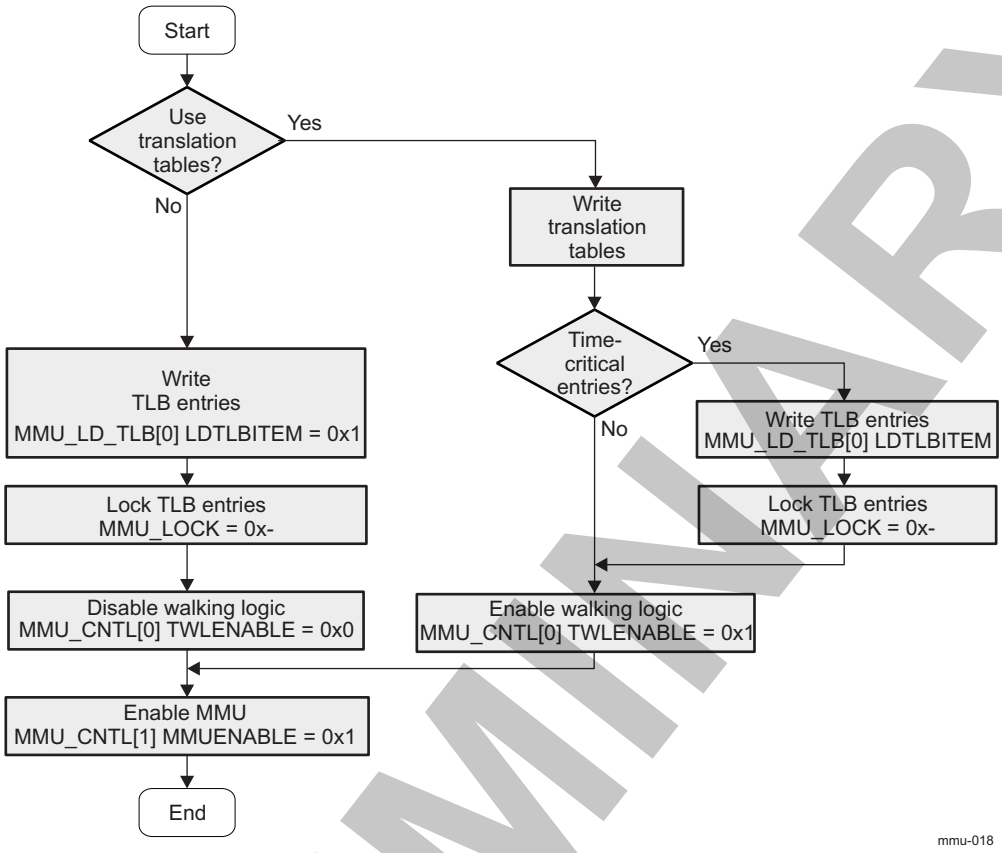


Table 20-10. Register Call Summary for Main Sequence - MMU Global Initialization

Register Name	Register Name	Register Name
MMU_LD_TLB	MMU_LOCK	MMU_CNTL

20.4.1.2.2 Subsequence - Configure a TLB entry

Table 20-11. Configure a TLB Entry

Step	Register / Bit Field / Programming Model	Value
Load the Virtual Address Tag	MMU_CAM[31:12] VATAG	0x-
Protect the TLB entry against flush	MMU_CAM[3] P	0x1
Validate the TLB entry	MMU_CAM[2] V	0x1
Define the page size	MMU_CAM[1:0] PAGESIZE	0x-

20.4.1.3 Operational Modes Configuration

20.4.1.3.1 Main Sequence - Writing TLB Entries Statically

Writing TLB entries statically avoids the need to write translation tables in memory and is commonly used for relatively small address spaces. This method ensures that the translation of time-critical data accesses execute as fast as possible with entries already present in the TLB. These entries must be locked to prevent them from being overwritten.

Table 20-12. MMU Writing TLB Entries Statically

Step	Register/ Bit Field / Programming Model	Value
Execute software reset	MMU_SYSCONFIG[1] SOFTRESET	0x1
Wait for reset to complete	MMU_SYSSTATUS[0] RESETDONE	=0x1
Enable power saving via automatic interface clock gating	MMU_SYSCONFIG[0] AUTOIDLE	0x1
Configure TLB entries	See Table 20-11	
Load the physical Address of the page	MMU_RAM[31:12] PHYSICALADDRESS	0x-
Define the endianness of the page (little endian or big endian)	MMU_RAM[9] ENDIANNESS	0x-
Select the element size	MMU_RAM[8:7] ELEMENTSIZE	0x-
Define mixed page attribute	MMU_RAM[6] MIXED	0x-
Specify the TLB entry you want to write	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Load the specified entry in the TLB	MMU_LD_TLB[0] LDTLBITEM	0x1
Enable multihit fault and TLB miss	MMU_IRQENABLE[4] MULTIHITFAULT	0x1
	MMU_IRQENABLE[0] TLBMISS	0x1
Enable memory translations	MMU_CNTL[1] MMUENABLE	0x1

20.4.1.3.2 Main Sequence - Protecting TLB Entries

The first *n* TLB entries (with *n* < total number of TLB entries) can be protected from being overwritten with new translations. This is useful to ensure that certain commonly used or time-critical translations are always in the TLB and do not require retrieval using the table walking process.

Table 20-13. Protecting TLB Entries

Step	Registe/Bit Field/Programming Model	Value
Locks the TLB entries	MMU_LOCK[14:10] BASEVALUE	0x-

20.4.1.3.3 Main Sequence - Deleting TLB Entries

Two mechanisms exist to delete TLB entries. All unpreserved TLB entries, that is, TLB entries written with the preserved bit set to zero, can be deleted by invoking a TLB flush. The preserved bit should only be used on protected TLB entries, as it does not prevent replacement by the table walking logic.

Table 20-14. Deleting TLB Entries

Step	Registet / Bit Field / Programming Model	Value
Flush all nonprotected TLB entries	MMU_GFLUSH[0] GLOBALFLUSH	0x1
Flush all TLB entries specified by the CAM register	MMU_FLUSH_ENTRY[0] FLUSHENTRY	0x1

20.4.1.3.4 Main Sequence - Read TLB Entries

TLB entries can be read by the programmer to determine the TLB content at runtime.

Table 20-15. Read TLB Entries

Step	Register / Bit Field / Programming Model	Value
Set the current victim pointer	MMU_LOCK[8:4] CURRENTVICTIM	0x-
Read RAM parts of the TLB entry	MMU_READ_RAM	
Read CAM parts of the TLB entry	MMU_READ_CAM

Spinlock

This chapter describes the Spinlock module of the device.

Topic **Page**

21.1 Spinlock Overview

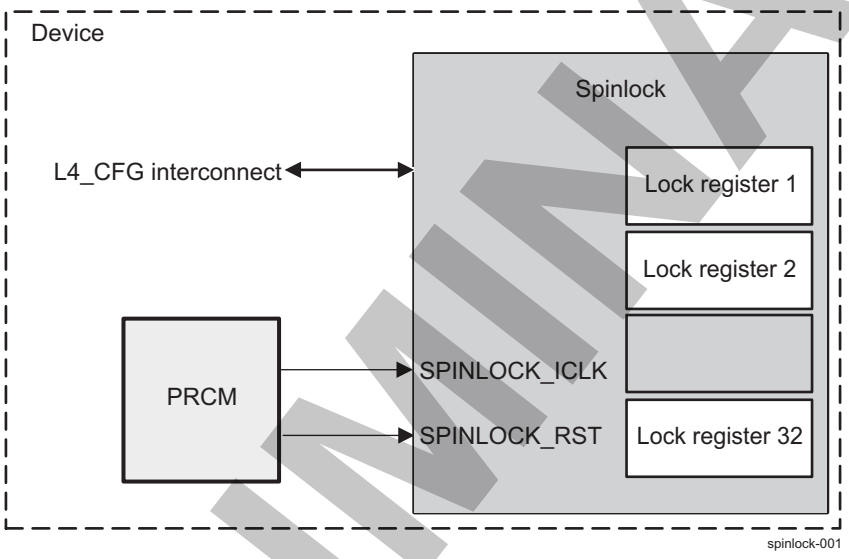
The Spinlock module provides hardware assistance for synchronizing the processes running on multiple processors in the device:

- Dual Cortex™-A15 microprocessor unit (MPU) subsystem
- Digital signal processor (DSP) subsystem
- Dual Cortex-M4 image processing unit (IPU) subsystem

The Spinlock module implements 32 spinlocks (or hardware semaphores), which provide an efficient way to perform a lock operation of a device resource using a single read-access, avoiding the need of a read-modify-write bus transfer that the programmable cores are not capable of.

Figure 21-1 shows the Spinlock module.

Figure 21-1. Spinlock Overview

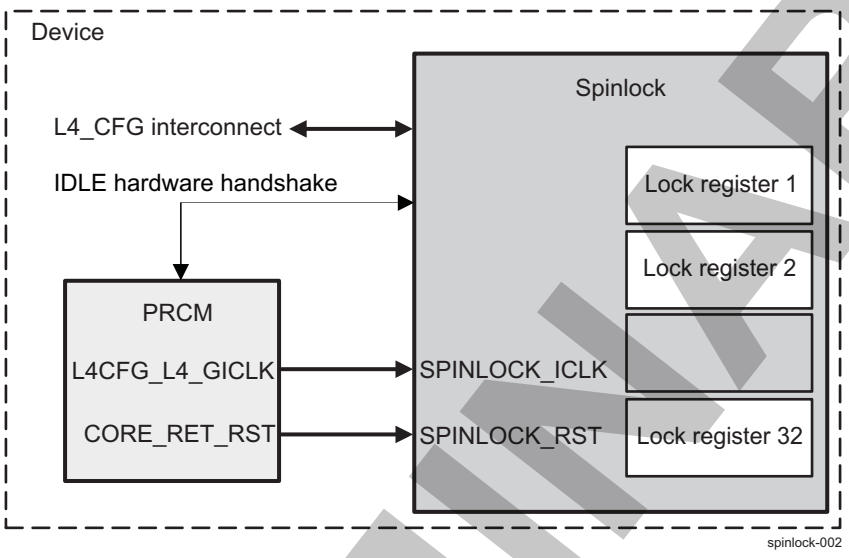


21.2 Spinlock Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 21-2 shows the Spinlock integration.

Figure 21-2. Spinlock Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Module-Level Clock Management, in *Power, Reset, and Clock Management* chapter.

Table 21-1 and Table 21-2 summarize the integration of the module in the device.

Table 21-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SPINLOCK	PD_CORE	L4_CFG

Table 21-2. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_ICLK	L4CFG_L4_GICLK	PRCM	Spinlock interface clock. This clock is used for all interface and functional operations.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SPINLOCK	SPINLOCK_RST	CORE_RET_RST	PRCM	Spinlock hardware reset. This reset is asynchronously applied to the Spinlock internal registers.

NOTE: The Spinlock module does not support any interrupt and DMA requests.

21.3 Spinlock Functional Description

21.3.1 Spinlock Software Reset

The Spinlock module can be reset by software through the SPINLOCK_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. The SPINLOCK_SYSTATUS[0] RESETDONE bit can be polled to check the reset status (reading 1 indicates that reset sequence is done; reading 0 indicates that reset sequence is in progress). The software must ensure that the software reset completes before doing Spinlock operations.

21.3.2 Spinlock Power Management

Table 21-3 describes power-management features available to the Spinlock module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Clock Domain-Level Clock Management, in *Power, Reset, and Clock Management* chapter.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Module-Level Clock Management, in *Power, Reset, and Clock Management* chapter.

Table 21-3. Local Power Management Features

Feature	Registers	Description
Clock auto gating	SPINLOCK_SYSCONFIG[0] AUTOGATING bit	This bit indicates that the module uses an automatic internal interface clock gating strategy, based on interface activity.
Slave idle modes	SPINLOCK_SYSCONFIG[4:3] SIDLEMODE bit field	This bit field indicates that the module uses smart-idle mode.
Clock activity	SPINLOCK_SYSCONFIG[8] CLOCKACTIVITY bit	This bit indicates that the interface clock is not required by the module during idle mode and may be switched off.
Global wake-up enable	SPINLOCK_SYSCONFIG[2] ENAWAKEUP bit	This bit indicates that the wake-up generation feature (at module level) is disabled.

NOTE: All the local power management features are non-configurable (that is, their respective bits or bit fields are read-only).

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY bit and Spinlock clock PRCM control bits.

The Spinlock module is normally idle, except when processing a request from its slave interface port. The smart-idle mode acknowledges idle requests from the PRCM only when the module is prepared to go idle. The Spinlock module is always ready to go idle if it does not have any request that it is processing.

The Spinlock module uses retention flops to retain state including the Taken state of each lock register. This means that the module can be placed in retention at any time when it is not processing a request and it is known that the system will not need to access the module.

Software must ensure to only power off the Spinlock module when no locks would be lost. In general, the steps to powering down the Spinlock module are:

- Check that all masters which might use the Spinlock module are either:

  (a) Already powered off, or

  (b) Notified that Spinlock is not available and the notification is acknowledged.

- If desired, check that no locks are currently held in the Spinlock module. The status of each bank of 32 locks can be read from the SPINLOCK_SYSTATUS register. If any locks are held, they are orphaned because they are not held by any master that is still active. Alternatively, you may decide to wait a timeout period to allow any active master to clean up its locks before powering down.
- The Spinlock module can now be powered off by writing the appropriate status to the PRCM.

In the case of powering off the whole system, these steps are unnecessary.

21.3.3 About Spinlocks

Spinlocks are present to solve the need for synchronization and mutual exclusion between heterogeneous processors and those not operating under a single, shared operating system. There is no alternative mechanism to accomplish these operations between processors in separate subsystems.

Spinlocks are not the best way to synchronize between tasks or threads on one CPU. Instead, spinlocks are for use in synchronization between different subsystems in the device that don't have any other means of hardware-based synchronization.

Spinlocks do not solve all system synchronization issues. They have limited applicability and should be used with care to implement higher level synchronization protocols.

A spinlock is appropriate for mutual exclusion for access to a shared data structure. It should be used only when:

1. The time to hold the lock is predictable and small (for example, a maximum hold time of less than 200 CPU cycles may be acceptable).
2. The locking task cannot be preempted, suspended, or interrupted while holding the lock (this would make the hold time large and unpredictable).
3. The lock is lightly contended, that is the chance of any other process (or processor) trying to acquire the lock while it is held is small.

If these conditions are met, then the locking code can retry a failed attempt to acquire the lock until success.

If the conditions are not met, then a spinlock is not a good candidate. One alternative is to use a spinlock for critical section control (engineered to meet the conditions) to implement a higher level semaphore that can support preemption, notification, timeout or other higher level properties.

21.3.4 Spinlock Functional Operation

The Spinlock module supports 32 spinlocks. It accepts only a single command at a time and processes the command fully before accepting the next command. A lock is requested by reading the SPINLOCK_LOCK_REG_i[0] TAKEN bit. There are two states: Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 1) or Not Taken (SPINLOCK_LOCK_REG_i[0] TAKEN = 0).

When the status of lock *i* (where i = 0 to 31) is Not Taken (free), a read from the SPINLOCK_LOCK_REG_i register returns 0 and sets the lock to Taken (locked). When the status of lock *i* is Taken, a read returns 1 and does not change the state of the lock.

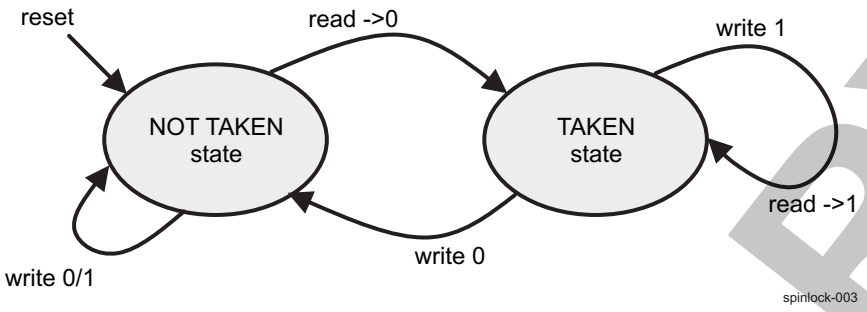
A write to the SPINLOCK_LOCK_REG_i register does not change the state of lock, unless when writing 0 when the lock is in Taken state. By doing this, the requester frees the lock.

CAUTION

Only 32-bit reads and writes are supported.

Figure 21-3 shows the SPINLOCK_LOCK_REG_i register state diagram.

Figure 21-3. Lock Register State Diagram



NOTE:

- There is no support to ensure that a lock register is locked and unlocked by the same process. This must be ensured in software.
- There is no support to check that the same initiator that acquired the lock is the one that is freeing the lock.

21.4 Spinlock Programming Guide

21.4.1 Spinlock Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the module.

21.4.1.1 Surrounding Modules Global Initialization

This procedure initializes the surrounding modules when the Spinlock module is used for the first time after a device reset.

Table 21-4. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Spinlock interface clock must be enabled. For more information, see CD_L4_CFG Clock Domain, in *Power, Reset, and Clock Management* chapter.
Interconnect	For more information about the L4_CFG interconnect configuration, see L4 Interconnects chapter.

21.4.1.2 Basic Spinlock Operations

The main spinlock operations are:

- Clear all the Taken spinlocks (only after a system bug recovery)
- Take a spinlock
- Release spinlock

21.4.1.2.1 Spinlocks Clearing After a System Bug Recovery

Module initialization (after reset) is not needed, except after system bug recovery. The following table presents the Spinlock initialization after a system bug recovery. Software should store 0 into each of the SPINLOCK_LOCK_REG_i registers at system startup to insure that all locks are initialized to Not Taken.

Table 21-5. Spinlock System Bug Recovery

Step	Register	Value
IF: SPINLOCK_SYSTATUS[0] IU0 = = 1?	SPINLOCK_SYSTATUS[0] IU0	
Free the 32 locks	SPINLOCK_LOCK_REG_i[0] TAKEN (i=0 to 31)	0x0
END		

21.4.1.2.2 Take and Release Spinlock

This procedure configures the take and release (free) operations for the Spinlock module. A spinlock should only be held with interrupts disabled. So, before attempting to obtain the spinlock, software should disable interrupts. Then it should read the SPINLOCK_LOCK_REG_i[0] TAKEN bit to attempt to obtain the lock. If it succeeds, it should proceed directly through the critical section then unlock and re-enable interrupts. If the acquisition attempt fails, the acquisition should be reattempted. To prevent unknown interrupt disabled time, interrupts should be re-enabled and then disabled before reattempting to acquire the lock. Figure 21-4 shows the described above procedure.

Timers

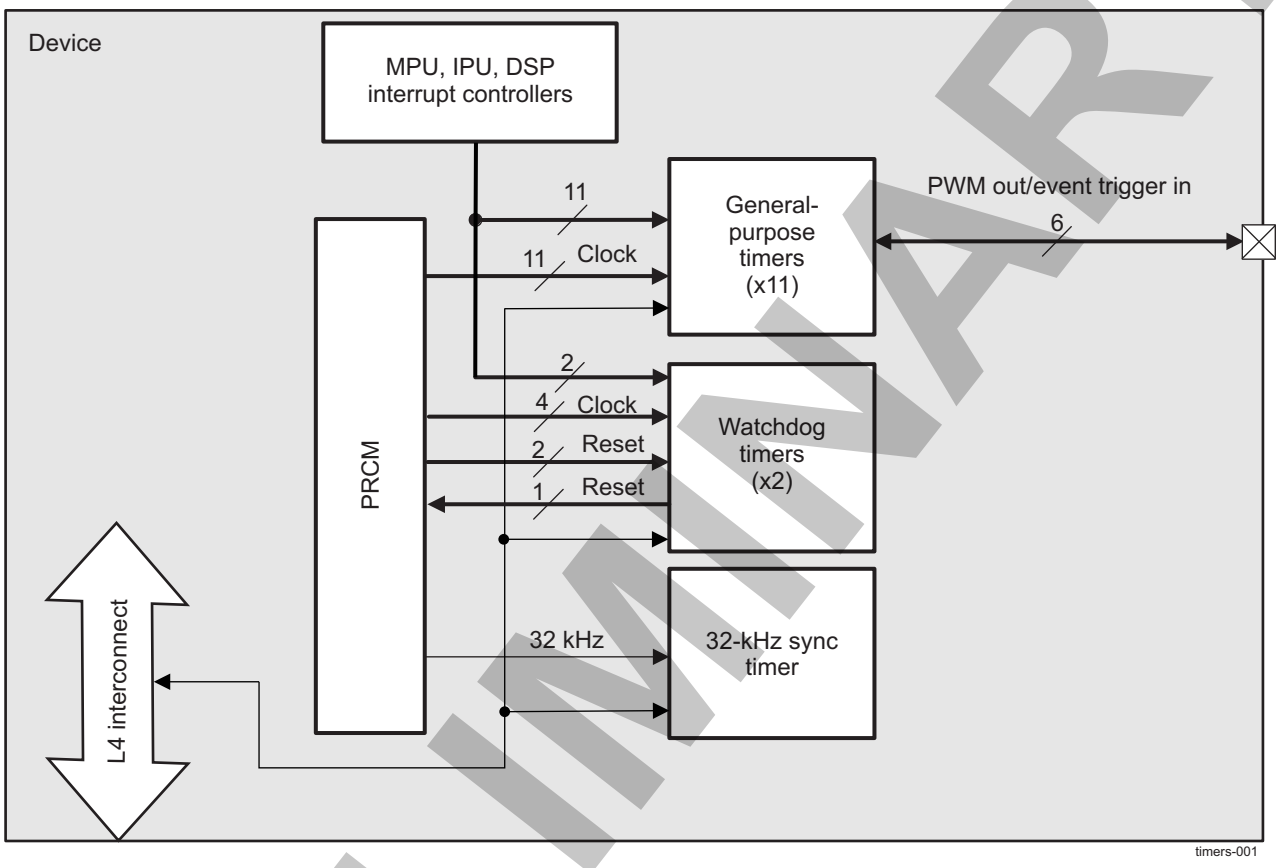
This chapter describes the timer modules for the device.

Topic **Page**

22.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose (GP) timers, two watchdog timers, and a 32-kHz synchronized timer (COUNTER_32K). Figure 22-1 is a high-level block diagram of the device timers.

Figure 22-1. Timers Overview



The two watchdog timers are clocked with 32-kHz clocks. The 32-kHz sync timer, which is reset only at power up, provides the operating system (OS) with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

22.2 General-Purpose Timers

22.2.1 General-Purpose Timers Overview

The device has 11 GP timers: TIMER1 through TIMER11.

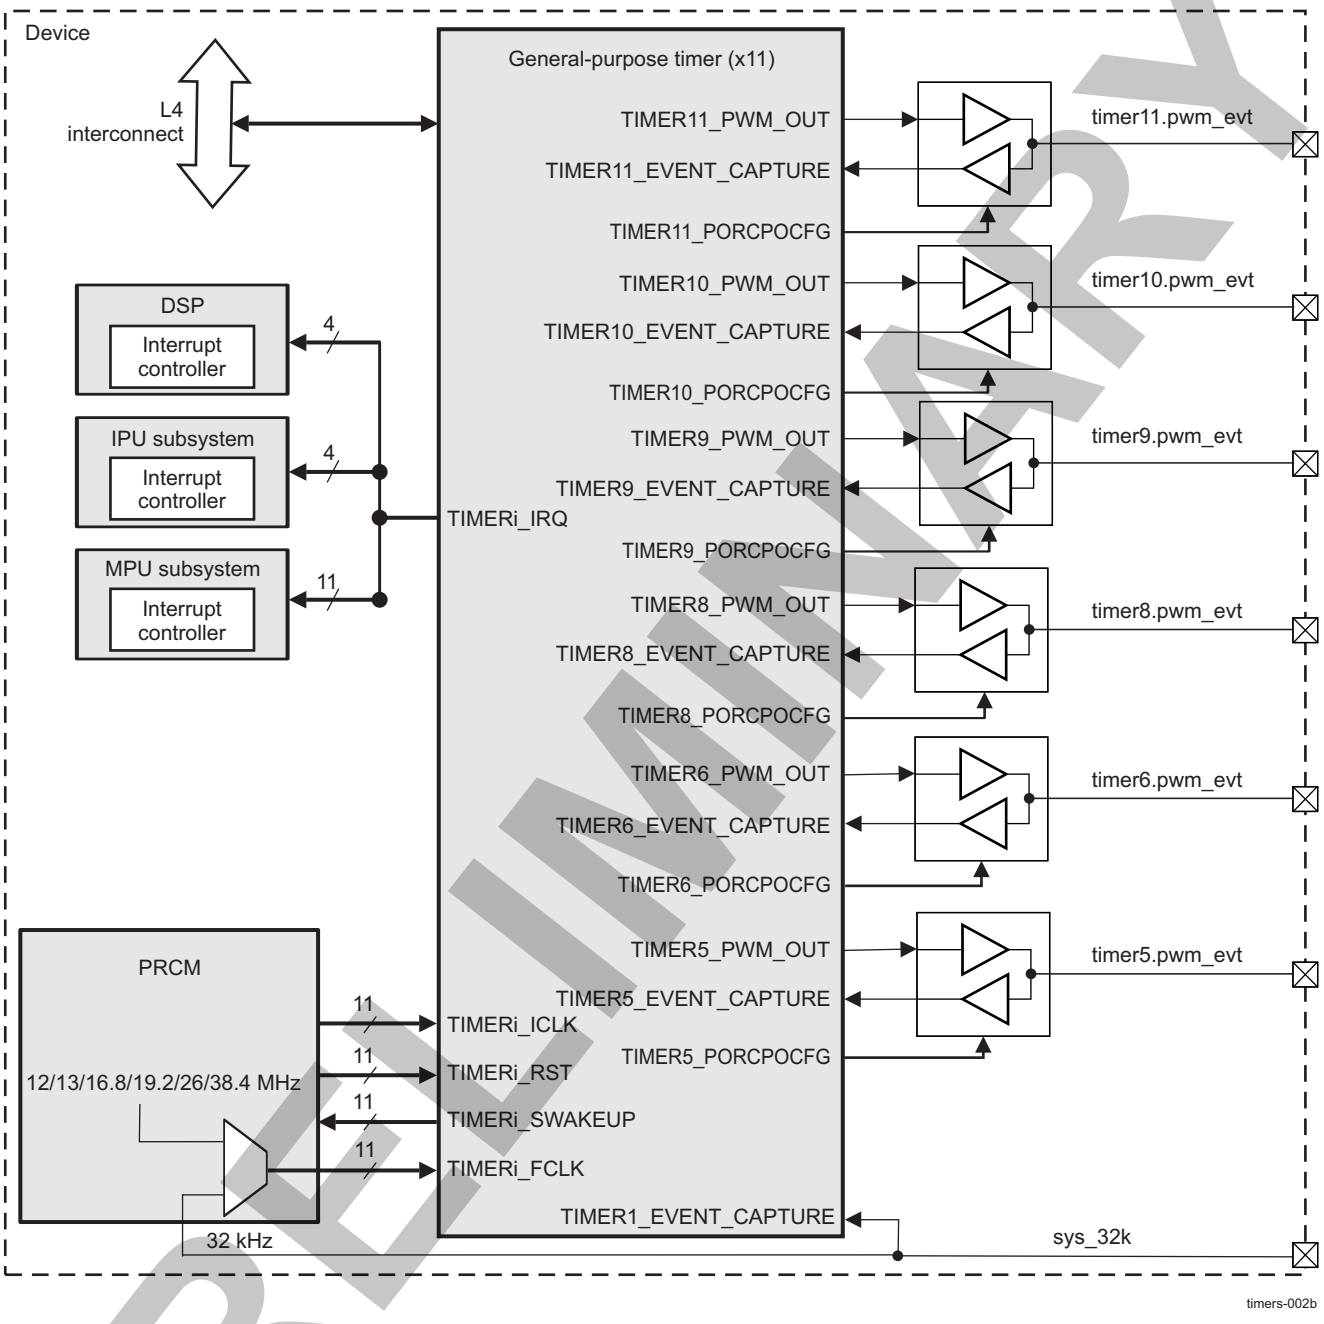
- TIMER1(1ms tick): has its event capture pin tied to 32KHz clock and can be used to gauge the system clock input and detects its frequency among 12, 16.8, 19.2, 26 or 38.4 MHz. It includes a specific functions to generate accurat tick interrupts to the operating system and it belons to the WKUP domain
- TIMER2 and TIMER10:(1ms tick timers): they include a specific functions to generate accurate tick interrupts to the operating system, TIMER2 & TIMER10 belong to the L4_PER domain
- TIMER3/4/9/11: they belong to the L4_PER domain
- TIMER5 trough TIMER8: belong to the Audio domain and are part of the ABE module

Each timer can be clocked from the system clock (12, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of clock source is made at the power, reset, and clock management (PRCM) module level. For more information, see Section 3.6.3.1, *PRM Clock Source*.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition TIMER3/4/9/11 can generate interrupt to IPU subsystem and TIMER5/6/7/8 can generate interrupts to the DSP subsystem.

TIMER5, TIMER6 and TIMER8 through TIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). Figure 22-2 is an overview of the GP timers.

Figure 22-2. GP Timers Overview



22.2.1.1 GP Timer Features

The following are the main features of the GP timer controllers:

- Level 4 (L4) slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported

- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n, where n = [0:8])
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32.768-Hz functional clock generated (only TIMER1, TIMER2, and TIMER10)

22.2.2 GP Timer Environment

22.2.2.1 GP Timer External System Interface

Six of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only TIMER5, TIMER6, and TIMER8 through TIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. TIMER1 is also configured to receive an event trigger input (TIMER1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input, detecting its frequency among 12, 16.8, 19.2, 26, or 38.4 MHz.

Figure 22-3 shows the external system interface for the GP timers, and Table 22-1 describes the GP timer inputs and outputs.

NOTE: Software control must ensure that MUX mode is configured to select the timerx_pwm_evt (where x = 5, 6, 8 to 11) signal on only one pad. Other pads on which the same signal is multiplexed must be configured in safe mode or non-dmtimer mode to avoid two different pads driving the same signal.

For more information about the configuration of the timerx_pwm_evt I/O pads, see Section 18.4.8, *PAD Functional Multiplexing and Configuration*.

Figure 22-3. GP Timers External System Interface

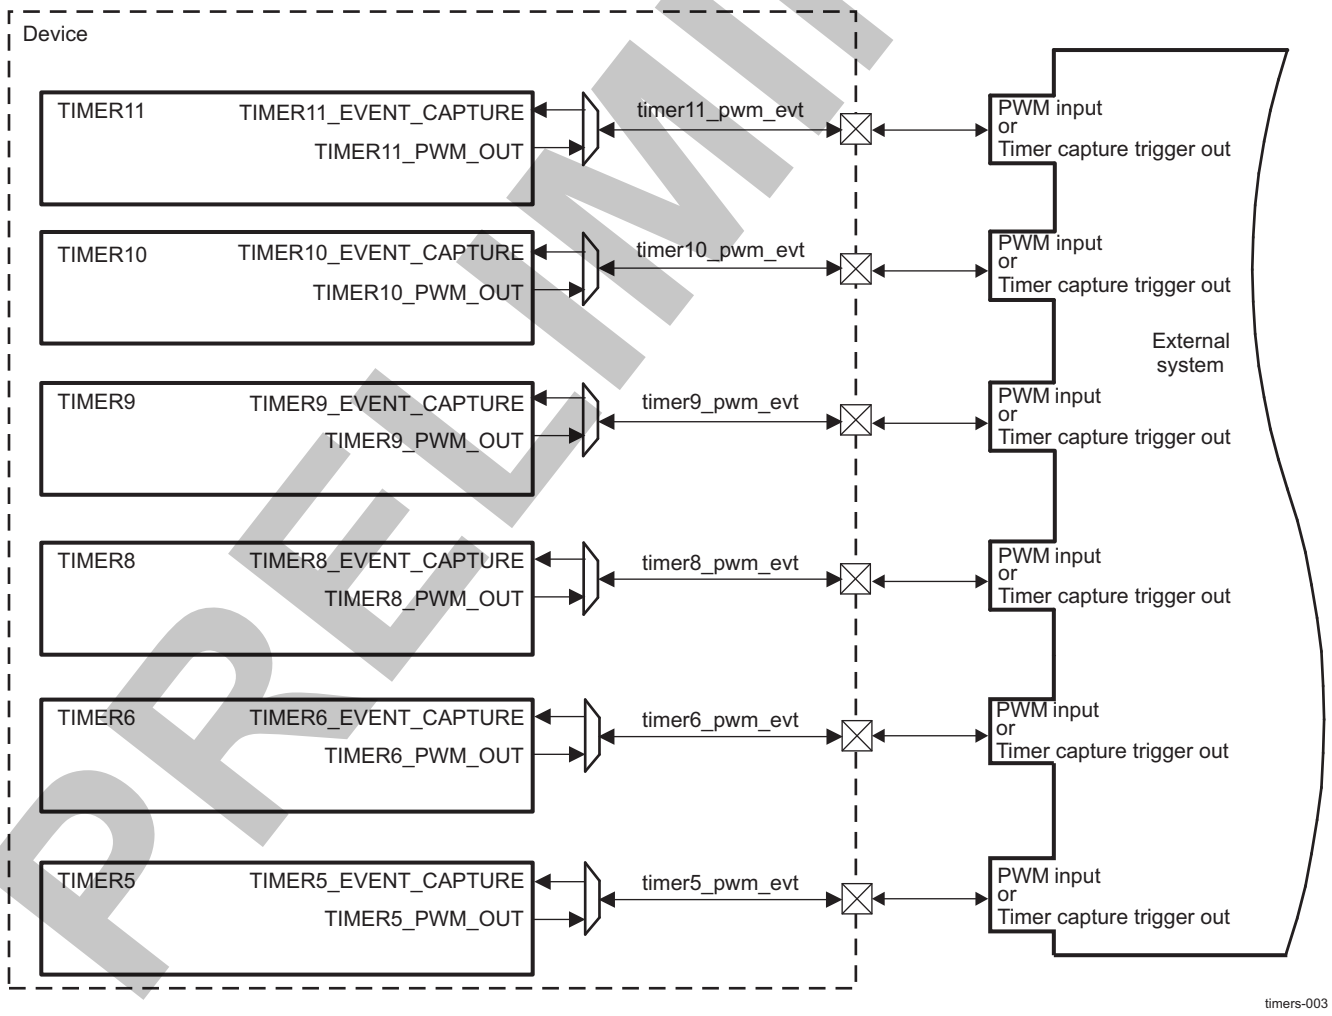


Table 22-1. Input/Output Description

Pin Name	Type [1]	Reset Value	Signal Name	Description
timer5_pwm_evt	I/O	0	TIMER5_EVENT_CAPTURE TIMER5_PWM_OUT	TIMER5 trigger input/ PWM output
timer6_pwm_evt	I/O	0	TIMER6_EVENT_CAPTURE TIMER6_PWM_OUT	TIMER6 trigger input/ PWM output
timer8_pwm_evt	I/O	0	TIMER8_EVENT_CAPTURE TIMER8_PWM_OUT	TIMER8 trigger input/ PWM output
timer9_pwm_evt	I/O	0	TIMER9_EVENT_CAPTURE TIMER9_PWM_OUT	TIMER9 trigger input/ PWM output
timer10_pwm_evt	I/O	0	TIMER10_EVENT_CAPTURE TIMER10_PWM_OUT	TIMER10 trigger input/ PWM output
timer11_pwm_evt	I/O	0	TIMER11_EVENT_CAPTURE TIMER11_PWM_OUT	TIMER11 trigger input/ PWM output

(1) When configured for that function; I = Input, O = Output

NOTE: The event trigger input (TIMERi_EVENT_CAPTURE) for TIMER2 through TIMER4, and TIMER7 is internally tied low, and the PWM output (TIMERi_PWM_OUT) is not connected.

NOTE: For TIMER5, TIMER6, and TIMER8 through TIMER11, the TIMERi_PORGPOCFG signal selects to connect the general purpose timer(GPT) PWM output or the GPTcapture input to the timerx_pwm_evt (where x = 5, 6, 8 to 11) pad at the top level.

When the TCLR[14] GPO_CFG bit = 0b1, the timerx_pwm_evt functions as a capture input.

When the TCLR[14] GPO_CFG bit = 0b0, the timerx_pwm_evt functions as a PWM output (GPO_CFG = 0b0).

22.2.3 GP Timer Integration

Figure 22-4 shows the integration of the GP timer in the device.

Figure 22-4. GP Timer Integration

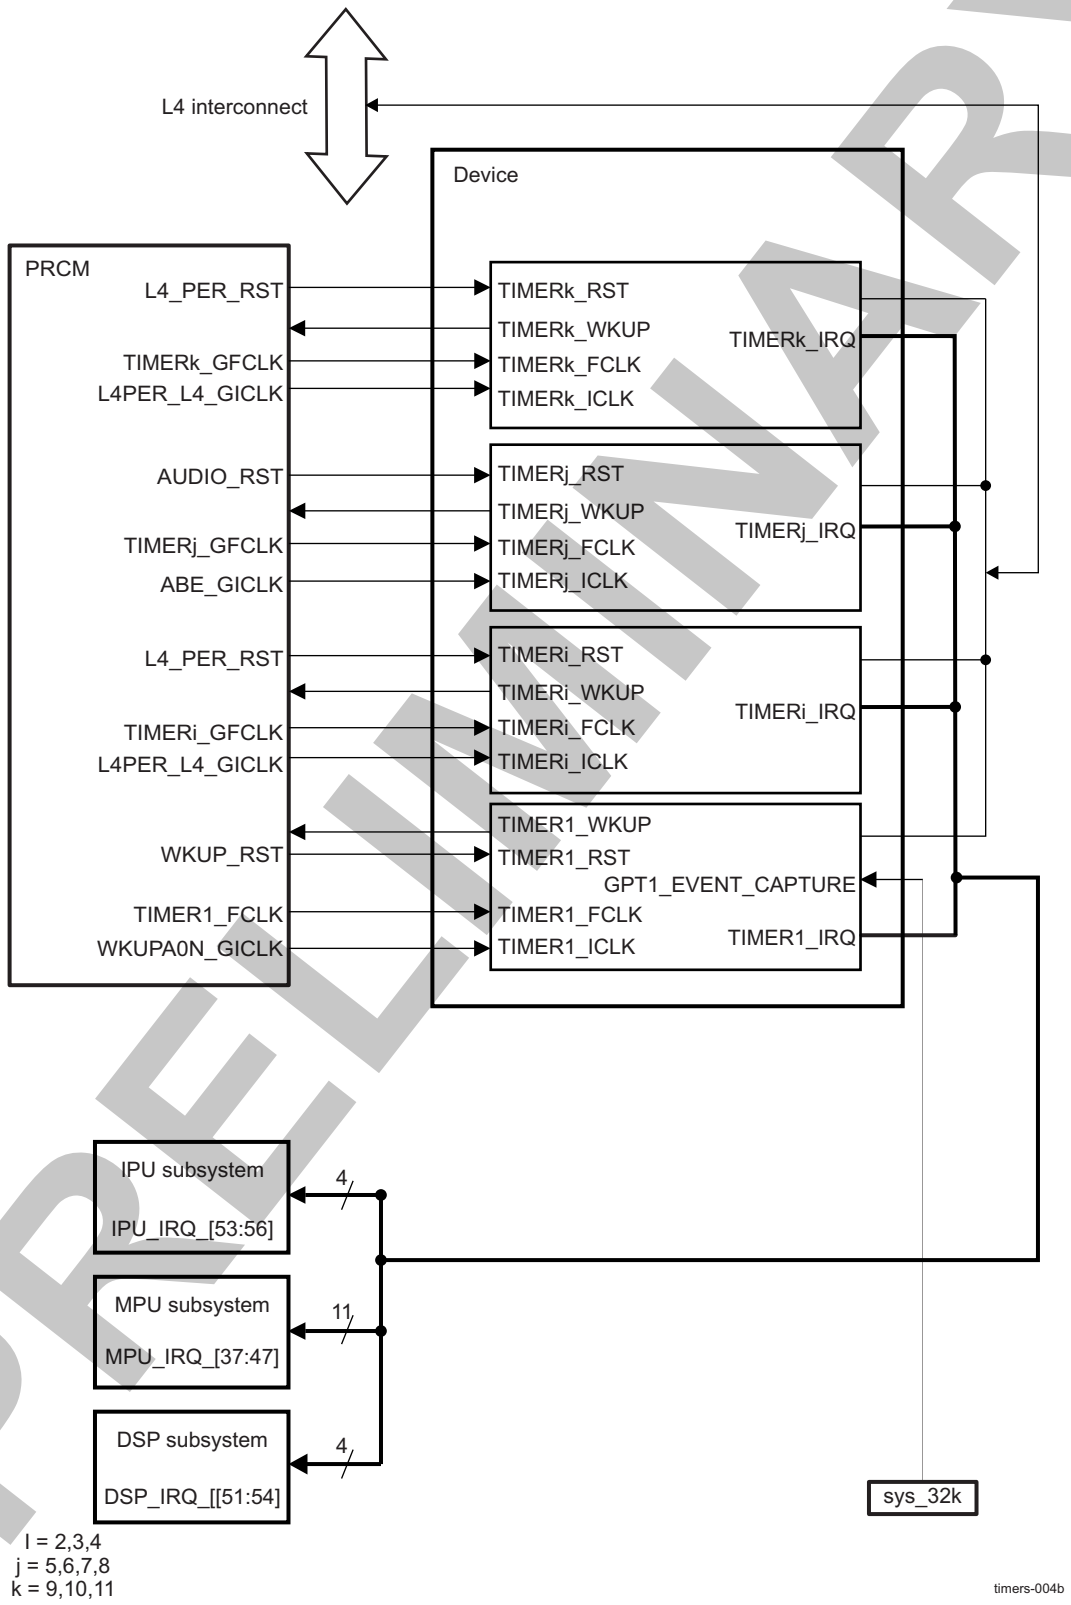

Table 22-2 through Table 22-4 summarize the integration of the module in the device.

Table 22-2. Integration Attributes

Module Instance	Attributes

NOTE: For the description of the interrupt source, see Section 22.2.4.4, *GP Timer Interrupts*.

22.2.4 GP Timer Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line.

Each internal interrupt source can be independently enabled and disabled by a dedicated bit in the IRQSTATUS_SET and IRQSTATUS_CLR register for the interrupt features, and a dedicated bit of the IRQWAKEEN register for the wake-up of TIMER1, TIMER2, and TIMER10. In addition, these timers have a mechanism implemented to generate an accurate tick interrupt.

For GP timers 3 through 9 and timer 11, each internal interrupt source can be independently enabled and disabled through the IRQENABLE_SET and IRQENABLE_CLR register for the interrupt features, and a dedicated bit of the IRQWAKEEN register for the wake-up features.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see Section 22.2.1, *GP Timer Overview*).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

The capture and compare modes are disabled by default after core reset.

22.2.4.1 GP Timer Block Diagram

Figure 22-5 is a block diagram of the common GP timers, and Figure 22-6 is a block diagram of the GP timers with a 1-ms tick generation module.

Figure 22-5. Block Diagram of TIMER3 Through TIMER9, and TIMER11

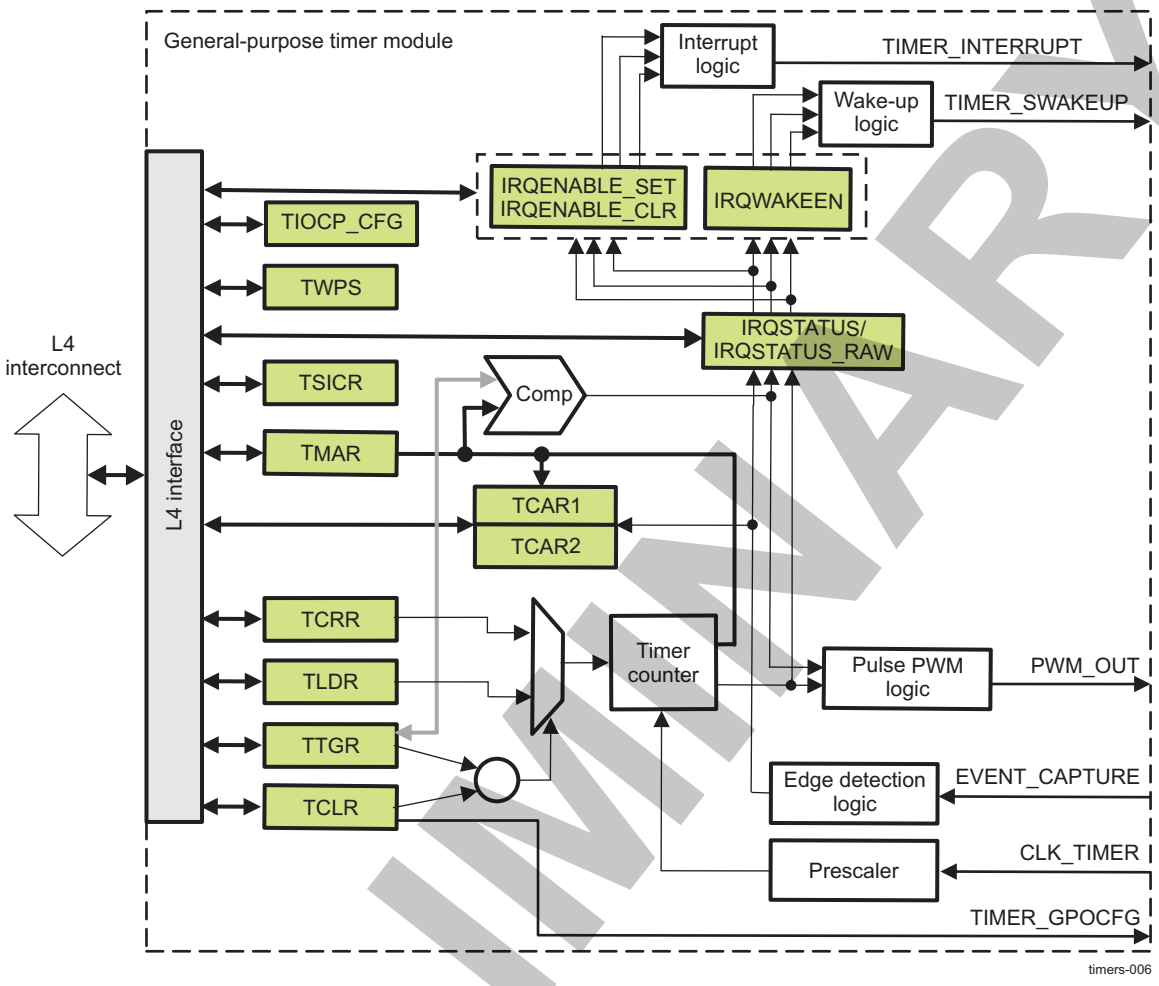

Figure 22-6. Block Diagram of TIMER1, TIMER2, and TIMER10

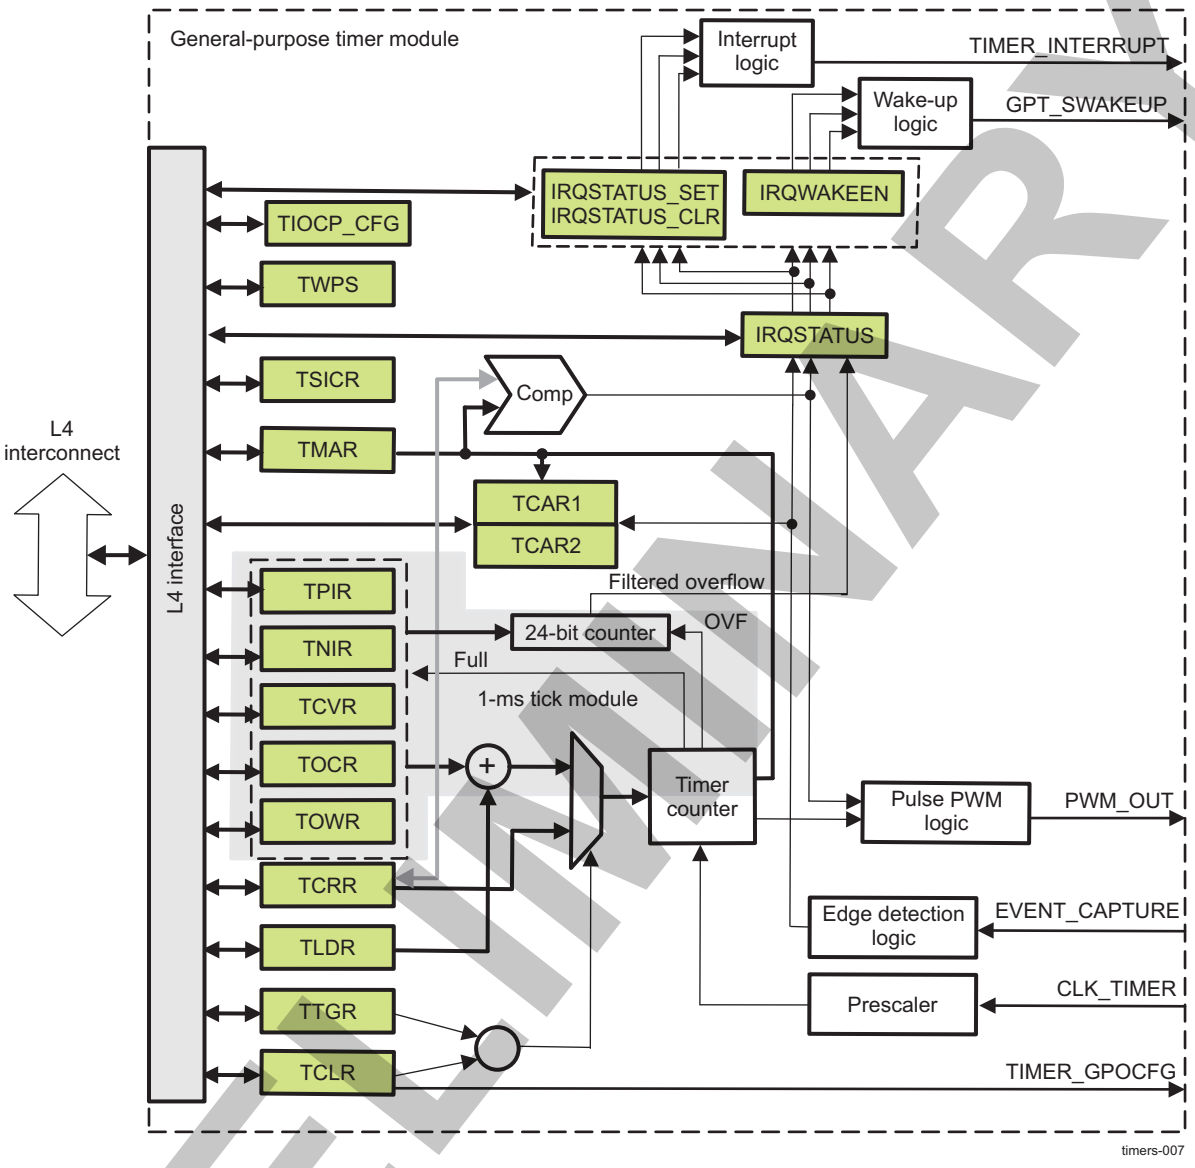


22.2.4.2 Power Management

At the PRCM module level, when all conditions to shut off the functional or interface output clocks in the PRCM module are met (see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the TIOCP_CFG[3:2] IDLEMODE bit field.

Table 22-5 lists the IDLEMODE settings and the related acknowledgment modes.

Table 22-5. IDLEMODE Settings

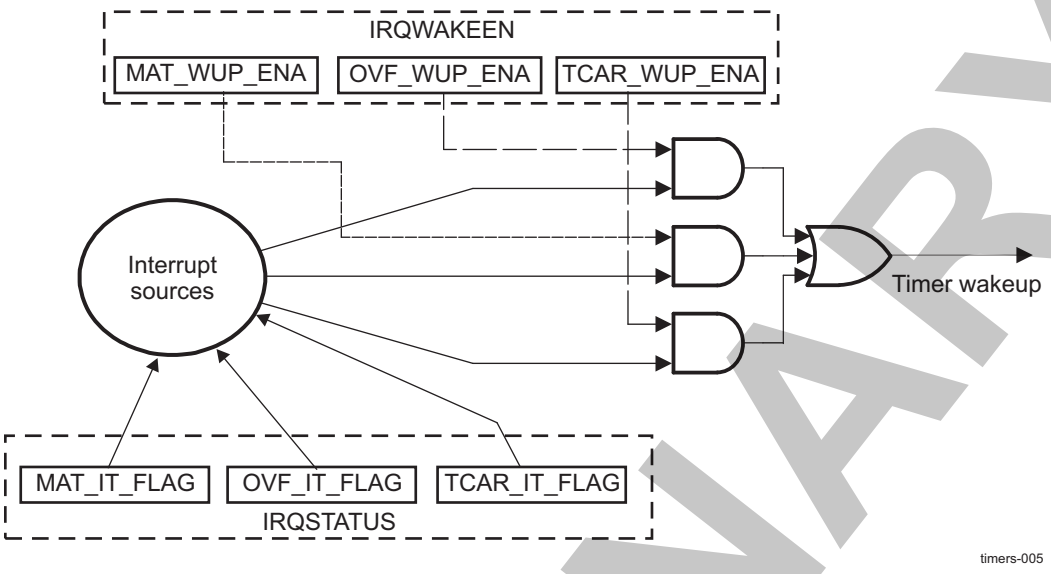
IDLEMODE Value	Selected Mode	Description
00	Force-idle	The GP timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off.
01	No-idle	The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
10	Smart-idle	The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach to efficient system power management.
11	Smart-idleWakeup	The module behaves like in Smart-idle mode, with the exception, that it can issue a wake-up request in sleep mode, if the functional clock is not cut off.

22.2.4.2.1 Wake-Up Capability

If the TIOCP_CFG[3:2] IDLEMODE bit field sets the smart-idle mode, the timer evaluates its internal capability to have the interface clock switched off. When there is no further internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the wake up capability is enabled by the corresponding bit field in IRQWAKEEN register.

Figure 22-7 shows the wake-up request generation. For more information about the GP timer clock control, Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset and Clock Management*.

Figure 22-7. Wake-Up Request Generation



The expected source of the wake-up event is an overflow (TCRR), a timer match (the compare result of TCRR and TMAR matches the counter value), and a timer capture.

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS). The pending wake-up event is reset when the set status bit is overwritten with 1.

NOTE: The status bit must be reset to re-enter idle mode.

22.2.4.3 Software Reset

Two bits can generate a software reset of the GP timer:

- TIOCP_CFG[0] SOFTRESET
- TSICR[1] SFT

For both bits, all read accesses return 0.

The TIOCP_CFG[0] SOFTRESET bit allows resetting of the functional and interface domains. The TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the TIOCP_CFG[0] SOFTRESET bit. This bit monitors the internal reset status.

22.2.4.4 GP Timer Interrupts

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled and disabled in the interrupt-enable register (IRQSTATUS_SET for TIMER1/2/10 and IRQENABLE_SET for other timers) and disabled in the interrupt-disable register (IRQSTATUS_CLR for TIMER1/2/10 and IRQENABLE_CLR for other timers). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (IRQSTATUS).

22.2.4.5 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (the TCLR[0] ST bit). The timer counter register (TCRR) can be loaded when stopped or on-the-fly (while counting). TCRR can be loaded directly by a TCRR write access with a new timer value. TCRR can also be loaded with the value held in the timer load register (TLDR) by a trigger register (TTGR) write access. The loading of TCRR is done regardless of the written value of TTGR. The value of TCRR can be read when stopped or captured on-the-fly by a TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the TCLR[1] AR bit is set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the TCLR[1] AR bit is set to 1), TCRR is reloaded with the value of TLDR after a counting overflow occurs.

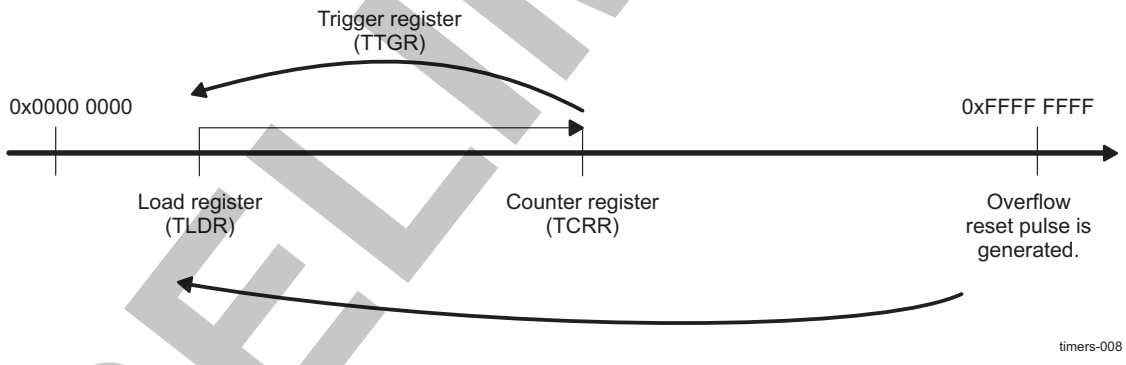
CAUTION

Do not put the overflow value (0xFFFF FFFF) in the TLDR register because it can lead to undesirable results.

An interrupt can be issued on overflow if the overflow interrupt-enable bit is set in the timer interrupt-enable register (the IRQSTATUS_SET[1] OVF_EN_FLAG bit is set to 1for TIMER1/2/10 and the IRQENABLE_SET[1]OVF_EN_FLAG bit is set to 1 for other timers). A dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The TCLR[12] PT bit selects pulse/toggle modulation (the TCLR[11:10] TRG bit field selects trigger mode).

Figure 22-8 shows the TCRR timing value.

Figure 22-8. TCRR Timing Value



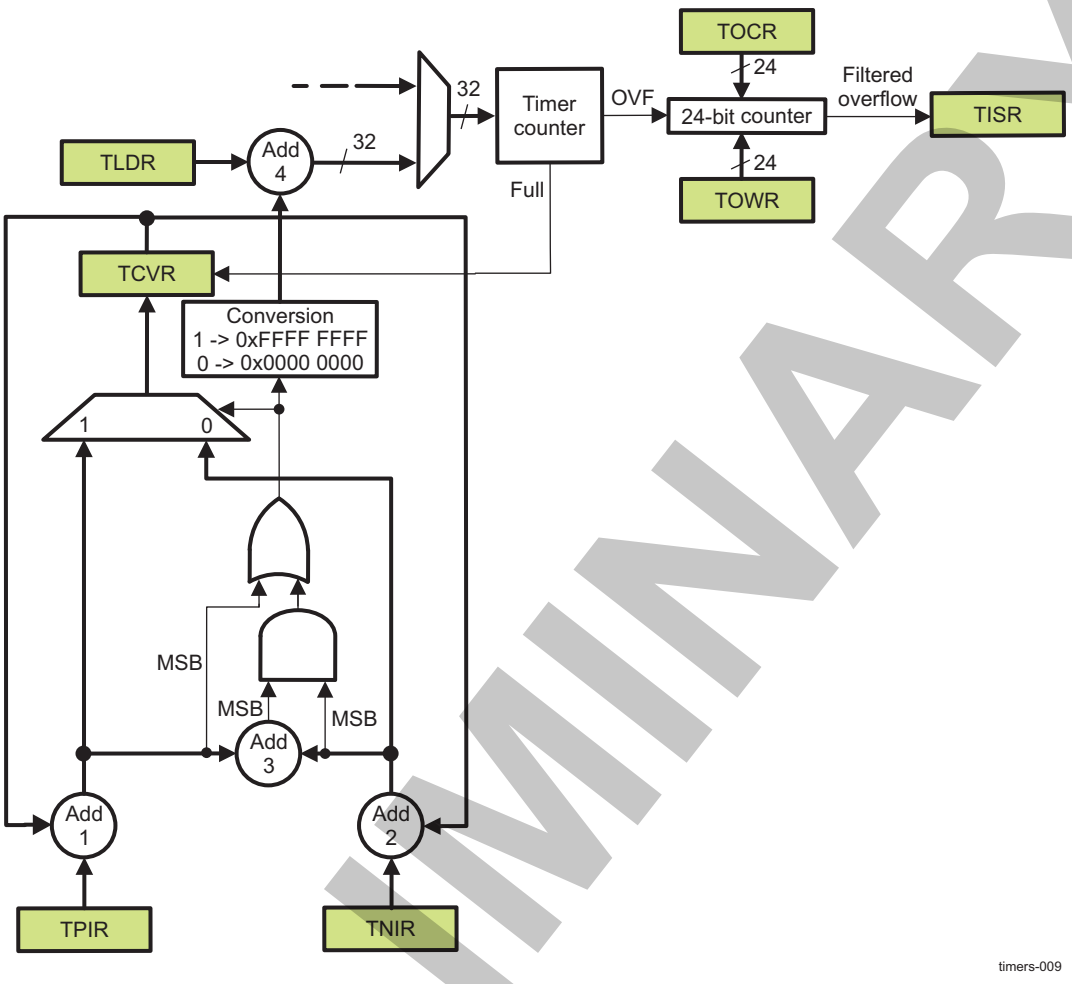
22.2.4.5.1 1-ms Tick Generation (Only TIMER1, TIMER2, and TIMER10)

The interrupt period is not exactly 1 ms, because the timer input clock is 32.768 Hz. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations from the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32.768-Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. See Figure 22-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (the TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (the TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 22-9. Block Diagram of the 1-ms Tick Module



The TPIR, TNIR, and TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (the TCRR[31:0] TIMER_COUNTER bit field) is the value of the TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of TLDR[31:0] LOAD_VALUE –1 (period greater than 1 ms).

Table 22-6 lists the value loaded in the TCRR according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value; MSB = 1: Negative value

Table 22-6. Value Loaded in TCRR to Generate 1-ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	Value of TCRR Register
0	0	0	TLDR[31:0] LOAD_VALUE bit field
0	0	1	TLDR[31:0] LOAD_VALUE bit field
0	1	0	TLDR[31:0] LOAD_VALUE bit field
0	1	1	TLDR[31:0] LOAD_VALUE –1
1	0	0	N/A
1	0	1	N/A
1	1	0	TLDR[31:0] LOAD_VALUE –1
1	1	1	TLDR[31:0] LOAD_VALUE –1

The values of the TPIR and TNIR registers are calculated using the following formulas:

- Positive increment value = ((INTEGER[$F_{clk} \times T_{tick}$] + 1) × 1e6) – ($F_{clk} \times T_{tick} \times$ 1e6)
- Negative increment value = (INTEGER[$F_{clk} \times T_{tick}$] × 1e6) – ($F_{clk} \times T_{tick} \times$ 1e6)

NOTE: F_{clk} clock frequency (kHz)

T_{tick} tick period (ms)

The timer overflow counter register (TOCR) and the timer overflow wrapping register (TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR. When the values in the 24-bit TOCR match the values in the 24-bit TOWR and the timer overflow is asserted, the TOCR is reset and an interrupt is generated to the IRQSTATUS register.

NOTE: TOWR has to be set to requested value + 1. For example, if no interrupt needs to be masked TOWR must be set to 0, if one interrupt needs to TOWR must be set to 2, if two interrupts need to be masked TOWR must be set to 3 and so on.

It is important to have in mind that the case when FFFFFF interrupts need to be masked is not possible.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of TIMER1, TIMER2, and TIMER10 remain unchanged.

For 1-ms tick with a 32.768-Hz clock:

- TPIR[31:0] POSITIVE_INC_VALUE = 232,000
- TNIR[31:0] NEGATIVE_INC_VALUE = –768,000
- TLDR[31:0] LOAD_VALUE = 0xFFFF FFE0

NOTE: Any value of the tick period can be generated with the appropriate value of the TPIR, TNIR, and TLDR.

By default, the TPIR, TNIR, TCVR, TOCR, and TOWR and the associated logic are in reset mode (all 0s) and have no effect on the programming model.

22.2.4.6 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the TCRR can be captured and saved in the TCAR1 or TCAR2 register function of the mode selected in the TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

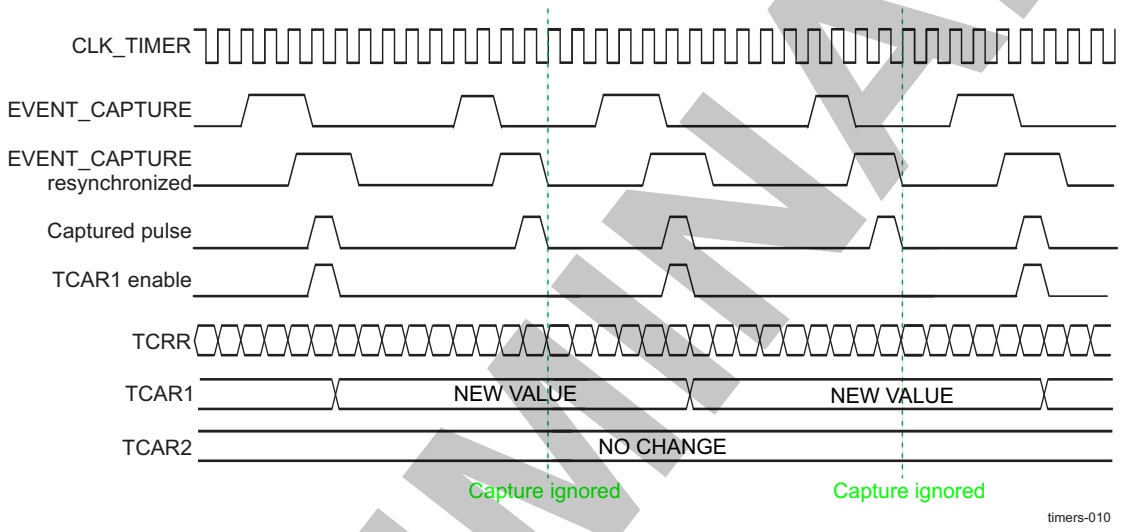
The rising edge, falling edge, or both, can be selected in the TCLR[9:8] TCM bit field to trigger the timer counter capture. The module sets the IRQSTATUS[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value TCRR is stored in timer capture register TCAR1 or TCAR2, as follows:

- If the TCLR[13] CAPT_MODE bit is 0, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and the next events are ignored (no update on the TCAR1 register and no interrupt triggering) until the detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG is cleared by writing 1 to it.
- If the TCLR[13] CAPT_MODE bit is 1, on the first enabled capture event, the value of the counter register is saved in the TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on TCAR1/TCAR2 and no interrupt triggering) until the detection logic is reset or the IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The IRQSTATUS[2] TCAR_IT_FLAG bit is cleared by writing 1 to it or when the edge detection mode bits (the TCLR[9:8] TCM bit field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). A negative or positive pulse input can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt-enable bit is set in the IRQSTATUS_SET[2] TCAR_EN_FLAG bit (for TIMER1/2/10) or in the IRQENABLE_SET[2] TCAR_EN_FLAG bit (for other timers). See the examples in Figure 22-10 and Figure 22-11.

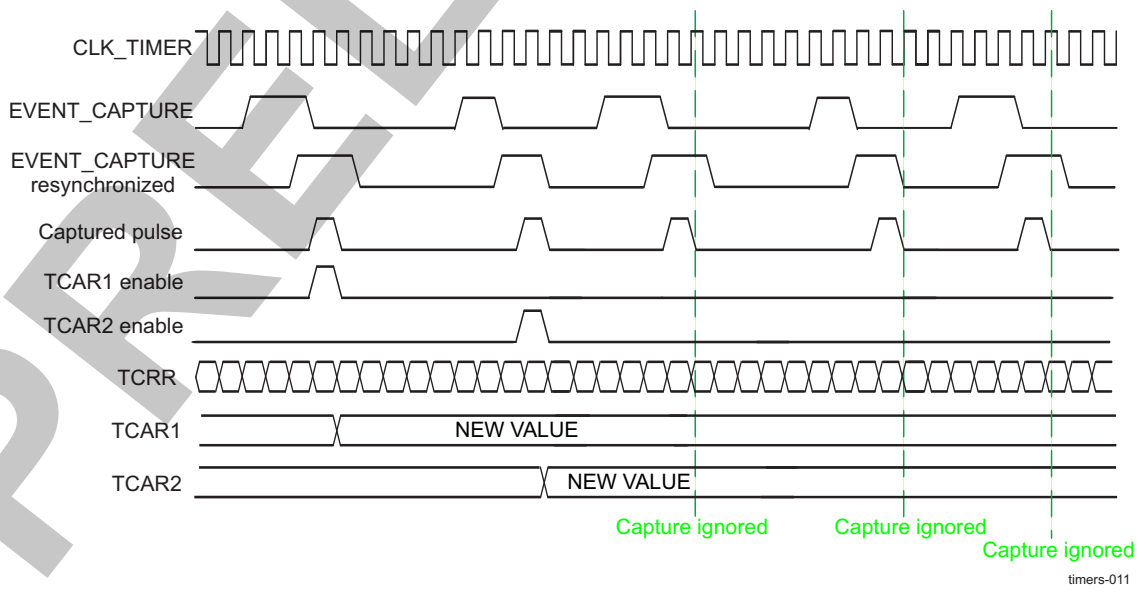
In Figure 22-10, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 and TCAR2 registers, and only the TCAR1 register updates.

Figure 22-10. Capture Wave Example for TCLR[13] CAPT_MODE = 0



In Figure 22-11, the value of the TCLR[9:8] TCM bit field is 0b01, and the TCLR[13] CAPT_MODE bit is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the TCAR1 register on the first enabled event, and the TCAR2 register updates on the second enabled event.

Figure 22-11. Capture Wave Example for TCLR[13] CAPT_MODE = 1



22.2.4.7 Compare Mode Functionality

When the compare-enable register TCLR[6] CE bit is set to 1, the timer value (the TCRR[31:0] TIMER_COUNTER bit field) is continuously compared to the value held in the timer match register (TMAR). The value of the TMAR[31:0] COMPARE_VALUE bit field can be loaded at any time (timer counting or stopped). When the TCRR and the TMAR values match, an interrupt is issued, if the IRQSTATUS_SET[0] MAT_EN_FLAG bit (for TIMER1, TIMER2, and TIMER10), or the IRQENABLE_SET[0] MAT_EN_FLAG bit (for other timers) is set.

To prevent any unwanted interrupts due to reset value matching effect, write a compare value to the TMAR before setting the TCLR[6] CE bit.

The dedicated output pin (timer PWM) can be programmed in the TCLR[12] PT bit through the TCLR[11:10] TRG bit field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

22.2.4.8 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the TCLR[5] PRE bit is set. The TCLR[4:2] PTV bit field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 22-7 lists the prescaler/timer reload values versus contexts.

Table 22-7. Prescaler/Timer Reload Values Versus Contexts

Context	Prescaler	Timer Counter
Overflow (when autoreload is on)	Reset	TLDR[31:0]
TCRR write	Reset	TCRR[31:0]
TTGR write	Reset	TLDR[31:0]
Stop	Reset	Frozen

22.2.4.9 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The TCLR[11:10] TRG bit field determines on which register value the PWM pin toggles. Either overflow or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

NOTE: In toggle mode, when TCLR[11:10] TRG = 0x2 (overflow and match), the first event that toggles the PWM line is an overflow event. If a match event occurs first, it does not toggle the PWM line (see Figure 22-13).

The TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the TCLR[11:10] TRG bit field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 22-12, the internal overflow pulse is set each time the (0xFFFF FFFF – TLDR[31:0] LOAD_VALUE + 1) value is reached, and the internal match pulse is set when the counter reaches the value of TMAR. Depending on the value of the TCLR[12] PT bit and TCLR[11:10] TRG bit field, the timer provides pulse or PWM event on the output pin (timer PWM).

The TLDR and TMAR must keep values below the overflow value (0xFFFF FFFF) by at least two units. If the PWM trigger events are both overflow and match, the difference between the values kept in the TMAR and the value in theTLDR must be at least two units. When match event is used, the compare mode TCLR[6] CE bit must be set.

In Figure 22-12, the TCLR[7] SCPWM bit is set to 0. In Figure 22-13, the TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (TCLR[7] SCPWM bit).

Figure 22-12. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 0

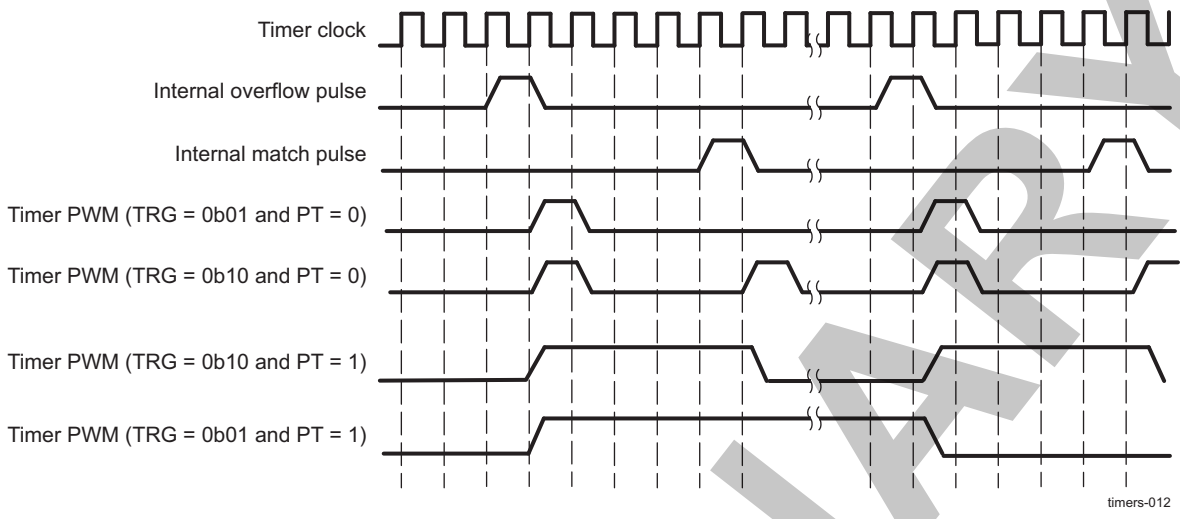


Figure 22-13. Timing Diagram of PWM With TCLR[7] SCPWM Bit = 1

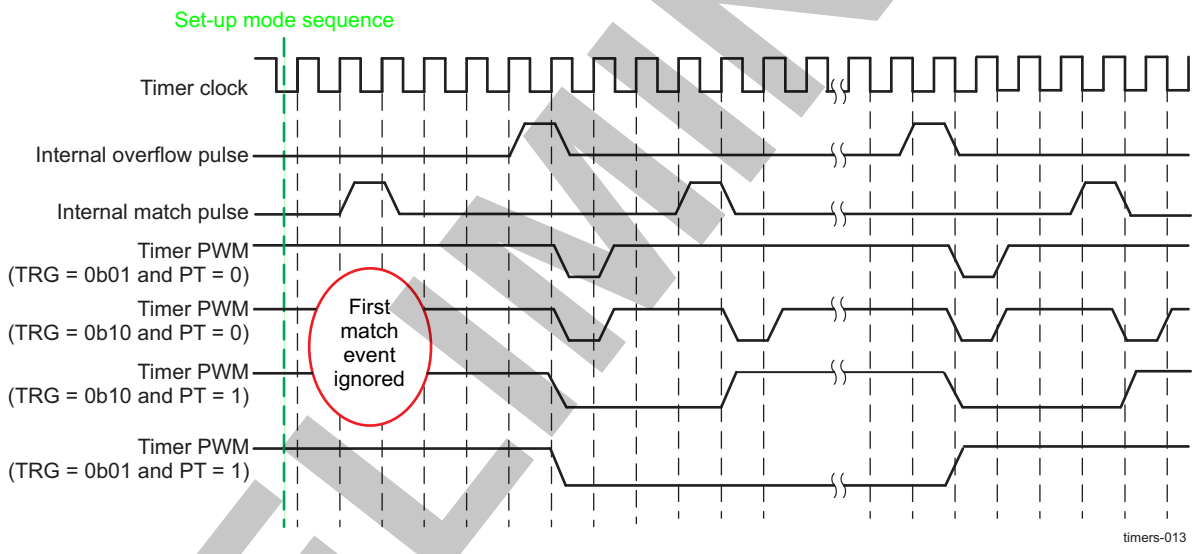

22.2.4.10 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (the TCLR[5] PRE bit and TCLR[4:2] PTV bit field)
- Value loaded into the TLDR

Table 22-8 lists the prescaler clock ratio values.

Table 22-8. Prescaler Clock Ratio Values

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Table 22-8. Prescaler Clock Ratio Values (continued)

TCLR[5] PRE	TCLR[4:2] PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

Thus, the timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – TLDR + 1) × (timer-functional clock period) × PS

With (timer-functional clock period) = 1/(timer-functional clock frequency) and PS = $2^{(PTV + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the TCLR[1] ST bit to have some latency before the register is updated:

2.5 × functional clock cycles write_TIMER_TCLR_latency 3.5 × functional clock cycles

Remember to consider this latency whenever the timer must be started or stopped by a software change to the TCLR[1] ST bit.

CAUTION

- In non-PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In PWM mode, TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and the TCLR[5] PRE bit set to 0, the timer output period is as listed in Table 22-9.

Table 22-9. Value and Corresponding Interrupt Period

TLDR[31:0] LOAD_VALUE	Interrupt Period
0x0000 0000	39 h
0xFFFF 0000	2.1 s
0xFFFF FFF0	524 µs
0xFFFF FFFE	65.5 µs

22.2.4.11 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the TIOCP_ CFG[1] EMUFREE bit.

If the TIOCP_CFG[1] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the TIOCP_CFG[1] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (timerx_pwm_evt, where x = [8:11]) is internally synchronized on two timer-clock rising edges.

22.2.4.12 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration. All registers are 32 bits wide, accessible through the OCP interface with 16- or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB) first. Write operations to the following GP timer registers can skip the MSB access if it is not necessary to update the 16 MSBs of the register:

- TIDR (all GP timers)
- TIOCP_CFG (all GP timers)
- IRQSTATUS_SET (GP timers 1, 2, 10)
- IRQSTATUS_RAW (all GP timers)
- IRQSTATUS (all GP timers)
- IRQENABLE_SET(all GP timers except 1,2,10)
- IRQENABLE_CLR(all GP timers except 1,2,10)
- IRQSTATUS_SET (GP timers 1, 2, 10)
- IRQSTATUS_CLR (GP timers 1, 2, 10)
- IRQWAKEEN (all GP timers)
- TSICR (all GP timers)

Write operations to the following functional registers must be complete (the MSB must be written even if the MSB data is not used):

- TCLR (all GP timers)
- TCRR (all GP timers)
- TLDR (all GP timers)
- TTGR (all GP timers)
- TMAR (all GP timers)
- TPIR (GP timers 1, 2, 10)
- TNIR (GP timers 1, 2, 10)
- TCVR (GP timers 1, 2, 10)
- TOCR (GP timers 1, 2, 10)
- TOWR (GP timers1, 2, 10)

The following L4 synchronous registers are not affected by the posted/nonposted mode selection; the write/read operation is effective and acknowledged (command accepted) after one L4 clock cycle from command assertion:

- TIDR
- TIOCP_CFG
- IRQSTATUS
- IRQSTATUS_RAW
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQSTATUS_SET
- IRQSTATUS_CLR
- IRQWAKEEN
- TWPS
- TSICR

22.2.4.12.1 Writing to Timer Registers

The host uses the OCP interface to write to the following registers synchronously with the timer interface clock:

- TLDR
- TCRR
- TCLR
- TIOCP_CFG
- IRQSTATUS
- IRQENABLE_SET
- IRQENABLE_CLR
- IRQWAKEEN
- TTGR
- TSICR
- TMAR

TIMER1, TIMER2, and TIMER10 also have the following registers:

- IRQSTATUS_SET
- IRQSTATUS_CLR
- TPIR
- TNIR
- TCVR
- TOCR
- TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

22.2.4.12.1.1 Write Posting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (TCLR, TCRR, TLDR, TTGR, TMAR, and TPIR, TNIR, TCVR, TOCR, and TOWR for TIMER1, TIMER2, and TIMER10). Therefore, the write transaction is immediately acknowledged on the open-core protocol (OCP) interface, although the effective write operation occurs later because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the tImer write-posted status (TWPS) register. In this mode, it is mandatory that software check this status bit before any write access. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the value of the timer counter register synchronously with the OCP clock. Consequently, any read access to TCRR does not add any resynchronization latency; the current value is always available.

NOTE: Because the overflow IRQ is generated when the value of TCRR reaches 0xFFFF FFFF, and not when it changes its value to the value after overflow, it is necessary to wait a delay of (1 × PS × timer functional clock period) before any read access to TCRR to ensure a correct reading of its content.

NOTE: If TTGR register is written during posted write to TCRR , the value to be written to TCRR will be discarded.

If a posted write to TCVR is started, the user must not write to TPIR or TNIR before the TCVR write is finished, because the value of TCVR is re-evaluated, so both the value to be written, and the recalculated value will be discarded.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: freq(timer clock) < freq(OCP interface clock) / 4.

22.2.4.12.1.2 Write Nonposting Synchronization Mode

This mode is used if the TSICR[2] POSTED bit is set to 0. It uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the OCP interface frequency and the timer clock frequency. Recommended frequency range is freq(timer clock) > = freq (OCP interface clock) / 4.

22.2.4.12.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (TCRR, TCAR1, and TCAR2) captures the current timer counter value. This must be followed by reading the 16 MSBs. The synchronization schemes for read posted and read non-posted transactions are the same as the corresponded write transactions described before.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

22.2.4.12.2.1 Read Posted

Read posted mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. The following functional frequency range is recommended:

freq(timer) < freq(OCP) / 4

Read posted mode is used if TSICR[2] POSTED is set to 0x1, or if TSICR[3]READ_MODE is set to 0. Read posted mode uses a posted-read scheme for reading any internal timer register. The read transaction is immediately acknowledged on the OCP interface. Because the value to be read has been previously resynchronized, neither the interconnect nor the device that requested the read transaction are stalled.

Read posted mode applies to the following registers:

- TCRR
- TCAR1
- TCAR2
- TCVR
- TOWR

These registers require resynchronization from functional to OCP clock domains.

22.2.4.12.2.2 Read Non-posted

Read non-posted mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. The following functional frequency range is recommended:

freq(timer) ≥ freq(OCP) / 4

Read non-posted mode is used if TSICR[2] POSTED = 0x0 and TSICR[3] READ_MODE = 0x1 . Read non-posted mode uses a non-posted read scheme for reading internal timer registers. The read transaction is not acknowledged on the OCP interface until the effective read operation occurs, after the resynchronization in the timer clock domain. The result is that both the interconnect and the device that requested the read transaction are stalled during this period.

Read non-posted mode applies to the following registers:

- TCRR
- TCAR1
- TCAR2
- TCVR
- TOWR

These registers require resynchronization from functional to OCP clock domains.

22.2.4.13 Posted Mode Selection

A choice between two synchronization modes is made. This choice takes into account the frequency ratio and the stall periods that can be supported by the system without impacting the global performance.

The posted mode selection applies only to registers that require synchronization on or from the timer clock domain.

For write operation, the following registers are affected by posted or non-posted selection:

- TCLR
- TLDR
- TCRR
- TTGR
- TMAR
- TPIR
- TNIR
- TCVR
- TOCR
- TOWR

For read operation, the following registers are affected by posted or non-posted selection:

- TCRR
- TCAR1
- TCAR2
- TCVR
- TOWR

The OCP clock domain synchronous registers (TIDR, TIOCP_CFG, IRQSTATUS, IRQSTATUS_SET, IRQWAKEEN, TWPS and TSICR) are not affected by the posted or non-posted mode selection. The operation (read or write) is effective and acknowledged one OCP clock cycle after the command assertion.

The configuration of the posted or non-posted mode can be changed (overwritten) by software by setting the TSICR[2] POSTED bit. The TSICR[3] READ_MODE bit defines how the read operation is performed when the module is configured in non-posted mode. The following cases are possible:

- TSICR[2] POSTED = 0x1 and TSICR[3]READ_MODE = x (don't care): Read and write operations are expected in posted mode.
- TSICR[2] POSTED = 0x0 and TSICR[3]READ_MODE = 0x0: The write operation is executed in non-posted mode and read is executed in posted mode.
- TSICR[2] POSTED = 0x0 and TSICR[3]READ_MODE = 0x1: Write is executed in non-posted mode and read is executed in non-posted mode.

22.2.5 GP Timer Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

22.2.5.1 Global Initialization

22.2.5.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the GP timer module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the GP timer. For more information, see Section 22.2.3, *GP Timers Integration*, and Section 22.2.2, *GP Timers Environment*. Table 22-10 summarizes the surrounding modules.

Table 22-10. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	The module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 18.4.8 *PAD Functional Multiplexing and Configuration,* in Chapter 18, *Control Module*.
MPU INTC	The MPU INTC configuration must be done to enable the interrupts from the GP timer module. See Chapter 4, *MPU Subsystem*.
DSP INTC	The DSP INTC configuration must be done to enable the interrupts from GP timer module. See Section 5.3.2.6, *INTC,* in Chapter 5, *DSP Subsystem*.

22.2.5.1.2 GP Timer Module Global Initialization

22.2.5.1.2.1 Main Sequence – GP Timer Module Global Initialization

Table 22-11 identifies the main steps for initializing the GP timer module when the module is to be used for the first time.

Table 22-11. GP Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	TIOCP_CFG[0] SOFTRESET	0x1
Wait until reset release?	TIOCP_CFG[0] SOFTRESET	0x0
Configure idle mode.	TIOCP_CFG[3:2] IDLEMODE	xx
Enable wake-up interrupt events.	IRQWAKEEN[2:0]	x
Select posted mode.	TSICR[2] POSTED	x

22.2.5.2 Operational Mode Configuration

22.2.5.2.1 GP Timer Mode

22.2.5.2.1.1 Main Sequence – GP Timer Mode Configuration

Table 22-12 lists the steps in the GP timer mode configuration.

Table 22-12. GP Timer Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	x
Set prescale timer value.	TCLR[4:2] PTV	xxx

Table 22-12. GP Timer Mode Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Enable prescaler.	TCLR[5] PRE	0x1
Enable overflow interrupt.	IRQSTATUS_SET[1] OVF_EN_FLAG(1) IRQENABLE_SET[1] OVF_EN_FLAG(2)	0x1
Load timer counter value.	TCRR	xxx
Load timer load value.	TLDR	xxx
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1, TIMER2, and TIMER10.
(2) Applies to TIMER3 through TIMER 9, and TIMER11.

22.2.5.2.2 GP Timer Compare Mode

22.2.5.2.2.1 Main Sequence – GP Timer Compare Mode Configuration

Table 22-13 lists the steps in the GP timer compare mode configuration.

Table 22-13. GP Timer Compare Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	x
Set prescale timer value.	TCLR[4:2] PTV	xxx
Enable prescaler.	TCLR[5] PRE	0x1
Enable match interrupt.	IRQSTATUS_SET[0] MAT_EN_FLAG(1) IRQENABLE_SET[0]MAT_EN_FLAG(2)	0x1
Load timer counter value.	TCRR	xxx
Load timer compare value.	TMAR	xxx
Enable compare mode.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER1, TIMER2, and TIMER10.
(2) Applies to TIMER3 through TIMER9, and TIMER11.

22.2.5.2.3 GP Timer Capture Mode

22.2.5.2.3.1 Main Sequence – GP Timer Capture Mode Configuration

Table 22-14 lists the steps in the GP timer capture mode configuration.

Table 22-14. GP Timer Capture Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Initialize capture mode.	See Section 22.2.5.2.3.2.	
Enable capture interrupt.	IRQENABLE_SET[2] TCAR_EN_FLAG (1) or IRQSTATUS_SET[2] TCAR_EN_FLAG (2)	0x1
Start the timer.	TCLR[0] ST	0x1
Detect event.	See Section 22.2.5.2.3.3.	

(1) Applies only to TIMER3 through TIMER9, and TIMER11.
(2) Applies only to TIMER1, TIMER2, and TIMER10.

22.2.5.2.3.2 Subsequence – Initialize Capture Mode

Table 22-15 lists the steps to initialize capture mode.

Table 22-15. Initialize Capture Mode

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	x
Set prescale timer value.	TCLR[4:2] PTV	xxx
Enable prescaler.	TCLR[5] PRE	0x1
Select TIMERx (where x = 8 to 11). Capture input at device pin dmtimerx_pwm_evt.	TCLR[14] GPO_CFG(1)	0x1
Select single or second event capture.	TCLR[13] CAPT_MODE	x
Select transition capture mode.	TCLR[9:8] TCM	xx

(1) TIMER5, TIMER6, and TIMER8 through TIMER11

22.2.5.2.3.3 Subsequence – Detect Event

Table 22-16 lists the steps in detecting an event.

Table 22-16. Detect Event

Step	Register/Bit Field/Programming Model	Value
Wait until event detected?	IRQSTATUS[2] TCAR_IT_FLAG	= 0x1
Read timer capture value.	TCAR1 and/or TCAR2	
Clear capture interrupt request.	IRQSTATUS[2] TCAR_IT_FLAG	0x1

22.2.5.2.4 GP Timer PWM Mode

22.2.5.2.4.1 Main Sequence – GP Timer PWM Mode Configuration

Table 22-17 lists the steps in the GP timer PWM mode configuration.

Table 22-17. GP Timer PWM Mode Configuration

Step	Register/Bit Field/Programming Model	Value
Select autoreload mode.	TCLR[1] AR	x
Set prescale timer value.	TCLR[4:2] PTV	xxx
Enable prescaler.	TCLR[5] PRE	0x1
Select trigger output mode.	TCLR[11:10] TRG	xx
Select pulse or toggle modulation PWM mode.	TCLR[12] PT	x
Select TIMERx (where x = 8 to 11) PWM output at device pin dmtimerx_pwm_evt.	TCLR[14] GPO_CFG(1)	0x0
Configure PWM output pin default value.	TCLR[7] SCPWM	x
Load timer load value.	TLDR	xxx
Load timer compare value.	TMAR	xxx
Enable compare.	TCLR[6] CE	0x1
Start the timer.	TCLR[0] ST	0x1

(1) Applies only to TIMER8 through TIMER11

22.2.6 GP Timer Register Manual

22.2.6.1 GP Timer Instance Summary

Table 22-18 lists the base address and block size for the GP timer module instances.

Table 22-18. GP Timer Instance Summary

Module Name	Base Address L4 Interconnect	Base Address L3_MAIN Interconnect	Base Address Cortex-A15 Private Access	Base Address DSP Private Access	Size
TIMER2	0x4803 2000	–	–	–	4 KiB
TIMER3	0x4803 4000	–	–	–	4 KiB
TIMER4	0x4803 6000	–	–	–	4 KiB
TIMER9	0x4803 E000	–	–	–	4 KiB
TIMER10	0x4808 6000	–	–	–	4 KiB
TIMER11	0x4808 8000	–	–	–	4 KiB
TIMER5	–	0x4903 8000	0x4013 8000	0x3 8000	4 KiB
TIMER6	–	0x4903 A000	0x4013 A000	0x3 A000	4 KiB
TIMER7	–	0x4903 C000	0x4013 C000	0x3 C000	4 KiB
TIMER8	–	0x4903 E000	0x4013 E000	0x3 E000	4 KiB
TIMER1	0x4AE1 8000	–	–	–	4 KiB

NOTE: Private access is access that does not use the L3/L4 interconnects.

22.2.6.2 GP Timer Registers

22.2.6.2.1 GP Timer Register Summary

CAUTION

The GP timer registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 22-19 through Table 22-25 provide the register summary and associated offset addresses for the 11 GP timer internal registers.

Table 22-19. TIMER1, TIMER2, and TIMER10 Register Mapping Summary

Description	This register controls the various parameters of the L4 interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE		EMUFREE	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Reserved	R	0x0000000
3:2	IDLEMODE	Power management, req/ack control 0x0: Force-idle mode: local target idle state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the IP module internal requirements. Back-up mode, for debug only. 0x1: No-idle mode: local target never enters idle state. Back-up mode, for debug only. 0x2: Smart-idle mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module should not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target idle state eventually follows (acknowledges) the system idle requests, depending on the IP module internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module *swake-up* output(s) is (are) implemented.	RW	0x0
1	EMUFREE	Emulation mode 0x0: The timer is frozen in emulation mode (PINSUSPENDN signal active). 0x1: The timer runs free, regardless of PINSUSPENDN value.	RW	0
0	SOFTRESET	Software reset 0x0: Read 0: reset done, no pending action Write 0: No action 0x1: Read 1: initiate software reset Write 1: Reset ongoing	RW	0

Description	This register controls optional features specific to the timer functionality.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	GPO_CFG	CAPT_MODE	PT	TRG		TCM		SCPWM	CE	PRE	PTV			AR	ST

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	GPO_CFG	General-purpose output - this register directly drives the TIMERi_PORGPOCFG output pin. For specific use of the GPO_CFG bit, see Section 22.2.2.1, *GP Timer External System Interface*. 0x0: TIMERi_PORGPOCFG drives 0. 0x1: TIMERi_PORGPOCFG drives 1.	RW	0

Bits	Field Name	Description	Type	Reset
13	CAPT_MODE	Capture mode select bit (first/second) 0x0: Single capture: Capture the first enabled capture event in TCAR1. 0x1: Capture on second event: Capture the second enabled capture event in TCAR2.	RW	0
12	PT	Pulse or toggle mode on TIMERi_PWM_out output pin 0x0: Pulse modulation 0x1: Toggle modulation	RW	0
11:10	TRG	Trigger output mode on TIMERi_PWM_out output pin 0x0: No trigger 0x1: Trigger on overflow. 0x2: Trigger on overflow and match. 0x3: Reserved	RW	0x0
9:8	TCM	Transition capture mode on TIMERi_EVENT_CAPTURE input pin (When the TCM field passed from (00) to any other combination, the TCAR_IT_FLAG and the edge detection logic are cleared.) 0x0: No capture 0x1: Capture on rising edges of TIMERi_EVENT_CAPTURE pin 0x2: Capture on falling edges of TIMERi_EVENT_CAPTURE pin 0x3: Capture on both edges of TIMERi_EVENT_CAPTURE pin	RW	0x0
7	SCPWM	Pulse width modulation output pin default setting This bit must be set or clear while the timer is stopped or the trigger is off. 0x0: Clear the TIMERi_PWM_out output pin and select positive pulse for pulse mode. 0x1: Set the TIMERi_PWM_out output pin and select negative pulse for pulse mode.	RW	0
6	CE	Compare enable 0x0: Compare mode is disable. 0x1: Compare mode is enable.	RW	0
5	PRE	Prescaler enable 0x0: The TIMER clock input pin clocks the counter. 0x1: The divided input pin clocks the counter.	RW	0
4:2	PTV	Prescale clock timer value The timer counter is prescaled with the value $2^{(PTV+1)}$. Example: PTV = 3, counter increases value (if started) after 16 functional clock periods.	RW	0x0
1	AR	Autoreload mode 0x0: One shot timer 0x1: Autoreload timer	RW	0
0	ST	Start/stop timer control 0x0: Stop timer: Only the counter is frozen. If one-shot mode selected (AR =0), this bit is automatically reset by internal logic when the counter is overflowed. 0x1: Start timer	RW	0

22.3 Watchdog Timers

22.3.1 Watchdog Timers Overview

The device includes two instances of the 32-bit watchdog timer: WD_TIMER2 and WD_TIMER3. Figure 22-14 shows how each timer is connected in the device.

NOTE: WD_TIMERi (where i is the watchdog timer instance: i = 2 or 3) stands for the following:

- WD_TIMER2: Watchdog timer 2, also called the MPU watchdog timer
- WD_TIMER3: IVA3 (IVA + DSP) watchdog, clocked by the SYS_32K clock, generates an MPU interrupt on overflow, which can be used by application software to trigger a reset condition to IVA3 (IVA + DSP). Embedded in ABE.

Each watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The WD_TIMER2 timer serves resets to the PRCM module (its interrupt outputs are unused), and the WD_TIMER3 timer serves watchdog interrupts to the MPU (its reset outputs are unused).

The watchdog timers can be accessed, loaded, and cleared by registers through the L4 interface. The watchdog timers have the 32-kHz clock for their timer clock input.

The MPU watchdog timer directly generates a warm reset condition on overflow. WD_TIMER3 generates an MPU interrupt condition on overflow, which can be used by the application software through the PRCM module to indirectly trigger a reset condition (that is, to the IVA subsystem).

The MPU watchdog timer connects to a single target agent port on the L4 interconnect.

Figure 22-14. Watchdog Timers Block Diagram

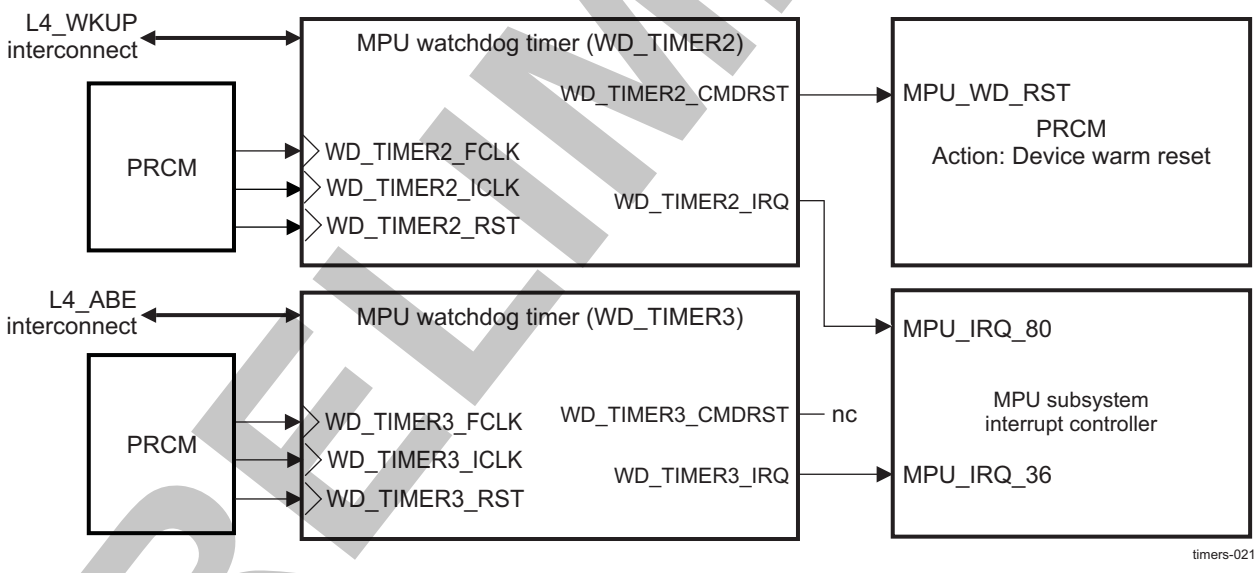

Table 22-72 lists the default state of the watchdog timers in the device.

Table 22-72. Watchdog Timers Default State

Timer	Default State	
WD_TIMER2	Enabled	Not running
WD_TIMER3	Enabled	Not running

NOTE: The default state of the watchdog timers described in Table 22-72 is considered to be their state immediately after ROM code execution. For more information, see Section 28.1, *Initialization*.

22.3.1.1 Watchdog Timers Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted mode supported
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n where n = [0:7])
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration (WD_TIMER2 or WD_TIMER3).

22.3.2 Watchdog Timer Environment

The watchdog timers are accessible through the L4 interface.

22.3.3 Watchdog Timer Integration

Figure 22-15 shows the integration of the watchdog timers in the device.

Figure 22-15. Watchdog Timers Integration

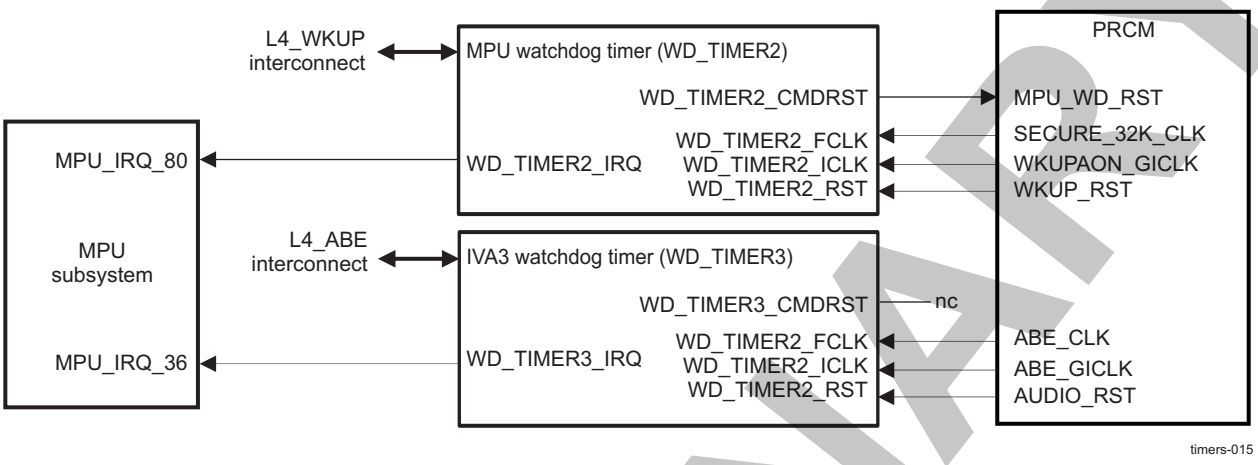

Table 22-73 through Table 22-75 summarize the integration of the module in the device.

Table 22-73. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
WD_TIMER2	PD_WKUP	Yes	L4_WKUP
WD_TIMER3	PD_AUDIO	Yes	L4_ABE

Table 22-74. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
WD_TIMER2	WD_TIMER2_FCLK	WKUPAON_32K_GFCLK	PRCM	WD_TIMER2 functional clock
WD_TIMER2	WD_TIMER2_ICLK	WKUPAON_GICLK	PRCM	WD_TIMER2 interface clock
WD_TIMER3	WD_TIMER3_FCLK	ABE_32K_CLK	PRCM	WD_TIMER3 functional clock
WD_TIMER3	WD_TIMER3_ICLK	ABE_GICLK	PRCM	WD_TIMER3 interface clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
WD_TIMER2	WD_TIMER2_RST	WKUPAON_RST	PRM	Reset to WD_TIMER2
WD_TIMER2	MPU_WD_TIMER2_RST	WD_TIMER2_CMDRST	WD_TIMER2	Reset to MPU
WD_TIMER3	WD_TIMER3_RST	ABE_RST	PRM	Reset to WD_TIMER3

NOTE: WD_TIMER2 is reset on power on or after a warm reset before it starts counting.

WD_TIMER3 is reset on power on or after a warm reset, and then it does not start counting.

Table 22-75. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**

Table 22-75. Hardware Requests (continued)

WD_TIMER2	WD_TIMER2_IRQ	MPU_IRQ_80	MPU	WD_TIMER2 interrupt to MPU
WD_TIMER3	WD_TIMER3_IRQ	MPU_IRQ_36	MPU	ABE watchdog overflow
No DMA Requests				

NOTE: For the description of the interrupt source, see Section 22.3.4.2, *Interrupts*.

22.3.4 Watchdog Timers Functional Description

22.3.4.1 Power Management

There are two clock domains in the watchdog timers:
