- Functional clock domain: WD_TIMERi_FCLK is the watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WD_TIMERi_ICLK is the watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WD_TIMERi_ICLK.

Table 22-74 lists the source clocks for each watchdog timer in the device. For more information about clock control and domains, see Section 3.6, *Clock Management Functional Description,* in Section 3.1.1, *Power, Reset, and Clock Management*.

From a global system power-management perspective, when one or both of the watchdog timer clocks is no longer required, the watchdog timers can be deactivated at the PRCM module level in the corresponding registers.

At the PRCM module level, when the conditions to shut off the PRCM module functional or interface output clocks are met (for more information, seeSection 3.1.1.1.4, *Clock Domain-Level Clock Management*), the PRCM module automatically launches a hardware handshake protocol to ensure the watchdog timer is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the watchdog timer.

Although this handshake is a hardware function and out of software control, the way on which the watchdog timer acknowledges the PRCM IDLE request is configurable through the WDSC[4:3] IDLEMODE bit field. Table 22-76 lists the settings and related acknowledgment modes of the IDLEMODE bit field.

Table 22-76. IDLEMODE Settings

IDLEMODE Value	Selected Mode	Description
00	Force-idle	The watchdog timer unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off.
01	No-idle	The watchdog timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM module output clock to be shut off and thus the power domain to be set to a lower power state.
10	Smart-idle	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management.
11	Smart-idle wakeup-capable mode	The watchdog timer acknowledges the IDLE request, basing its decision on its internal activity. The timer generates (IRQ-request-related) wake-up events when in IDLE state if the WIRQWAKEEN[1:0] bit field is set to 1.

22.3.4.1.1 Wake-Up Capability

If the WDSC[4:3] IDLEMODE bit field sets smart-idle wakeup-capable mode (= 0 × 3), the timer evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the WIRQWAKEEN[0] OVF_WK_ENA and/or the WIRQWAKEEN[1] DLY_WK_ENA bits enable the overflow and/or the delay wake-up capability.

22.3.4.2 Interrupts

Table 22-77 list the event flags, and their masks that cause module interrupts.

Table 22-77. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WIRQSTAT[0] EVENT_OVF	WIRQENSET/WIRQENCLR[0] OVF_IT_ENA	WD_TIMERi_IRQ	Watchdog timer overflow
WIRQSTAT[1] EVENT_DLY	WIRQENSET/WIRQENCLR[1] DLY_IT_ENA	WD_TIMERi_IRQ	Watchdog delay value reached

22.3.4.3 General Watchdog Timer Operation

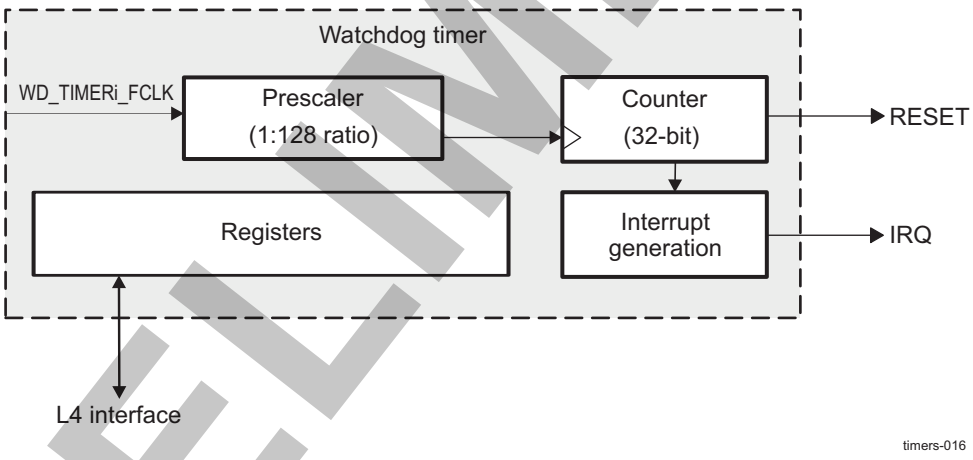
The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see Figure 22-14. The interrupt generation mechanism is controlled through the WIRQENSET/WIRQENCLR and WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WCLR[4:2] PTV bit field and the WCLR[5] PRE bit of the watchdog control register (WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WCRR), modified by accessing the watchdog timer load register (WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register (WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WSPR) can start and stop the watchdog timers.

Figure 22-16 is a functional block diagram of the watchdog timer.

Figure 22-16. 32-Bit Watchdog Timer Functional Block Diagram



22.3.4.4 Reset Context

The watchdog timers are enabled after reset. Table 22-78 lists the default reset values of the two watchdog timer load registers (WLDR) and prescaler ratios (the WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 22-78. Count and Prescaler Default Reset Values

Timer	WLDR Reset Value	PTV Reset Value
MPU watchdog timer (WD_TIMER2)	0xFFFB 0000	0
IVA3 (IVA + DSP) watchdog timer (WD_TIMER3)	0xFFFB 0000	0

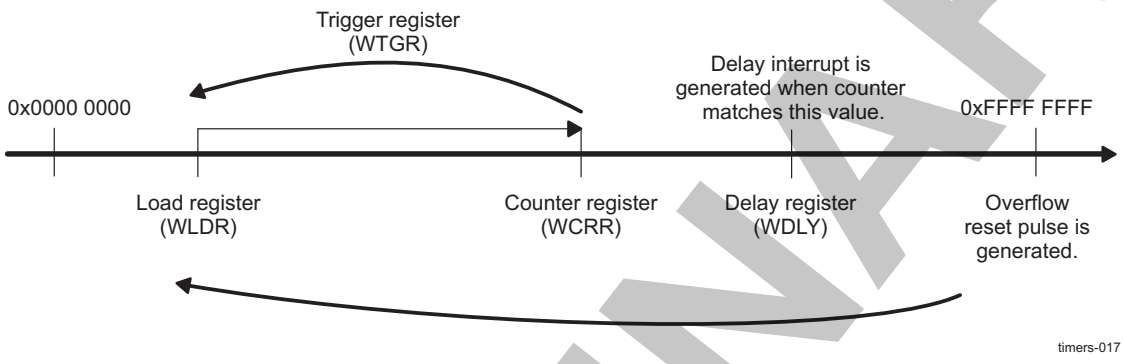
22.3.4.5 Overflow/Reset Generation

When the WCRR overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the WLDR and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 22-17 shows a general functional view of the watchdog timers.

Figure 22-17. Watchdog Timers General Functional View



22.3.4.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WCLR[5] PRE bit and the WCLR[4:2] PTV bit field)
- Value loaded into WLDR

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WCLR [4:2] PTV bit field) and is enabled with the WCLR[5] PRE bit.

Table 22-79 lists the prescaler clock ratio values.

Table 22-79. Prescaler Clock Ratio Values

WLCR[5] PRE	WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (0xFFFF FFFF – WLDR + 1) × (timer clock period) × PS

where wd-functional clock period = 1 / (timer clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WSPR before WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WD_TIMER_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 22-80.

Table 22-80. Reset Period Examples

WLDR Value	Reset Period
0x0000 0000	74 h 56 min
0xFFFF 0000	4 s
0xFFFF FFF0	1 ms
0xFFFF FFFF	62.5 µs

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WLDR[31:0] = 0xFFFF FFFF is a special case, although such value of WLDR is meaningless. When WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 22-81 lists the default reset periods for the watchdog timers.

Table 22-81. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
MPU/ABE	32 kHz	10 s

22.3.4.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WTGR using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WTGR differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

22.3.4.8 Start/Stop Sequence for Watchdog Timers (Using the WSPR Register)

To start and stop a watchdog timer, access must be made through the WSPR using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xXXXX AAAA in the WSPR.
2. Write 0xXXXX 5555 in the WSPR.

To enable the timer, follow this sequence:

1. Write 0xXXXX BBBB in the WSPR.
2. Write 0xXXXX 4444 in the WSPR.

All other write sequences on the WSPR have no effect on the start/stop feature of the module.

22.3.4.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WCRR), the prescaler ratio (the WCLR[4:2] PTV bit field), delay configuration value (the WDLY[31:0] DLY_VALUE bit field), or the load value (the WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WSPR).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WTGR).

22.3.4.10 Watchdog Counter Register Access Restriction (WCRR)

A 32-bit shadow register is implemented to read a coherent value of the WCRR because the WCRR is directly related to the timer counter value and is updated on the timer clock (WD_TIMER_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WD_TIMER_ICLK) is completely asynchronous with the timer clock (WD_TIMER_FCLK), some synchronization is performed to ensure that the value of the WCRR is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside the WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

22.3.4.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WISR[0] OVF_IT_FLAG or WISR[1] DLY_IT_FLAG bit) is set to 1. The output interrupt line (WD_TIMERi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WISR. Reading the WISR and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt-enable register (WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WD_TIMER_IRQ) is asserted (active low) when status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WIER [0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt-enable register (WIER[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDLY), the corresponding interrupt status bit is set in the watchdog status register (WISR) and the output interrupt line is asserted (active low) when the flag (DLY_IT_FLAG) and enable (DLY_IT_ENA) bits are set to 1 in the WISR and WIER registers, respectively; the order (normally enable, then flag) is not relevant. This interrupt can be disabled by setting the WIER[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WISR[0] OVF_IT_FLAG or WISR[1] DLY_IT_FLAG bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WD_TIMERi_FCLK) during the updating of the interrupt status register.

The WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WLDR) and the programmed value in this register (WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDLY – WLDR + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1 / (Timer clock frequency)
- Clock divider = 2PTV

If the counter value (WCRR) reaches the programmed value (WDLY), the status bit (EVENT_DLY) is set in the interrupt status register (WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (the WDLY[31:0] WDLY_VALUE bit field), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the WDLY register is less than the value stored in the WLDR.

22.3.4.12 Watchdog Timers Under Emulation

During emulation mode, the watchdog timer can or cannot continue to run, according to the value of the WDSC[5] EMUFREE bit of the system configuration register (WDSC).

- When EMUFREE is 1, watchdog timer execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting emulation mode.

22.3.4.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WD_TIMERi_FCLK). For write/read operation, the following registers are affected:

- WCLR
- WCRR
- WLDR
- WTGR
- WDLY
- WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WD_TIMER_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WIDR
- WDSC
- WDST
- WISR
- WIER
- WWER
- WWPS

NOTE: Accesses to WD_TIMER2 and WD_TIMER3 are posted.

22.3.5 Watchdog Timer Low-Level Programming Model

This section covers the low-level hardware programming sequences for the configuration and use of the module.

22.3.5.1 Global Initialization

22.3.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 22-82). For more information, see Section 22.3.2, *Watchdog Timer Environment*, and Section 22.3.3, *Watchdog Timer Integration.*

Table 22-82. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see Section 18.4.8, *PAD Functional Multiplexing and Configuration* in Figure 18-1, *Control Module*.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer. See Section 4.1, *Dual Cortex-A15 MPU Subsystem*.

22.3.5.1.2 Watchdog Timer Module Global Initialization

22.3.5.1.2.1 Main Sequence – Watchdog Timer Module Global Initialization

Table 22-83 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 22-83. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDSC[1] SOFTRESET	0x1
Wait until reset release?	WDSC[1] SOFTRESET	0x0
Configure idle mode.	WDSC[4:3] IDLEMODE	xx
Enable delay wakeup.	WIRQWAKEEN[1] DLY_WK_ENA	0x1
Enable overflow wakeup.	WIRQWAKEEN[0] OVF_WK_ENA	0x1
Enable delay interrupt.	WIRQENSET[1] ENABLE_DLY	0x1
Enable overflow interrupt.	WIRQENSET[0] ENABLE_OVF	0x1

22.3.5.2 Operational Mode Configuration

22.3.5.2.1 Watchdog Timer Basic Configuration

22.3.5.2.1.1 Main Sequence – Watchdog Timer Basic Configuration

Table 22-84 lists the steps for the basic configuration of the watchdog timer.

Table 22-84. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 22.3.5.2.1.2.	
Set prescaler value.	WCLR[4:2] PTV	xxx
Enable prescaler.	WCLR[5] PRE	0x1
Load delay configuration value.	WDLY	xxx
Load timer counter value.	WCRR	xxx
Enable the watchdog timer.	See Section 22.3.5.2.1.3.	

22.3.5.2.1.2 Subsequence – Disable the Watchdog Timer

Table 22-85 lists the steps to disable the watchdog timer.

Table 22-85. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WSPR	0xXXXX AAAA
Write disable sequence Data2.	WSPR	0xXXXX 5555

22.3.5.2.1.3 Subsequence – Enable the Watchdog Timer

Table 22-86 lists the steps to enable the watchdog timer.

Table 22-86. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WSPR	0xXXXX BBBB
Write enable sequence Data2.	WSPR	0xXXXX 4444

22.3.6 Watchdog Timer Register Manual

22.3.6.1 Watchdog Timer Instance Summary

Table 22-87 lists the base address and address space for the watchdog timer module instances.

Table 22-87. Watchdog Timer Instance Summary

Module Name	Base Address L4 Interconnect	Base Address L3 Interconnect	Base Address Cortex-A15 Private Access	Base Address DSP Private Access	Size
WD_TIMER2	0x4AE1 4000	–	–	–	4 KiB
WD_TIMER3	–	0x4903 0000	0x4013 0000	0x3 0000	4 KiB

NOTE: Private access is access that does not use the L3/L4 interconnects.

22.3.6.2 Watchdog Timer Registers

22.3.6.2.1 Watchdog Timer Register Summary

CAUTION

The watchdog timers registers are limited to 32- and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 22-88 lists the WD_TIMER2 registers.

22.4 32-kHz Synchronized Timer

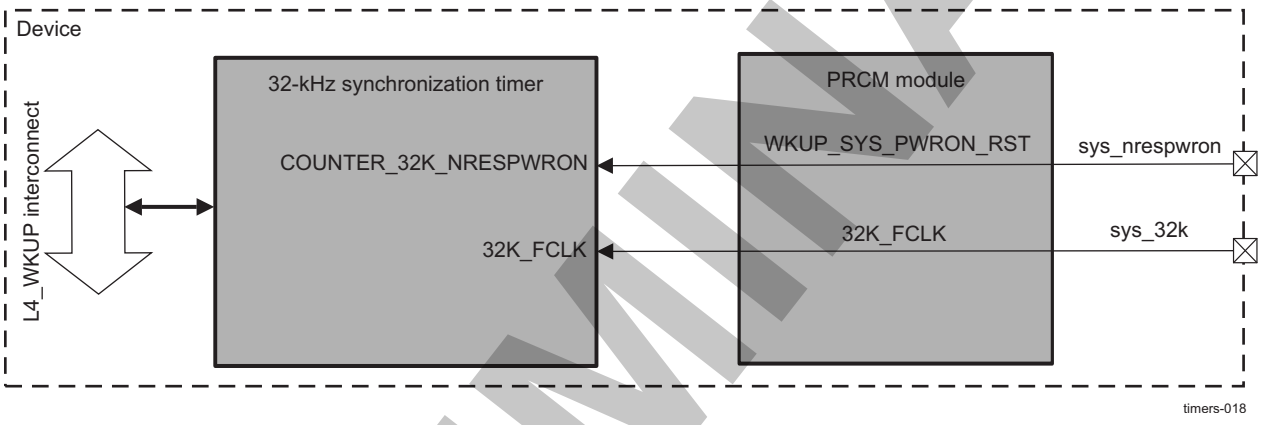
22.4.1 32-kHz Synchronized Timer Overview

The 32-kHz synchronized timer is a 32-bit counter clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (sys_nrespwron) primary I/O is active (main device reset). When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again.

Figure 22-18 is the block diagram of the 32-kHz synchronized timer.

NOTE: sys_nrespwron is an active-low I/O.

Figure 22-18. 32-kHz Synchronized Timer Block Diagram



22.4.1.1 32-kHz Synchronized Timer Features

The main features of the 32-kHz synchronized timer controller are:

- L4 slave interface (OCP) support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 16-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode not supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0; highest value reached: 0xFFFF FFFF
- On-the-fly read (while counting)

22.4.2 32-kHz Synchronized Timer Environment

The synchronized timer is accessible only through the L4 interface.

22.4.3 32-kHz Synchronized Timer Integration

Table 22-126 through Table 22-128 summarize the integration of the module in the device.

Table 22-126. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
COUNTER_32K	PD_WKUP	No	L4_WKUP

22.4.4 32-kHz Synchronized Timer Functional Description

The synchronized timer is a counter that starts on the rising edge of an external asynchronous signal (sys_nrespwron). When sys_nrespwron is released (on the rising edge of sys_nrespwron), the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock after three inverted 32-kHz clock periods. After reaching its highest value, the counter wraps back to 0 and starts counting again with no additional delay. When sys_nrespwron is released (on the rising edge of sys_nrespwron), after three inverted 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock.

Figure 22-19 shows the reset synchronization timing diagram. After reaching its highest value, the counter wraps back to 0 and starts counting again without any extra delay.

Figure 22-19. Reset Resynchronization Timing Diagram

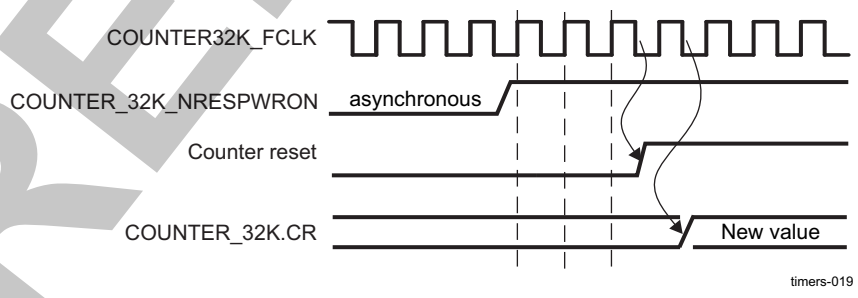

Figure 22-20 is the block diagram of the synchronized timer.

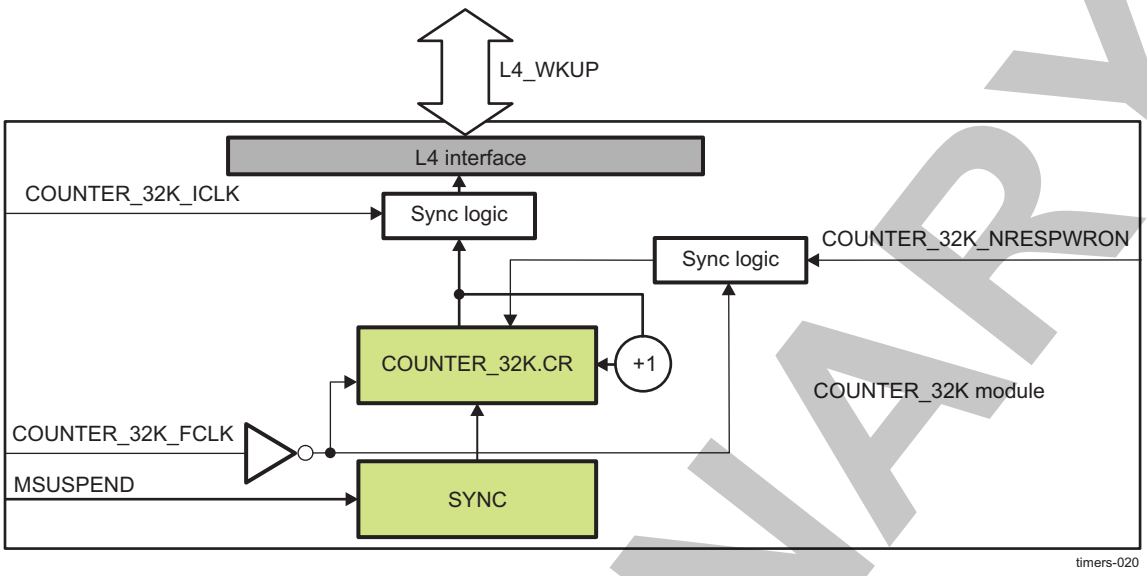
NOTE: sys_nrespwron is an active-low input.

Figure 22-20. CONTER_32K Block Diagram



The sync logic ensures the correctness of the read transaction by synchronizing the counter register read access on COUNTER_32K_ICLK, because the COUNTER_32K_ICLK clock signal is completely asynchronous with COUNTER_32K_FCLK. The sys_nrespwron input resets the counter register (CR). The inverted COUNTER_32K_FCLK clocks the sys_nrespwron reset signal.

22.4.4.1 Reading the 32-kHz Synchronized Timer

The counter register (CR) is 32 bits wide. For correct count capture, it must be accessed as 16-bit LSB access first and 16-bit MSB access next.The value of the counter is read through the L4 interconnect slave interface. Internal synchronization logic allows the reading of the counter value with COUNTER_32K_ICLK while the counter is running. The time latency to read the synchronized counter register is one COUNTER_32K_ICLK clock period.

The user can select between two syncronization schemes by setting SYSCONFIG[0]SYNCMODE bit.

- SYSCONFIG[0] SYNCMODE = 0x0 - default mode. In this mode the COUNTER_32K timer uses Gray encode/decode scheme. When the L4 interface sends a LSB16 read request command, the 32 bit coded value is registered directly to the interface domain. Due to the characteristics of this encoding if a read command arrives during a count up event either the old or the new value of CR is captured, not a transient value. The captured value will be decoded and sent on the SDATA bus. The MSB16 read command reads upper 16 bits of the 32 bit value of counter register captured during the last LSB16 read access.
- SYSCONFIG[0] SYNCMODE = 0x1 - legacy synchronization scheme. In this mode the value of the CR is synchronized to the OCP domain at every count up event. This synchronization is possible because the COUNTER_32K_ICLK is much faster than the 32KHz clock. The drawback of this method is that if the interface clock is switched off by PRCM during idle mode, the synchronization stops until the interface clock is switched back. The syncronized value will be updated the next count up event after wake up from idle mode, until then it will be incorrect.

22.4.5 COUNTER_32K Timer Register Manual

Table 22-129 lists the base address and block size for the 32-kHz synchronized timer. It is memory-mapped to the L4 peripheral bus memory space.

Table 22-129. COUNTER_32KTimer Instance Summary

Serial Communication Interfaces

This chapter describes the features and operation of the device serial communication interfaces (SCI).

NOTE: Some of the serial interfaces and some of their features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

For details, see Section 1.5, *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

23.1 Multimaster High-Speed I²C Controller

This section describes the five high-speed inter-integrated circuit (I²C™) controller modules in the device.

23.1.1 HS I²C Overview

The device contains five multimaster high-speed (HS) inter-integrated circuit (I²C) controllers (I2C*i* modules, where *i* = 1, 2, 3, 4, 5), each of which provides an interface between a local host (LH), such as a digital signal processor (DSP), and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit and receive up to 8 bits of data to and from the LH device through the 2-wire I²C interface.

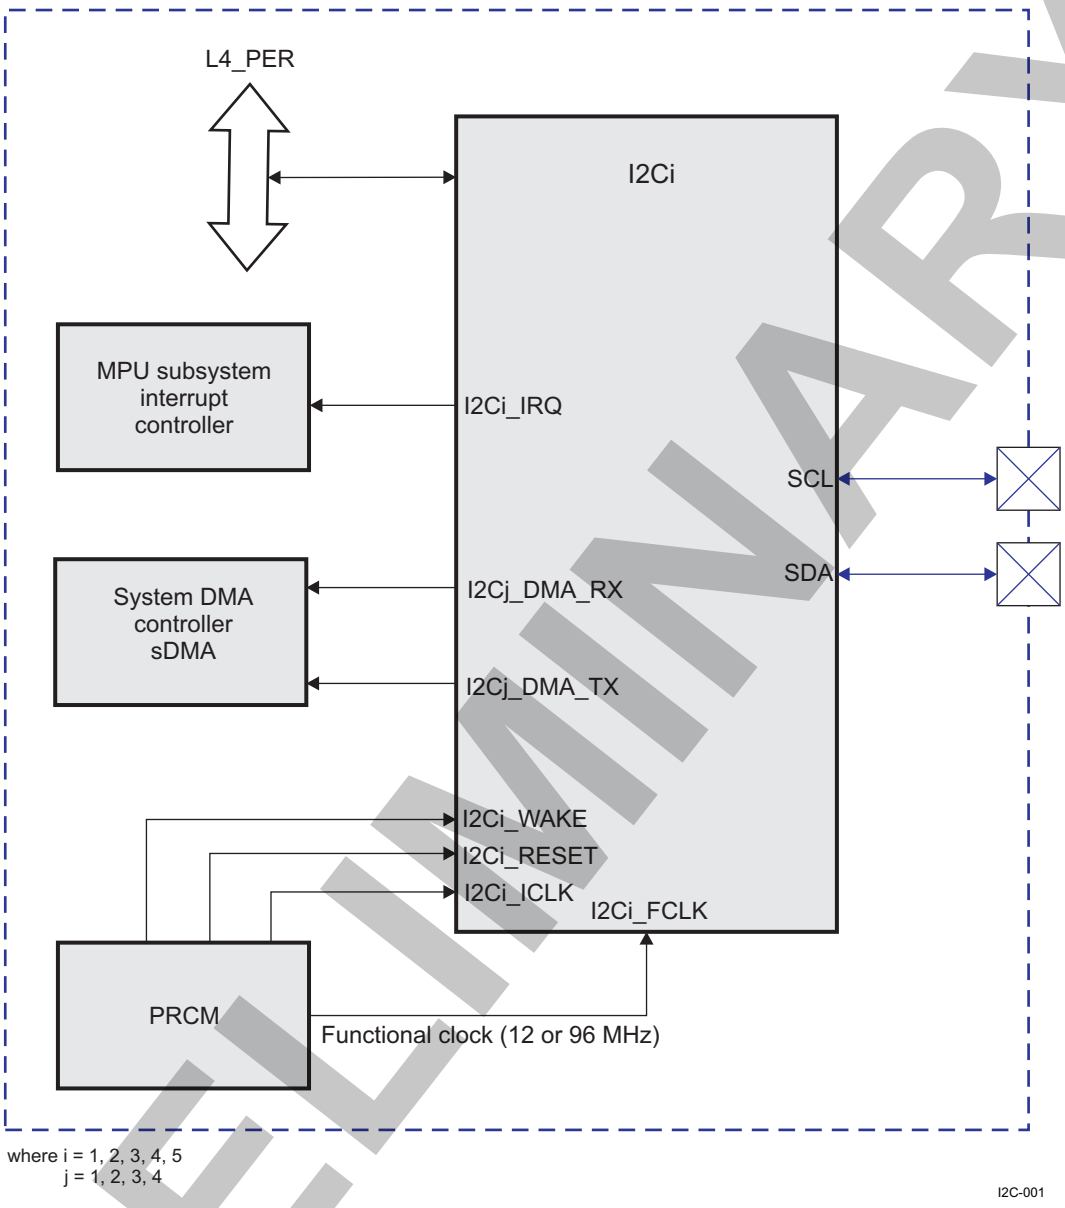
Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device.

The device contains additional sixth I2C for SmartReflex1.5™ voltage control, and seventh in HDMI interface which are not described in this section but in the PRCM and Display SubSystem respectively.

The I2C1 instance is typically reserved for platform specific usage to control the power-management-, audio-, and battery-management- companion integrated circuits (ICs)

Figure 23-1 shows the I²C.

Figure 23-1. HS I²C Controllers



The multimaster HS I²C controllers have the following features:

- Compliant with Philips I²C specification version 2.1
- Supports a standard mode (up to 100 kbps) and fast mode (up to 400 kbps)
- Supports HS mode for transfer up to 3.4 Mbps
- 7-bit and 10-bit device addressing modes
- General call
- Start/Restart/Stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in configurable FIFOs (8, 16, 32, 64 bytes) for buffered read or write
- Module enable/disable capability

- Programmable multislave channel (responds to four separate addresses)
- Programmable clock generation
- 8-bit-wide data access
- Designed for low power consumption
- Implement Auto Idle mechanism
- Implement Idle Request/Idle Acknowledge handshake mechanism
- Support for asynchronous wakeup mechanism
- Two direct memory access (DMA) channels
- Wide interrupt capability

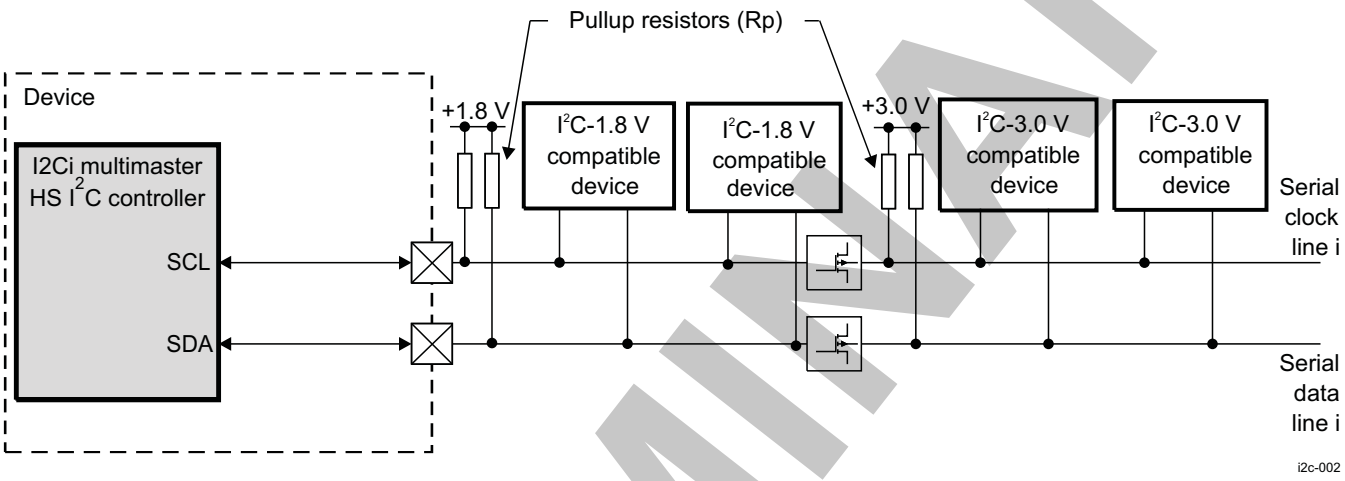
23.1.2 HS I²C Environment

This section describes the HS I²C application fields from an environment point of view (external connections). It describes HS I²C connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

23.1.2.1 HS I²C Typical Application

Figure 23-2 shows the multimaster HS I²C controllers and their related connections with I²C-compliant devices.

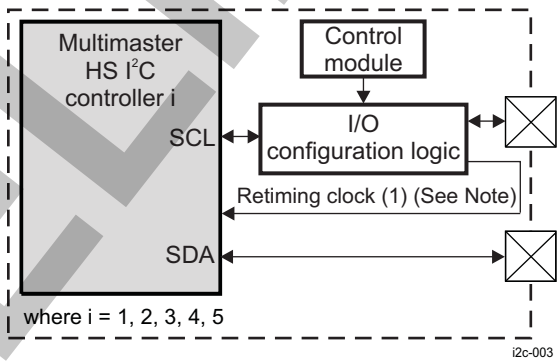
Figure 23-2. HS I²C and Typical Connections to I²C Devices



23.1.2.1.1 HS I²C Pins for Typical Connections in I²C Mode

Figure 23-3 shows the multimaster HS I²C controller pins used for typical connections with I²C devices.

Figure 23-3. HS I²C Interface Signals



(1) In master mode, the clock signal (IP clk configured as output) is also used as a retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

23.1.2.1.2 HS I²C Interface Typical Connections

Table 23-1 lists the pins associated with the I²C interface.

Table 23-1. HS I²C Input/Output

Signal	Device Level Signal	I/O[1]	Description	Reset Value
SCL	i2c1_pmic_scl	I/O	Master platform I2C clock	1

[1] I = Input; O = Output

Table 23-1. HS I²C Input/Output (continued)

Signal	Device Level Signal	I/O[1]	Description	Reset Value
SDA	i2c1_pmic_sda	I/O	Master platform I2C data	1
SCL	i2c*i*_scl[2]	I/O	I²C serial clock line[3]. Open-drain output buffer. Requires external pullup resistor (Rp).	1
SDA	i2c*i*_sda[2]	I/O	I²C serial data line. Open-drain output buffer. Requires external Rp.	1

(2) i= 2 to 5

(3) This output signal is also used as retiming input.

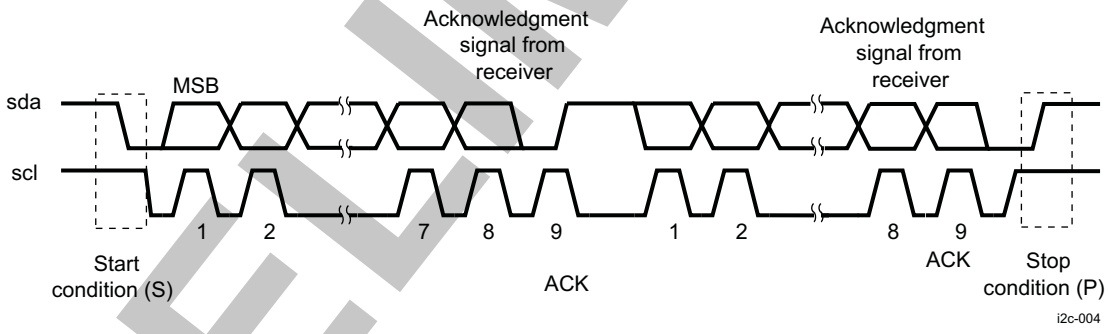
NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. Refer to the sections Section 18.4.8 *Pad Functional Multiplexing and Section 18.4.12.7.5 Configuration* and *Device Interfaces Signal Group Controls Mapping* of the chapter *Figure 18-1 Control Module*, for more information.

23.1.2.1.3 HS I²C Typical Connection Protocol and Data Format

23.1.2.1.3.1 HS I²C Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 23-4 shows a typical I²C communication format.

Figure 23-4. HS I²C Data Transfer

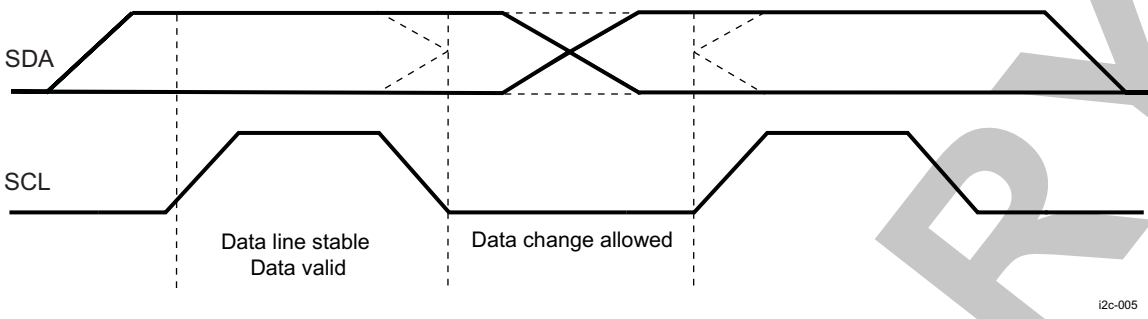


23.1.2.1.3.2 HS I²C Data Validity

The data on the serial data line (SDA) must be stable during the high period of the serial clock line. The high and low states of the data line can change only when the clock signal on the serial clock line (SCL) is low.

Figure 23-5 is an example of data validity requirements.

Figure 23-5. HS I²C Bit Transfer on the I²C Bus



23.1.2.1.3.3 HS I²C Start and Stop Conditions

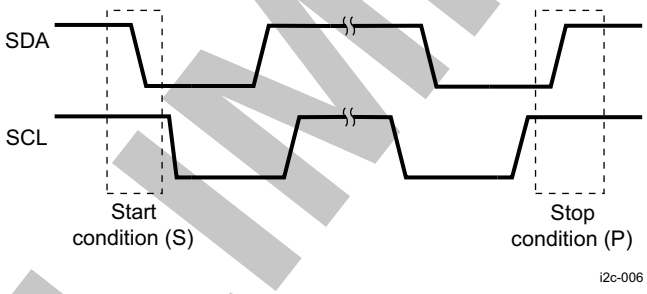
The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the serial data line while serial clock line is high.
- A P condition is a low-to-high transition on the serial data line while serial clock line is high.

The bus is considered busy after the S condition (the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit is 0 to indicate that the bus is free).

Figure 23-6 shows the waveforms that occur during an S and a P condition.

Figure 23-6. HS I²C S and P Condition Events



23.1.2.1.3.4 HS I²C Addressing

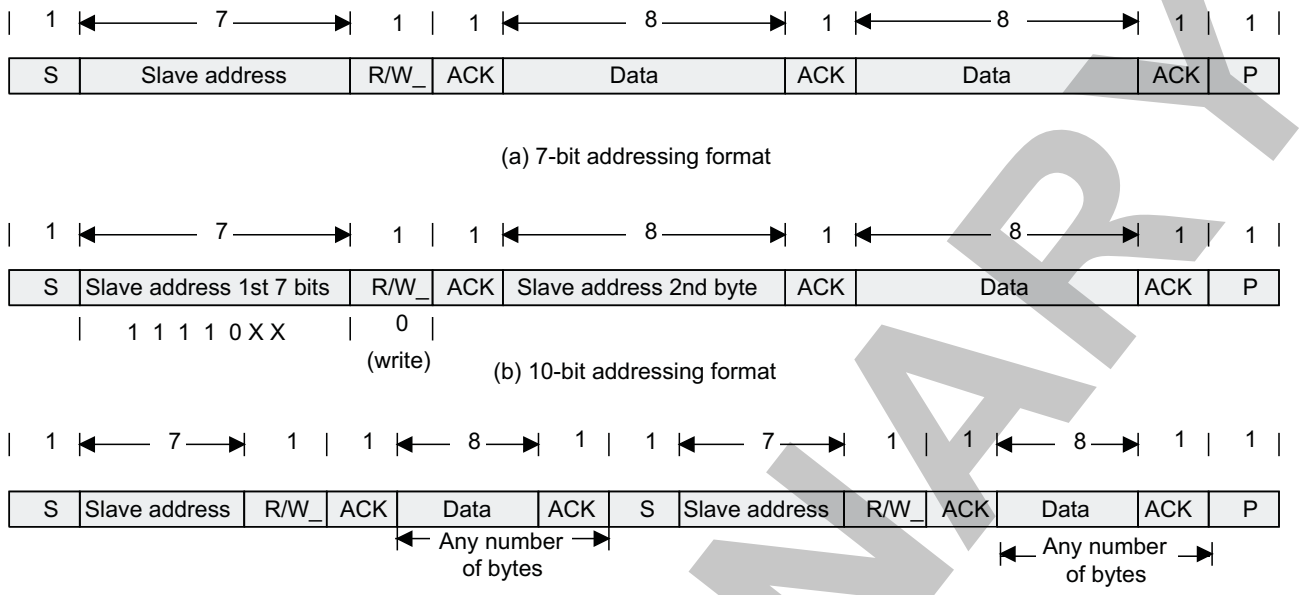
The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

23.1.2.1.3.4.1 Data Transfer Formats in F/S Mode

Figure 23-7 shows the I²C data transfer formats in F/S mode.

Figure 23-7. HS I²C Data Transfer Formats in F/S Mode



The first word after an S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

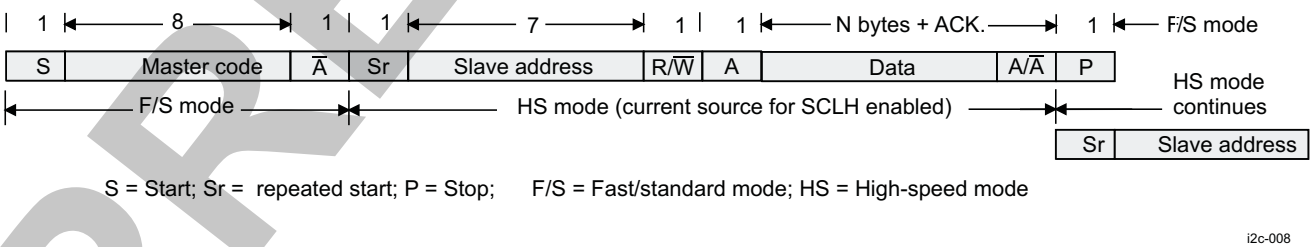
The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

23.1.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 23-8 shows the I²C data transfer format in HS mode.

Figure 23-8. HS I²C Data Transfer in HS Mode



Each multimaster HS I²C controller can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 23-8.

23.1.2.1.3.5 HS I²C Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in sync with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL is held low when the intervention of the processor is required (XUDF) after a byte is transmitted.

23.1.2.1.3.6 HS I²C Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 23-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line SDAI are shifted in synchronization with the self-generated clock pulses on SCLI.

23.1.2.1.3.7 HS I²C Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 23-7), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ is transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in sync with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (XUDF).

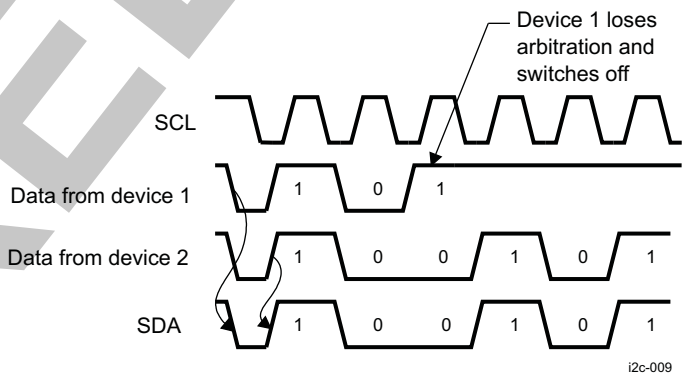
23.1.2.1.3.8 HS I²C Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in sync with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the LH is required (ROVR) after a byte is received.

23.1.2.1.3.9 HS I²C Bus Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 23-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 23-9. HS I²C Arbitration Between Master Transmitters



23.1.2.1.3.10 HS I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. However, there are two or more master devices during the arbitration procedure, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is

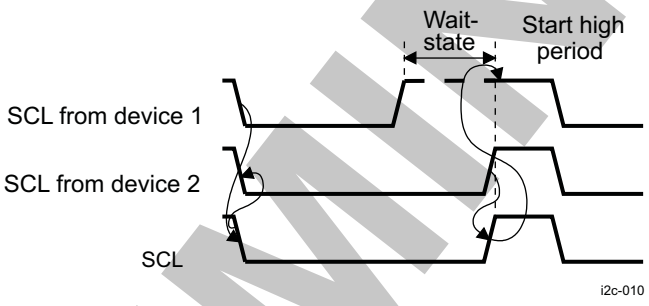
then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period. If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or prepare a byte to be transmitted (clock stretching).

NOTE: In case the SCL or SDA lines are stuck low, a bus clearing operation is supported:

- If the clock line (SCL) is stuck low, the preferential procedure is to reset the bus using the hardware reset signal if your I²C devices have hardware reset inputs. If the I²C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit.
- If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, then use the hardware reset or cycle power to clear the bus.

Figure 23-10 shows clock synchronization.

Figure 23-10. HS I²C Clock Generators Synchronization



23.1.2.1.3.11 HS I²C External Clock Configuration

Each multimaster HS I²C controller is clocked with an independent functional clock (I2C*i*_FCLK) and an interface clock (I2C*i*_ICLK) for interfacing with the L4_PER interconnect. These clocks are provided by the APE PRCM module for I2C*i* (where *i* = 1, 2, 3, 4, 5).

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller. For detailed information about the module clocking, see Section 3.6 *Clock Management Functional Description, in* Section 3.1.1, *Power, Reset, and Clock Management*.

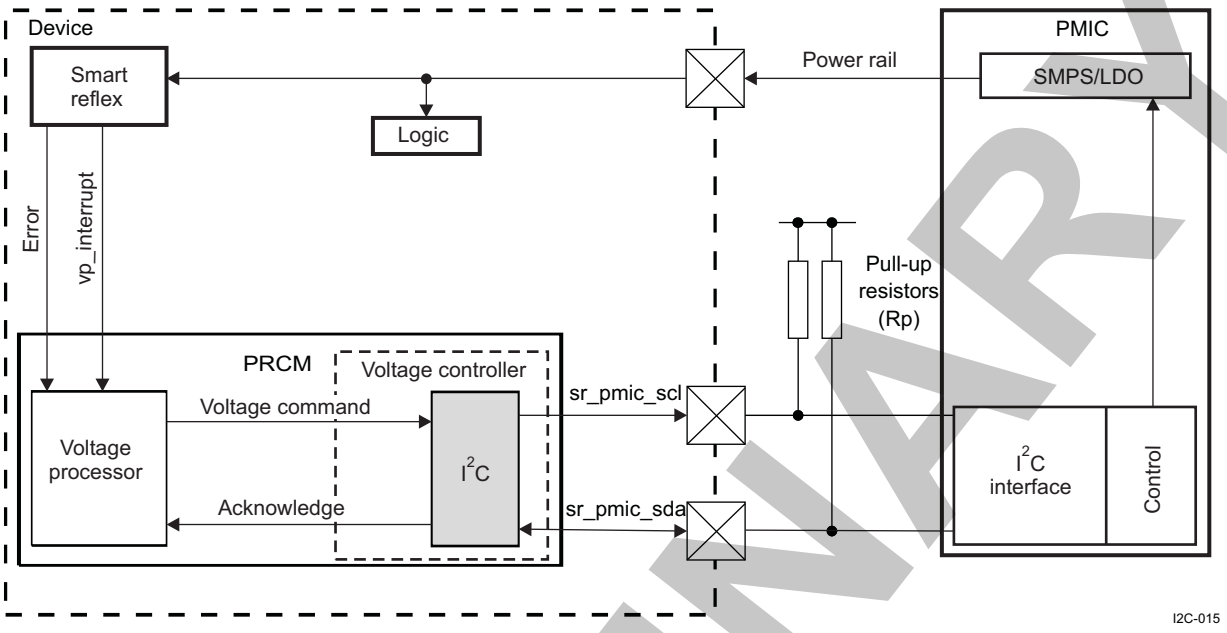
The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2C*i*.I2C_PSC[7:0] PSC bit field (where *i* = 1, 2, 3, 4, 5) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2C*i*_FCLK/(I2C*i*.I2C_PSC[7:0] PSC bit field value + 1, where *i* = 1, 2, 3, 4, 5).

23.1.2.2 HS I²C for Communication With Power Chip(s)

The device contains additional sixth I²C for SmartReflex1.5™ voltage control. Figure 23-11 shows a typical connection between the SmartReflex1.5™ and external power chip using I2C interface. For more information about communicationg with power chips through I2C interface, see Section 3.1.1, *Power, Reset, and Clock Management.*

Figure 23-11 shows a typical connection with power chip using the I2C interface.

Figure 23-11. HS I²C and Typical Connection Between the HS I²C and Power Chip(s)



23.1.2.2.1 HS I²C Typical Connections Protocol and Data Format for SR I2C

23.1.2.2.1.1 Serial Data Format for SR I2C

Serial data format for Smart Reflex I2C controller is the same as described in Section 23.1.2.1.3.1

23.1.2.2.1.2 SR I2C Data Validity

Data validity is the same as described in Section 23.1.2.1.3.2

23.1.2.2.1.3 Start and Stop Conditions

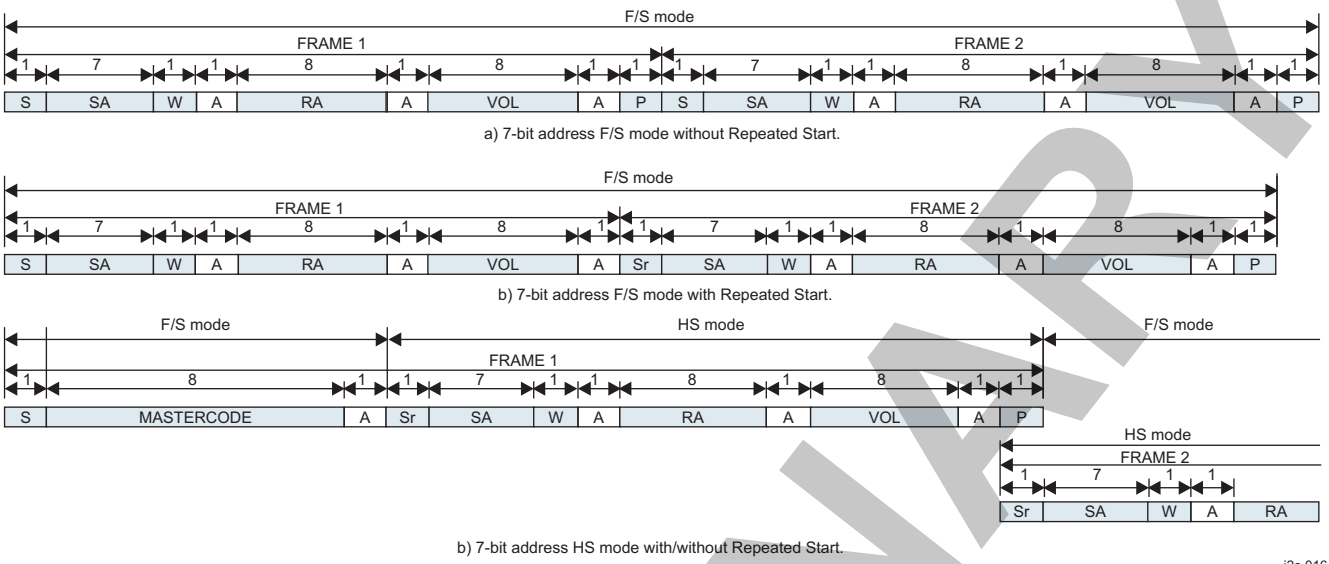
Start and Stop conditions for SR I2C are the same as described in Section 23.1.2.1.3.3

23.1.2.2.1.4 HS I²C Addressing for SR I²C

The master transmitter SR I2C controller supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

The following figure shows the SR I²C frame types for F/S and HS mode.

Figure 23-12. SR I2C Frame Types



a) 7-bit address F/S mode without Repeated Start.

b) 7-bit address F/S mode with Repeated Start.

b) 7-bit address HS mode with/without Repeated Start.

NOTE:

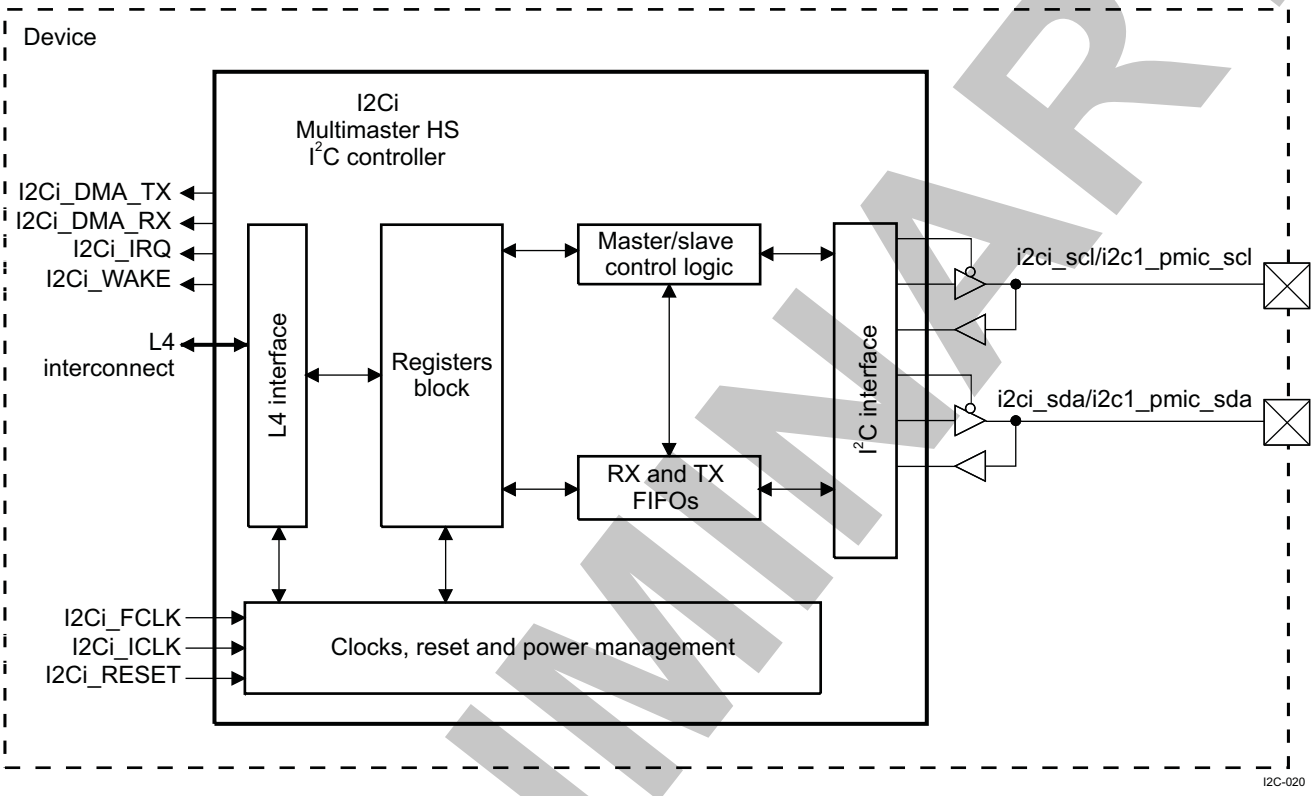
- For a description of interrupt source, see Table 23-10.
- For a description of DMA source, see Table 23-11.

23.1.4 HS I²C Functional Description

23.1.4.1 HS I²C Block Diagram

Figure 23-14 is the multimaster I²C HS controller block diagram.

Figure 23-14. HS I²C Block Diagram



The five multimaster HS I²C controllers can be configured in F/S I²C mode or HS I²C mode. The operation mode is selected by configuring the I2C*i*.I2C_CON[13:12] OPMODE bit field. Table 23-5 lists the available operation modes.

NOTE: The sixth master transmitter HS I²C interface in the power, reset, and clock management (PRCM) could also be configured in High-speed mode.

Table 23-5. HS I²C Operation Mode Selection

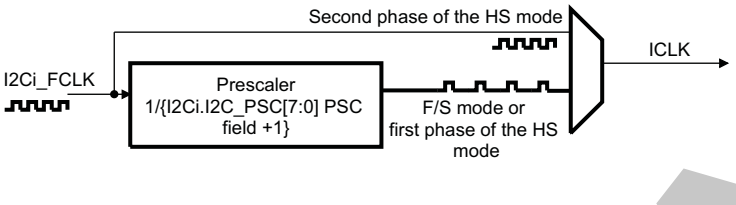
Operation Mode	Value of I2C*i*.I2C_CON[13:12] OPMODE Bit Field
F/S I²C	0x0
HS I²C	0x1
Reserved	0x2
Reserved (not used)	0x3

23.1.4.2 HS I²C Clocks

23.1.4.2.1 HS I²C Clocking

Figure 23-15 shows the I²C clock generation of the HS I²C controllers.

Figure 23-15. HS I²C Clock Generation



Each multimaster HS I²C controller uses the I2C*i*_FCLK functional clock in the PRCM module. The internal sampling clock I2C*i*_INTERNAL_CLK is generated by dividing the functional clock by the I2C*i*.I2C_PSC[7:0] PSC bit field value + 1 in F/S mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2C*i*_SCL signal is determined by the I2C*i*.I2C_SCLL[7:0] SCLL bit field in F/S mode and in the first phase of HS mode; or by the I2C*i*.I2C_SCLL[15:8] HSSCLL bit field in the second phase of HS mode.

The high time of the I2C*i*_SCL signal is determined by the I2C*i*.I2C_SCLH[7:0] SCLH bit field in F/S mode and in the first phase of HS mode; or by the I2C*i*.I2C_SCLH[15:8] HSSCLH bit field in the second phase of HS mode.

The low time of the SR I2C signal is determined by the PRM_VC_CFG_I2C_CLK[15:8] SCLL bit field in F/S mode or in the first phase of HS mode; or by the PRM_VC_CFG_I2C_CLK[31:24] HSSCLL bit field in the second phase of HS mode.

The high time of the SR I2C signal is determined by the PRM_VC_CFG_I2C_CLK[7:0] SCLH bit field in F/S mode or in the first phase of HS mode; or by the PRM_VC_CFG_I2C_CLK[23:16] HSSCLH bit field in the second phase of HS mode.

Table 23-6 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 23-6. HS I²C t_{LOW} and t_{high} Values of the I²C Clock

Mode	I2C*i* Clock	t_{LOW}	t_{high}	
			DFILTEREN = 0	DFILTEREN = 1
F/S or HS first phase	I2C*i*_INTERNAL_CLK = I2C*i*_FCLK / (I2C*i*.I2C_PSC[7:0] PSC bit field + 1)	(I2C*i*.I2C_SCLL[7:0] SCLL bit field value + 7) x I2C*i*_INTERNAL_CLK period	(I2C*i*.I2C_SCLH[7:0] SCLH bit field value + 5 + PROP_DELAY0) x I2C*i*_INTERNAL_CLK period	(I2Ci.I2C_SCLH [7:0] SCLH bit filed value + 5 + PROP_DELAY1) x I2Ci_INTERNAL_CLK period
HS second phase	I2C*i*_FCLK	(I2C*i*.I2C_SCLL[15:8] HSSCLL bit field value + 7) x I2C*i*_FCLK period	(I2C*i*.I2C_SCLH[15:8] HSSCLH bit field value + 5 + PROP_DELAY0) x I2C*i*_FCLK period	(I2Ci.I2CSCLL [15:8] HSSCLH bit field value + 5 + PROP_DELAY1) x I2Ci_FCLK period
FS or first phase of HS mode for SR I2C	SR I2C_FCLK	(VC_CFG_I2C_CLK[15:8]SCLL + 1) x SR I2C_FCLK period	(VC_CFG_I2C_CLK [7:0] SCLH + 5 + PROP_DELAY0) xSR I2C_FCLK period	(VC_CFG_I2C_CLK [7:0] SCLH + 5 + PROP_DELAY1) x SR I2C_FCLK period
Second phase of HS mode for SR I2C	SR I2C_FCLK	(VC_CFG_I2C_CLK [31:24] HSSCLL + 1) x SR I2C_FCLK period	(VC_CFG_I2C_CLK [23:16] HSSCLH +5 + PROP_DELAY0) x SR I2C_FCLK period	(VC_CFG_I2C_CLK [23:16] HSSCLH +5 + PROP_DELAY1) x SR I2C_FCLK period

NOTE: For HS mode, the I2C*i*.I2C_SCLL[15:8] HSSCLL and I2C*i*.I2C_SCLL[7:0] SCLL bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, the I2C*i*.I2C_SCLH[15:8] HSSCLH and I2C*i*.I2C_SCLH[7:0] SCLH bit fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

NOTE: The equations in Table 23-6 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual tlow and thigh periods may vary depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board.

CAUTION

During active mode (the I2C*i*.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2C*i*.I2C_SCLL and I2C*i*.I2C_SCLH registers. Changes may result in unpredictable behavior.

NOTE: Each multimaster HS I²C controller can be used with an internal secondary pullup. Pullups can be programmed through the CONTROL_I2C_0[16] I2C1_PMIC_SCL_PULLUPRESX bit or CONTROL_I2C_0[24] I2C1_PMIC_SDA_PULLUPRESX bit for I2C1, the CONTROL_I2C_0[18] I2C2_SCL_PULLUPRESX bit or CONTROL_I2C_0[26] I2C2_SDA_PULLUPRESX bit for I2C2, the CONTROL_I2C_0[20] I2C3_SCL_PULLUPRESX bit or CONTROL_I2C_0[28] I2C3_SDA_PULLUPRESX bit for I2C3, the CONTROL_I2C_0[22] I2C4_SCL_PULLUPRESX bit or CONTROL_I2C_0[30] I2C4_SDA_PULLUPRESX bit for I2C4, and the CONTROL_I2C_0[12] I2C5_SCL_PULLUPRESX bit or CONTROL_I2C_0[14] I2C5_SDA_PULLUPRESX bit for I2C5.

Table 23-7 lists the register values for obtaining the maximum I2C bit rates and the maximum period of the filtered spikes in F/S mode and HS mode.

Table 23-7. HS I²C Register Values for Maximum I²C Bit Rates in I²C F/S, I²C HS Modes(1)

	I²C Mode for I2C*i*,			Description	I²C Mode for SmartReflex I2C Fast and High-Speed Mode		
	Standart Mode	**Fast Mode**	**High-Speed Mode**				
I2C*i*_FCLK frequency (MHz)	96					38.4	SYS_CLK clock frequency
I2C *i* .I2C_PSC[7:0] PSC bit field value	**23**	**9**	**1**	Prescaler value for F/S and HS modes	Not accessible by software		
I2C*i*_INTERNAL_CLK frequency (MHz)	4	9.6	96				
I2C *i* .I2C_SCLL[7:0] SCLL bit field value	**13**	**7**	**115**	Value for F/S mode and first phase of HS mode	**PRM_VC_CFG_I2C_CLK[15:8] SCLL** see Section 3.1.1, *Power, Reset, and Clock Management*	**43**	Value for F/S mode and first phase of HS mode
I2C *i* .I2C_SCLH[7:0] SCLH bit field value	**15**	**5**	**113**	Value for F/S mode and first phase of HS mode	**PRM_VC_CFG_I2C_CLK[7:0] SCLH** see Section 3.1.1, *Power, Reset, and Clock Management*	**41**	Value for F/S mode and first phase of HS mode
Maximum bit rate (Mbps)	0.1	0.4	0.4	F/S mode and first phase in HS mode maximum bit rate		0.4	F/S mode and first phase in HS mode maximum bit rate
Maximum filter period (ns)	250	104.2	10			50	
I2C *i* .I2C_SCLL[15:8] HSSCLL bit field value			**12**	Values for second phase of HS mode	**PRM_VC_CFG_I2C_CLK[31:24] HSSCLL** see Section 3.1.1, *Power, Reset, and Clock Management*	**14**	Values for second phase of HS mode
I2C *i* .I2C_SCLH[15:8] HSSCLH bit field value			**5**	Values for second phase of HS mode	**PRM_VC_CFG_I2C_CLK[23:16] HSSCLH** see Section 3.1.1, *Power, Reset, and Clock Management*	**0**	Values for second phase of HS mode
HS mode maximum bit rate (Mbps)			3.31	HS mode maximum bit rate		3.2	HS mode maximum bit rate according to the corresponding SYS_CLK clock frequency
Maximum filter period (ns)			10			10	

(1) Programmable fields are in bold.

NOTE: There is only one clock domain for Voltage Controller module. PRM module can provide only one clock signal(system clock signal) which is used for SR I2C FS and HS mode. The clock frequencies are only some examples.

NOTE: This table presents informative values only for the configuration parameters and the I²C bus performance obtained according to these values. The delays added by the analog pads are not considered in these figures.For further information regarding the delays added by the pads, refer to the device Data Manual, available through your TI representative.

NOTE: Fof I2Ci (where i=1, 2, 3, 4, 5)

I2Ci_INTERNAL_CLK freq = SYS_CLK / (PSC +1)

F/S filter period = 1 / I2Ci_INTERNAL_CLK

HS filter period = 1 / SYS_CLK freq

If DFILTEREN bit = 0:

HS bit rate = I2Ci_FCLK freq / (HSSCLL+7 + HSSCLH+5 + PROP_DELAY0)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL+7 + SCLH+5 + PROP_DELAY0)

- If DFILTEREN bit = 1:

HS bit rate = I2Ci_FCLK freq / (HSSCLL+7 + HSSCLH+5 + PROP_DELAY1)

FS bit rate = I2Ci_INTERNAL_CLK / (SCLL+7 + SCLH+5 + PROP_DELAY1)

For SR I2C (SmartReflex I2C) :

SR I2C_FCLK freq = SYS_CLK freq

HS/FS filter period = 1 / SR I2C_FCLK freq

- If DFILTEREN bit = 0:

HS bit rate = SR I2C_FCLK freq / (HSSCLL+1 + HSSCLH+5 +PROP_DELAY0)

FS bit rate = SR I2C_FCLK freq / (SCLL+1 + SCLH+5 + PROP_DELAY0)

- If DFILTEREN bit = 1:

HS bit rate = SR I2C_FCLK freq / (HSSCLL+1 + HSSCLH+5 + PROP_DELAY1)

FS bit rate = SR I2C_FCLK freq / (SCLL+1 + SCLH+5 + PROP_DELAY1)

DFILTEREN refers to VC_CFG_I2C_MODE [6] DFILTEREN bit field. PROP_DELAYx (x= 0 or 1) represents frequency normalized IO low to high propagation delay.

PROP_DELAY0= 0 or 3 (values for bit rate max/min range)

PROP_DELAY1= 1 or 4 (values for bit rate max/min range)

23.1.4.2.2 HS I²C Automatic Blocking of the I²C Clock Feature

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock can be performed independently for each Own Address (I2C*i*.I2C_OA, where *i* = 1, 2, 3, 4, 5 and I2C*i*.I2C_OAx registers) by deasserting the corresponding bit in the I2C*i*.I2C_SBLOCK register.

23.1.4.3 HS I²C Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2C*i*.I2C_SYSC[1] SRST bit (1: reset; 0: normal mode).

The software reset status can be checked by accessing the I2C*i*.I2C_SYSS[0] RDONE bit (1: reset is done; 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2C*i*.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2C*i*.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2C*i*.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2C*i*.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2C*i*.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2C*i*.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2C*i*.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

23.1.4.4 HS I²C Power Management

Table 23-8 describes power-management features available for the multimaster HS I²C controllers.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module Level Clock Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module Level Clock Management*, in Section 3.1.1, *Power, Reset, and Clock Management*.

Table 23-8. HS I²C Local Power-Management Features

Feature	Registers	Description
Clock auto gating	I2C*i*.I2C_SYSC[0] AUTOIDLE	This bit allows a local power optimization inside the module.
Slave idle modes	I2C*i*.I2C_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	For configuration details, see Table 23-9.
Global wake-up enable	I2C*i*.I2C_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.

NOTE: The voltage controllers, in which the HS I²C controller is implemented, have no idle request/acknowledge mechanism. The idle modes for the voltage controllers are directly managed by the PRCM module.

Table 23-9. HS I²C Clock Activity Settings

I2C*i*.I2C_SYSC[9:8] CLOCKACTIVITY	Clock State When Module is in IDLE State		Features Available/Unavailable When Module is in IDLE State
	I2C*i*_ICLK	I2C*i*_ FCLK	
00	OFF	OFF	Both clocks are disabled.
10	OFF	ON	Interface clock is disabled; functional clock is enabled
01	ON	OFF	Functional clock is disabled; interface clock is enabled
11	ON	ON	Both clocks are enabled.

CAUTION

The PRCM module has no hardware means of reading the settings of CLOCKACTIVITY. Thus, software must ensure consistent programming between the I²C CLOCKACTIVITY and I²C clock PRCM control bits. For a description of the ClockActivity feature, see Section 3.1.1.1.2, *Module Level Clock Management* in Section 3.1.1, *Power, Reset, and Clock Management*.

23.1.4.5 HS I²C Interrupt Requests

Table 23-10 lists the event flags, and their mask, that can cause module interrupts.

Table 23-10. HS I²C Events

Event Flag	Event Mask	Event Unmask	Map to	Description
I2C*i*.I2C_IRQSTATUS[0] AL	I2C*i*.I2C_IRQENABLE_SET[0] AL_IE	I2C*i*.I2C_IRQENABLE_CLR[0] AL_IE	I2C*i*_IRQ	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to the microprocessor unit (MPU) subsystem. During reads, it always returns 0.
I2C*i*.I2C_IRQSTATUS[1] NACK	I2C*i*.I2C_IRQENABLE_SET[1] NACK_IE	I2C*i*.I2C_IRQENABLE_CLR[1] NACK_IE	I2C*i*_IRQ	No acknowledgement IRQ enabled status. Bit is set when No Acknowledge is received, an interrupt is signaled to the MPU subsystem. Write 1 to clear this bit.
I2C*i*.I2C_IRQSTATUS[2] ARDY	I2C*i*.I2C_IRQENABLE_SET[2] ARDY_IE	I2C*i*.I2C_IRQENABLE_CLR[2] ARDY_IE	I2C*i*_IRQ	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to the MPU subsystem. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[3] RRDY	I2C*i*.I2C_IRQENABLE_SET[3] RRDY_IE	I2C*i*.I2C_IRQENABLE_CLR[3] RRDY_IE	I2C*i*_IRQ	Receive data ready IRQ enabled status. Set to 1 by core when receiver mode, a new data can be read. When set to 1 by core, an interrupt is signaled to the MPU subsystem. Write 1 to clear.

Table 23-10. HS I²C Events (continued)

Event Flag	Event Mask	Event Unmask	Map to	Description
I2C*i*.I2C_IRQSTATUS[4] XRDY	I2C*i*.I2C_IRQENABLE_SET[4] XRDY_IE	I2C*i*.I2C_IRQENABLE_CLR[4] XRDY_IE	I2C*i*_IRQ	Transmit data ready IRQ enabled status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to the MPU subsystem. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[5] GC	I2C*i*.I2C_IRQENABLE_SET[5] GC_IE	I2C*i*.I2C_IRQENABLE_CLR[5] GC_IE	I2C*i*_IRQ	General call IRQ enabled status. Set to 1 by core when General call address detected and interrupt signaled to the MPU subsystem. Write 1 to clear.
I2C*i*.I2C_IRQSTATUS[6] STC	I2C*i*.I2C_IRQENABLE_SET[6] STC_IE	I2C*i*.I2C_IRQENABLE_CLR[6] STC_IE	I2C*i*_IRQ	Start condition IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[7] AERR	I2C*i*.I2C_IRQENABLE_SET[7] AERR_IE	I2C*i*.I2C_IRQENABLE_CLR[7] AERR_IE	I2C*i*_IRQ	Access Error IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[8] BF	I2C*i*.I2C_IRQENABLE_SET[8] BF_IE	I2C*i*.I2C_IRQENABLE_CLR[8] BF_IE	I2C*i*_IRQ	Access Error IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[9] AAS	I2C*i*.I2C_IRQENABLE_SET[9] AAS_IE	I2C*i*.I2C_IRQENABLE_CLR[9] AAS_IE	I2C*i*_IRQ	Address recognized as slave IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[10] XUDF	I2C*i*.I2C_IRQENABLE_SET [10] XUDF_IE	I2C*i*.I2C_IRQENABLE_CLR[10] XUDF_IE	I2C*i*_IRQ	Transmit underflow enabled status. Writing into this bit has no effect.
I2C*i*.I2C_IRQSTATUS[11] ROVR	I2C*i*.I2C_IRQENABLE_SET [11] ROVR_IE	I2C*i*.I2C_IRQENABLE_CLR[11] ROVR_IE	I2C*i*_IRQ	Receive overrun enabled status. Writing into this bit has no effect.
I2C*i*.I2C_IRQSTATUS[12] BB	Reserved	Reserved	I2C*i*_IRQ	Bus busy status.
I2C*i*.I2C_IRQSTATUS[13] RDR	I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE	I2C*i*.I2C_IRQENABLE_CLR[13] RDR_IE	I2C*i*_IRQ	Receive draining IRQ enabled status.
I2C*i*.I2C_IRQSTATUS[14] XDR	I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE	I2C*i*.I2C_IRQENABLE_CLR[14] XDR_IE	I2C*i*_IRQ	Transmit draining IRQ enabled status.

23.1.4.6 HS I²C DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. Table 23-11 lists the DMA requests with mapping on the sDMA controller. For information about DMA generation, see Section 23.1.4.8.3, *HS I²C FIFO DMA Mode (I²C Mode Only)*.

Table 23-11. HS I²C DMA Requests

Name	Source	Destination	Description
I2C1_DMA_TX	I2C1	DMA_SYSTEM_DREQ_26	I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register
I2C1_DMA_RX	I2C1	DMA_SYSTEM_DREQ_27	I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register
I2C2_DMA_TX	I2C2	DMA_SYSTEM_DREQ_28	I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register
I2C2_DMA_RX	I2C2	DMA_SYSTEM_DREQ_29	I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register
I2C3_DMA_TX	I2C3	DMA_SYSTEM_DREQ_24	I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register
I2C3_DMA_RX	I2C3	DMA_SYSTEM_DREQ_25	I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register
I2C4_DMA_TX	I2C4	DMA_SYSTEM_DREQ_123	I2C4 DMA write request to inform the sDMA to write new data in the I2C4.I2C_DATA[7:0] register
I2C4_DMA_RX	I2C4	DMA_SYSTEM_DREQ_124	I2C4 DMA read request to inform the sDMA to read the data in the I2C4.I2C_DATA[7:0] register

NOTE: The HS I²C controller I2C5 does not generate any DMA requests.

23.1.4.7 HS I²C Programmable Multislave Channel Feature

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2C*i*.I2C_OA and I2C*i*.I2C_OAx registers (where *i* = 1, 2, 3). An additional register (I2C*i*.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2C*i*.I2C_CON[7] XOA, I2C*i*.I2C_CON[6] XOA1, I2C*i*.I2C_CON[5] XOA2, or I2C*i*.I2C_CON[4] XOA3).

23.1.4.8 HS I²C FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

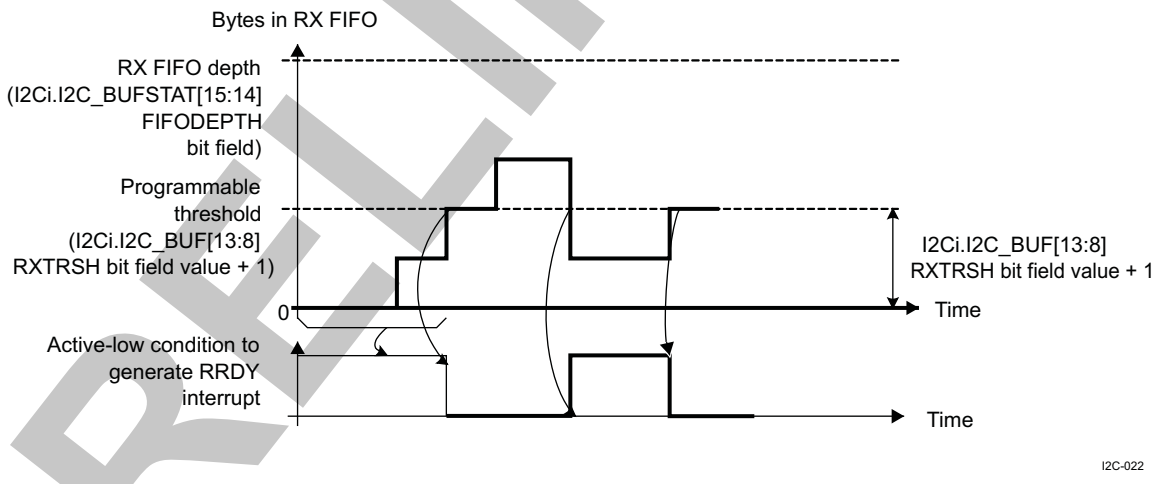
The depth of the RX and TX FIFOs can be checked by reading the I2C*i*.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

23.1.4.8.1 HS I²C FIFO Interrupt Mode

In FIFO interrupt mode (relevant interrupts enabled by the I2C*i*.I2C_IRQENABLE_SET register), an interrupt signal informs the processor of the receiver and transmitter status. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2C*i*.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX FIFO or the I2C*i*.I2C_BUF[5:0] XTRSH bit field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 23-16 and Figure 23-17 show receive and transmit operations, respectively, from a FIFO management point of view.

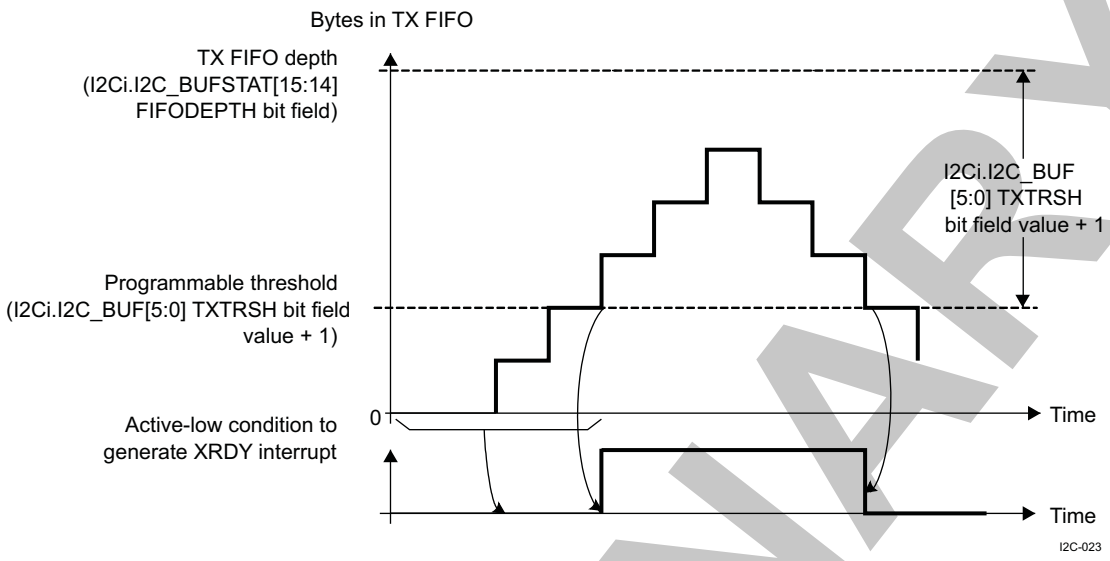
Figure 23-16. HS I²C Receive FIFO Interrupt Request Generation



In Figure 23-16, the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the corresponding bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2C*i*.I2C_BUF[13:8] RTRSH bit field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

Figure 23-17. HS I²C Transmit FIFO Interrupt Request Generation



In Figure 23-17, the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by setting the I2C*i*.I2C_IRQENABLE_CLR [4] XRDY_IE bit to 1 after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is not met.
- When detecting an interrupt request (XRDY or RRDY type), the LH can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF[5:0] TXTRSH + 1 or I2C_BUF[5:0] RXTRSH + 1). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY or RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 23.1.4.8.4, *Draining Feature [I²C Mode Only]*).

NOTE: In slave transmit mode (the I2C*i*.I2C_CON[10] MST bit is cleared and the I2C*i*.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2C*i*.I2C_BUF[6] TXFIFO_CLR bit.

23.1.4.8.2 HS I²C FIFO Polling Mode

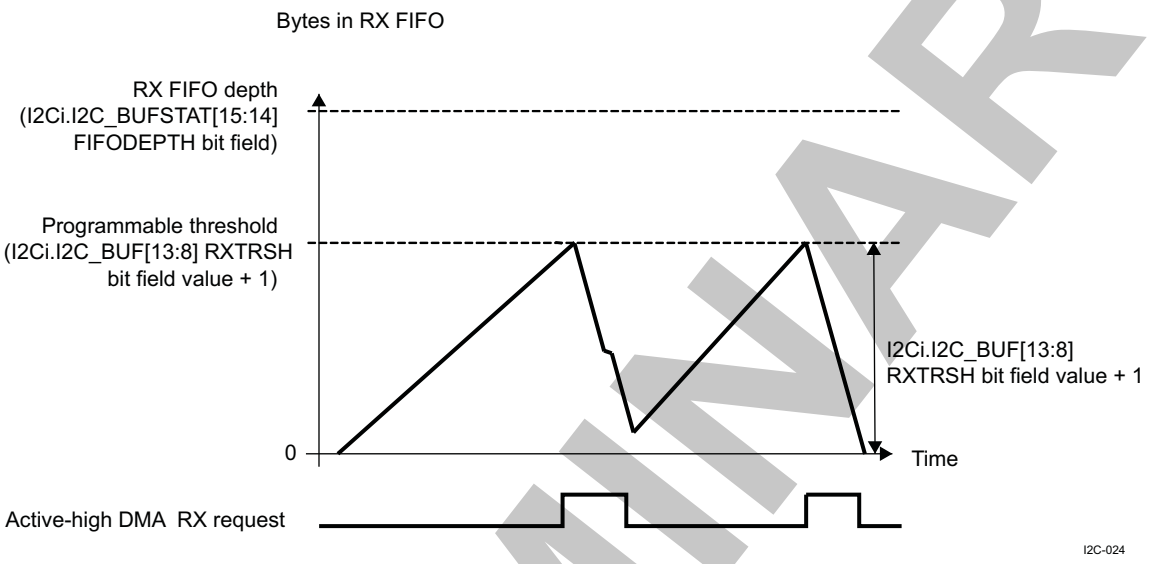
In FIFO polling mode (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE and I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR and I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bits can also be polled if the draining feature is enabled). The I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY and I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bits accurately reflect the interrupt conditions described in the discussion of FIFO interrupt mode.

23.1.4.8.3 HS I²C FIFO DMA Mode

In receive mode, a DMA request is generated by the I2C*i*_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (the I2C*i*.I2C_BUF[13:8] RTRSH bit field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the DMA controller.

Figure 23-18 shows the DMA request generation in receive mode.

Figure 23-18. HS I²C Receive FIFO DMA Request Generation



In transmit mode, a DMA request is automatically asserted by the I2C*i*_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (the I2C*i*.I2C_BUF[5:0] XTRSH bit field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 23-19 and Figure 23-20 show the DMA TX transfers with different values for the I2C*i*.I2C_BUF[5:0] XTRSH bit field.

Figure 23-19. HS I²C Transmit FIFO Request Generation (High Threshold)

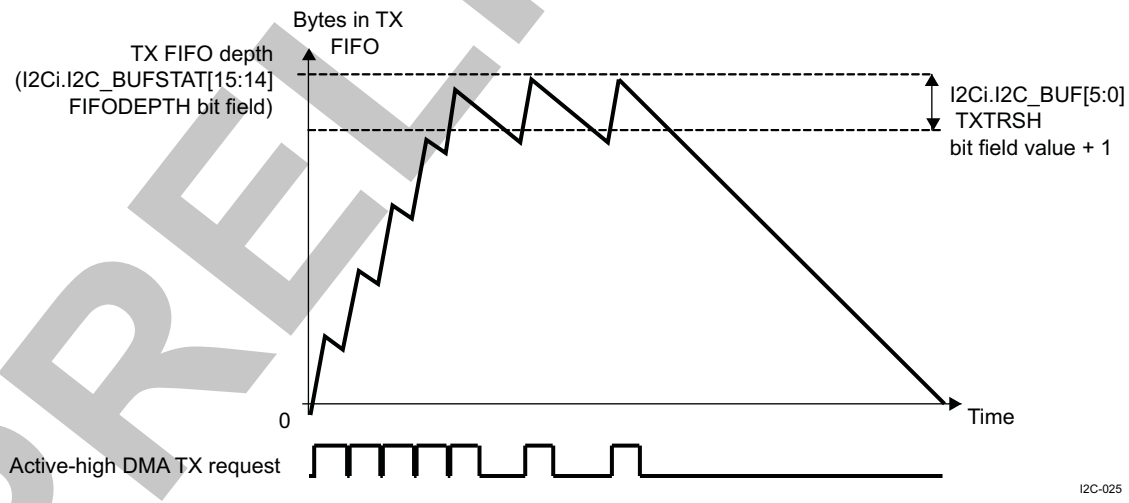


Figure 23-20. HS I²C Transmit FIFO Request Generation (Low Threshold)

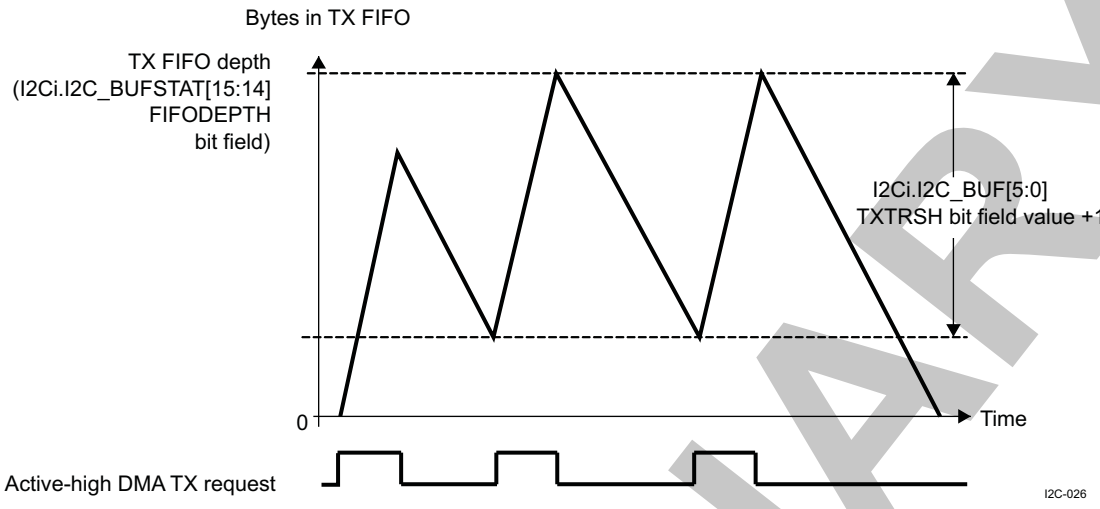

The I2C module provides the possibility to the user to clear the RX or TX FIFO, by setting the I2Ci.I2C_BUF[14]RXFIFO_CLR and I2Ci.I2C_BUF[6]TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the following conditions are met:

1. The module is configured as a transmitter
2. The external receiver responds with a NACK in the middle of the transfer
3. There is still data in TX FIFO waiting to be transferred

23.1.4.8.4 HS I²C Draining Feature

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (the I2C*i*.I2C_BUF[13:8] RTRSH bit field value + 1 for the RX threshold and the I2C*i*.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold). It can also transfer the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit.

The draining mechanism generates an interrupt using the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR or I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT or I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RTRSH bit field value + 1) is not reached, but the transfer ends on the I²C bus and data remains in the RX FIFO (less than the threshold), the receive draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [13] RDR bit) is asserted to inform the LH that it can read the amount of data in the RX FIFO (the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field). The LH performs a number of data read accesses equal to the I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit field (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2C*i*.I2C_IRQSTATUS_RAW [14] XDR bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field). The LH must write the required number of data bytes specified by the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT bit field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately not check the values of the I2C*i*.I2C_BUFSTAT[5:0] TXSTAT and I2C*i*.I2C_BUFSTAT[13:8] RXSTAT bit fields, because it can obtain this information internally (by computing the I2C*i*.I2C_CNT[15:0] DATACOUNT bit field value modulo I2C*i*.I2C_BUF[13:8] RXTRSH or I2C*i*.I2C_BUF[5:0] TXTRSH).

By default, the draining feature is disabled; it can be enabled using the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE or I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2C*i*.I2C_BUF[5:0] TXTRSH bit field value + 1 for the TX threshold or the I2C*i*.I2C_BUF[13:8] RXTRSH bit field value + 1 for the RX threshold).

23.1.4.9 HS I²C Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2C*i*_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For standard mode (for example, the I2C*i*.I2C_PSC[7:0] PSC bit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the 2C*i*.I2C_PSC[7:0] PSC bit field.

23.1.4.10 HS I²C System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2C*i*.I2C_SYSTEST[15] ST_EN bit to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2C*i*.I2C_SYSTEST [13:12] TMODE bit field selects the type of test. Table 23-12 lists the tests available for the multimaster HS I²C controllers.

Table 23-12. HS I²C List of Tests

I2C*i*.I2C_SYSTEST[13:12] TMODE	Test	Description
00	Functional mode	Normal operation mode
01	Reserved (not used)	
10	Test of i2c*i*_scl serial clock line	The i2c*i*_scl line is driven with a permanent clock as if mastered with the parameters set in the I2C*i*.I2C_PSC, I2C*i*.I2C_SCLL, and I2C*i*.I2C_SCLH registers.
11	Loop-back mode + i2c*i*_scl/ i2c*i*_sda I/O	In master transmit mode only, data transmitted out of the I2C*i*.I2C_DATA register (write action) is received in the same I2C*i*.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2c*i*_scl and i2c*i*_sda are controlled with the I2C*i*.I2C_SYSTEST[4:0] bits.

NOTE: When the I2C*i*.I2C_SYSTEST[13:12] TMODE bit field is set to 11, the I²C controller must be configured in I²C F/S (I2C*i*.I2C_CON[13:12] OPMODE set to 00) or I²C HS mode (I2C*i*.I2C_CON[13:12] OPMODE set to 01).

NOTE: In normal operation mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit cleared to 0), the I2C*i*.I2C_SYSTEST[4:0] bits that control the i2c*i*_scl, i2c*i*_sda lines in system test mode are read-only bits.

In system test mode (the I2C*i*.I2C_SYSTEST[15] ST_EN bit set to 1), the I2C*i*.I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK status bits can be set to 1 when the I2C*i*.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2C*i*.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2C*i*.I2C_IRQSTATUS_RAW bits to 0. The I2C*i*.I2C_IRQSTATUS_RAW bit field can be cleared to 0 only by writing 1 in the corresponding bits.

23.1.5 HS I²C Programming Guide

23.1.5.1 HS I²C Low-Level Programming Models

23.1.5.1.1 HS I²C Programming Model

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

23.1.5.1.1.1 Main Program

23.1.5.1.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see Table 23-3).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock by programming the corresponding value in the I2C*i*.I2C_PSC[7:0] PSC bit field. This value depends on the frequency of the functional clock (I2C*i*_FCLK).
3. Program the I2C*i*.I2C_SCLL[7:0] SCLL and I2C*i*.I2C_SCLH[7:0] SCLH bit fields to obtain a bit rate of 100 kbps, 400 kbps, or 1 Mbps. These values depend on the internal sampling clock frequency (see Table 23-6).
4. (Optional) Program the I2C*i*.I2C_SCLL[15:8] HSSCLL and I2C*i*.I2C_SCLH[15:8] HSSCLH bit fields to obtain a bit rate of 400 kbps or 3.4 Mbps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see Table 23-6).
5. Configure the Own Address of the I²C controller by storing it in the I2C*i*.I2C_OA register. Up to four Own Addresses can be programmed in the I2C*i*.I2C_OAx registers (where x = 0, 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2C*i*.I2C_CON register.

6. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2C*i*.I2C_BUF[5:0] XTRSH bit field to (TX threshold – 1) and the I2C*i*.I2C_BUF[13:8]RTRSH bit field to (RX threshold – 1), where the TX and RX thresholds are greater than or equal to 1.
7. Take the I²C controller out of reset by setting the I2C*i*.I2C_CON[15] I2C_EN bit to 1.

23.1.5.1.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2C*i*.I2C_CON register:
   - For master or slave mode, set the I2C*i*.I2C_CON[10] MST bit (0: slave; 1: master).
   - For transmitter or receiver mode, set the I2C*i*.I2C_CON[9] TRX bit (0: receiver; 1: transmitter).
2. If using an interrupt to transmit and receive data, set the corresponding bit in the I2C*i*.I2C_IRQENABLE_SET register to 1 (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit for the transmit interrupt, the I2C*i*.I2C_IRQENABLE_SET [3] RRDY bit for the receive interrupt).
3. If using DMA to receive and transmit data, set the corresponding bit in the I2C*i*.I2C_BUF register to 1 (the I2C*i*.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2C*i*.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

23.1.5.1.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2C*i*.I2C_SA[9:0] SA bit field and the number of data bytes (I^2C data payload) associated with the transfer by programming the I2C*i*.I2C_CNT[15:0] DCOUNT bit field.

NOTE: For a 10-bit address, set the I2C*i*.I2C_CON[8] XSA bit to 1.

23.1.5.1.1.1.4 Initiate a Transfer

Poll the I2C*i*.I2C_IRQSTATUS_RAW [12] BB bit. If it is cleared to 0 (bus not busy), configure the I2C*i*.I2C_CON[0] STT and I2C*i*.I2C_CON[1] STP bits. To initiate a transfer, the I2C*i*.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2C*i*.I2C_CON[1] STP bit to 1.

23.1.5.1.1.1.5 Receive Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit, or use the RRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2C*i*.I2C_BUF[15] RDMA_EN bit must be set to 1 together with I2C_DMARXENABLE_SET) to read the receive data in the I2C*i*.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (the I2C*i*.I2C_BUF[13:8] RTRSH bit field + 1), use the draining feature (enable the RDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2C*i*.I2C_IRQSTATUS_RAW [11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I^2C controller simply holds i2c*i*_scl to low to prevent other bytes from being received.

The I2C*i*.I2C_IRQSTATUS_RAW[7] AERR bit is set to 1 when a read access is performed in the I2C*i*.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

23.1.5.1.1.1.6 Transmit Data

Poll the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit, or use the XRDY interrupt (the I2C*i*.I2C_IRQENABLE_SET [4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2C*i*.I2C_BUF[7] XDMA_EN bit must be set to 1 together with I2C_DMATXENABLE_SET) to write data to the I2C*i*.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (the I2C*i*.I2C_BUF[5:0] TXTRSH bit field + 1), use the draining feature (enable the XDR interrupt by setting the I2C*i*.I2C_IRQENABLE_SET [14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2C*i*.I2C_IRQSTATUS_RAW [10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the value of the I2C*i*.I2C_CNT[15:0] DCOUNT bit field is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I^2C master device still requests data bytes to be read.

The I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit is set to 1 when a write access is performed in the I2C*i*.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2C*i*.I2C_IRQENABLE_SET [7] AERR_IE bit to 1.

23.1.5.1.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (the I2C*i*.I2C_IRQSTATUS_RAW [0] AL bit) and resolve accordingly.
2. Test for no acknowledgment (the I2C*i*.I2C_IRQSTATUS_RAW [1] NACK bit) and resolve accordingly.
3. Test for register access ready (the I2C*i*.I2C_IRQSTATUS_RAW [2] ARDY bit) and resolve accordingly.
4. Test for receive data ready (the I2C*i*.I2C_IRQSTATUS_RAW [3] RRDY bit) and resolve accordingly.
5. Test for transmit data ready (the I2C*i*.I2C_IRQSTATUS_RAW [4] XRDY bit) and resolve accordingly.
6. Test for general call (the I2C*i*.I2C_IRQSTATUS_RAW [5] GC bit) and resolve accordingly.
7. Test for start (S) condition (the I2C*i*.I2C_IRQSTATUS_RAW [6] STC bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (the I2C*i*.I2C_IRQSTATUS_RAW [7] AERR bit) and resolve accordingly.
9. Test for bus free (the I2C*i*.I2C_IRQSTATUS_RAW [8] BF bit) and resolve accordingly.

23.1.5.1.1.3 Programming Flow Diagrams

Figure 23-21 through Figure 23-29 are procedure flow charts for programming the F/S and HS I²C modes.

(1) *i* = 1 to 4

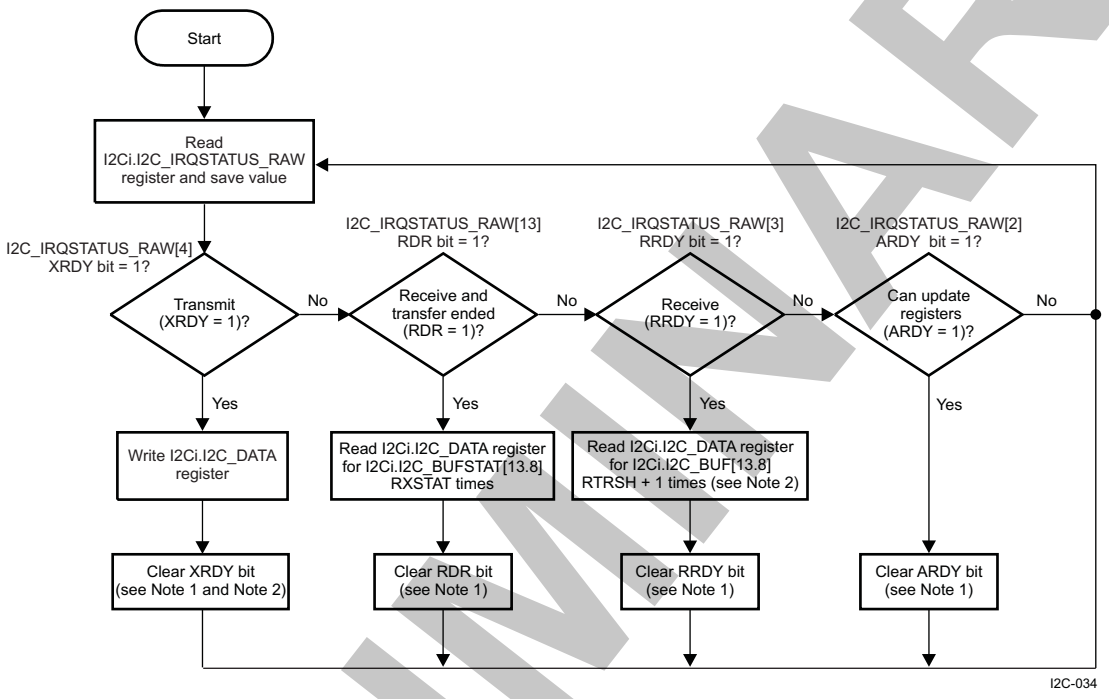
Figure 23-28. HS I²C Slave Transmitter/Receiver Mode, Polling



(1) The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS_RAW register.

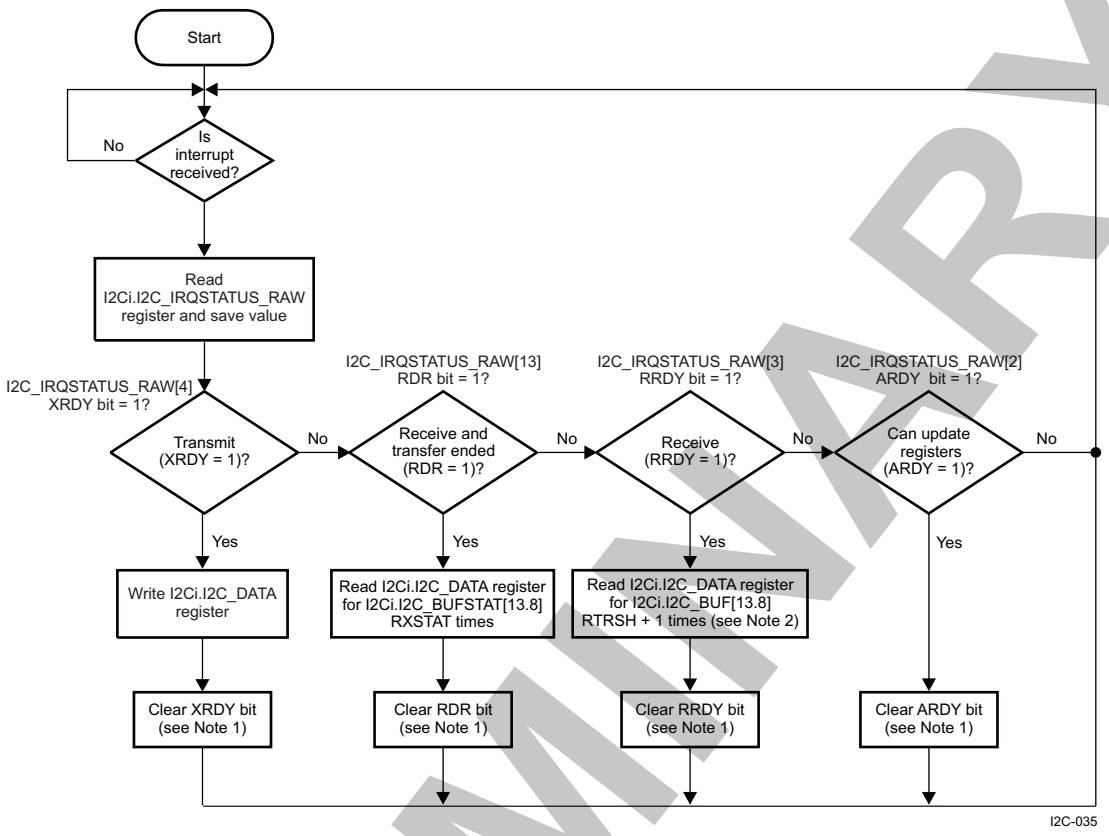
(2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2C*i*.I2C_BUF[5:0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

Table 23-21. HS I²C Register Call Summary for Sequence – Slave Transmitter/Receiver Mode, Polling

Register Name	Register Name
I2C*i*.I2C_IRQSTATUS_RAW (1)	I2C*i*.I2C_BUFSTAT (1)
I2C*i*.I2C_DATA (1)	I2C*i*.I2C_BUF (1)

(1) *i* = 1 to 4

Figure 23-29. HS I²C Slave Transmitter/Receiver Mode, Interrupt



(1) The XRDY, RDR, RRDY, and ARDY bits are cleared by writing 1 to each corresponding bit in the I2C*i*.I2C_IRQSTATUS_RAW register.

(2) In slave transmitter mode, the amount of data requested by the external master I²C device is unknown; thus, the I2C*i*.I2C_BUF[5:0] XTRSH bit field must be configured to 0x0 (TX threshold = 1).

Table 23-32. I2C_IRQSTATUS_RAW

Address Offset	0x0000 0024
Physical Address	0x4806 0024 0x4807 0024 0x4807 2024 0x4807 A024 0x4807 C024
Description	Per-event raw interrupt status vector. The raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug
Type	RW

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	XDR	RDR	BB	ROVR	XUDF	AAS	BF	AERR	STC	GC	XRDY	RRDY	ARDY	NACK	AL

Bits	Field Name	Description	Type	Reset
15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
14	XDR	Transmit draining IRQ status. 0x0: Transmit draining inactive. 0x1: Transmit draining enabled.	RW	0
13	RDR	Receive draining IRQ status. 0x0: Receive draining inactive. 0x1: Receive draining enabled.	RW	0
12	BB	Bus busy status. Writing into this bit has no effect. Read 0x1: Bus is occupied. Read 0x0: Bus is free.	R	0
11	ROVR	Receive overrun status. Writing into this bit has no effect. Read 0x1: Receiver overrun. Read 0x0: Normal operation.	RW	0
10	XUDF	Transmit underflow status. Writing into this bit has no effect. Read 0x1: Transmit underflow. Read 0x0: Normal operation.	RW	0
9	AAS	Address recognized as slave IRQ status. 0x0: No action. 0x1: Address recognized.	RW	0
8	BF	Bus Free IRQ status. 0x0: No action. 0x1: Bus Free.	RW	0
7	AERR	Access Error IRQ status. 0x0: No action. 0x1: Access Error.	RW	0
6	STC	Start Condition IRQ status. 0x0: No action. 0x1: Start Condition detected.	RW	0

Bits	Field Name	Description	Type	Reset
5	GC	General call IRQ status. Set to 1 by core when General call address detected and interrupt signaled to MPUSS. (1) 0x0: No general call detected. 0x1: General call address detected.	RW	0
4	XRDY	Transmit data ready IRQ status. Set to 1 by core when transmitter and when new data is requested. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: Transmision ongoing. 0x1: Transmit data ready.	RW	0
3	RRDY	Receive data ready IRQ status. Set to 1 by core when receiver mode, a new data is able to be read. When set to 1 by core, an interrupt is signaled to MPUSS. (1) 0x0: No data available. 0x1: Receive data available.	RW	0
2	ARDY	Register access ready IRQ status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. (1) 0x0: Module busy. 0x1: Access ready.	RW	0
1	NACK	No acknowledgement IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. (1) 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW	0
0	AL	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW	0

(1) Writing 1 in the bit field will only set the respective field to 1, used mainly for debug.

2	ARDY	Register access ready IRQ enabled status. When set to 1 it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write 1 to clear. 0x0: Module busy. 0x1: Access ready.	RW W1toClr	0
1	NACK	No acknowledgement IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write 1 to clear this bit. 0x0: Normal operation. 0x1: Not Acknowledge detected.	RW W1toClr	0
0	AL	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0x0: Normal operation. 0x1: Arbitration lost detected.	RW W1toClr	0

23.2 HDQ1W

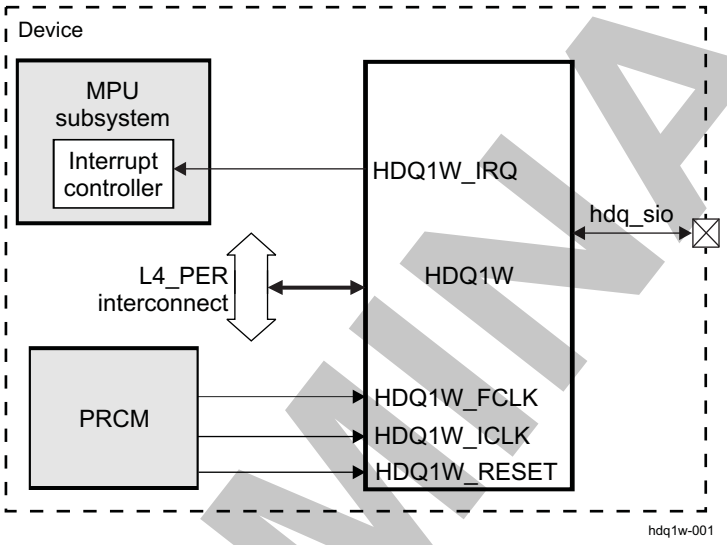
This section describes the HDQ™/1-Wire® interface for the device.

23.2.1 HDQ1W Overview

The HDQ1W module implements the hardware protocol of the master functions of the TI/Benchmarq HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ1W controller) and the slaves (HDQ/1-Wire external compliant devices).

Figure 23-30 shows the HDQ1W.

Figure 23-30. HDQ1W Overview



The HDQ1W has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The 1-pin interface is implemented as an open-drain output at the device level.

The main features supported by the HDQ1W are the following:

- Benchmarq HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ1W provides a communication rate of 5 Kbps over an address space of 128 bytes.

A typical application of the HDQ1W is the communication with battery monitor (gas gauge) integrated circuits.

23.2.2 HDQ1W Environment

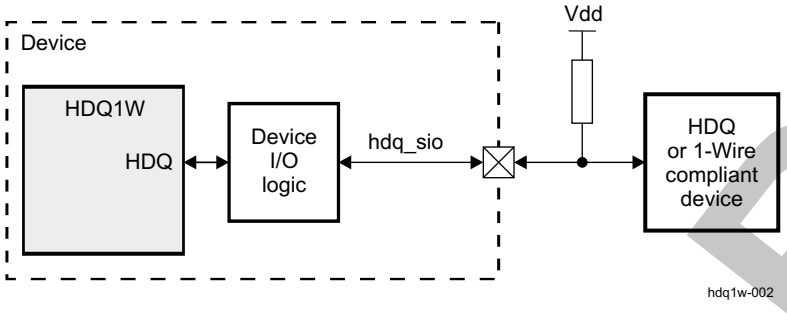
23.2.2.1 HDQ1W Functional Modes

The HDQ1W has two main modes: HDQ and 1-Wire. Each of these modes includes idle, active, and power-down submodes. Table 23-88 lists the HDQ1W functional modes, and Figure 23-31 shows an overview of a typical application.

Table 23-88. Functional Modes

Functions	Description
HDQ	Benchmarq HDQ protocol
1-Wire	Dallas Semiconductor 1-Wire protocol

Figure 23-31. HDQ1W Typical Application System Overview



An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command by any of the connected devices, the line is pulled to a logical high level).

The HDQ1W operates according to a command structure that is programmed into transmit command registers (as described in Section 23.2.5.1.2, *HDQ1W Low-level Programming Model*).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 23-89 describes the external signal of the HDQ/1-Wire compliant module.

Table 23-89. I/O Description

Signal	I/O[1]	Description	Value at Reset
hdq_sio	I/O	Serial data input/output. Output is open drain type.	HiZ (pulled to 1 by pullup)

(1) I = Input; O = Output

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

23.2.2.2 HDQ and 1-Wire (SDQ) Protocols

23.2.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit. The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

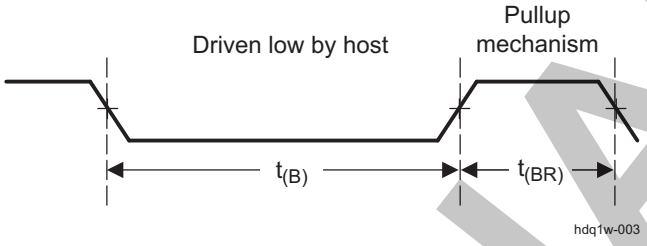
The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. Sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5 Kbps. The least-significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time t(B) or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time t(BR). The slave is then ready for a command from the host processor. Figure 23-32 shows this behavior.

An interrupt condition indicates a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 23-32. HDQ Break-Pulse Timing Diagram

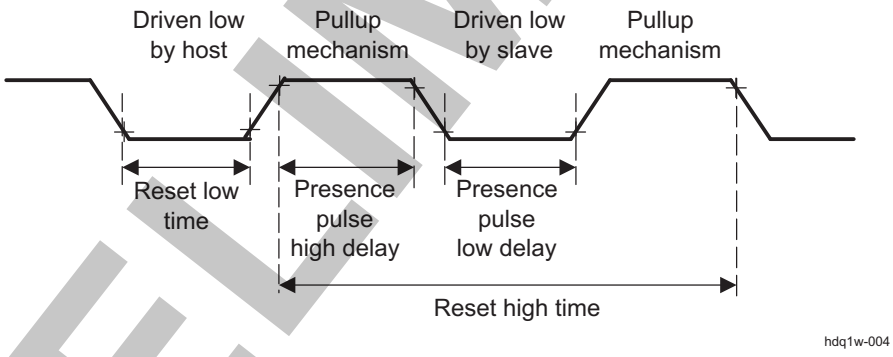


23.2.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-level pulse on the line initiated by the slave. The timing diagram in Figure 23-33 shows the 1-Wire (SDQ) reset sequence.

Figure 23-33. 1-Wire (SDQ) Reset Timing Diagram



The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

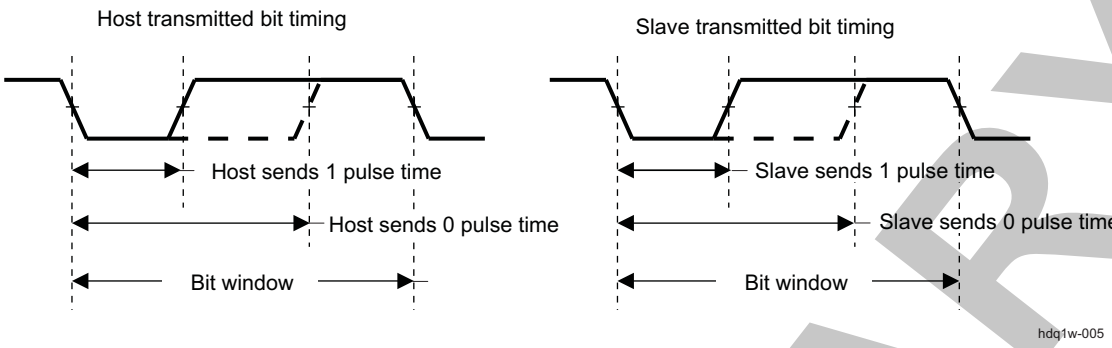
On the other hand, if the slave sends back its presence pulse within the specified time interval, the communication can be enabled after the reset high time.

23.2.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

The description in this section applies to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 23-34.

Figure 23-34. HDQ1W Transmitted Bit Timing



The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 23-90 lists the command byte values.

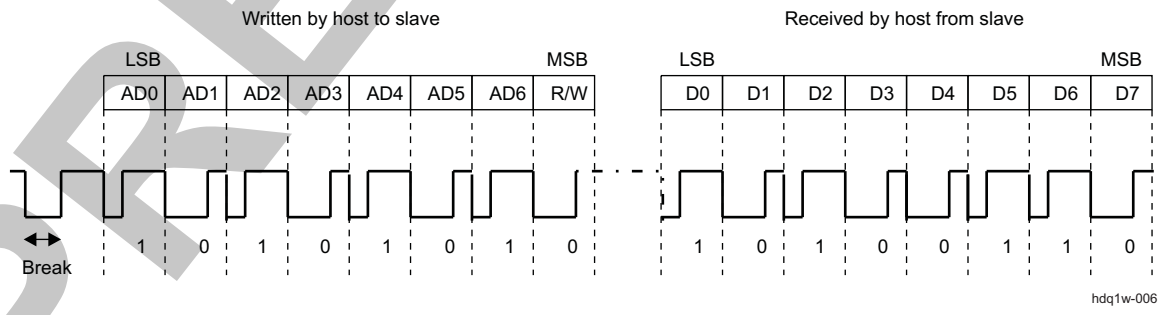
Table 23-90. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

R/W Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.

AD6-AD0 Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed.
The communication sequence example in Figure 23-35 shows a read command at address 0x55; the received data is 0x65.

Figure 23-35. HDQ/1-Wire Communication Sequence



23.2.3 HDQ1W Integration

Figure 23-36 shows HDQ1W integration in the device.

Figure 23-36. HDQ1W Integration

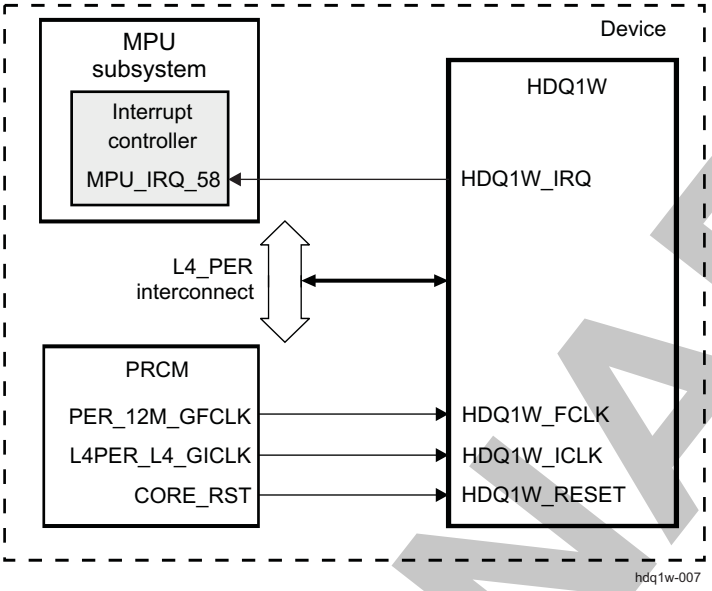


Table 23-91 through Table 23-93 summarize the integration of the module in the device.

HDQ1W	HDQ1W_IRQ	MPU_IRQ_58	MPU	Interrupt to the MPU subsystem interrupt controller (INTC).

NOTE: For the description of the interrupt source, see Section 17.4.1, *INTC_MPU Functional Description*, in chapter *Interrupt Controllers*.

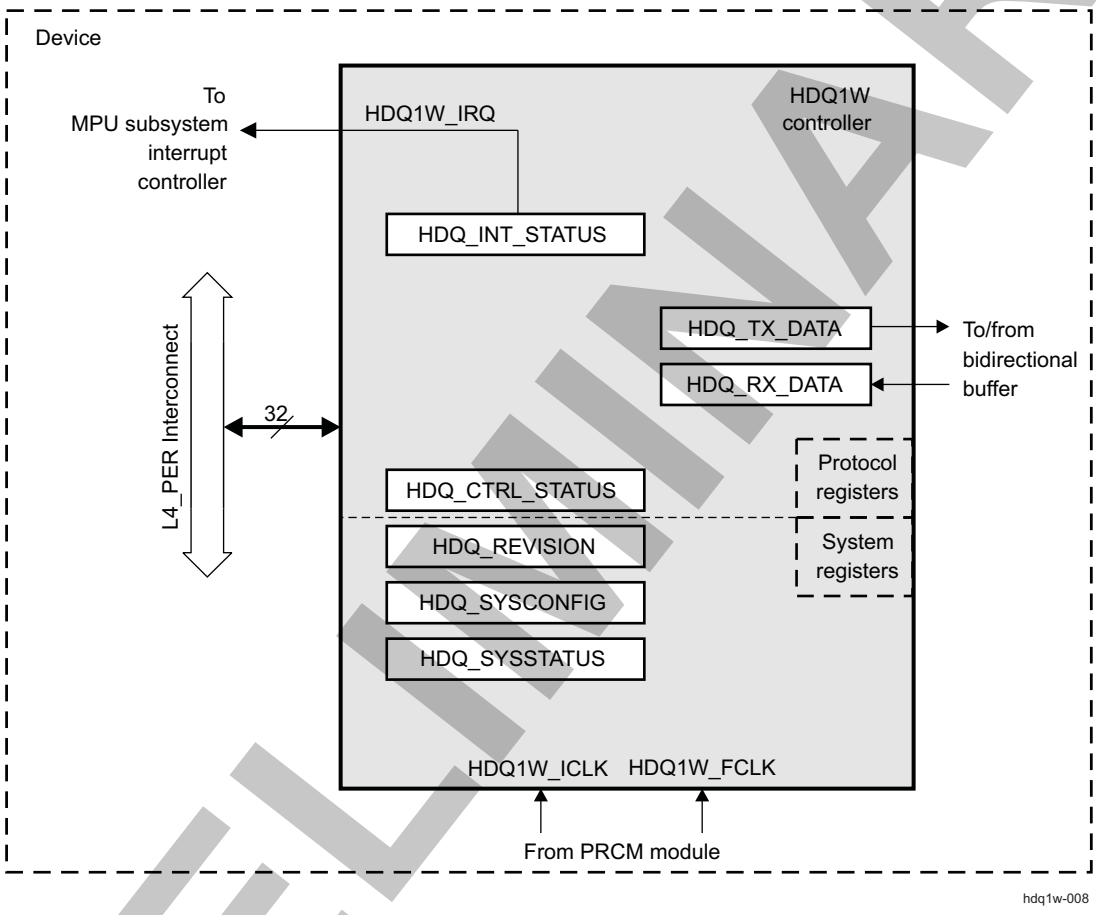
23.2.4 HDQ1W Functional Description

The HDQ1W works with HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

23.2.4.1 HDQ1W Block Diagram

Figure 23-37 is the HDQ1W block diagram.

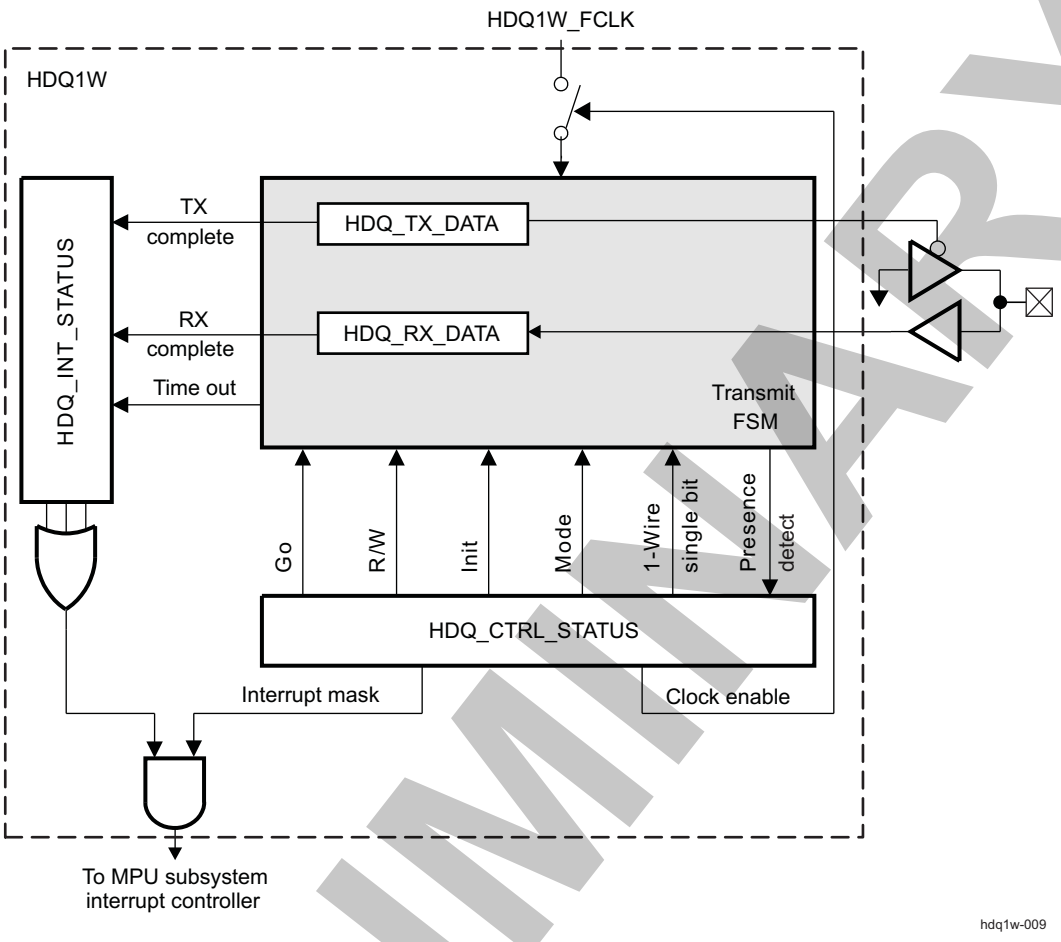
Figure 23-37. HDQ1W Block Diagram



The HDQ_CTRL_STATUS[0] MODE bit allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 23-38 shows the protocol-dedicated register scheme.

Figure 23-38. Protocol Registers Description



The receive and transmit operations of the HDQ1W module are performed with respect to the timing of the slower HDQ protocol. When the 1-Wire protocol is used, it runs at lower speed than its full capabilities, but is still able to meet the timing requirements and practical considerations.

23.2.4.2 HDQ1W Clocking Configuration

23.2.4.2.1 HDQ1W Clocks

The HDQ1W module operates from two clocks: a functional clock (HDQ1W_FCLK) and an interface clock (HDQ1W_ICLK). When these clocks are set in the PRCM module, the following rule must be observed: HDQ1W_ICLK ≥ HDQ1W_FCLK.

- The HDQ1W_FCLK functional clock is a fixed clock provided by the PRCM module. It is used to clock the internal module logic.

  For more information about the clock and the PRCM register settings, see Section 3.6.15, *CD_L4_PER Clock Domain*, in chapter *Power, Reset, and Clock Management*.

  When the HDQ1W no longer requires the HDQ1W_FCLK, the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.
- The HDQ1W_ICLK interface clock runs at L4 interconnect clock speed and is used to trigger access to the HDQ1W L4 interface.

  When the HDQ1W no longer requires the HDQ1W_ICLK (no transfer is in progress), the software can disable it at the PRCM level. The clock is effectively cut, provided the other modules that receive it do not require it either.

23.2.4.3 HDQ1W Hardware and Software Reset

Global reset of the module is done at the power, reset, and clock management (PRCM) module level (for more information, see Section 3.6.15, *CD_L4_PER Clock Domain*) or by setting the HDQ_SYSCONFIG[1] SOFTRESET bit to 1. Setting this bit enables an active software reset functionality equivalent to a hardware reset. The HDQ1W_FCLK functional clock must be enabled from the PRCM level and locally through the HDQ_CTRL_STATUS[5] CLOCKENABLE bit (set to 1) for the software reset to complete.

23.2.4.4 HDQ1W Power Management

Table 23-94 describes power-management features available to the HDQ1W.

Table 23-94. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	HDQ_SYSCONFIG [0] AUTOIDLE bit	Auto-idle mode
Slave idle modes	N/A	N/A
Clock enable	HDQ_CTRL_STATUS[5] CLOCKENABLE bit	Power-down mode
Master standby modes	N/A	N/A
Global wake-up enable	N/A	N/A
Wake-up sources enable	N/A	N/A

23.2.4.4.1 Auto-Idle Mode

The HDQ1W provides an auto-idle function in its interconnect clock domain.

The interconnect clock auto-idle power-saving mode is enabled or disabled through the HDQ_SYSCONFIG[0] AUTOIDLE bit. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ1W_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

The auto-idle mode can be enabled in order to reduce power consumption.

23.2.4.4.2 Power-Down Mode

The HDQ1W also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (HDQ_CTRL_STATUS[5] CLOCKENABLE bit) to 0 shuts off the functional clock (HDQ1W_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

Before shutting off the functional clock, the software must wait for transaction-complete interrupt. In write operation the software must check whether the interrupt was generated after address/command byte was sent or after data byte was sent. The functional clock must not be shut off after address/command byte is sent; otherwise, the data is not written to the slave.

The register values are not affected by disabling the functional clock.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ1W clocks while the module is performing a transfer. This would result in loss of data being transferred.

23.2.4.5 HDQ Interrupt Requests

The HDQ1W can generate one interrupt:

- HDQ1W_IRQ: This is an interrupt to the MPU subsystem INTC. It is mapped on MPU_IRQ_58.

Table 23-95 lists the events that can generate this interrupt.

Table 23-95. Events

Event Flag	Event Mask	Sync	Sensitivity	Description
HDQ_INT_STATUS[2] TXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	A write operation of one byte was completed.
HDQ_INT_STATUS[1] RXCOMPLETE	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	A byte has been successfully read.
HDQ_INT_STATUS[0] TIMEOUT	HDQ_CTRL_STATUS[31] INTERRUPTMASK	Yes	Level	After a read command initiated by the host, the slave did not pull the line low within the specified time.

23.2.4.6 HDQ Mode (Default)

23.2.4.6.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmarq HDQ protocol
- Power-down mode

23.2.4.6.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the HDQ_CTRL_STATUS[2] INITIALIZATION bit and then setting the HDQ_CTRL_STATUS[4] GO bit creates this pulse by pulling the line down for a defined duration. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the HDQ_INT_STATUS[0] TIMEOUT bit is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

23.2.4.6.3 Single-Bit Mode

In HDQ mode, the single-bit mode (HDQ_CTRL_STATUS[7] ONE_WIRE_SINGLE_BIT bit set to 1) has no effect because the HDQ protocol supports only byte transfers.

23.2.4.6.4 Interrupt Conditions

The HDQ1W provides the following interrupt status:

- Transmission complete:

  A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Read complete:

  In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Presence detect/time-out:

  In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

  In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

23.2.4.7 1-Wire Mode

23.2.4.7.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

23.2.4.7.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent when the HDQ_CTRL_STATUS[2] INITIALIZATION bit is set and the HDQ_CTRL_STATUS[4] GO bit is set afterwards.

When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line for a defined duration. The module detects this low-level pulse and sets the HDQ_CTRL_STATUS[3] PRESENCEDETECT bit.

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the HDQ_INT_STATUS[0] TIMEOUT bit is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0, or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most-significant bit (MSB) in the receive data register (HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

23.2.4.7.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (ONE_WIRE_SINGLE_BIT bit HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). The ONE_WIRE_SINGLE_BIT bit is cleared by hardware after every single bit is received. Software must set this bit to re-enable reception in single-bit mode. Bit 0 of the RX register (HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ_TX_DATA) contains the bit to be sent.

23.2.4.7.4 Interrupt Conditions

The HDQ1W provides the following interrupt status:

- Transmission complete:

  A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Read complete:

  In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).
- Presence detect/time-out:

  In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ_INT_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

23.2.4.7.5 Status Flags

The presence-condition-detected status flag is contained in the HDQ_CTRL_STATUS[3] PRESENCEDETECT bit. This is valid only in 1-Wire mode. The flag is updated when the HDQ_INT_STATUS[0] TIMEOUT bit is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

23.2.4.8 BITFSM Delay

The return-to-one mechanism on the HDQ/1-Wire bus is a simple pull-up resistor. Consequently, an excessive wire load of the HDQ/1-Wire bus can cause a significant delay to the bus rise time. This can prevent the module state machine from working correctly by reading back an improper value caused by the line delay. To correct such condition by software, it is possible to configure the HDQ_CTRL_STATUS[10:8] BITFSM register bitfield with the expected line delay. This way the module state machine waits the proper time interval, before reading back the line value. The delay can be adjusted in 1.33 µs steps. The default value of BITFSM = 0x0 corresponds to 1.33 µs delay.

Bus delay can be calculated as follows: $T_{delay} \sim= 2.2 \times R_{pullup} \times C_{line}$

See more information in the *Device Data Manual*.

23.2.5 HDQ1W Low-Level Programming Model

This section describes the low-level hardware programming sequences for configuration and usage of the module. The basic protocol functions, such as slave initialization (reset), read-byte, and write-byte operations, are described. For a description of the high-level functions, see the HDQ/1-Wire protocol documentation and the slave device datasheet.

23.2.5.1 Global Initialization

23.2.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HDQ1W module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the HDQ1W. Refer to the HDQ1W Module Integration and Environment Sections for further information.

Table 23-96. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. The interface clock must not be slower than the functional clock (HDQ1W_ICLK ≥ HDQ1W_FCLK). For more information about the module configuration, see Section 3.1.1, *Power, Reset, and Clock Management*.
Control Module	Module specific pad muxing and pullup must be set in the control module. For more information about the module configuration, see Figure 18-1, *Control Module*.
MPU INTC	MPU INTC configuration must be done to enable the interrupts from HDQ1W module. See Section 17.4.1, *INTC_MPU Functional Description,* in Section 17.1, *Interrupt Controllers*.

23.2.6.1 HDQ1W Instance Summary

Table 23-106. HDQ1W Instance Summary

Module Name	Base Address	Size
HDQ1W	0x480B 2000	4 KiB

23.2.6.2 HDQ1W Registers

CAUTION

The following rules must be observed when accessing the module registers:

- A read from the HDQ_INT_STATUS register or the HDQ_RX_DATA register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the HDQ_CTRL_STATUS register, no access to the HDQ_TX_DATA or HDQ_CTRL_STATUS register is allowed until the processor has been interrupted by the module.
- Polling of the HDQ_INT_STATUS register by software to determine whether an interrupt was generated is not allowed.

CAUTION

The HDQ1W registers are limited to 32-bit data accesses; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.

23.3 UART/IrDA/CIR

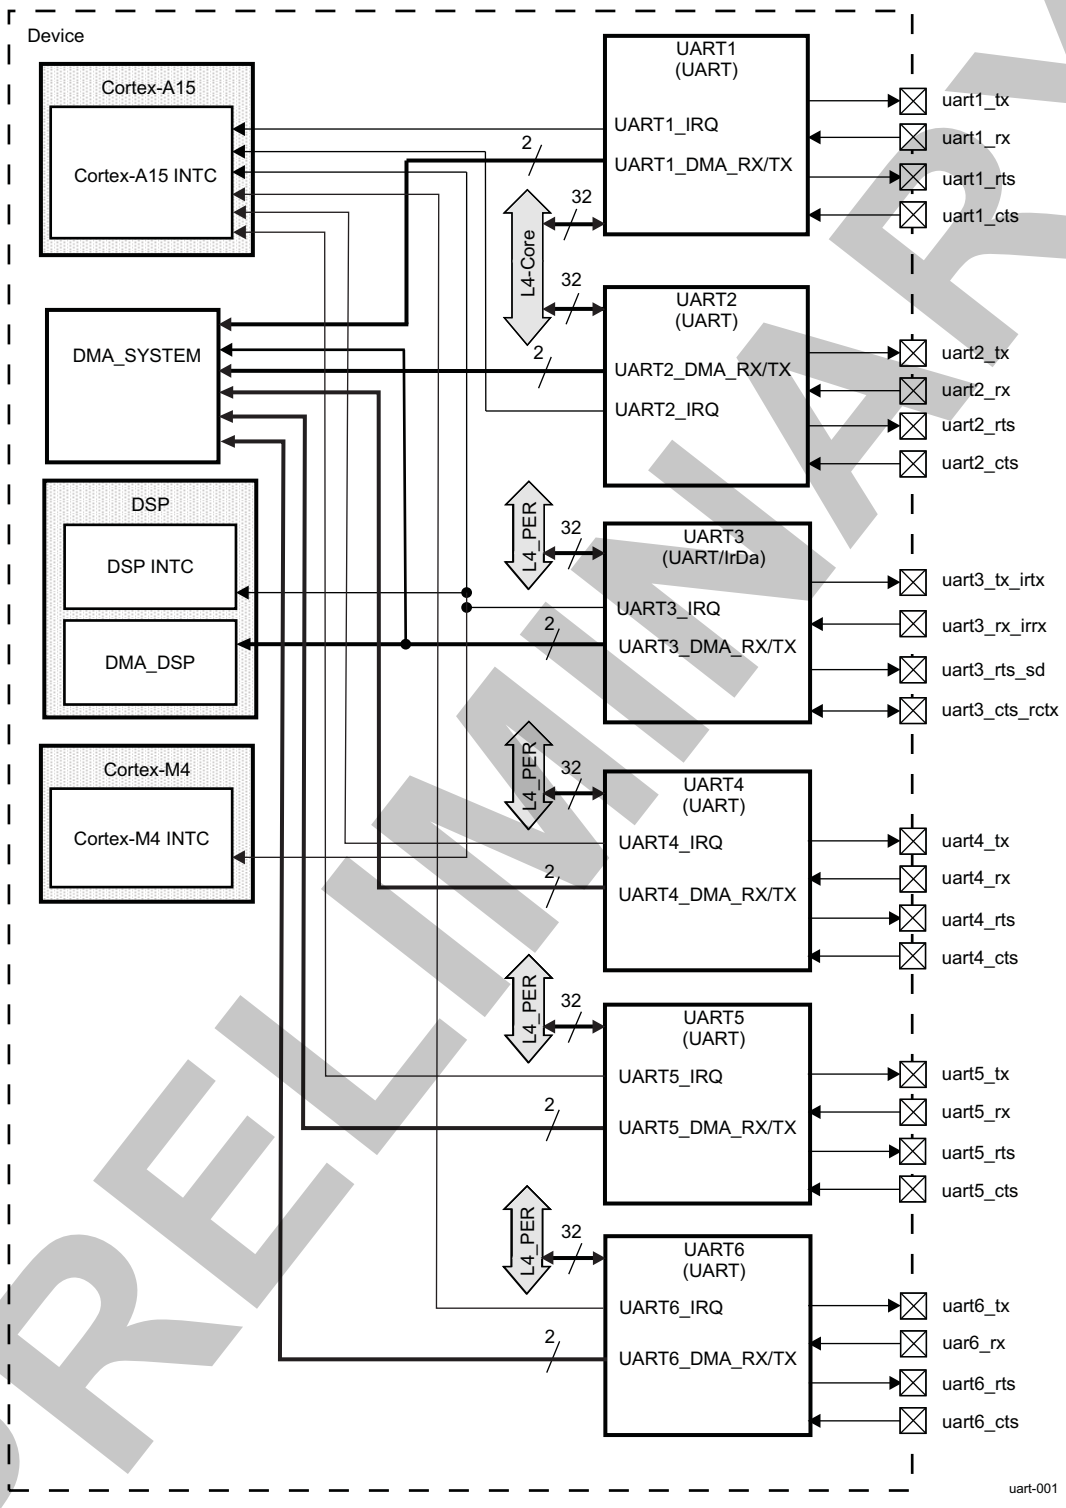
This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module in the device.

23.3.1 UART/IrDA/CIR Overview

The device contains four UART devices controlled by the microprocessor unit (MPU) (see Figure 23-39):

- Five UART-only modules (UART1, UART2, UART4, UART5, and UART6) are pinned out for use as UART devices only.
- UART3, which adds infrared communication support, is pinned out for use as a UART, IrDA, or CIR device, and can be programmed to any available operating mode.

Figure 23-39. UART Module



23.3.1.1 UART Features

The UARTs (UART1, UART2, UART3 when in UART mode, UART4, UART5, and UART6) include the following features:

- 16C750 compatibility

- 64-byte FIFO buffer for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (where N = 1…16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is one of two options:

- Baud rate = (functional clock / 16) / N
- Baud rate = (functional clock / 13) / N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format:
  - Data bit: 5, 6, 7, or 8 bits
  - Parity bit: Even, odd, none
  - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6864 Mbps. Table 23-122 lists the supported baud rates, requested divisor, and corresponding error versus the standard baud rate.

Table 23-122. UART Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	Oversampling	Divisor	Error (%)
300	16	10,000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	312	0.16
14,400	16	208	0.16
19,200	16	156	0.16
28,800	16	704	0.16
38,400	16	78	0.16
57,600	16	52	0.16
115,200	16	26	0.16
230,400	16	13	0.16
460,800	13	8	0.16
921,600	13	4	0.16
1,843,200	13	2	0.16
3,000,000	16	1	0
3,686,400	13	1	0.16

23.3.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications:
  - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
  - Uplink/downlink cyclic redundancy check (CRC) generation/detection
  - Asynchronous transparency (automatic insertion of break character)

- Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
- Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

Table 23-123 lists the supported baud rates, requested divisor, and corresponding error versus the standard baud rate.

Table 23-123. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

Baud Rate	IR Mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19,200	SIR	3/16	156	0.16
38,400	SIR	3/16	78	0.16
57,600	SIR	3/16	52	0.16
115,200	SIR	3/16	26	0.16
576,000	MIR	1/4	2	0
1,152,000	MIR	1/4	1	0
4,000,000	FIR	4 PPM(1)	1	0

(1) PPM = Pulse-position modulation

23.3.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following features to provide CIR support for remote-control applications:

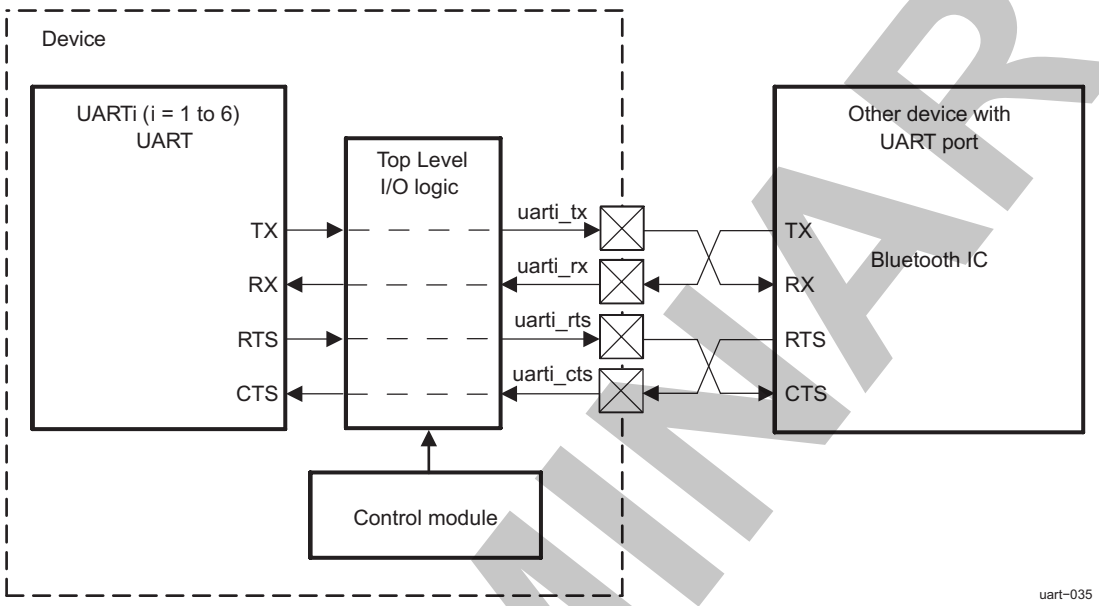
- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

23.3.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

Figure 23-40 *UART Controller I/O signals*, illustrates module pin signals mapping to signals visible at device pad level.

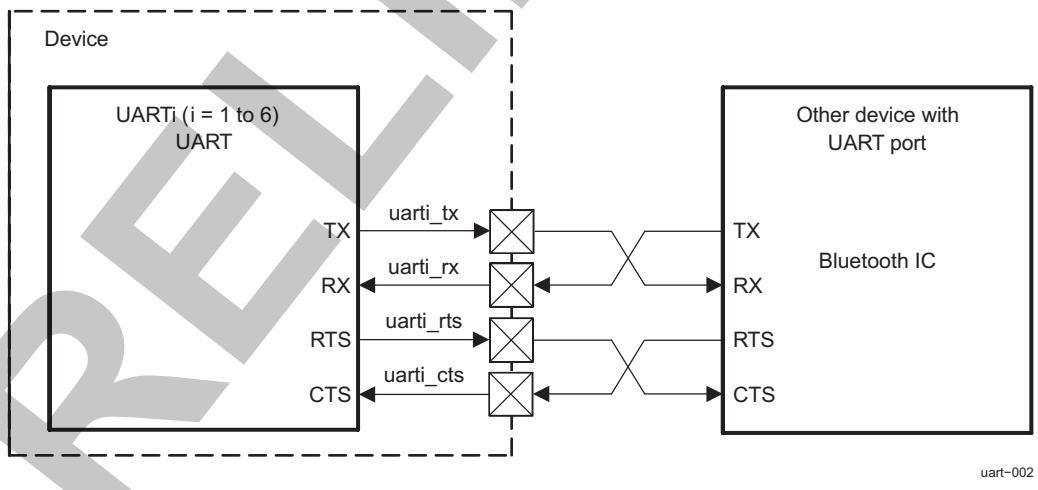
Figure 23-40. UART Controller I/O signals



23.3.2.1 System Using UART Communication With Hardware Handshake

Each UART instance can be easily connected to the UART port of an external IC (see Figure 23-41).

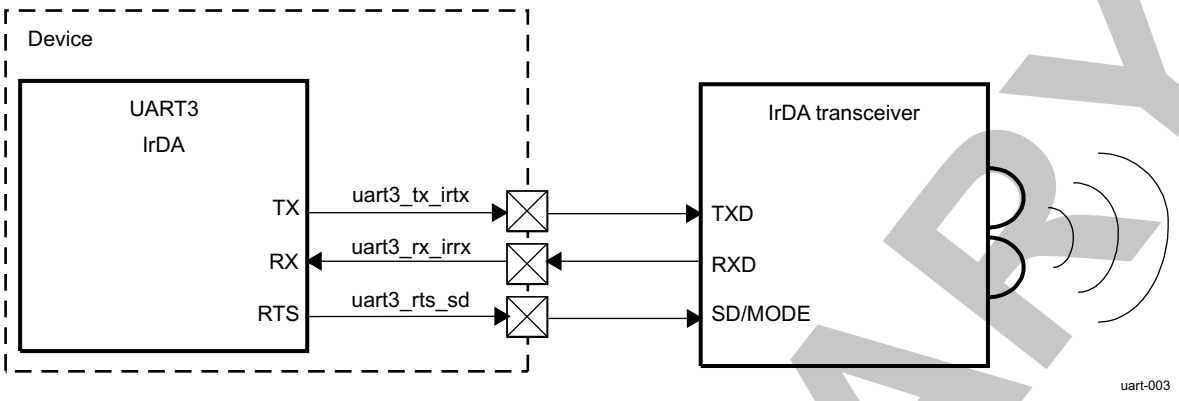
Figure 23-41. UART Mode Bus System Overview



23.3.2.2 System Using IrDA Communication Protocol

As Figure 23-42 shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

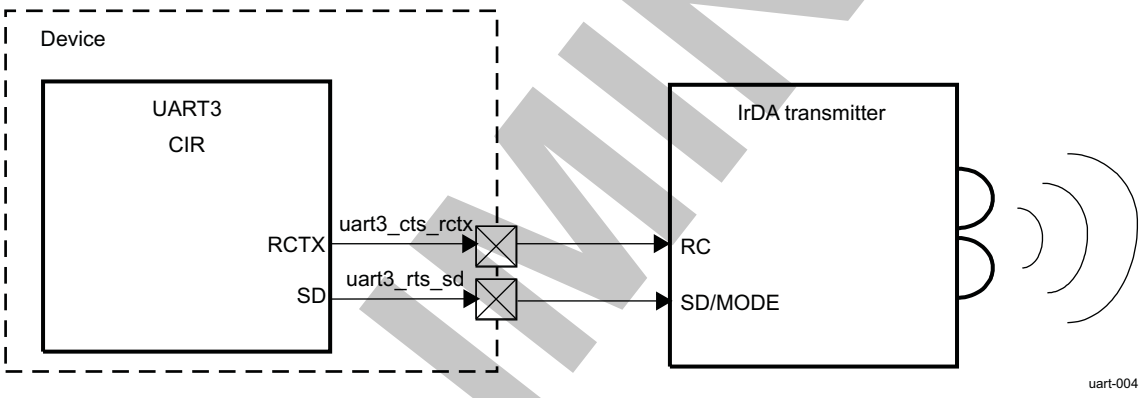
Figure 23-42. IrDA System Overview



23.3.2.3 System Using CIR Communication Protocol With Remote Control

UART3 can be connected to an external infrared transceiver in CIR mode (see Figure 23-43).

Figure 23-43. CIR System Overview



23.3.2.4 UART Interface

23.3.2.4.1 Description

Table 23-124 lists the UART interface input/output (I/O) signals.

Table 23-124. UART I/O Pins

Signal	I/O[1]	Description	Reset
UART Modem Signals			
uarti_rx	I	Serial data input	Unknown
uarti_tx	O	Serial data output Because this pin is active high in IrDA mode and the output is muxed, this pin is set to low on reset (when the UARTi.UART_MDR1[2:0] bit field is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how the UARTi.UART_MDR1 register is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).	1
uarti_cts	I	Clear to send	Unknown

(1) I = Input; O = Output; I/O = Bidirectional

Table 23-124. UART I/O Pins (continued)

Signal	I/O[1]	Description	Reset
		Active-low modem status signal. Reading the UARTi.UART_MSR[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.UART_MSR[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.	
uarti_rts	O	Request to send When active (low), the module is ready to receive data. Setting the UARTi.UART_MCR[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.UART_MCR[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.	1

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

23.3.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x (<= 230.4 kbps)
- UART 16x with autobauding (>= 1200 bps and >= 115.2 kbps)
- UART 13x (>= 460.8 kbps)

CAUTION

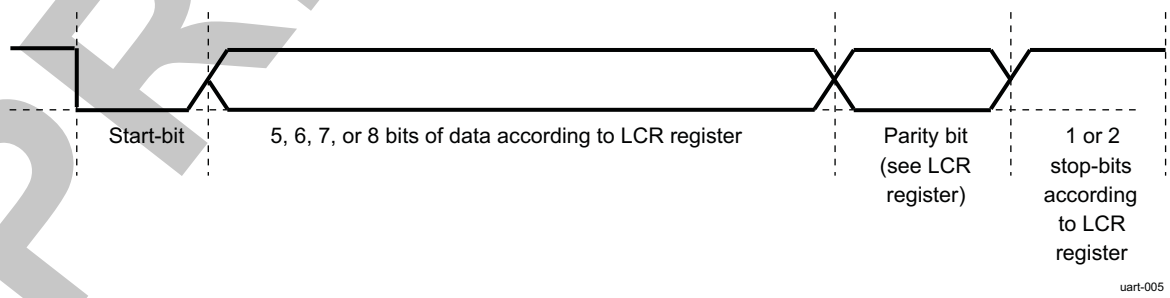
To be used as a UART, the operating mode must be programmed appropriately in the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to select UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 23-44 shows the UART frame data format.

Figure 23-44. UART Frame Data Format



23.3.2.5 IrDA Functional Interfaces

23.3.2.5.1 UART3 Interface Description

Table 23-125 lists the UART3 interface I/O signals.

Table 23-125. UART3 I/O Signals

Signal	I/O[1]	Description	Reset
IrDA Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_tx_irtx	O	Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

23.3.2.5.2 IrDA Protocol and Data Format

23.3.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start-bit, 8 data bits, and 1 stop-bit, and is unaffected by the use and settings of the UART3.UART_LCR register.

The UART3.UART_BLR[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine sends an escape character (0x7D), inverts the fifth bit of the real data to be sent, and then sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, or a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to find possible errors of the received frame.

NOTE: The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the description of the UART3.UART_ACREG[5] DIS_IR_RX bit. This applies to all three modes: SIR, MIR, and FIR.

Infrared output in SIR mode can be 1.6-µs or 3/16 encoding, selected by the UART3.UART_ACREG[7] PULSE_TYPE bit. In 1.6-µs encoding, the infrared pulse width is 1.6 µs; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/baud rate).

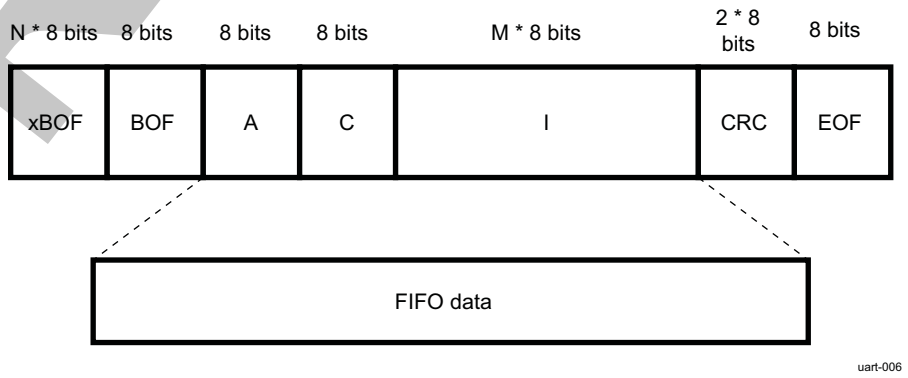
For back-to-back frames, the transmitting device must send at least two start flags at the start of each frame.

NOTE: Reception supports variable-length stop-bits.

23.3.2.5.2.1.1 Frame Format

Figure 23-45 shows the IrDA SIR frame format.

Figure 23-45. IrDA SIR Frame Format



The CRC is applied on the address (A), control (C), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

23.3.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
  - Inserts a control escape (CE) byte preceding the byte
  - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

  The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).
- In reception:

  For the A, C, I, and CRC fields:
  - Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO.
  - If the byte is equal to the CE byte, discards the CE byte
  - Complements bit 5 of the byte following the CE
  - Sends the complemented byte to the CRC detector and stores it in the RX FIFO

23.3.2.5.2.1.3 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

When a 0x7D character that is followed immediately by a 0xC1 character is received without transparency, the receiver treats the frame as an aborted frame.

23.3.2.5.2.1.4 Pulse Shaping

The SIR mode supports the 3/16 and the 1.6-µs pulse duration methods. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse-width method in transmit mode.

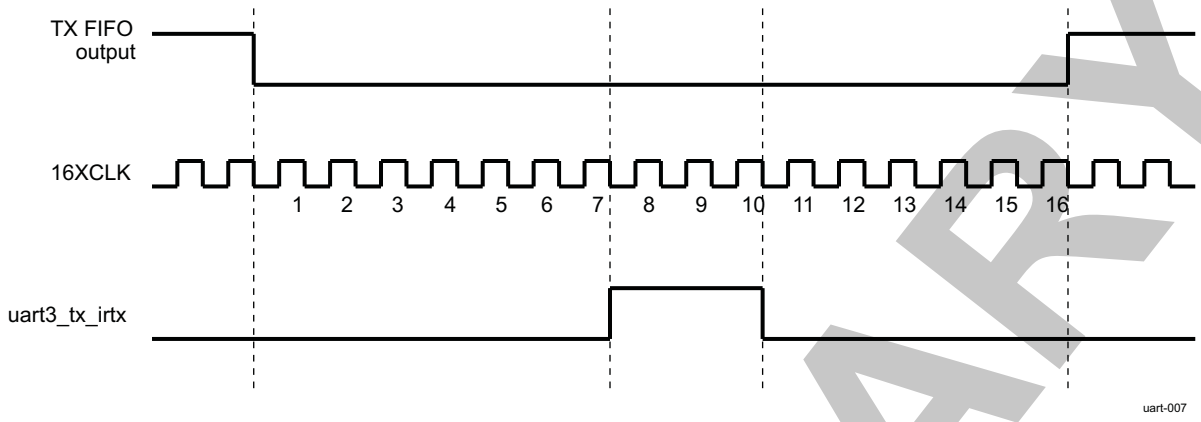
23.3.2.5.2.1.5 Encoder

Serial data from the transmit state-machine are encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the uart3_tx_irtx line is always low, and the counter used to form a pulse on uart3_tx_irtx is cleared continuously.

After the TX FIFO output resets to 0, uart3_tx_irtx rises on the falling edge of the seventh 16XCLK. On the falling edge of the tenth 16XCLK pulse, uart3_tx_irtx falls, creating a 3-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the seventh clock to the tenth clock of each 16-clock bit cycle.

Figure 23-46 shows the IrDA SIR encoding mechanism.

Figure 23-46. IrDA SIR Encoding Mechanism

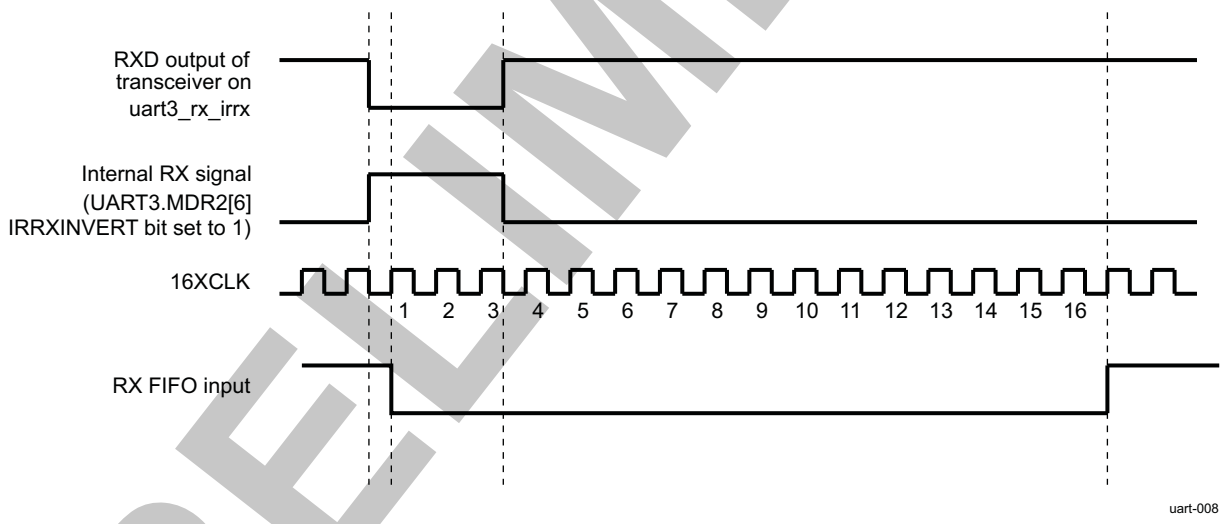


23.3.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 23-47 shows the IrDA SIR decoding mechanism.

Figure 23-47. IrDA SIR Decoding Mechanism



The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the uart3_rx_irrx input can be disabled using the UART3.UART_ACREG[5] DIS_IR_RX bit. The UART3.UART_MDR2[6] IRRXINVERT bit can invert the signal from the transceiver (RXD) pin to the IR RX logic in the UART. This inversion is performed by default.

23.3.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting the UART_EFR[1:0] bit field (see Table 23-126), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the UART3.UART_XON1_ADDR1[7:0] and UART3.UART_XON2_ADDR2[7:0] bit fields.

Table 23-126. UART_EFR[1:0] IR Address Checking Options

UART_EFR[1]	UART_EFR[0]	IR Address Checking
0	0	All address-checking operations disabled
0	1	Only address 1 checking enabled
1	0	Only address 2 checking enabled
1	1	All address-checking operations enabled

23.3.2.5.2.2 SIR Free-Format Mode

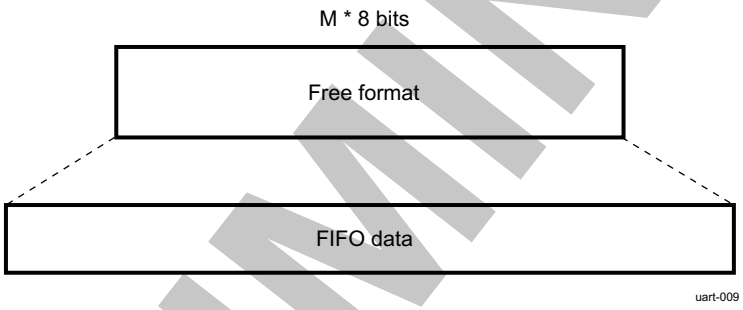
To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free-format (FF) mode is a subfunction of the existing SIR mode. In FF mode, all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

The FF mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

Figure 23-48 shows SIR FF mode.

Figure 23-48. SIR FF Mode

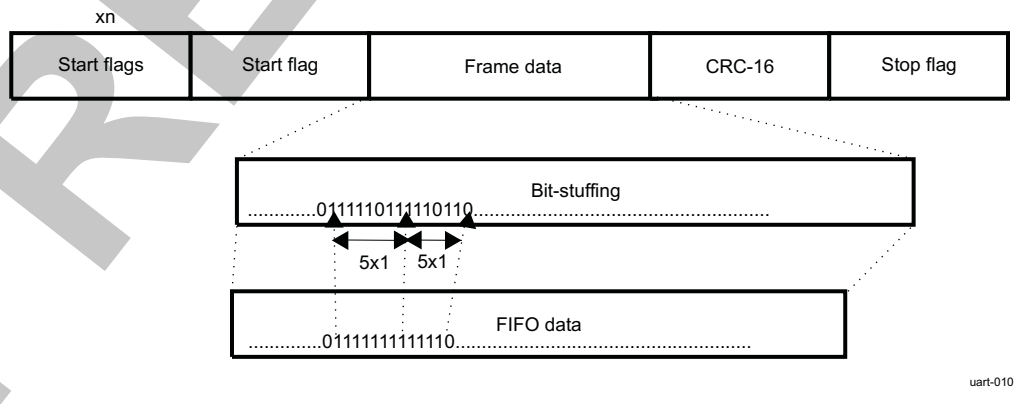


In SIR FF mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

23.3.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152 Mbps. A MIR transmit frame starts with at least two start flags, followed by a frame data and a CRC-16, and ends with a stop flag (see Figure 23-49).

Figure 23-49. MIR Transmit Frame Format



On transmit, the MIR state-machine attaches start flags, a CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

In MIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for start and stop flags (unambiguously, not data, because of bit-stuffing).
- An abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit-stuffing).
- Back-to-back frames are allowed with three or more stop flags between them. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

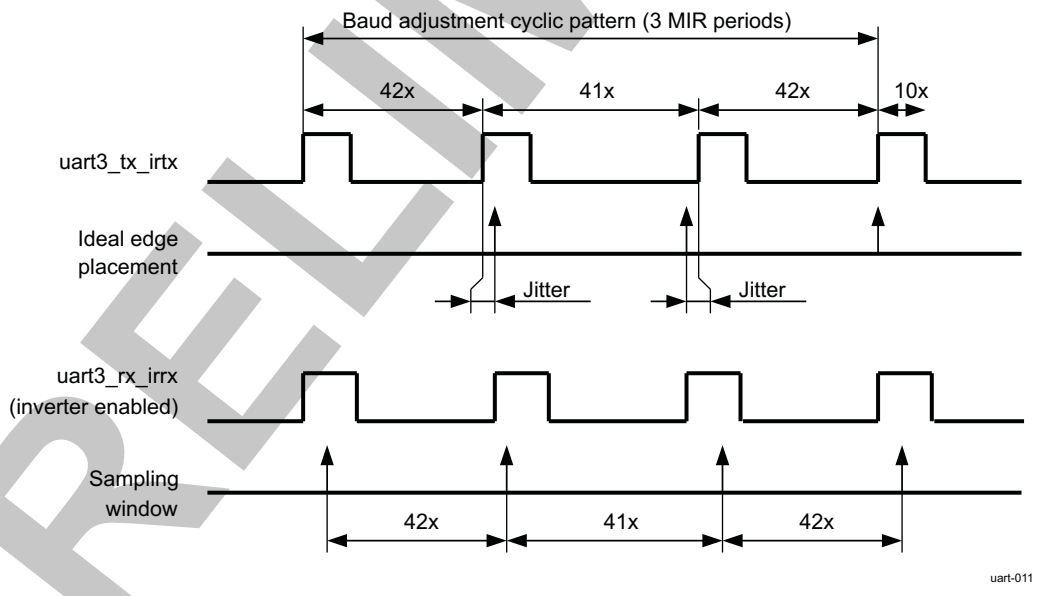
23.3.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by IrDA specifications.

Figure 23-50 shows the MIR baud rate adjustment mechanism.

Figure 23-50. MIR Baud Rate Adjustment Mechanism

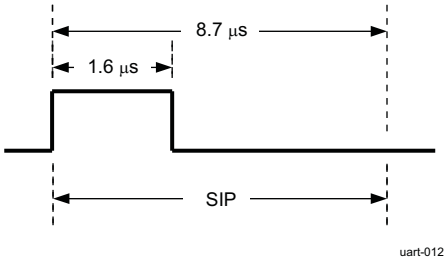


23.3.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is occupied.

Figure 23-51 shows the SIP.

Figure 23-51. SIP



23.3.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4 Mbps. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 23-52 shows the FIR transmit frame format.

Figure 23-52. FIR Transmit Frame Format

Preamble (16x)	Start flag	Frame data	CRC-32	Stop flag

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see Table 23-127) and generates the SIP (see Section 23.3.2.5.2.3.2, *SIP Generation*).

Table 23-127. 4-PPM Format

Data Bit Pair (Bin)	4-PPM Data Symbol (Bin)
00	1000
01	0100
10	0010
11	0001

The four symbols described in Table 23-127 are the legal, encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see Table 23-128).

Table 23-128. FIR Preamble, Start Flag, and Stop Flag

Frame Part	Transmitted Frame (Bin)
Preamble	1000 0000 1010 1000 (16 repeated transmissions)
Start flag	0000 1100 0000 1100 0110 0000 0110 0000
Stop flag	0000 1100 0000 1100 0000 0110 0000 0110

All fields are transmitted LSBs of each byte first (see Table 23-129).

Table 23-129. FIR Data Byte Transmission Order Example

Data Byte (Hex)	Data Byte Pair (Bin)	4-PPM Data Symbol (Bin)	Transmission Order
0x0B	00	1000	4
	00	1000	3
	10	0010	2
	11	0001	1

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors of the received frame.

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

23.3.2.6 CIR Functional Interfaces

23.3.2.6.1 CIR Interface Description

Table 23-130 lists the CIR interface I/O signals.

Table 23-130. CIR I/O Signals

Signal	I/O[1]	Description	Reset
CIR Signals			
uart3_rx_irrx	I	Serial data input	Unknown
uart3_cts_rctx	O	Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state).	0
uart3_rts_sd	O	SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.UART_ACREG[6] SD_MOD bit.	1

(1) I = Input; O = Output

23.3.2.6.2 CIR Protocol and Data Format

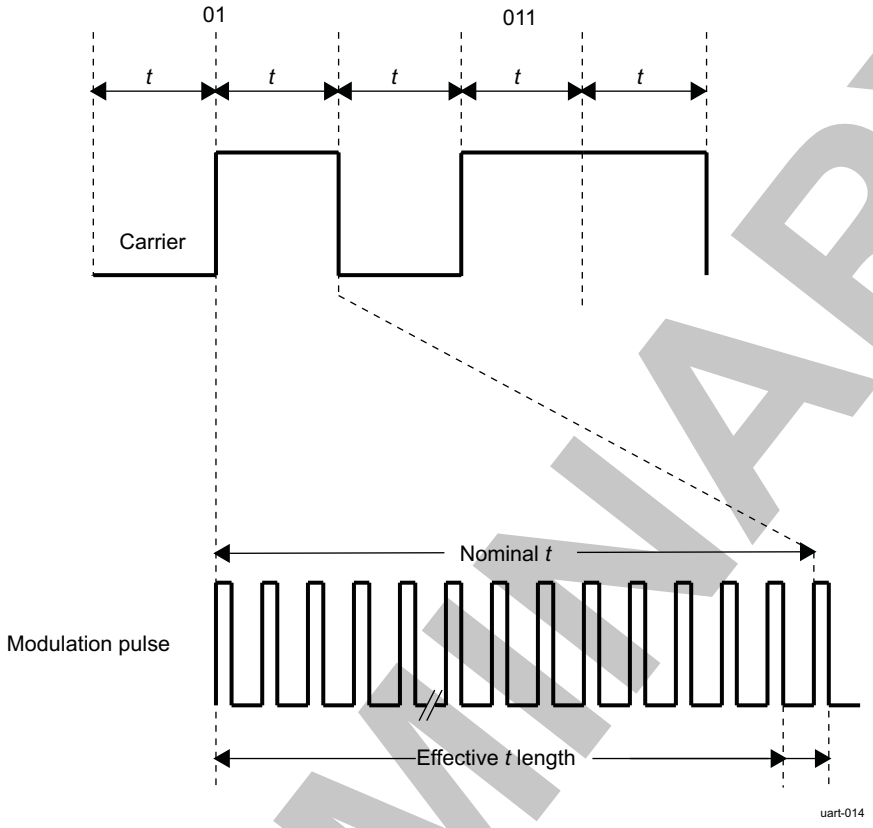
In CIR mode, the infrared operation functions as a programmable (universal) remote control.

CIR mode uses a variable PWM technique (based on multiples of a programmable *t* period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on user-defined frame structure and packet content.

23.3.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 23-53).

Figure 23-53. CIR Pulse Modulation

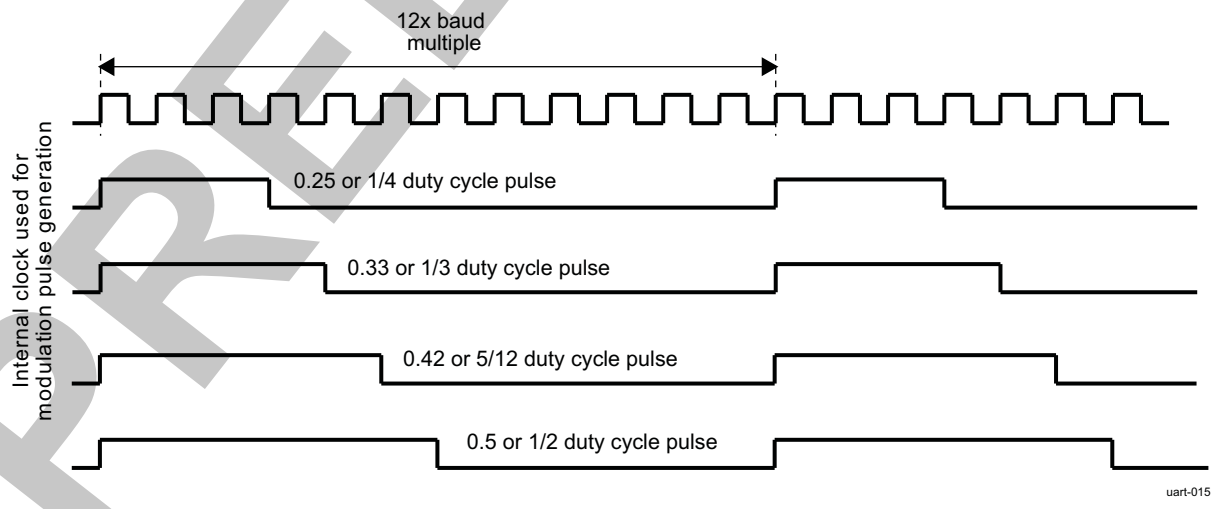


23.3.2.6.2.2 Pulse Duty Cycle

The programmer can choose one of four duty cycles for modulation pulses by setting the appropriate value in the UART3.UART_MDR2[5:4] CIR_PULSE_MODE bit field (1/4, 1/3, 5/12, or 1/2).

Figure 23-54 shows the CIR modulation duty cycles.

Figure 23-54. CIR Modulation Duty Cycle



The transmission logic ensures that all pulses are transmitted completely (no cutoff during transmission). While transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end requires it.

23.3.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote-control applications:

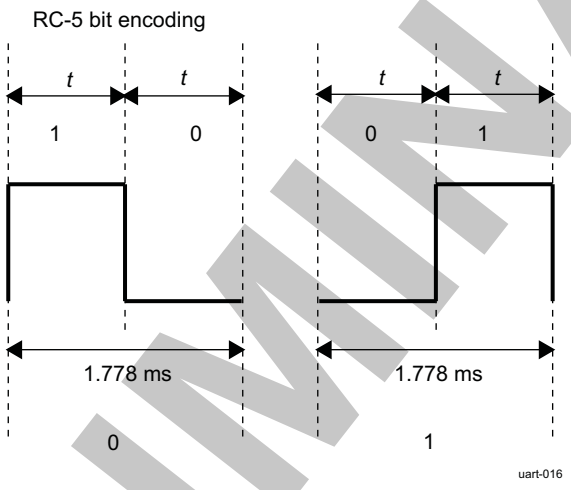
- Pulse duration encoding (time-extended bit forms): A variable pulse distance, or duration, in which the difference between logic 1 and logic 0 is the length of the pulse width
- Biphase encoding: The encoding of logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively.

Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

CIR mode uses a completely flexible free-format encoding in which 1 is transmitted from the TX FIFO as a modulated pulse with duration *t*.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 23-55).

Figure 23-55. RC-5 Bit Encoding

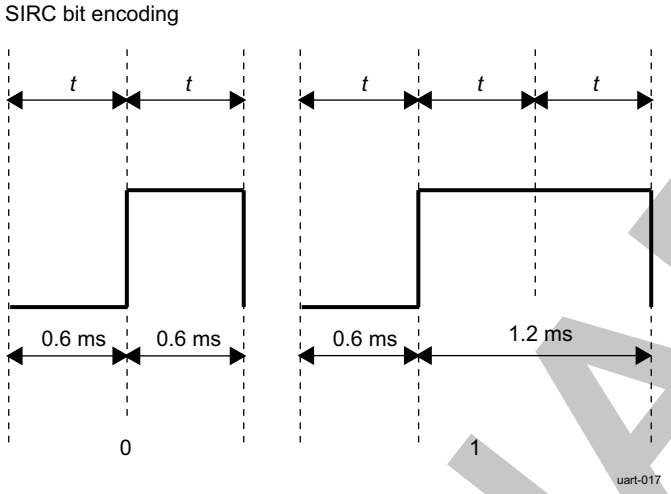


Because CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (multiples of *t*) is used to distinguish between 1 and 0. The subsequent SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 23-56 shows SIRC bit encoding.

Figure 23-56. SIRC Bit Encoding



To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 23-57 shows a standard RC-5 frame as detected by UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two *t* pulses (digital bits) from the TX FIFO.

Figure 23-57. RC-5 Standard Packet Format

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0

uart-018

Where:

S1, S2:	Start-bits (always 1)
T:	Toggle bit
A4..A0:	Address (or system) bits
C5..C0:	Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that lets the command range increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits in the standard frame length varies.

Figure 23-58 shows the packet format and bit encoding. As Figure 23-59 shows, 1 start-bit of 2.4 ms and control codes are followed by data that constitute the entire frame.

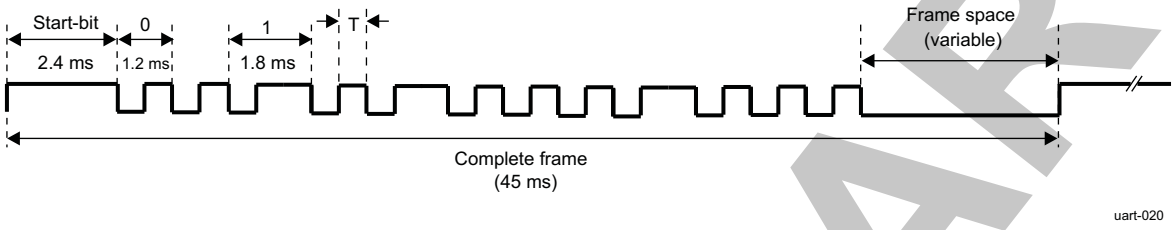
Figure 23-58. SIRC Packet Format

S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4

uart-019

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for sending and receiving data packets must exercise a scheme of interpacket delay, where successive packets can be sent only after a real-time delay expires.

Figure 23-59. SIRC Bit Transmission Example



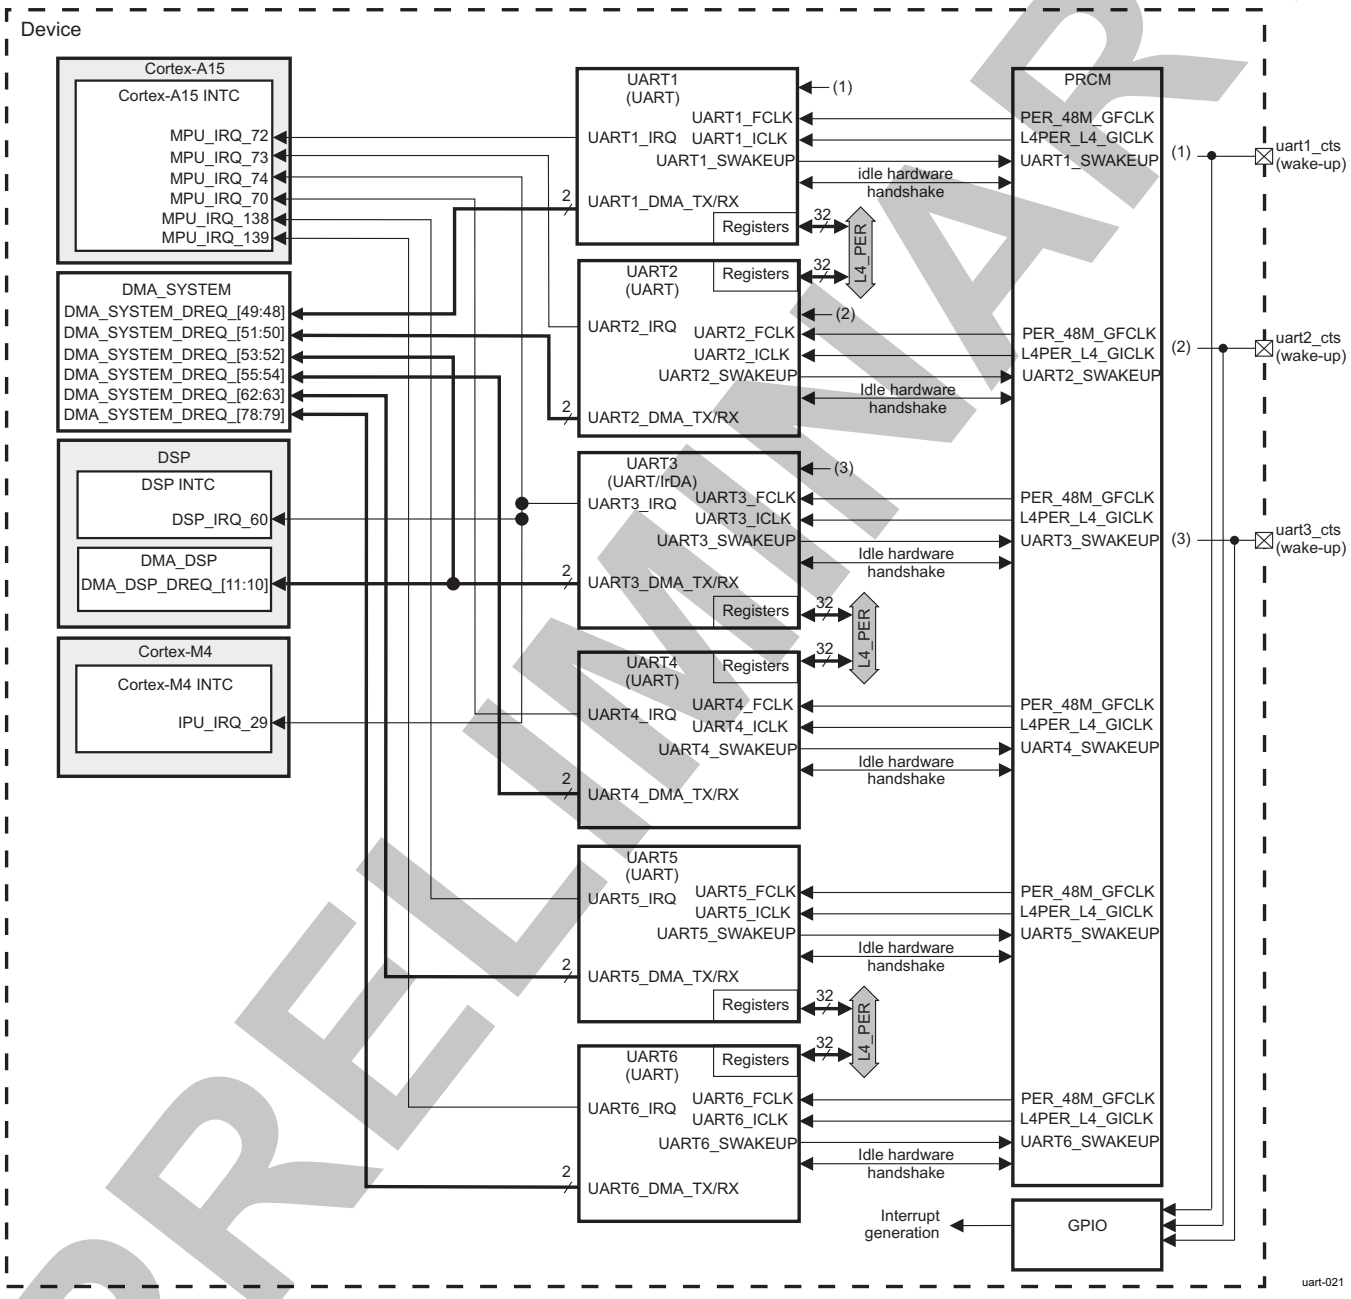
This document does not describe all encoding methods and techniques; the previous information discusses the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol use.

23.3.3 UART/IrDA/CIR Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-60 shows the device internal connections with related modules for UART functions.

Figure 23-60. UART/IrDA/CIR Integration



NOTE: For more information about the idle and standby hardware handshakes and the wake-up request, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*

Table 23-131 through Table 23-133 summarize the integration of the module in the device.

Table 23-131. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
UART1	PD_CORE	Yes	L4_PER
UART2	PD_CORE	Yes	L4_PER
UART3	PD_CORE	Yes	L4_PER
UART4	PD_CORE	Yes	L4_PER
UART5	PD_CORE	Yes	L4_PER
UART6	PD_CORE	Yes	L4_PER

Table 23-132. Clocks and Resets

Clocks				
Module Instance	**Destination Signal**	**Source Signal**	**Source**	**Description**
UART1	UART1_ICLK	L4PER_L4_GICLK	PRCM	UART1 interface clock

	UART6_DMA_RX	DMA_SYSTEM_DREQ_79	DMA_SYSTEM	UART module 6 – receive request

23.3.4 UART/IrDA/CIR Functional Description

23.3.4.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 23.3.4.7, *Mode Selection*.

Protocol formatting has three subcategories:

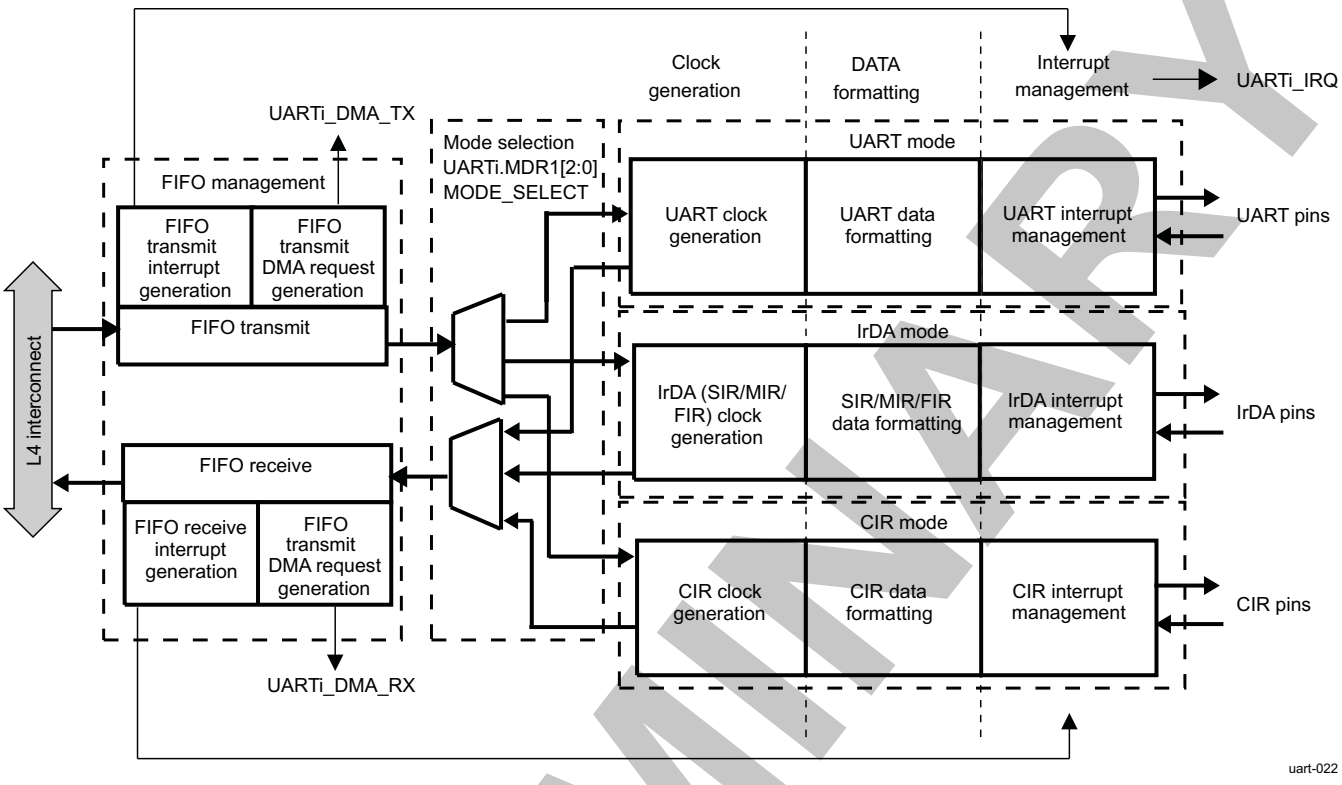
- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

  In each mode, when an interrupt is generated, the UART_IIR register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 23-61 is the UART/IrDA/CIR block diagram.

Figure 23-61. UART/IrDA/CIR Functional Specification Block Diagram



23.3.4.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see Section 3.1.1.1.4, *Clock Domain Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

23.3.4.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

23.3.4.4 Power Management

23.3.4.4.1 UART Mode Power Management

23.3.4.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.

- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 23.3.4.5.1.2, *Wake-Up Interrupt*.

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL or UARTi.UART_DLH register.

23.3.4.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

23.3.4.4.2 IrDA Mode Power Management (UART3 Only)

23.3.4.4.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the UART3.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all of the following conditions exist:

- The serial data input line, uart3.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uart3_rx_irrx line or when data is written to the TX FIFO.

23.3.4.4.2.2 System Power Saving

System power saving for the IrDA mode has the same function as for the UART mode (see Section 23.3.4.4.1.2, *System Power Saving*).

23.3.4.4.3 CIR Mode Power Management (UART3 Only)

23.3.4.4.3.1 Module Power Saving

Module power saving for the CIR mode has the same function as for the IrDA mode (see Section 23.3.4.4.2.1, *Module Power Saving*).

23.3.4.4.3.2 System Power Saving

System power saving for the CIR mode has the same function as for the UART mode (see Section 23.3.4.4.1.2, *System Power Saving*).

23.3.4.4.4 Local Power Management

Table 23-134 describes power-management features available for the UART.

NOTE: For information about source clock gating and the sleep/wake-up transitions description, see Section 3.1.1.1.2, *Module Level Clock Management*, Chapter 3, *Power, Reset, and Clock Management*.

Table 23-134. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

23.3.4.5 Interrupt Requests

23.3.4.5.1 UART Mode Interrupt Management

23.3.4.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 23-135 summarizes the interrupt control functions.

Table 23-135. UART Mode Interrupts

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable)	Read the UART_RHR register until the interrupt condition disappears.
			RX FIFO above trigger level (FIFO enable)	
000010	3	THR interrupt	TFE (UART_THR empty) (FIFO disable)	Write to the UART_THR until the interrupt condition disappears.
			TX FIFO below trigger level (FIFO enable)	

Table 23-135. UART Mode Interrupts (continued)

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000000	4	Modem status	See the UART_MSR register.	Read the UART_MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS	RTS pin or CTS pin change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

23.3.4.5.1.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RX_CTS_WU_EN bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UART3.UART_SSR[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit. This bit must be reenabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

23.3.4.5.2 IrDA Mode Interrupt Management

23.3.4.5.2.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER and UART3.UART_IIR mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 23-136). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 23-136. IrDA Mode Interrupts

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.

Table 23-136. IrDA Mode Interrupts (continued)

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read the UART_RESUME register. OR 2. Read the UART_IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR register.

23.3.4.5.2.2 Wake-Up Interrupts

The wake-up interrupt for IrDA mode has the same function as that for UART mode (see Section 23.3.4.5.1.2, *Wake-Up Interrupt*).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

23.3.4.5.3 CIR Mode Interrupt Management

23.3.4.5.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UART3.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UART3.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.UART_IER and UART3.UART_IIR mappings, depending on the selected mode.

Table 23-137 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.UART_IIR[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 23-137. CIR Mode Interrupts

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR register until the interrupt condition disappears.
2	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
3	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

Table 23-137. CIR Mode Interrupts (continued)

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
5	TX status	Transmission of the last bit of the frame is complete successfully.	Read the UART_IIR register.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

23.3.4.5.3.2 Wake-Up Interrupts

The wake-up interrupt for CIR mode has the same function as that for UART mode (see Section 23.3.4.5.1.2, *Wake-Up Interrupt*).

23.3.4.6 FIFO Management

The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

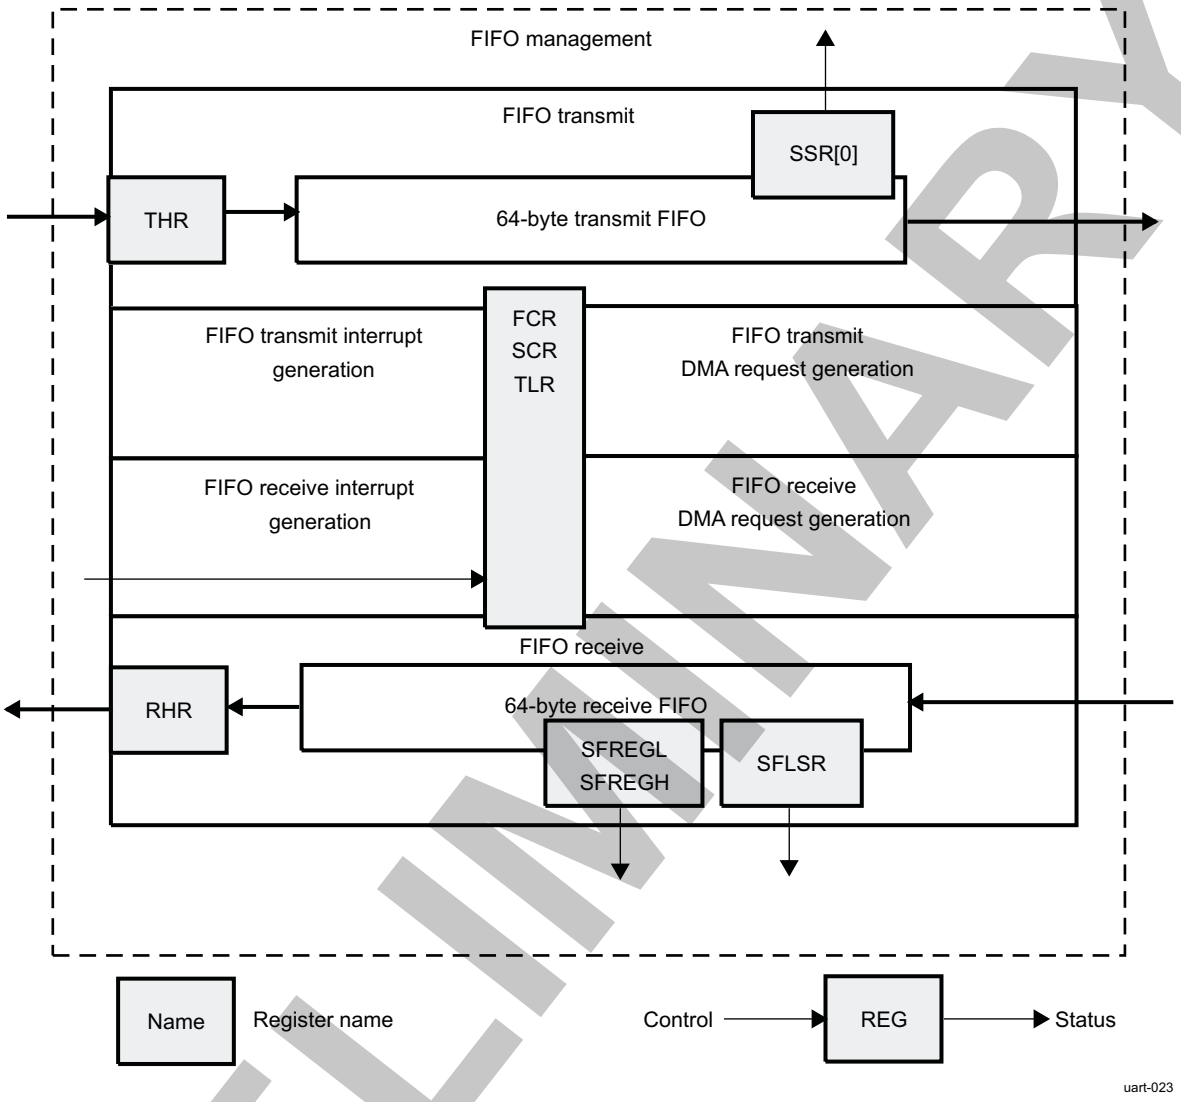
The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 23-62 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: The UARTi.UART_SFLSR, UARTi.UART_SFREGL, and UARTi.UART_SFREGH status registers are used in IrDA mode only. For information about their use, see Section 23.3.4.8.2.3, *IrDA Data Formatting*.

NOTE: Bits UART_FCR[2] TX_FIFO_CLEAR and UART_FCR[1] RX_FIFO_CLEAR are automatically cleared by hardware after 4* L4PER_L4_GICLK + 5* PER_48M_GFCLK clock cycles. This delay is needed to finish the resetting of the corresponding FIFO and DMA control registers.

Figure 23-62. FIFO Management Registers



23.3.4.6.1 FIFO Trigger

23.3.4.6.1.1 Transmit FIFO Trigger

Table 23-138 lists the TX FIFO trigger level settings.

Table 23-138. TX FIFO Trigger Level Setting Summary

UART_SCR[6]	UART_TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 space required). All zeros result in unpredictable behavior.

23.3.4.6.1.2 Receive FIFO Trigger

Table 23-139 lists the RX FIFO trigger-level settings.

Table 23-139. RX FIFO Trigger-Level Setting Summary

UART_SCR[7]	UART_TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of 1 character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 × [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 × (1 + CHAR_LENGTH + Parity + Stop – 0.5)] × Baud_rate + 4 × FCLK

  NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

23.3.4.6.2 FIFO Interrupt Mode

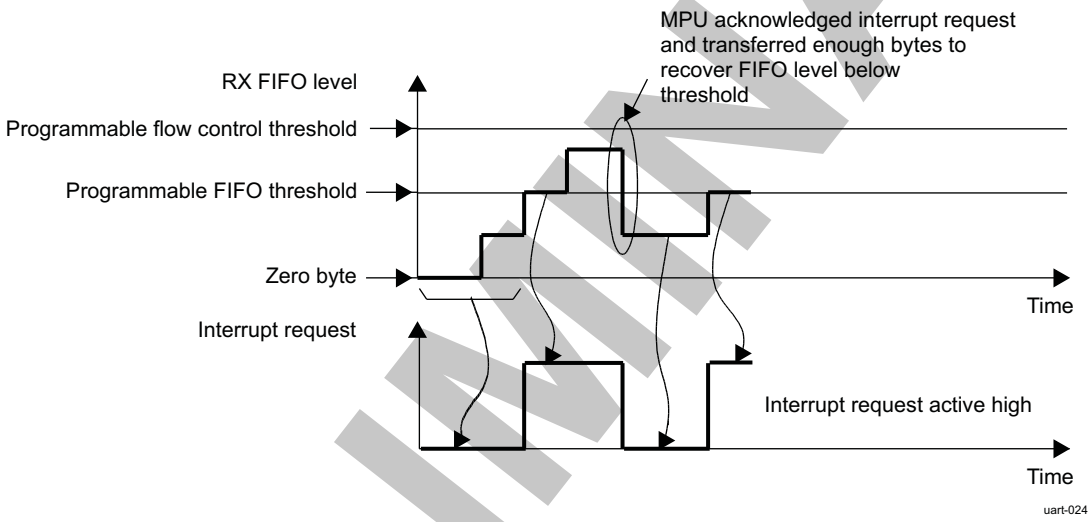
In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 23-63 shows the generation of the RX FIFO interrupt request.

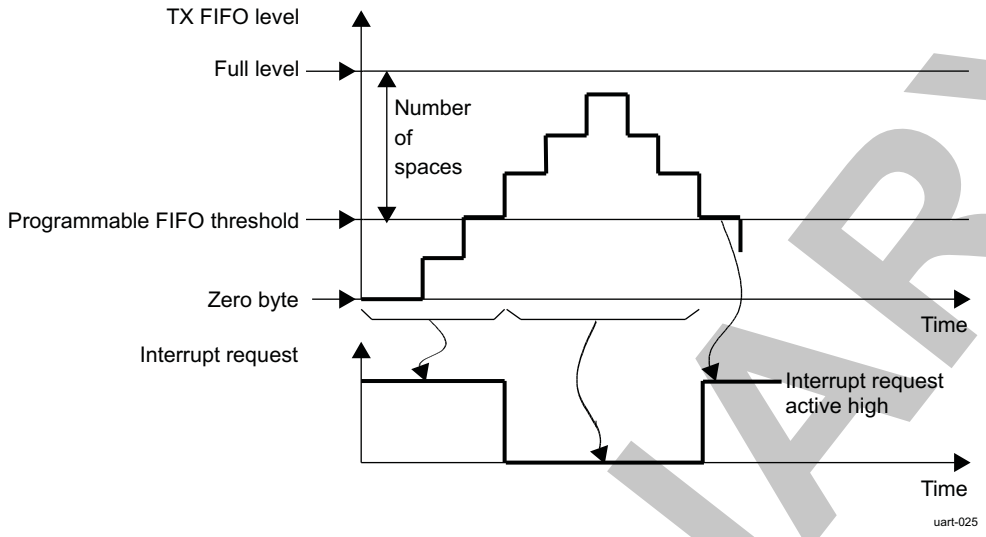
Figure 23-63. RX FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 23-64 shows the generation of the TX FIFO interrupt request.

Figure 23-64. TX FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

23.3.4.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

23.3.4.6.4 FIFO DMA Mode Operation

Although the DMA operation includes four modes (DMA modes 0 through 3), the information in Table 23-133 assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S_DMA_48
- S_DMA_50
- S_DMA_52/D_DMA_10
- S_DMA_54

The following signals are not used by the module in mode 2 and mode 3:

- S_DMA_49
- S_DMA_51
- S_DMA_53/D_DMA_11
- S_DMA_55

These signals can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3] DMA_MODE_CTL bit to 0 enables DMA mode 0. Setting the DMA_MODE_CTL bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.UART_FCR[2:1] DMA_MODE_2 bit field

determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

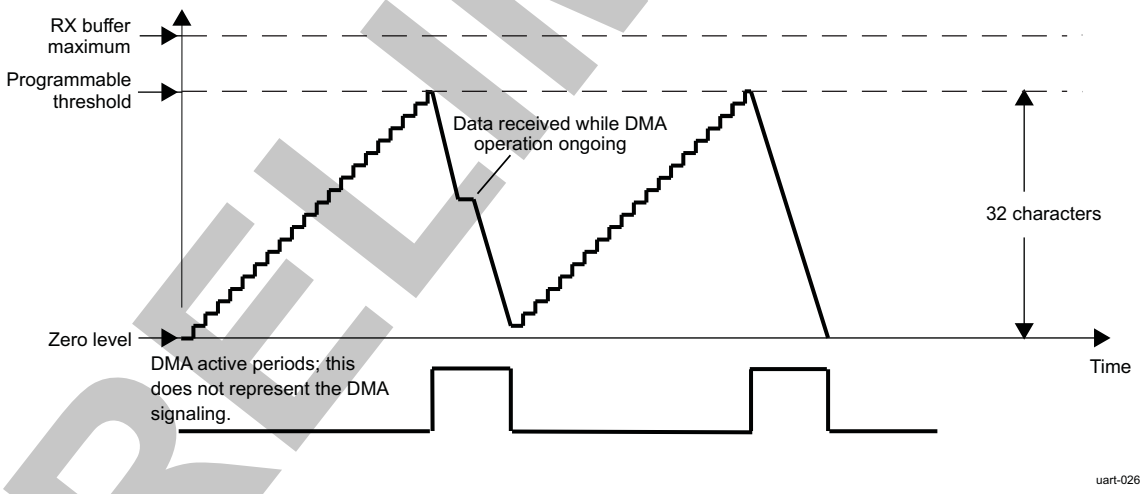
  The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

23.3.4.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 23-65 through Figure 23-68 show the supported DMA operations.

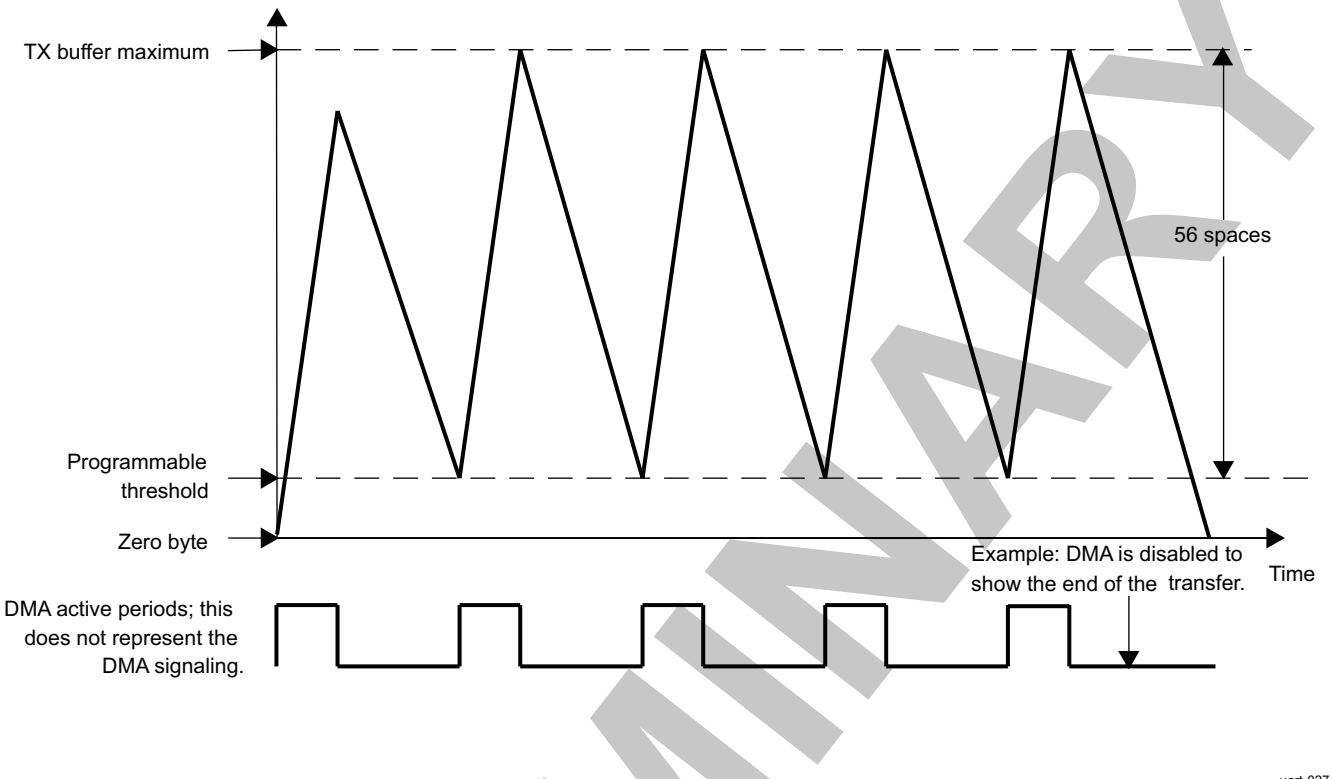
Figure 23-65. Receive FIFO DMA Request Generation (32 Characters)



In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 23-66. Transmit FIFO DMA Request Generation (56 Spaces)



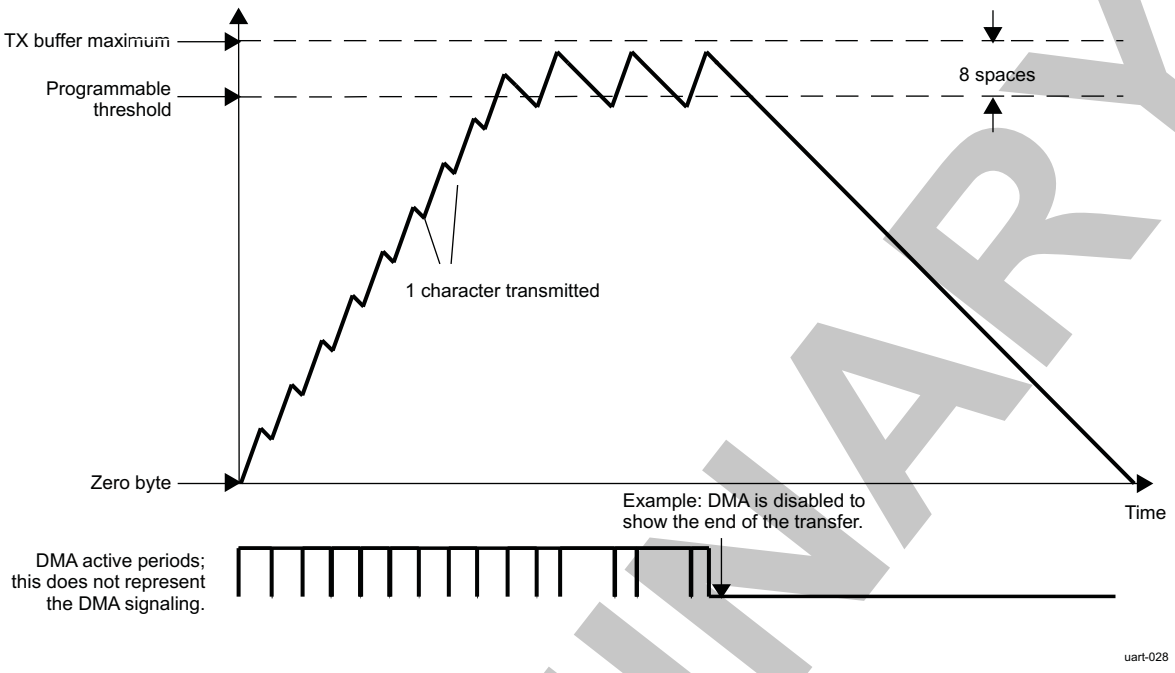
The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 23-66 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 23-67 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Figure 23-67. Transmit FIFO DMA Request Generation (8 Spaces)

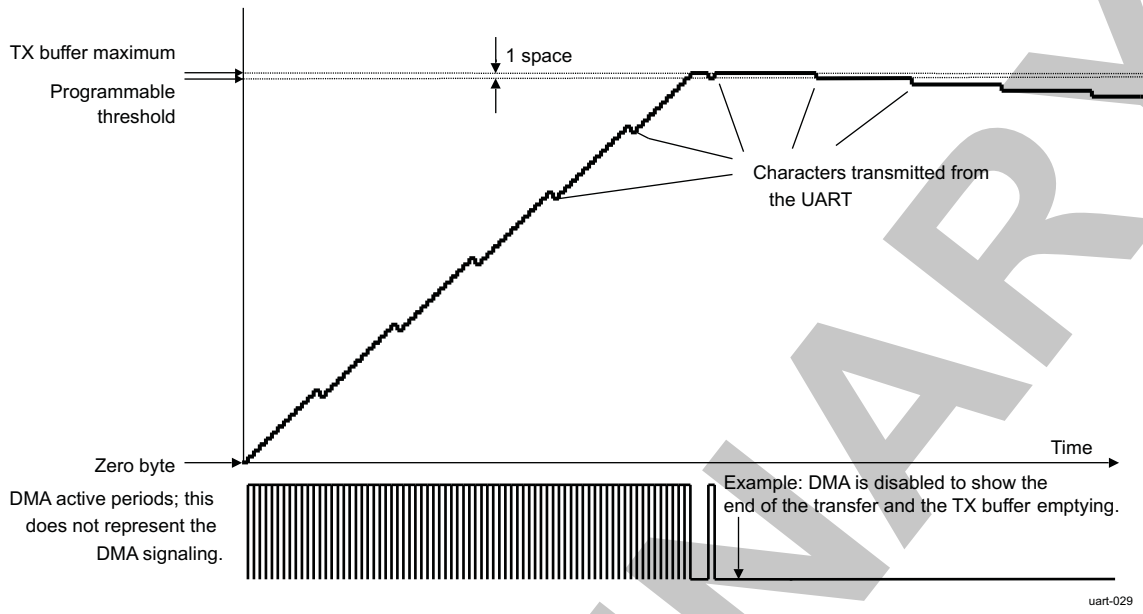


The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 23-68). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 23-68. Transmit FIFO DMA Request Generation (1 Space)



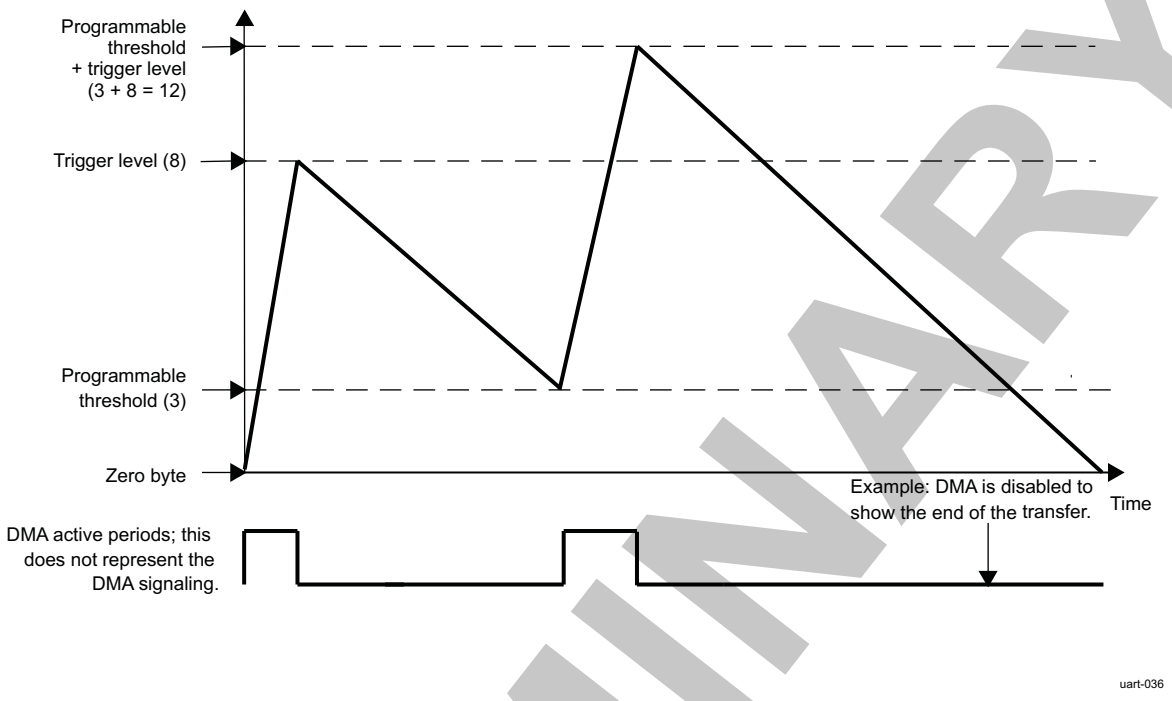
The final example illustrates the setting of eight spaces but setting the TX DMA threshold directly by setting UART_MDR3[1] NONDEFAULT_FREQ bit and UART_TX_DMA_THRESHOLD register (see Figure 23-69). In the example UART_TX_DMA_THRESHOLD[5:0] TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the BAUD rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer will be emptied at the rate specified by the BAUD Rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level + trigger level exceeds max buffer size, then the original TX DMA threshold method is used to prevent TX overrun, regardless of the UART_MDR3[1] value.

The DMA settings should correspond to the system's Local Host DMA controller settings in order to ensure the correct operation of this logic.

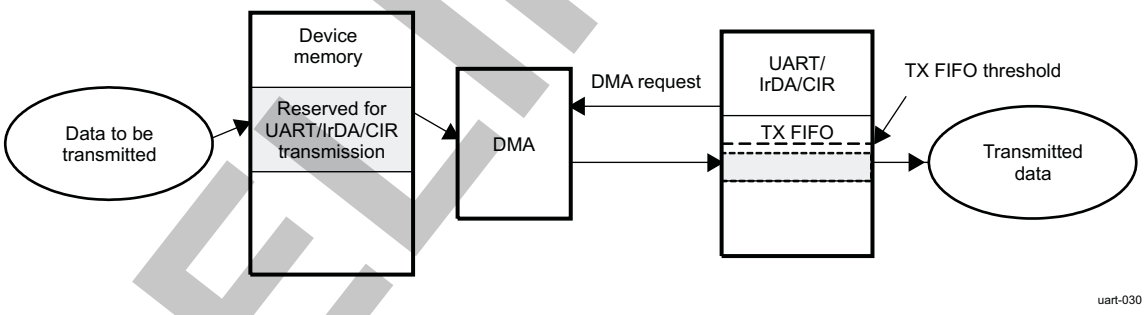
Figure 23-69. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)



23.3.4.6.4.2 DMA Transmission

Figure 23-70 shows DMA transmission.

Figure 23-70. DMA Transmission



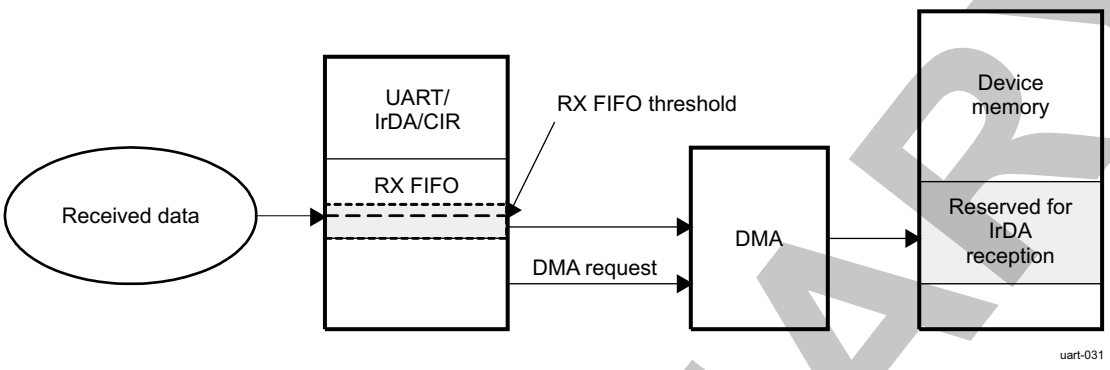
1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
   (a) Until the TX FIFO trigger level is not reached, a DMA request is generated
   (b) An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

23.3.4.6.4.3 DMA Reception

Figure 23-71 shows DMA reception.

Figure 23-71. DMA Reception



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   (a) At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   (b) An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

23.3.4.7 Mode Selection

23.3.4.7.1 Register Access Modes

23.3.4.7.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 23-140).

Table 23-140. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

23.3.4.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in Section 23.3.6, *UART/IrDA/CIR Register Manual*.

Table 23-141 through Table 23-143 summarize the register access submodes.

Table 23-141. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 23-142. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 23-143. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

23.3.4.7.1.3 Registers Available for the Register Access Modes

Table 23-144 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 23-144. UART/IrDA/CIR Register Access Mode Overview

Address Offset	Registers

23.3.4.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field (see Table 23-145).

Table 23-145. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode (UART3 only)
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode (UART3 only)
0x5:	FIR mode (UART3 only)
0x6:	CIR mode (UART3 only)

MODE_SELECT is effective when the module is in operational mode (see Section 23.3.4.7.1, *Register Access Modes*).

23.3.4.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 23-146 are used for the UART function.

23.3.4.8 Protocol Formatting

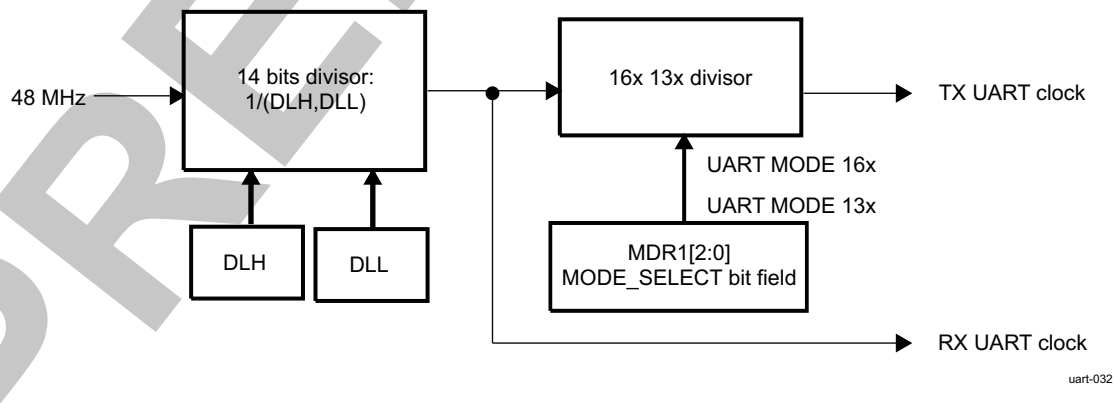
23.3.4.8.1 UART Mode

23.3.4.8.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 23-72 shows the baud rate generator and associated controls.

Figure 23-72. Baud Rate Generation



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

23.3.4.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency / (16x baud rate)
- UART 13x mode: Divisor value = Operating frequency / (13x baud rate)

Table 23-149 describes the UART baud rate settings.

Table 23-149. UART Baud Rate Settings (48-MHz Clock)

23.3.4.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

23.3.4.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 23-150).

Table 23-150. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

23.3.4.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rts is an active-low signal.

- Auto-CTS:

  The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_cts is an active-low signal.

23.3.4.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 23-151).

Two other enhanced features relate to software flow control:

- XON-any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 23-151. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

23.3.4.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

23.3.4.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

23.3.4.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UART_UASR is updated with the configuration detected by the autobauding logic.

UART_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

23.3.4.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 23-135 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 23-135 for the UART mode interrupts).

23.3.4.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

23.3.4.8.1.3.7 Time-Out and Break Conditions

23.3.4.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.UART_RHR register is read.

23.3.4.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

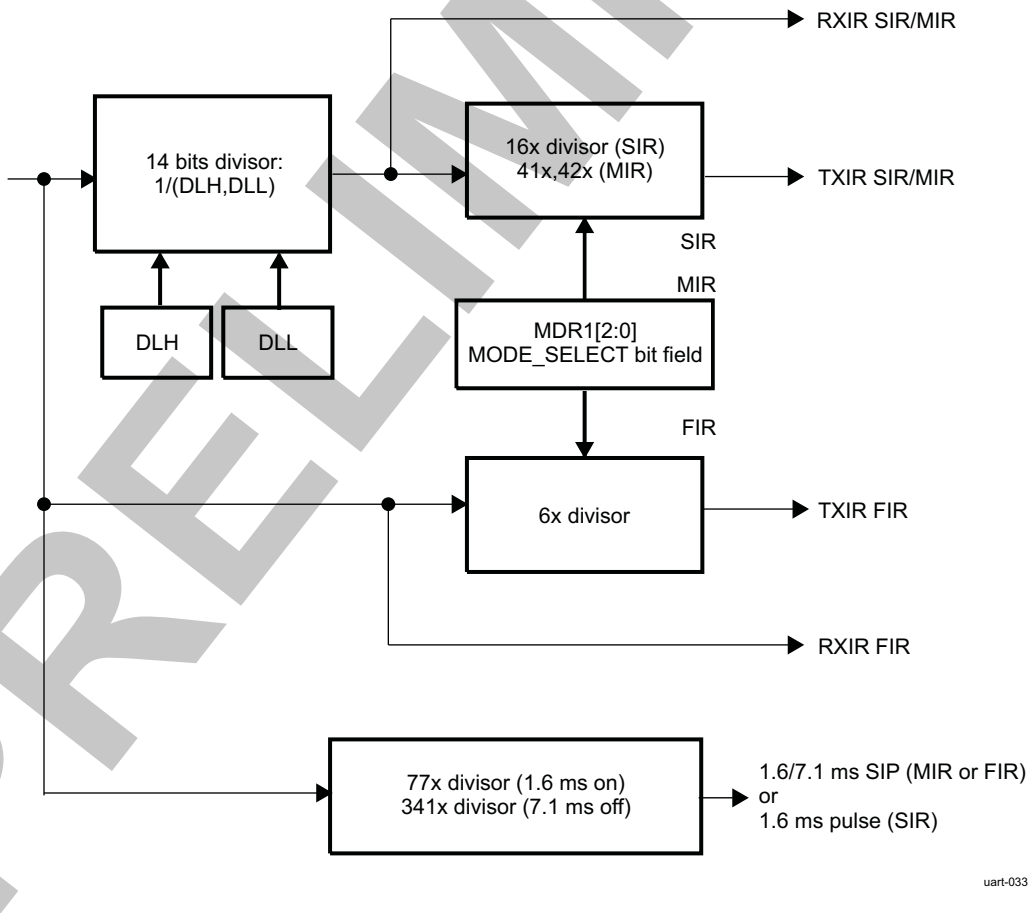
23.3.4.8.2 IrDA Mode (UART3 Only)

23.3.4.8.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 23-73 shows the baud rate generator and associated controls.

Figure 23-73. Baud Rate Generator



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

23.3.4.8.2.2 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 23-152 lists the IrDA baud rate settings.

Table 23-152. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 µs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 µs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 µs

(1) Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

23.3.4.8.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

23.3.4.8.2.3.1 IR RX Polarity Control

The UART3.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

23.3.4.8.2.3.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.UART_ACREG[5] DIS_IR_RX bit.

23.3.4.8.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UART3.UART_XON1_ADDR1[7:0] XON_WORD1 and UART3.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

23.3.4.8.2.3.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UART3.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UART3.UART_TXFLH and UART3.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

23.3.4.8.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

23.3.4.8.2.3.6 Error Detection

When the UART3.UART_LSR register is read, the UART3.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 23-136). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

23.3.4.8.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UART3.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UART3.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

23.3.4.8.2.3.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 23.3.4.8.1.3.6, *Overrun During Receive*).

23.3.4.8.2.3.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UART3.UART_SFREGH[3:0] MSB and UART3.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UART3.UART_SFLSR register. Reading the UART3.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

23.3.4.8.2.4 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

23.3.4.8.2.4.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UART3.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

23.3.4.8.2.4.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-µs pulse duration methods. The UART3.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

23.3.4.8.2.4.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UART3.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UART3.UART_MDR2[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UART3.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UART3.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

23.3.4.8.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.UART_LSR) to detect errors in the received frame.

When the UART3.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.UART_ACREG[3] SEND_SIP bit.

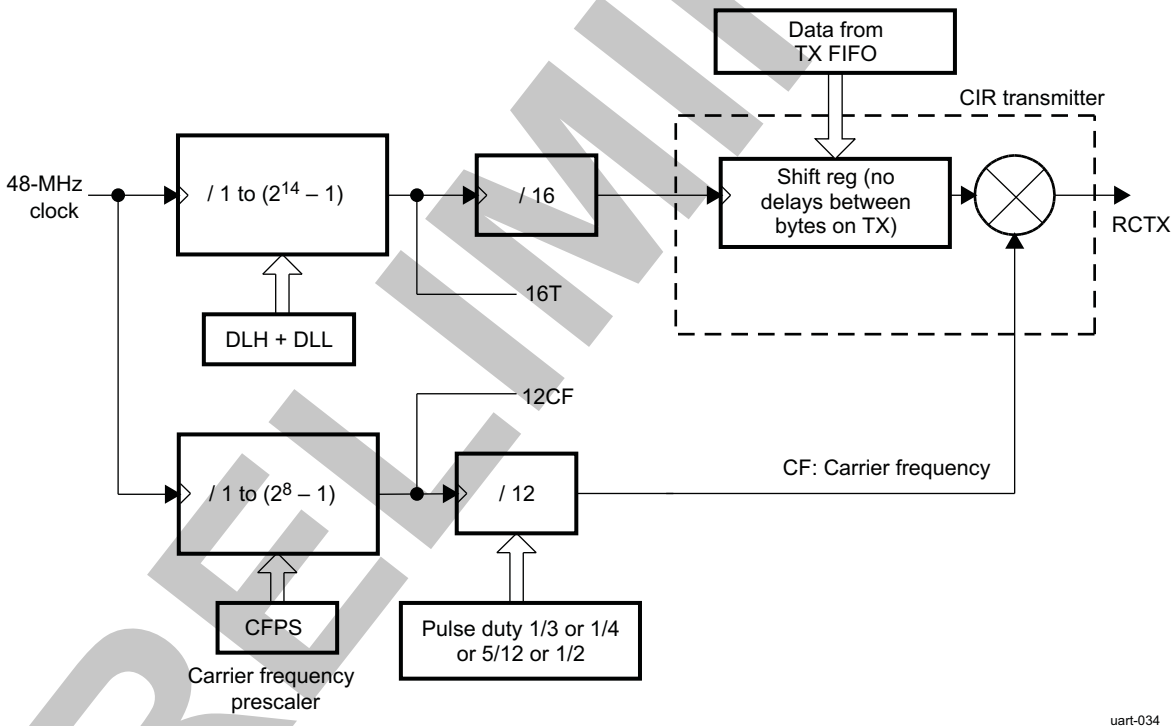
The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

23.3.4.8.3 CIR Mode (UART3 Only)

23.3.4.8.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a *t* period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in Figure 23-74.

Figure 23-74. CIR Mode Block Components



Based on the requested modulation frequency, the UART3.UART_CFPS register must be set with the correct dividing value to provide an accurate pulse frequency:

Dividing value = (FCLK / 12) / MODfreq

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the value of UART_CFPS must be set to 0x7 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The UART3.UART_CFPS register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.UART_MDR2 register. Table 23-153 shows the duty cycle.

Table 23-153. Duty Cycle

UART_MDR2[5:4]	Duty Cycle (High-Level)
00	1/4
01	1/3
10	5/12
11	1/2

23.3.4.8.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

23.3.4.8.3.2.1 IR RX Polarity Control

The IR RX polarity control for CIR mode has the same function as that for IrDA mode (see Section 23.3.4.8.2.3.1, *IR RX Polarity Control*).

23.3.4.8.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start-bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a *t* period
- Using an external system timer to control the delay between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
  - Controlling the start of the frame using the UART3.UART_MDR1[5] SCT bit and the UART3.UART_ACREG[2] SCTX_EN bit, depending on the timer status
  - Using the UART3.UART_IIR[5] TX_STATUS_IT interrupt bit to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame)

23.3.5 UART/IrDA/CIR Basic Programming Model

23.3.5.1 UART Programming Model

23.3.5.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 23.3.4.7.1, *Register Access Modes*.

23.3.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
   Set the UARTi.UART_SYSC[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
   Poll the UARTi.UART_SYSS[0] RESETDONE bit until it equals 1.

23.3.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 1 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
4. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 2 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_FCR[7:6] RX_FIFO_TRIG
   - UARTi.UART_FCR[5:4] TX_FIFO_TRIG
   - UARTi.UART_FCR[3] DMA_MODE
   - UARTi.UART_FCR[0] FIFO_ENABLE (0: Disable the FIFO; 1: Enable the FIFO)

   NOTE: The UARTi.UART_FCR register is not readable.
6. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
   Set the following bits to the desired values:
   - UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
   - UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_SCR[7] RX_TRIG_GRANU1

- UARTi.UART_SCR[6] TX_TRIG_GRANU1
- UARTi.UART_SCR[2:1] DMA_MODE_2
- UARTi.UART_SCR[0] DMA_MODE_CTL

9. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See Section 23.3.4.6.1.1, *Transmit FIFO Trigger,* to choose the following values:

- UARTi.UART_FCR[5:4] TX_FIFO_TRIG
- UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
- UARTi.UART_SCR[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See Section 23.3.4.6.1.2, *Receive FIFO Trigger*, to choose the following values:

- UARTi.UART_FCR[7:6] RX_FIFO_TRIG
- UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
- UARTi.UART_SCR[7] RX_TRIG_GRANU1

DMA mode enables DMA requests. See Section 23.3.4.6.4, *FIFO DMA Mode Operation*, to choose the following values:

- UARTi.UART_FCR[3] DMA_MODE
- UARTi.UART_SCR[2:1] DMA_MODE_2
- UARTi.UART_SCR[0] DMA_MODE_CTL

23.3.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

1. Disable UART to access the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
3. Enable access to the UARTi.UART_IER[7:4] bit field:
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.UART_IER register:
   Set the UARTi.UART_LCR register value to 0x0000.
5. Clear the UARTi.UART_IER register (set the UARTi.UART_IER[4] SLEEP_MODE bit to 0 to change the UARTi.UART_DLL and UARTi.UART_DLH registers). Set the UARTi.UART_IER register value to 0x0000.
6. Switch to register configuration mode B to access the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new divisor value:
   Set the UARTi.UART_DLL[7:0] CLOCK_LSB and UARTi.UART_DLH[5:0] CLOCK_MSB bit fields to the desired values.
8. Switch to register operational mode to access the UARTi.UART_IER register:
   Set the UARTi.UART_LCR register value to 0x0000.
9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):

Set the following bits to the desired values:

- UARTi.UART_IER[7] CTS_IT
- UARTi.UART_IER[6] RTS_IT
- UARTi.UART_IER[5] XOFF_IT
- UARTi.UART_IER[4] SLEEP_MODE
- UARTi.UART_IER[3] MODEM_STS_IT
- UARTi.UART_IER[2] LINE_STS_IT
- UARTi.UART_IER[1] THR_IT
- UARTi.UART_IER[0] RHR_IT

10. Switch to register configuration mode B to access the UARTi.UART_EFR register:

    Set the UARTi.UART_LCR register value to 0x00BF.

11. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register operational mode:

    Set the UARTi.UART_LCR[7] DIV_EN bit to 0.

    Set the UARTi.UART_LCR[6] BREAK_EN bit to 0.

    Set the following bits to the desired values:

    - UARTi.UART_LCR[5] PARITY_TYPE_2
    - UARTi.UART_LCR[4] PARITY_TYPE_1
    - UARTi.UART_LCR[3] PARITY_EN
    - UARTi.UART_LCR[2] NB_STOP
    - UARTi.UART_LCR[1:0] CHAR_LENGTH

13. Load the new UART mode:

    Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to the desired value.

See Section 23.3.4.8.1.2, *Choosing the Appropriate Divisor Value*, to choose the following values:

- UARTi.UART_DLL[7:0] CLOCK_LSB
- UARTi.UART_DLH[5:0] CLOCK_MSB
- UARTi.UART_MDR1[2:0] MODE_SELECT

See Section 23.3.4.8.1.3.1, *Frame Formatting*, to choose the following values:

- UARTi.UART_LCR[5] PARITY_TYPE_2
- UARTi.UART_LCR[4] PARITY_TYPE_1
- UARTi.UART_LCR[3] PARITY_EN
- UARTi.UART_LCR[2] NB_STOP
- UARTi.UART_LCR[1:0] CHAR_LENGTH

23.3.5.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 23.3.4.7.1, *Register Access Modes*.

23.3.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

1. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x0080.
2. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.
   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
3. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
4. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2):
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:
   Set the following bits to the desired values:
   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 4a.
   Set the following bits to the desired values:
   - UARTi.UART_EFR[7] AUTO_CTS_EN (0: Disable; 1: Enable)
   - UARTi.UART_EFR[6] AUTO_RTS_EN (0: Disable; 1: Enable)

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
7. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   Set the UARTi.UART_LCR register value to 0x0080.
8. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 23.3.4.8.1.3.2, *Hardware Flow Control*, to choose the following values:

- UARTi.UART_EFR[7] AUTO_CTS_EN
- UARTi.UART_EFR[6] AUTO_RTS_EN
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

23.3.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register.
   (a) Save the current UARTi.UART_LCR register value.
   (b) Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode XOFF to access the UARTi.UART_XOFF1 and UARTi.UART_XOFF2 registers:
   (a) Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   (b) Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 0.
3. Load the new software flow control characters:
   Set the following bits to the desired values:
   - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
   - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2

- UARTi.UART_XOFF1[7:0] XOFF_WORD1
- UARTi.UART_XOFF2[7:0] XOFF_WORD2

4. Enable access to the UARTi.UART_MCR[7:5] bit field and enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):

   Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Switch to register configuration mode A to access the UARTi.UART_MCR register:

   Set the UARTi.UART_LCR register value to 0x0080.
6. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2) and enable or disable XON any function:

   (a) Save the UARTi.UART_MCR[6] TCR_TLR value.

   (b) Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.

   (c) Set the UARTi.UART_MCR[5] XON_EN bit to the desired value (0: Disable; 1: Enable).
7. Switch to register configuration mode B to access the UARTi.UART_EFR register:

   Set the UARTi.UART_LCR register value to 0x00BF.
8. Load the new start and halt trigger values for software flow control:

   Set the following bits to the desired values:
   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
9. Enable or disable special character function and load the new software flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a:

   Set the following bits to the desired values:
   - UARTi.UART_EFR[5] SPEC_CHAR (0: Disable; 1: Enable)
   - UARTi.UART_EFR[3:0] SW_FLOW_CONTROL

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:

    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR bit value saved in Step 6a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 23.3.4.8.1.3.3, *Software Flow Control*, to choose the following values:

- UARTi.UART_EFR[5] SPEC_CHAR
- UARTi.UART_EFR[3:0] SW_FLOW_CONTROL
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT
- UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
- UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
- UARTi.UART_XOFF1[7:0] XOFF_WORD1
- UARTi.UART_XOFF2[7:0] XOFF_WORD2

23.3.5.2 IrDA Programming Model (UART3 Only)

23.3.5.2.1 SIR Mode

23.3.5.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5 kbps, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):
   UART3.UART_DLL = 0x1A
   UART3.UART_DLH = 0x00
4. Set SIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x1
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
6. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 0x1

23.3.5.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_EFR register:
   UART3.UART_LCR = 0xBF
3. Enable the enhanced features (the UART_EFR[4] ENAHNCED_EN bit = 1):
   Set the UART3.UART_EFR register value to 0x10.
4. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):
   UART3.UART_DLL = 0x1A
   UART3.UART_DLH = 0x00
6. Set SIR mode (the UART_MDR1[2:0] MODE_SELECT bit field = 0x1):
   UART3.UART_MDR1 = 0x01
7. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
8. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 1
9. Optional: Enable the THR interrupt:
   UART3.UART_IER[1] THR_IT = 1
10. Set transmit frame length to 6 bytes:
    UART3.UART_TXFLL = 0x06

11. Set 7 starts of frame transmission:
    UART3.UART_EBLR = 0x08
12. Optional: Set SIR pulse width to be 1.6 µs:
    UART3.UART_ACREG[7] PULSE_TYPE = 1
13. Load the UART_THR register with the data to be transmitted.

23.3.5.2.2 MIR Mode

23.3.5.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UART3.UART_DLL = 0x01
   UART3.UART_DLH = 0x00
4. Set MIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
6. Force DTR output to active (UART_MCR[0] DTR = 1):
   Force RTS output to active (UART_MCR[1] RTS = 1).
   UART3.UART_MCR = 0x3
7. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 1

23.3.5.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UART3.UART_DLL = 0x01
   UART3.UART_DLH = 0x00
4. Set MIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UART3.UART_LCR = 0x00
6. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:

UART3.UART_IER[1] THR_IT = 1

8. Set the frame length to 60 bytes:
   UART3.UART_TXFLL = 0x3C
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

23.3.5.2.3 FIR Mode

23.3.5.2.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
   Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UART3.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UART3.UART_LCR register in IrDA mode.)
3. FIFO clear and enable:
   UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4])
   UART3.UART_LCR[7] = 0
4. Set FIR mode:
   UART3.UART_MDR1[2:0] MODE_SELECT = 0x5
5. Set frame length:
   UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to the UART3.UART_DLL registers and UART3.UART_DLH and switch to register operational mode:
   UART3.UART_LCR[7] DIV_EN = 0x0
7. Optional: Enable the RHR interrupt:
   UART3.UART_IER[0] RHR_IT = 1

23.3.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

1. Disable the UART before accessing the UART3.UART_DLL and UART3.UART_DLH registers:
   Set the UART3.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to EFR_REG:
   UART3.UART_LCR = 0xBF
3. Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1):
   UART3.UART_EFR = 0x10
4. FIFO clear and enable:
   UART3.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4]).
   UART3.UART_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:
   UART3.UART_MDR1 = 0x45
6. Set frame length:

UART3.UART_TXFLL = 0x4
UART3.UART_TXFLH = 0x0
UART3.UART_RXFLL = 0xA (Data + CRC + STOP)
UART3.UART_RXFLH = 0x0

7. Force DTR output to active:
   UART3.UART_MCR[0] DTR = 0x1
8. Optional: Enable the THR interrupt:
   UART3.UART_IER[1] THR_IT = 0x1
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UART3.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UART3.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

23.3.6 UART/IrDA/CIR Register Manual

23.3.6.1 UART/IrDA/CIR Instance Summary

Table 23-154 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 23-154. UART/IrDA/CIR Instance Summary

Module Name	Base Address	Size
UART1[(1)]	0x4806 A000	4 KiB
UART2[(1)]	0x4806 C000	4 KiB
UART3[(2)]	0x4802 0000	4 KiB
UART4[(1)]	0x4806 E000	4 KiB
UART5[(1)]	0x4806 6000	4 KiB
UART6[(1)]	0x4806 8000	4 KiB

(1) UART mode only
(2) UART, IrDA, or CIR mode

23.3.6.2.2 UART/IrDA/CIR Register Description

Table 23-158. UART_THR

Address Offset	0x0000 0000		
Physical Address	0x4806 A000	**Instance**	UART1
	0x4806 C000		UART2
	0x4802 0000		UART3
	0x4806 E000		UART4
	0x4806 6000		UART5
	0x4806 8000		UART6
Description	The transmitter section consists of the transmit holding register (THR) and the transmit shift register. The THR is a 64-byte FIFO. The local host (LH) writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location 0 of the FIFO stores the data.

Address Offset	0x0000 0000		
Physical Address	0x4806 A000 0x4806 C000 0x4802 0000 0x4806 E000 0x4806 6000 0x4806 8000	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6
Description	The receiver section consists of the receiver holding register (RHR) and the receiver shift register. The RHR is a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location 0 of the FIFO stores the single data character. **Note:** If an overflow occurs, the data in the RHR is not overwritten.		
Type	R

	0x4806 E004		UART4
	0x4806 6004		UART5
	0x4806 8004		UART6
Description	There are 6 types of interrupt in these modes, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt and RHR interrupt and they can be enabled/disabled individually. Notes: The RX_STOP_IT interrupt is generated based on the value set in the BOF Length register (EBLR). In IR-CIR mode, contrary to the IR-IRDA mode, the TX_STATUS_IT has only one meaning corresponding to the case MDR2[0] = 0.

RESERVED																								RX_FIFO_TRIG		TX_FIFO_TRIG		DMA_MODE	TX_FIFO_CLEAR	RX_FIFO_CLEAR	FIFO_EN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write has no effect.	W	0x000000
7:6	RX_FIFO_TRIG	Sets the trigger level for the RX FIFO: If UART_SCR[7] = 0 and UART_TLR[7:4] = 0000: 00: 8 characters 01: 16 characters 10: 56 characters 11: 60 characters If UART_SCR[7] = 0 and UART_TLR[7:4] != 0000, RX_FIFO_TRIG is not considered. If UART_SCR[7] = 1, RX_FIFO_TRIG is 2 LSBs of the trigger level (1-63 on 6 bits) with the granularity 1.	W	0x0
5:4	TX_FIFO_TRIG	Sets the trigger level for the TX FIFO: If UART_SCR[6] = 0 and UART_TLR[3:0] = 0000: 00: 8 spaces 01: 16 spaces 10: 32 spaces 11: 56 spaces If UART_SCR[6] = 0 and UART_TLR[3:0] != 0000, TX_FIFO_TRIG is not considered. If UART_SCR[6] = 1, TX_FIFO_TRIG is 2 LSBs of the trigger level (1-63 on 6 bits) with the granularity 1	W	0x0
3	DMA_MODE	This register is considered if UART_SCR[0] = 0. Write 0x0: DMA_MODE 0 (No DMA) Write 0x1: DMA_MODE 1 (UART_nDMA_REQ[0] in TX, UART_nDMA_REQ[1] in RX)	W	0
2	TX_FIFO_CLEAR	Write 0x0: No change Write 0x1: Clears the TX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
1	RX_FIFO_CLEAR	Write 0x0: No change Write 0x1: Clears the RX FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.	W	0
0	FIFO_EN	Write 0x0: Disables the transmit and RX FIFOs. The transmit and receive holding registers are 1-byte FIFOs. Write 0x1: Enables the transmit and RX FIFOs. The transmit and receive holding registers are 64-byte FIFOs.	W	0

Table 23-179. Register Call Summary for Register UART_FCR

UART/IrDA/CIR

Table 23-180. UART_EFR

Address Offset	0x0000 0008		
Physical Address	0x4806 A008	**Instance**	UART1
	0x4806 C008		UART2
	0x4802 0008		UART3
	0x4806 E008		UART4
	0x4806 6008		UART5
	0x4806 8008		UART6
Description	Enhanced feature register		
	This register enables or disables enhanced features. Most of the enhanced functions apply only to UART modes, but UART_EFR[4] enables write accesses to UART_FCR[5:4], the TX trigger level, which is also used in IrDA modes.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								AUTO_CTS_EN	AUTO_RTS_EN	SPECIAL_CHAR_DETECT	ENHANCED_EN	SW_FLOW_CONTROL			

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	AUTO_CTS_EN	Auto-CTS enable bit 0x0: Normal operation 0x1: Auto-CTS flow control is enabled. Transmission is halted when the CTS* pin is high (inactive).	RW	0

Bits	Field Name	Description	Type	Reset
6	AUTO_RTS_EN	Auto-RTS enable bit 0x0: Normal operation 0x1: Auto-RTS flow control is enabled. RTS* pin goes high (inactive) when the RX FIFO HALT trigger level, UART_TCR[3:0], is reached, and goes low (active) when the RX FIFO RESTORE transmission trigger level is reached.	RW	0
5	SPECIAL_CHAR_DETECT	0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to the RX FIFO and the UART_IIR[4] bit is set to 1 to indicate that a special character was detected.	RW	0
4	ENHANCED_EN	Enhanced functions write enable bit 0x0: Disables writing to IER bits 4-7, UART_FCR bits 4-5, and MCR bits 5-7. 0x1: Enables writing to IER bits 4-7, UART_FCR bits 4-5, and MCR bits 5-7.	RW	0
3:0	SW_FLOW_CONTROL	Combinations of software flow control can be selected by programming bit 3 - bit 0. See Table 23-151.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0.	R	0x000000
7	THR_EMPTY	Read 0x0: Transmit holding register (TX FIFO) is not empty.	R	1
		Read 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete.		
6	STS_FIFO_FULL	Read 0x0: Status FIFO not full	R	0
		Read 0x1: Status FIFO full		

Bits	Field Name	Description	Type	Reset
5	RX_LAST_BYTE	Read 0x0: The RX FIFO (RHR) does not contain the last byte of the frame to be read. Read 0x1: The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It determines the frame boundary. It is cleared on a single read of the LSR register. See the note below.	R	0
4	FRAME_TOO_LONG	Read 0x0: No frame-too-long error in frame Read 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO, (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.	R	0
3	ABORT	Read 0x0: No abort pattern error in frame Read 0x1: Abort pattern is received. SIR and MIR: Abort pattern FIR: Illegal symbol	R	0
2	CRC	Read 0x0: No CRC error in frame Read 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read)	R	0
1	STS_FIFO_E	Read 0x0: Status FIFO not empty Read 0x1: Status FIFO empty	R	1
0	RX_FIFO_E	Read 0x0: No data in the RX FIFO Read 0x1: At least one data character in the RX FIFO	R	1

	0x4806 8018		UART6
Description	Transmission control register		
	This register stores the RX FIFO threshold levels to start/stop transmission during hardware/software flow control. Notes: Trigger levels from 0 to 60 bytes are available with a granularity of 4. (Trigger level = 4 x [4-bit register value]) The programmer must ensure that UART_TCR[3:0] > UART_TCR[7:4] when auto-RTS or software flow control is enabled to avoid a mis-operation of the device. In FIFO interrupt mode with flow control, the programmer must ensure that the trigger level to halt transmission is greater than or equal to the RX FIFO trigger level (UART_TLR[7:4] or UART_FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because a DMA request is sent each time a byte is received.		
Type	RW

	0x4806 E020		UART4
	0x4806 6020		UART5
	0x4806 8020		UART6
Description	Mode definition register 1		
	The mode of operation can be programmed by writing to MDR1[2:0] and therefore the MDR1 must be programmed on startup after configuration of the configuration registers (UART_DLL, UART_DLH, and UART_LCR). The value of MDR1[2:0] must not be changed again during normal operation. **Note:** If the module is disabled by setting the MODE_SELECT field to 111, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows UART mode interrupt flags.		
Type	RW

	0x4802 0024		UART3
	0x4806 E024		UART4
	0x4806 6024		UART5
	0x4806 8024		UART6
Description	Mode definition register 2		
	IR-IrDA and IR-CIR modes only. UART_MDR2[0] describes the status of the interrupt in UART_IIR[5]. The IRTX_UNDERRUN bit should be read after an UART_IIR[5] TX_STATUS_IT interrupt. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in UART_MDR1[2:0]. **Note:** The UART_MDR2[6] gives the flexibility to invert the RX pin in the UART to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most transceivers invert the IR receive pin.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								SET_TXIR_ALT	IRRXINVERT	CIR_PULSE_MODE		UART_PULSE	STS_FIFO_TRIG		IRTX_UNDERRUN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	SET_TXIR_ALT	Provide alternate function for MDR1[4] (SET_TXIR). 0x0: Normal mode 0x1: Alternate mode for SET_TXIR	R	0
6	IRRXINVERT	IR mode only (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed.	RW	0
5:4	CIR_PULSE_MODE	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles	RW	0x0
3	UART_PULSE	UART mode only. Allows pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with a pulse shaping	RW	0
2:1	STS_FIFO_TRIG	IR-IrDA mode only. Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IRTX_UNDERRUN	IrDA transmission status interrupt. When the UART_IIR[5] interrupt occurs, the meaning of the interrupt is: Read 0x0: The last bit of the frame transmitted successfully without error. Read 0x1: An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the UART_RESUME register is read.	R	0

	0x4806 E030		UART4
	0x4806 6030		UART5
	0x4806 8030		UART6
Description	Status FIFO register low		
	IrDA modes only. The frame lengths of received frames are written into the status FIFO. This information can be read by reading the UART_SFREGL and UART_SFREGH registers (these registers do not physically exist). The LsBs are read from UART_SFREGL and the MSBs are read from UART_SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers should be read before the pointer is incremented by reading the UART_SFLSR register.

	0x4806 E038		UART4
	0x4806 6038		UART5
	0x4806 8038		UART6
Description	UART autobauding status register		
	UART autobauding mode only. This status register returns the speed, the number of bits by characters, and the type of the parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. **Note:** When the UART is in autobauding mode, this register, instead of the LCR, DLL, and DLH registers, is used to set up transmission according to the characteristics of the previous reception. To reset the autobauding hardware (to start a new AT detection), set MDR1[2:0] to 111 (reset value), then set MDR1[2:1] to 010 (UART in autobaud mode). To set the UART to standard mode (no autobaud), set MDR1[2:1] to 000.

Address Offset	0x0000 003C		
Physical Address	0x4806 A03C 0x4806 C03C 0x4802 003C 0x4806 E03C 0x4806 603C 0x4806 803C	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6
Description	Auxiliary control register. IR-IrDA and IR-CIR modes only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								PULSE_TYPE	SD_MOD	DIS_IR_RX	DIS_TX_UNDERRUN	SEND_SIP	SCTX_EN	ABORT_EN	EOT_EN

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0. Write has no effect.	RW	0x000000
7	PULSE_TYPE	SIR pulse width select 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 µs	RW	0
6	SD_MOD	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low.	RW	0
5	DIS_IR_RX	0x0: Normal operation (RX input automatically disabled during transmit but enabled outside of transmit operation) 0x1: Disables RX input (permanent state - independent of transmit)	RW	0
4	DIS_TX_UNDERRUN	It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, garbage data is sent over TX line. 0x0: Long stop-bits cannot be transmitted; TX underrun is enabled. 0x1: Long stop-bits can be transmitted; TX underrun is disabled.	RW	0
3	SEND_SIP	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is cleared automatically at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse.	RW	0
2	SCTX_EN	Store and controlled TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.	RW	0
1	ABORT_EN	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. If TX FIFO is not empty and MDR1[5] = 1, UART IrDA starts a new transfer with data of the previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.	RW	0

Bits	Field Name	Description	Type	Reset
0	EOT_EN	EOT (end of transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in set-EOT bit frame closing method. This bit is cleared automatically when the LH writes to the THR (TX FIFO).	RW	0

Description	BOF length register IR-IrDA and IR-CIR modes only. In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must account for the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. The value 0 sends 1 BOF plus 255 XBOF. In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In IR-CIR mode, this register specifies the number of consecutive 0s to be received before generating the RX_STOP interrupt (UART_IIR[2]). All received 0s are stored in the RX FIFO. When the register is set to 0, this feature is deactivated and always in reception state, which can be disabled by setting the ACREG[5] to 1. **Note:** If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with 0s and passed into the RX FIFO.		
Type	RW

Physical Address	0x4806 A054 0x4806 C054 0x4802 0054 0x4806 E054 0x4806 6054 0x4806 8054	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6
Description	System configuration register The AUTOIDLE bit controls a power-saving technique to reduce the logic power consumption of the open-core protocol (OCP) interface. When the feature is enabled, the clock is gated off until an OCP command for this device is detected. When the software reset bit is set high, it causes a full device reset.		
Type	RW

	0x4806 805C		UART6
Description	Wake-up enable register		
	The UART wake-up enable register is used to mask and unmask a UART event that would subsequently notify the system. An event is any activity in the logic that could cause an interrupt and/or an activity that would require the system to wake up. Even if the wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART registers the interrupt.		
Type	RW

Address Offset	0x0000 0060		
Physical Address	0x4806 A060 0x4806 C060 0x4802 0060 0x4806 E060 0x4806 6060 0x4806 8060	**Instance**	UART1 UART2 UART3 UART4 UART5 UART6
Description	Carrier frequency prescaler Because the consumer IR works at modulation rates of 30 to 56.8 kHz, the 48-MHz clock must be prescaled before the clock can drive the IR logic. This register sets the divisor rate to give a range to accommodate the remote-control requirements in baud multiples of 12x. The value of the CFPS at reset is 0105 decimal, which equals 38.1 kHz output from starting conditions. The 48-MHz carrier is prescaled by the CFPS, which is then divided by the 12x baud multiple.

23.4 Multichannel Serial Port Interface

This section describes the four multichannel serial port interface (MCSPI) modules for the device.

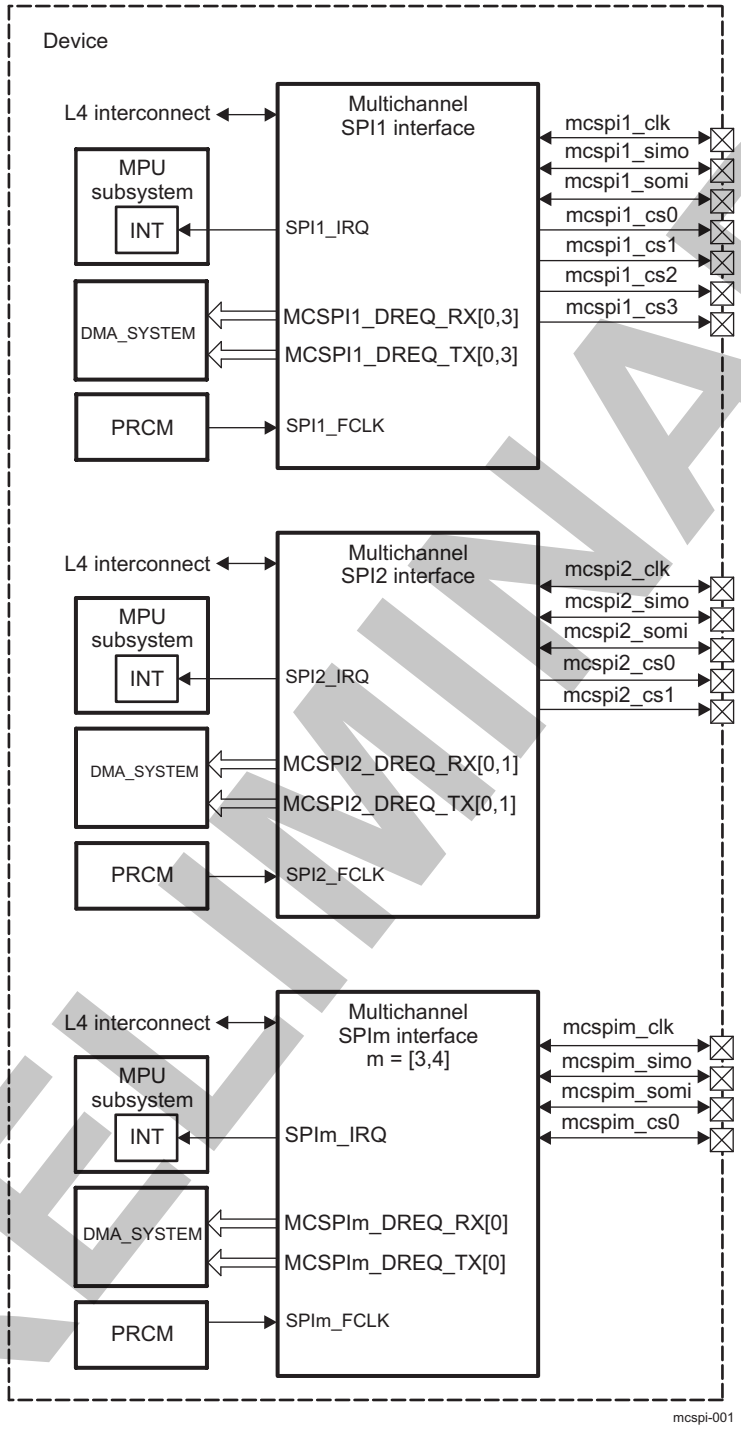
23.4.1 MCSPI Overview

The MCSPI is a master/slave synchronous serial bus. The MCSPI has four separate modules (SPI1, SPI2, SPI3, and SPI4) in the device (see Figure 23-75). The MCSPI modules differ as follows: SPI1 supports up to four peripherals and master mode only, SPI2 supports up to two peripherals and master mode only, SPI3 and SPI4 supports only one peripheral and master and slave mode.

NOTE: In this chapter, *m = [1,4]* represents the module instance and *x* represents the channel in signal and register naming. The MCSPI has four instances, with each module instance having different channel numbers:

- SPI1: 4 channels (if *m = 1*, *x = 4*)
- SPI2: 2 channels (if *m = 2*, *x = 2*)
- SPI3: 1 channel (if *m = 3*, *x = 1*)
- SPI4: 1 channel (if *m = 4*, *x = 1*)

Figure 23-75. Multichannel Modules SPI1, SPI2, SPI3, and SPI4



The MCSPI instances include the following main features:

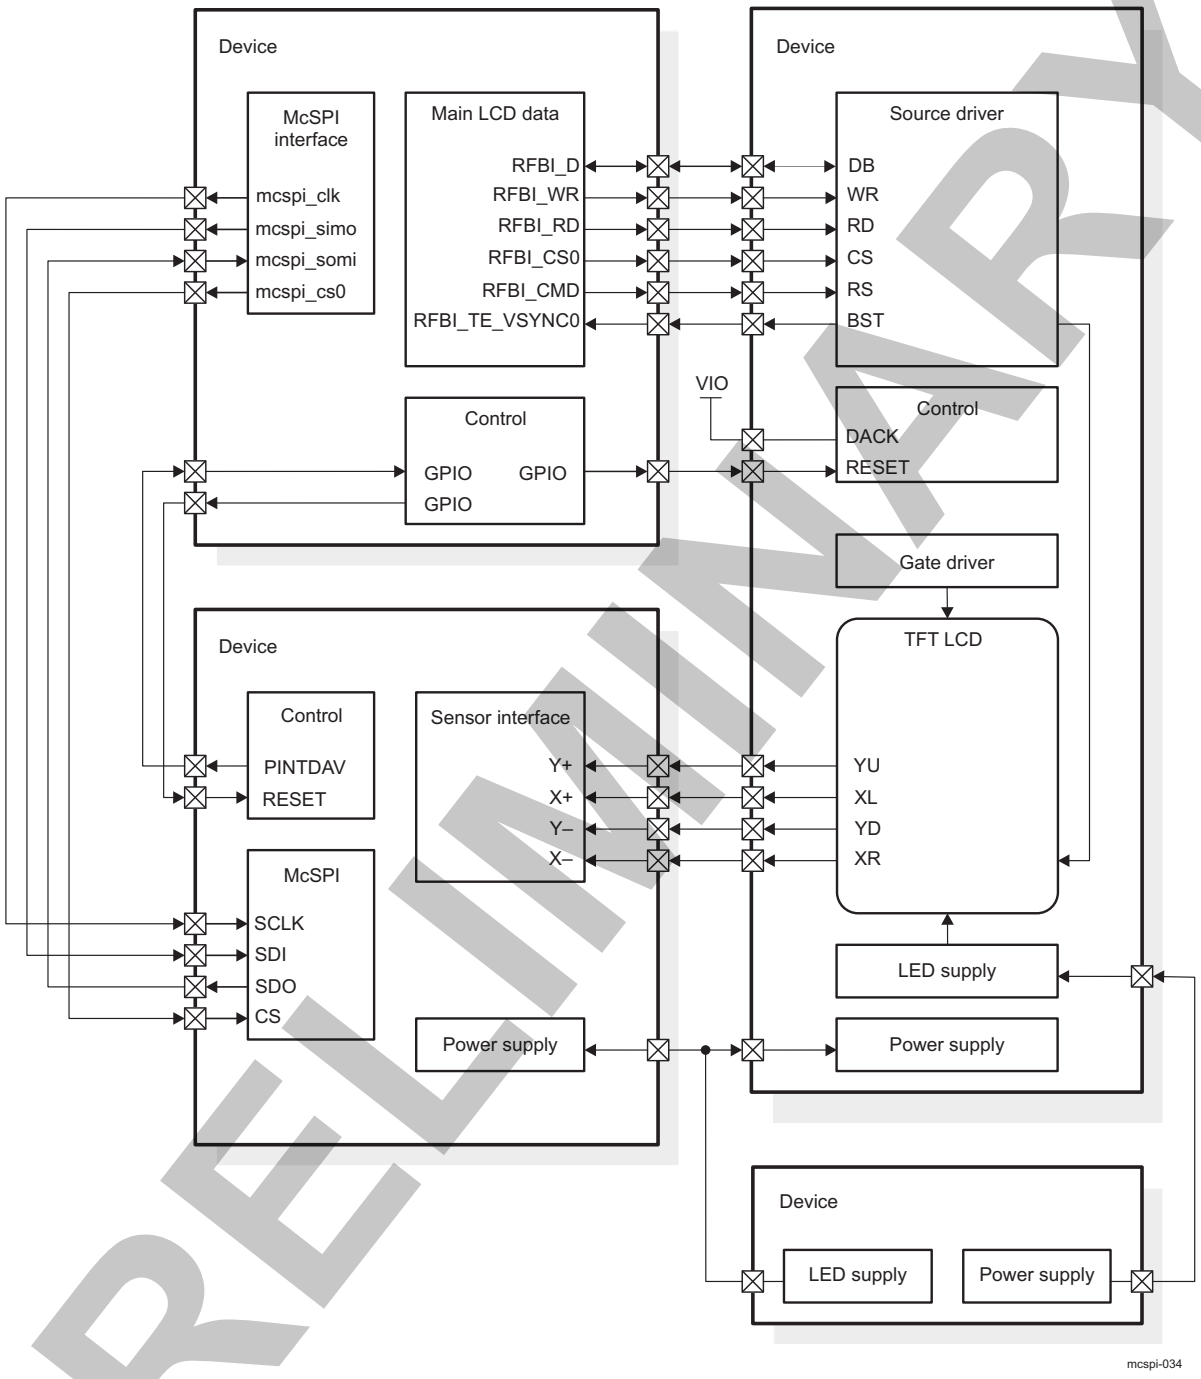
- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths, ranging from 4 to 32 bits
- Up to four master channels, or single channel in slave mode
- Master multichannel mode:
  - Full duplex/half duplex
  - Transmit-only/receive-only/transmit-and-receive modes

  - Flexible input/output (I/O) port controls per channel
  - Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Supports start-bit write command
- Supports start-bit pause and break sequence
- 64-byte built-in FIFO available for a single channel
- Force CS mode for continuous transfers

23.4.2 MCSPI Environment

Figure 23-76 shows a simplified overview of a typical application system using the MCSPI. This example is based on a TFS chipset, including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a 4-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with a touch-screen controller, powered by a power-management unit, and driven by the device. The MCSPI device interface is set to master mode; the touch-screen MCSPI controller interface operates in slave mode.

Figure 23-76. Typical Application Using the MCSPI



23.4.2.1 MCSPI Interface

23.4.2.1.1 Basic MCSPI Pins for Master Mode

Figure 23-77 shows all of the MCSPI interface signals in master mode.

Figure 23-77. MCSPI Interface Signals in Master Mode

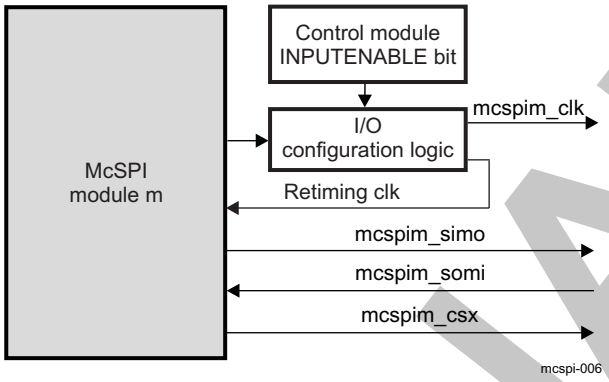


Table 23-264 describes the MCSPI I/O in master mode.

Table 23-264. MCSPI I/O Description (Master Mode)

Signal Name	I/O[1]	Description	Reset [2]
mcspim_clk	O	SPIm module serial clock[3]	Unknown
mcspim_simo	O	SPIm module serial data master out (slave input, master output)	Unknown
mcspim_somi	I	SPIm module serial data master input (slave output, master input)	–
mcspim_csx	O	SPIm module chip-select x output	Low

(1) I = Input; O = Output

(2) After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL].)

(3) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

23.4.2.1.2 Basic MCSPI Pins for Slave Mode

Figure 23-78 shows all of the MCSPI interface signals in slave mode.

Figure 23-78. MCSPI Interface Signals in Slave Mode

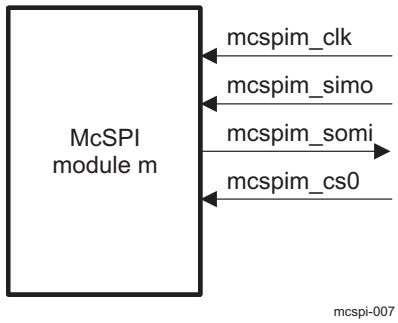

Table 23-265 describes the MCSPI I/O in slave mode.

Table 23-265. MCSPI I/O Description (Slave Mode)

Signal Name	I/O[1]	Description	Reset [2]
mcspim_clk	I	SPIm module serial clock	Unknown
mcspim_simo	I	SPIm module serial data master out (slave input, master output)	Unknown
mcspim_somi	O	SPIm module serial data master input (slave output, master input)	–
mcspim_csx	I	SPIm module chip-select x output	Low

(1) I = Input; O = Output

(2) After reset, the SPI modules are in slave mode by default. This paragraph implies that the MCSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL].)

23.4.2.1.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (mcspim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

MCSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length

  MCSPI supports any SPI word ranging from 4 bits to 32 bits long (the SPIm.MCSPI_CHxCONF[11:7] WL bit field).

  SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.

- SPI enable (mcspim_csx, for channel x of instance m)

  The polarity of the SPI enable signals is programmable (the SPIm.MCSPI_CHxCONF[6] EPOL bit). mcspim_csx signals can be active high or low.

  Assertion of the mcspim_csx signals is programmable and can be done manually or automatically. The manual assertion mode is available in single master mode only. mcspim_csx can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.

  Two consecutive words for two different slave devices can go along with active mcspim_csx signals with different polarity.

- Programmable start-bit

  In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.

- Programmable SPI clock
  - Bit rate

    In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock managment [PRCM] module). Table 23-266 lists the spim_clk bit rates obtained for data transfer when programming the clock divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 23-266. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz

Table 23-266. SPI Master Clock Rates (continued)

Divider	Clock Rate
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz

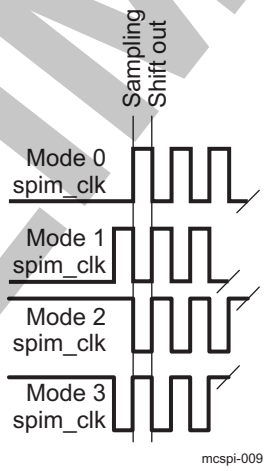
– Polarity and phase

The polarity (the SPIm.MCSPI_CHxCONF[1] POL bit) and the phase (the SPIm.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (mcspim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See Table 23-267 and Figure 23-79.

Table 23-267. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	Mode 0	mcspim_clk is active high and sampling occurs on the rising edge.
0	1	Mode 1	mcspim_clk is active high and sampling occurs on the falling edge.
1	0	Mode 2	mcspim_clk is active low and sampling occurs on the falling edge.
1	1	Mode 3	mcspim_clk is active low and sampling occurs on the rising edge.

Figure 23-79. Phase and Polarity Combinations



23.4.2.1.3.1 Transfer Format

In master and slave modes, the MCSPI drives the data lines when spim_csx is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

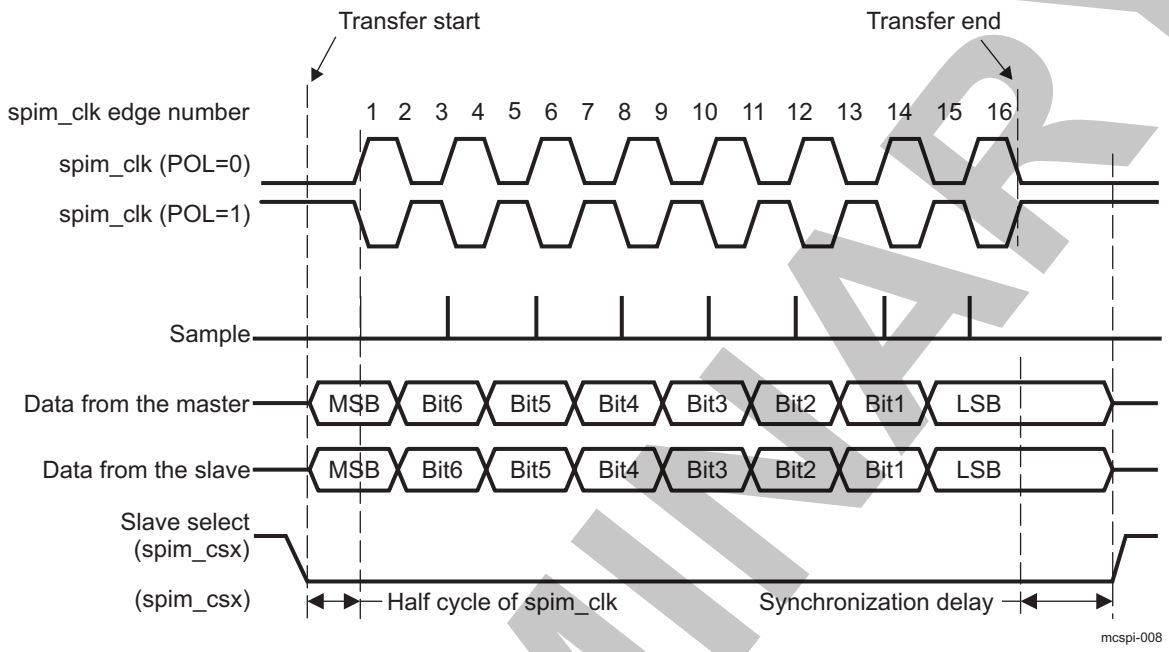
  When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one-half cycle of spim_clk after the assertion of spim_csx.

  Therefore, the first edge of the mcspim_clk line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next mcspim_clk edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the spim_clk line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See Figure 23-80.

Figure 23-80. Full-Duplex Transfer Format With PHA = 0



- Transmission in mode 1 and mode 3 (PHA = 1)

  When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following mcspim_clk edge (one-half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the activation of mcspim_csx and the first mcspim_clk edge.

  The received data bit is shifted into the shift register on the third mcspim_clk edge.

  This process continues for a number of pulses on the mcspim_clk line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

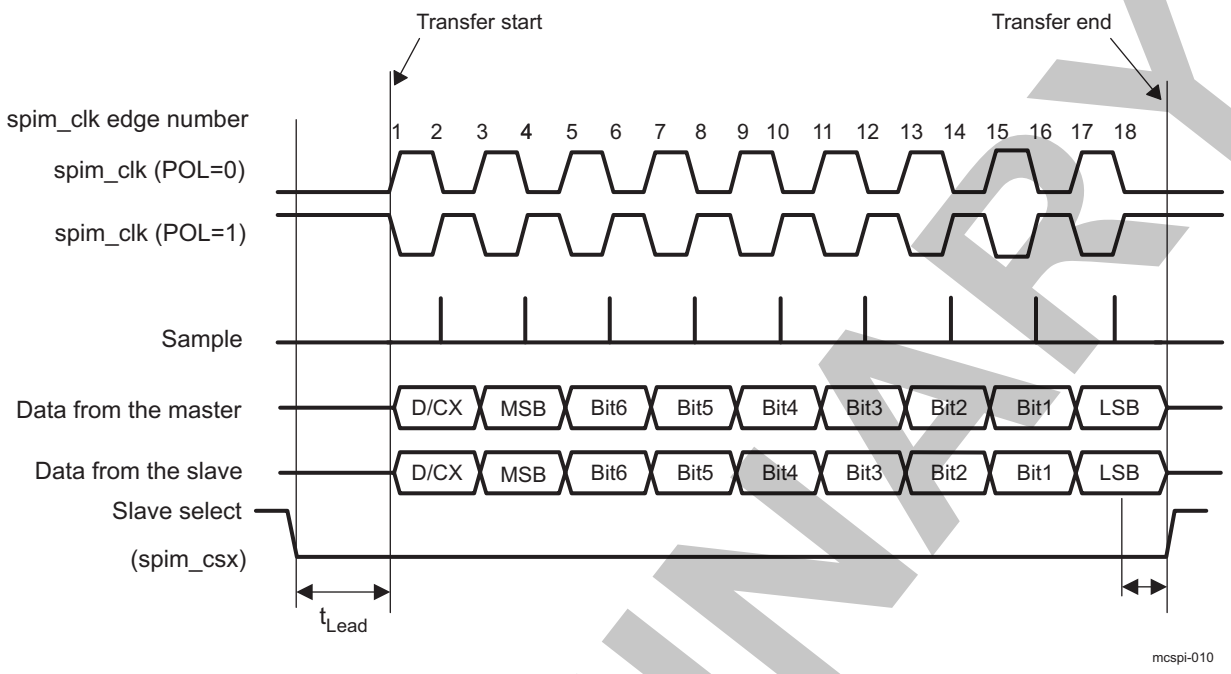
  NOTE: The minimum synchronization delay is one cycle of mcspim_clk, if the frequency of mcspim_clk equals the frequency of SPIm_FCLK (MCSPIm functional clock) in master mode. The minimum synchronization delay is one-half cycle of mcspim_clk, if the frequency of mcspim_clk is lower than the frequency of SPIm_FCLK in the master and slave modes.

- Transmission with a start-bit (SBE = 1)

  When the SPIm.MCSPI_CHxCONF[23] SBE bit is set to 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

  Figure 23-81 shows an example of a data transfer with an extra start-bit.

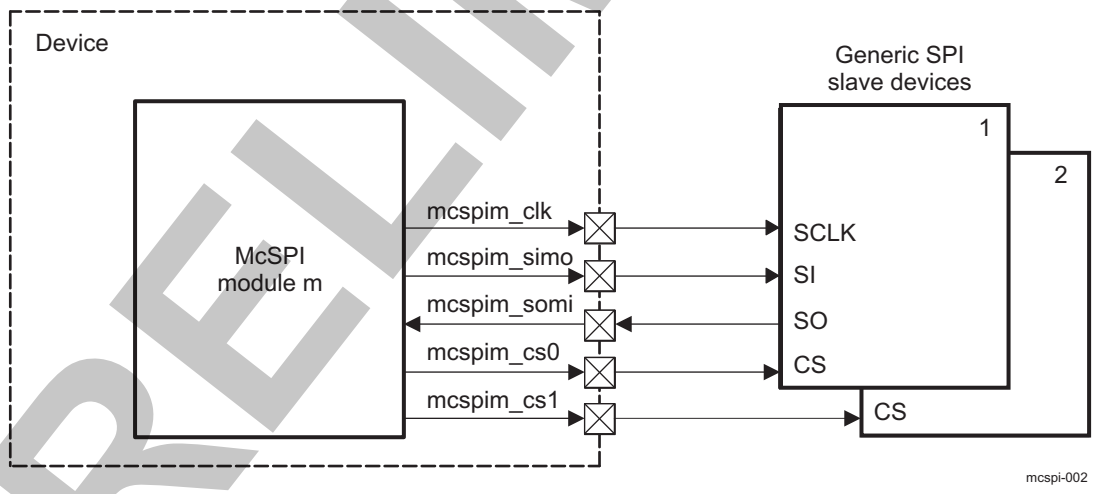
Figure 23-81. Extended SPI Transfer With a Start-Bit (SBE = 1)



23.4.2.2 SPI in Master Mode

Figure 23-82 shows a case in master mode (full-duplex) where the MCSPI module is connected with two slave devices.

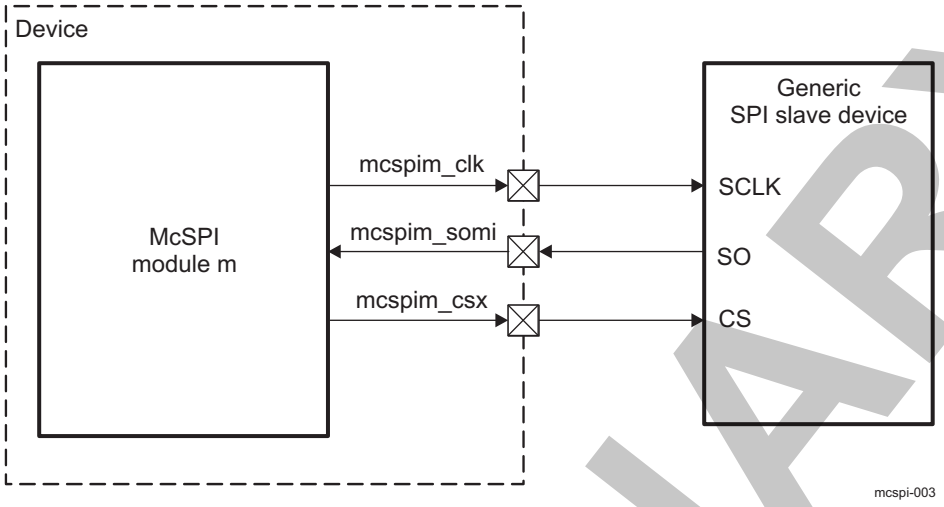
Figure 23-82. MCSPI Master Mode (Full Duplex)



NOTE: In this case m = [1,3].

Figure 23-83 shows the master single mode, which can also be configured in receive-only mode.

Figure 23-83. MCSPI Master Single Mode (Receive Only)



23.4.2.3 SPI in Slave Mode

Figure 23-84 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, but the chip-enable signal can be connected to any mcspim_csx pin and then rerouted internally to channel 0 (the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0]). For more information, see Section 23.4.4.3, *Slave Mode*.

Figure 23-84. MCSPI Slave Mode (Full Duplex)

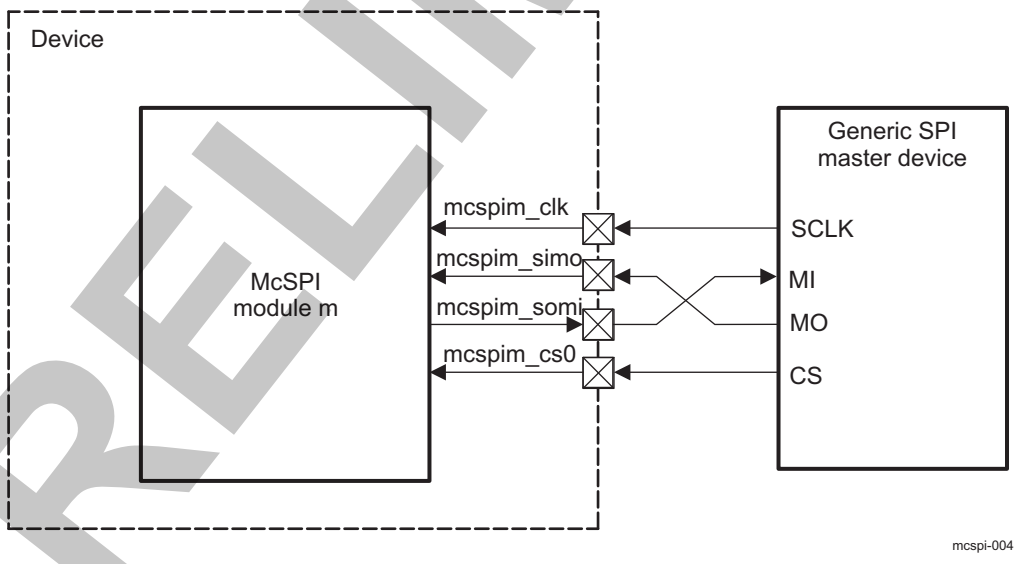


Figure 23-85 shows the slave single mode, which can also be configured in transmit-only mode.

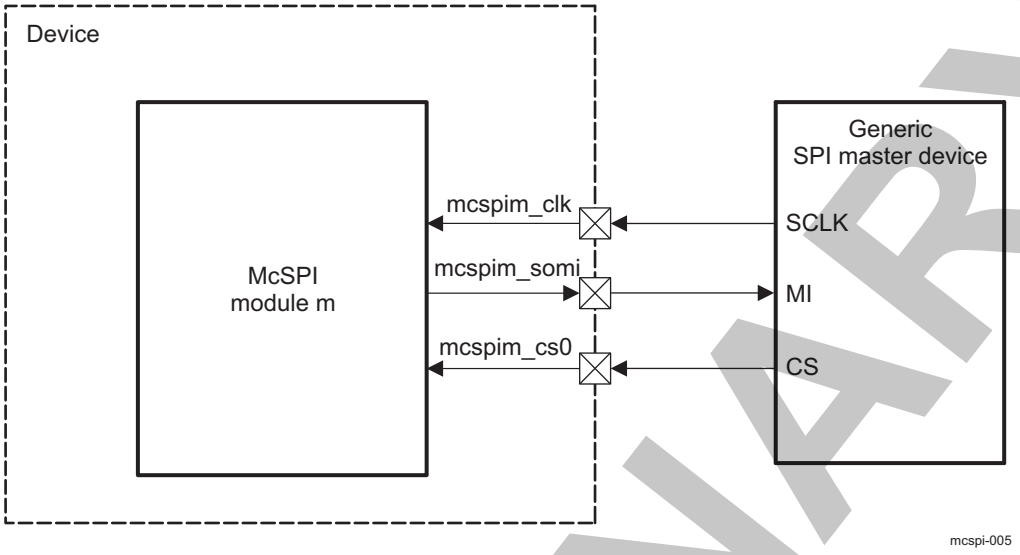
Figure 23-85. MCSPI Slave Single Mode (Transmit Only)

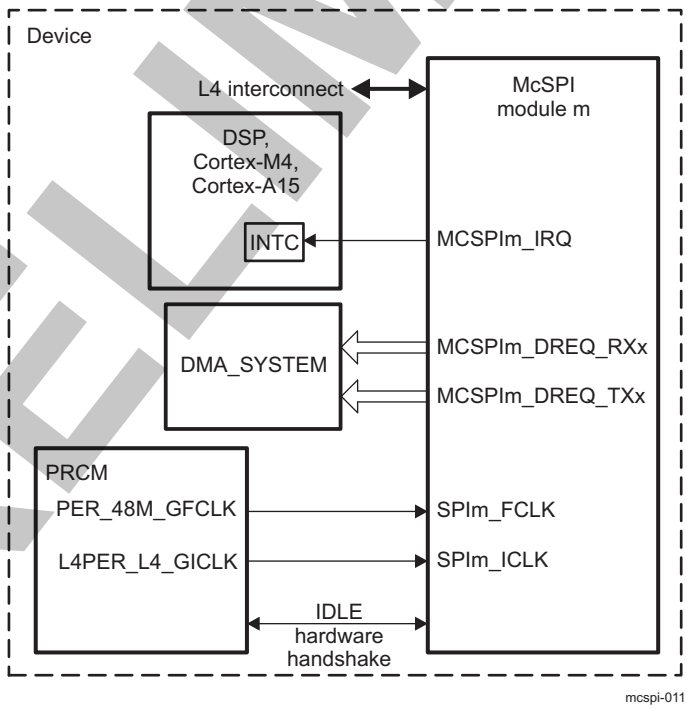


23.4.3 MCSPI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-86 shows MCSPI integration.

Figure 23-86. MCSPI Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1 Device Power-Management Architecture Building Blocks in Chapter PRCM.

NOTE: For the names of the signals going from the MCSPI to the DSP, Cortex-M4, and Cortex-A15 interrupt controllers (INTCs), see Section 17.1.

Table 23-268 through Table 23-270 summarize the integration of the module in the device.

Table 23-268. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MCSPI1	PD_CORE	L4_PER
MCSPI2	PD_CORE	L4_PER

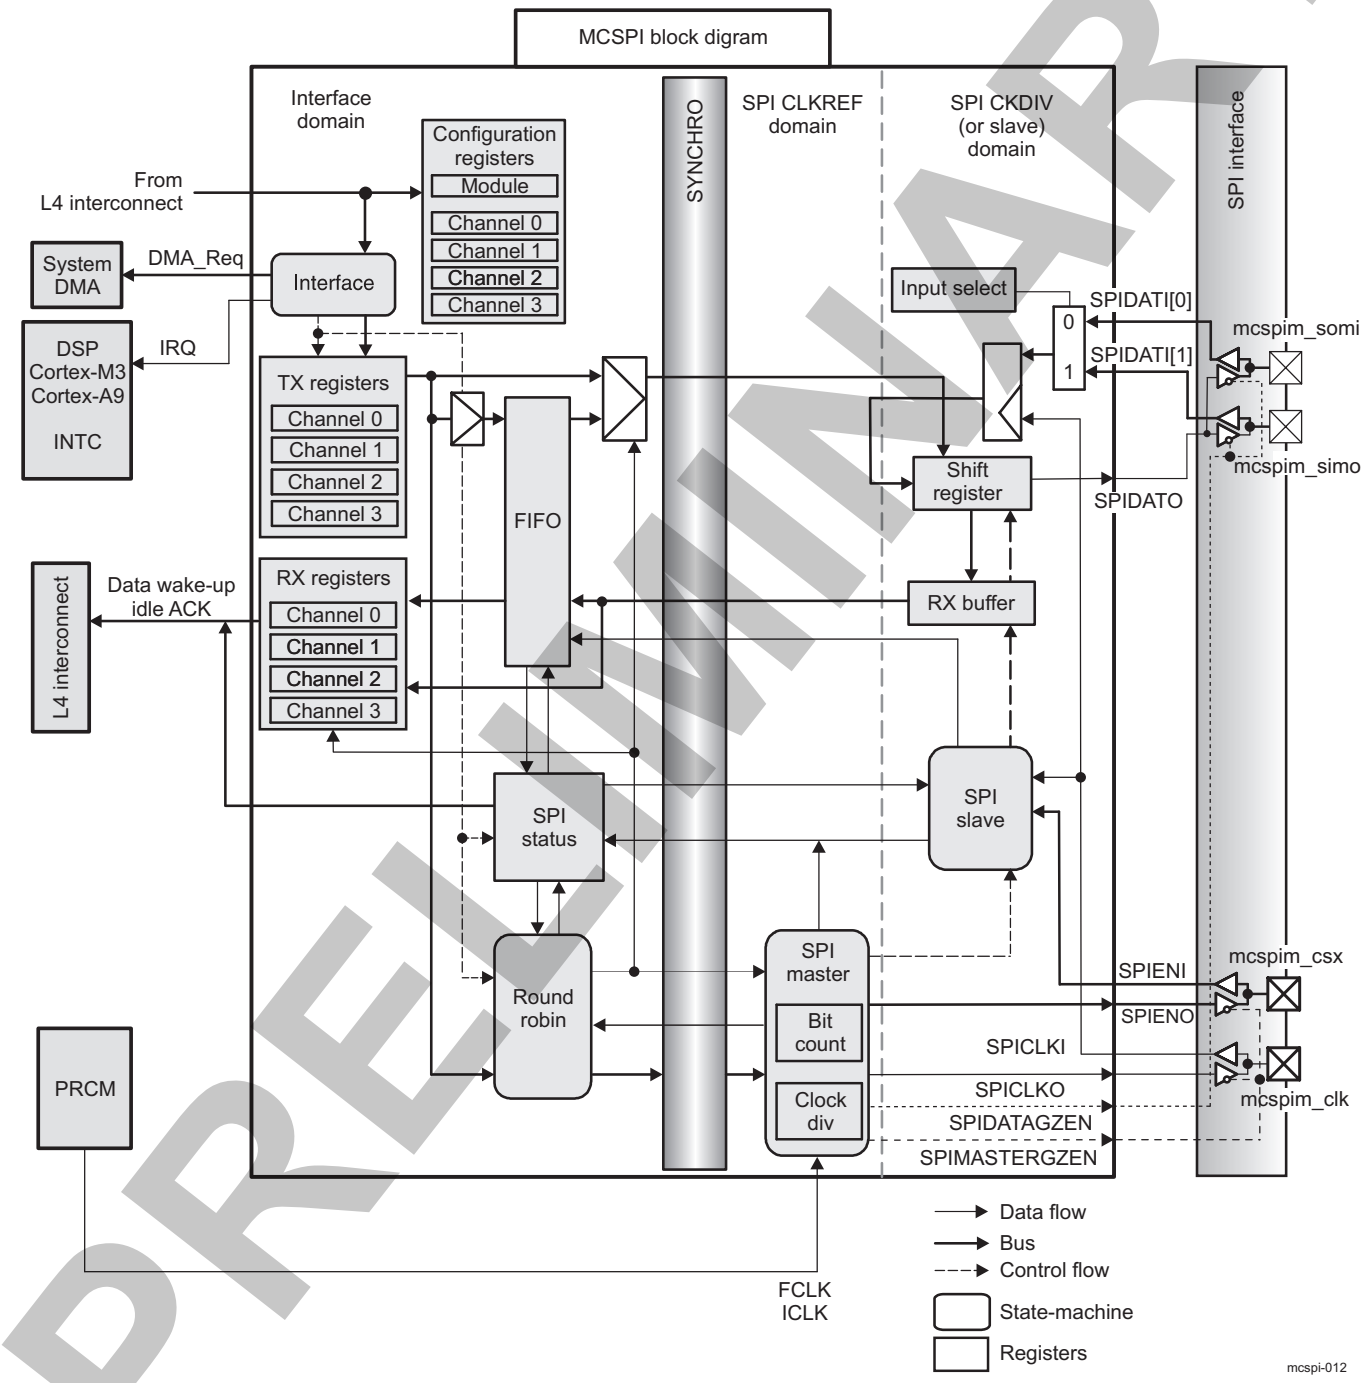
23.4.4 MCSPI Functional Description

23.4.4.1 MCSPI Block Diagram

Figure 23-87 shows the MCSPI module.

Figure 23-87. MCSPI Block Diagram



23.4.4.2 Master Mode

23.4.4.2.1 Master Mode Features

The MCSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The MCSPI initiates a data transfer on the data lines (mcspim_simo and mcspim_somi) and generates clock (mcspim_clk) and control (mcspim_csx) signals.

Connected to multiple external devices, the MCSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of MCSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information about interrupts, see Section 23.4.4.5.1, *Interrupt Events in Master Mode*).

23.4.4.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on mcspim_simo) and received (shifted in serially on mcspim_somi) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field).

Channel access to the shift registers for transmission/reception is based on the MCSPI_TXx transmitter register state, the MCSPI_RXx receiver register state, and round-robin arbitration.

Channels that meet the following rules are included in the round-robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

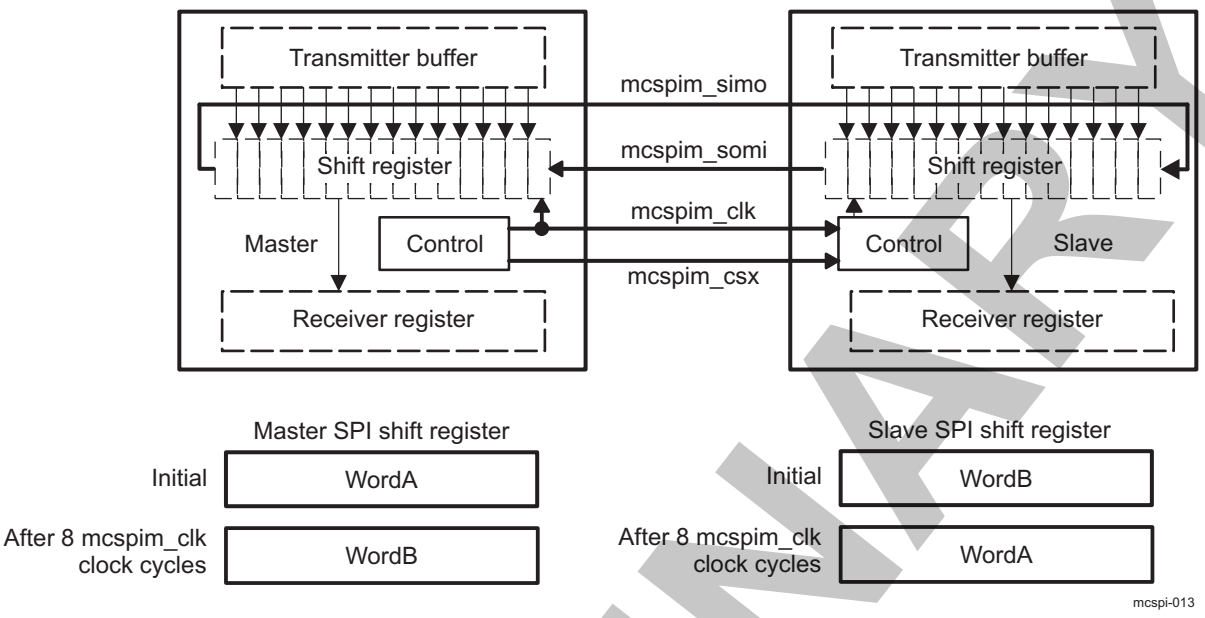
- Rule 1: Only enabled channels (the SPIm.MCSPI_CHxCTRL[0] EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its MCSPI_TXx transmitter register is not empty (the SPIm.MCSPI_CHxSTAT[1] TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the MCSPI_TXx register is empty when the shift register is assigned, the TXx_UNDERFLOW event is activated, and the next enabled channel with new data to transmit is scheduled (see also transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) when the shift register is assigned (see also receive-only mode). Therefore, the MCSPI_RXx register cannot be overwritten. The SPI1.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set to this mode.

When SPI word transfer completes (the SPIm.MCSPI_CHxSTAT[2] EOT bit is set), the updated MCSPI_TXx register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (mcspim_clk) synchronizes shifting and sampling of the information on the two serial data lines (mcspim_simo and mcspim_somi). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

Figure 23-88 shows an example of a full-duplex system with a master device (MCSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock mcspim_clk, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 23-88. SPI Full-Duplex Transmission (Example)



23.4.4.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the microprocessor unit (MPU) from reading the MCSPI_RXx register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field). Transmission starts only after data is loaded into the MCSPI_TXx register.

Rule 1 and Rule 2, defined in Section 23.4.4.2.2, apply in this mode.

Rule 3, defined in Section 23.4.4.2.2, does not apply.

In master transmit-only mode, the MCSPI_RXx register state FULL does not prevent transmission and the MCSPI_RXx register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the RX0_OVERFLOW bit in the SPIm.MCSPI_IRQSTATUS register is never set in this mode.

The hardware automatically disables the RX_FULL interrupt and the DMA read requests.

The transfer status is given by the SPIm.MCSPI_CHxSTAT[2] EOT bit.

23.4.4.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the MCSPI_TXx register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field).

The master receive-only mode enables channel scheduling only on the empty state of the MCSPI_RXx register.

Rule 1 and Rule 3, defined in Section 23.4.4.2.2, apply in this mode.

Rule 2, defined in Section 23.4.4.2.2, does not apply.

In the master receive-only mode, software must write dummy data to the MCSPI_TXx register. Only one dummy write is enough to receive any number of words from the slave. Software must ensure that the MCSPI_TXx register is always full (the TXx_EMPTY bits of SPIm.MCSPI_IRQSTATUS) when receiving. The content of the MCSPI_TXx register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the MCSPI_TXx register, the TXx_EMPTY and TXx_UNDERFLOW bits in the SPIm.MCSPI_IRQSTATUS register are never set in receive-only mode.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the status of serialization. The RXx_FULL bits of the SPIm.MCSPI_IRQSTATUS register are set when received data is loaded from the shift register to the corresponding MCSPI_RXx register. The SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

23.4.4.2.5 Single-Channel Master Mode

When the MCSPI is configured as a master device with a single enabled channel, the assertion of the mcspim_csx signal can be controlled in two different ways:

- If the MCSPI_MODULCTRL[0] SINGLE bit is set to 0, mcspim_csx assertion and deassertion after each SPI word is automatically controlled by the MCSPI (see the subsections of Section 23.4.4.2.1, *Master Mode Features*).
- If the MCSPI_MODULCTRL[0] SINGLE and MCSPI_CHxCONF[20] FORCE bits are set to 1, mcspim_csx assertion and deassertion is controlled by software (see Section 23.4.4.2.5.1, *Programming Tips When Switching to Another Channel*).

23.4.4.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for the SPI word transfer to complete (wait until the SPIm.MCSPI_CHxSTAT[2] EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel, and then enable the other channel.

23.4.4.2.5.2 Force mcspim_csx Mode

Continuous transfers are allowed manually by keeping the mcspim_csx signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the mcspim_csx line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the mcspim_csx active mode is supported when:

- A single channel is used (with the SPIm.MCSPI_MODULCTRL[0] SINGLE bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (SPIm.MCSPI_CHxCONF).

  The state of the mcspim_csx signal is programmable:

  – Writing 1 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the mcspim_csx line high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. mcspim_csx is driven low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.

  – Writing 0 to the SPIm.MCSPI_CHxCONF[20] FORCE bit drives the mcspim_csx line low when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 0. mcspim_csx is driven high when the SPIm.MCSPI_CHxCONF[6] EPOL bit is set to 1.

- A single channel is enabled (the SPIm.MCSPI_CHxCTRL[0] EN bit is set to 1). The first enabled channel activates the mcspim_csx line.

When the channel is enabled, the mcspim_csx signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the MCSPI_TXx register (the SPIm.MCSPI_CHxSTAT[1] TXS bit), the status of the MCSPI_RXx register (the SPIm.MCSPI_CHxSTAT[1] RXS bit), and the defined mode (the SPIm.MCSPI_CHxCONF[13:12] TRM bit field) of the channel enabled.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULL bit in the SPIm.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the mcspim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, mcspim_csx polarity and mcspim_clk phase and mcspim_clk polarity must not be modified when the mcspim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration to another (for instance, from transmit-only to receive-only) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI_CHxCTRL[0] EN bit set to 0) and mcspim_csx can be forced to its INACTIVE state using the SPIm.MCSPI_CHxCONF[20] FORCE bit.

Figure 23-89 and Figure 23-90 show successive transfers with mcspim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 23-89. Continuous Transfers With mcspim_csx Maintained Active (Single-Data-Pin Interface Mode)

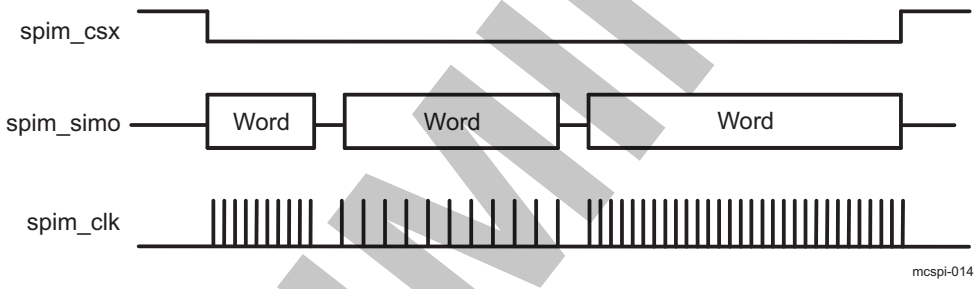


Figure 23-90. Continuous Transfers With mcspim_csx Maintained Active (Dual-Data-Pin Interface Mode)

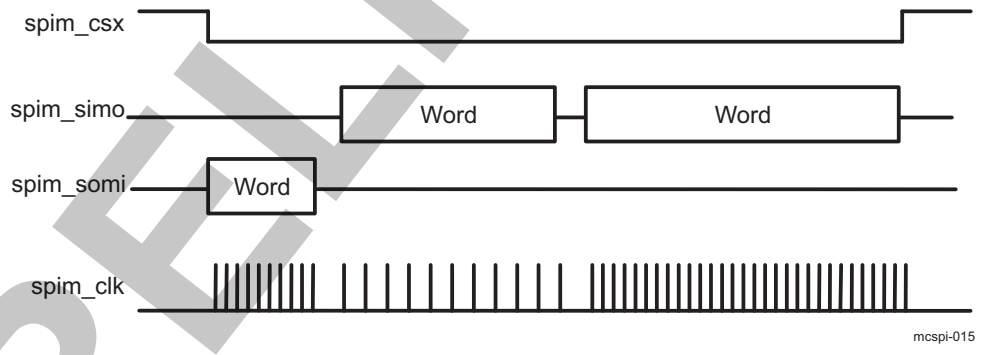


NOTE: Turbo mode, described in Section 23.4.4.2.5.3, *Turbo Mode*, maintains mcspim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel (the SPIm.MCSPI_CHxCONF[19] TURBO bit is set to 1).

23.4.4.2.5.3 Turbo Mode

Turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the MCSPI_RXx register are full. Turbo mode is time saving when a transfer exceeds two words. This mode is programmable per channel (through the SPI1.MCSPI_CHxCONF[9] TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 apply, but Rule 3 does not (see Section 23.4.4.2.2, *Master Transmit-and-Receive Mode (Full Duplex)*). An enabled channel can be scheduled if its receive register is full (the SPIm.MCSPI_CHxSTAT[0] RXS bit) when the shift-register is assigned until the shift register is full.

The MCSPI_RXx register cannot be overwritten in turbo mode. Consequently, the SPIm.MCSPI_IRQSTATUS[3] RX0_OVERFLOW bit is never set in this mode.

23.4.4.2.6 Start-Bit Mode

In start-bit mode, an extended bit is added before the SPI word to indicate whether the next SPI word must be handled as a command or as data. This feature is available only in master mode. Start-bit mode cannot be used at the same time as turbo mode and/or force mcspim_csx mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The polarity of the extended bit is programmable per channel. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 0, the SPI word must be handled as a command. When the SPIm.MCSPI_CHxCONF[24] SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start-bit transfer without disabling the channel for reconfiguration; in this case, users must configure the SPIm.MCSPI_CHxCONF[24] SBPOL bit before writing the SPI word to be transmitted to the TX register.

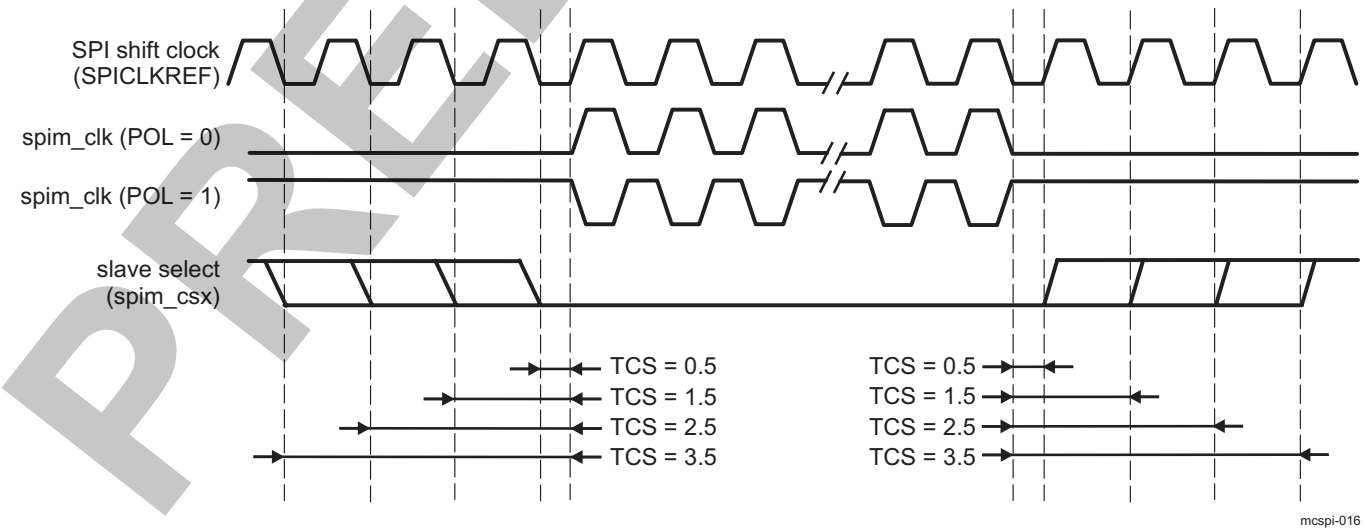
23.4.4.2.7 Chip-Select Timing Control

The chip-select (CS) timing control is available only in master mode with automatic CS generation (the MCSPI_MODULCTRL[0] SINGLE bit set to 0) to add a programmable delay between CS assertion and first clock edge, or CS removal and last clock edge.

This mode is programmable per channel (the SPIm.MCSPI_CHxCONF TCS bit).

Figure 23-91 shows the CS SPIEN timing controls.

Figure 23-91. CS SPIEN Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between CS assertion and the first clock edge with PHA = 1 or between CS removal and the last clock edge with PHA = 0.

23.4.4.2.8 Programmable SPI Clock (mcspim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field) to generate the bit rate of the serial output clock mcspim_clk. Table 23-271 summarizes the supported divisor values.

Table 23-271. SPI Master Clock Rates

Divider	Clock Rate
1	48 MHz
2	24 MHz
4	12 MHz
8	6 MHz
16	3 MHz
32	1.5 MHz
64	750 kHz
128	375 kHz
256	~187 kHz
512	~93.7 kHz
1024	~46.8 kHz
2048	~23.4 kHz
4096	~11.7 kHz
8192 and higher: Division not supported	–

23.4.4.2.8.1 Clock Ratio Granularity

By default, the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power-of-2 granularity leading to a clock division in the range 1 to 4096; in this case, the duty cycle is always 50 percent. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle; in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit-wide division ratio in the range 1 to 4096.

When granularity is one clock cycle (the CLKG bit set to 1), for the odd value of the clock ratio, the clock high level lasts one clock cycle more than the low level, depending on the SPIm.MCSPI_CHxCONF[1] POL and SPIm.MCSPI_CHxCONF[0] PHA bits (see Table 23-272).

Table 23-272. CLKSPIO High/Low Time Computation

Clock Ratio F_{RATIO}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{HIGH_REF}	T_{LOW_REF}
Even >= 2	T_ref * (F_{RATIO}/2)	T_ref * (F_{RATIO}/2)
Odd >= (POL = PHA)	T_ref * (F_{RATIO}– 1)/2	T_ref * (F_{RATIO} + 1)/2
Odd >= (POL =! PHA)	T_ref * (F_{RATIO}+ 1)/2	T_ref * (F_{RATIO} – 1)/2

NOTE: F_{RATIO} = spi1_clk frequency (F_{OUT}) division ratio
T_{HIGH} = spi1_clk high time period
T_{LOW} = spi1_clk low time period
T_ref = SPI1_FCLK period
T_{HIGH_REF} = SPI1_FCLK high time period
T_{LOW_REF} = SPI1_FCLK low time period

If the CLKG bit is set to 1; F_{RATIO} = EXTCLK concatenated with CLKD + 1.

For odd ratio values, the duty cycle is calculated as follows:

Duty_cycle = $(1 – 1/F_{RATIO})/2$

Table 23-273 shows examples of clock granularity with a clock source frequency of 48 MHz.

Table 23-273. Clock Granularity Examples

EXTCLK	CLKD	CLKG	F_{RATIO}	PHA	POL	T_{HIGH} (ns)	T_{LOW} (ns)	T_{PERIOD} (ns)	Duty Cycle	F_{OUT} (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50–50	48
X	1	0	2	X	X	20.8	20.8	41.6	50–50	24
X	2	0	4	X	X	41.6	41.6	83.2	50–50	12
X	3	0	8	X	X	83.2	83.2	166.4	50–50	6
0	0	1	1	X	X	10.4	10.4	20.8	50–50	48
0	1	1	2	X	X	20.8	20.8	41.6	50–50	24
0	2	1	3	1	0	41.6	20.8	62.4	66–33	16

23.4.4.3 Slave Mode

To select the MCSPI slave mode, set the SPIm.MCSPI_MODULCTRL[2] MS bit.

A MCSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the MCSPI initiates data transfer on the data lines (mcspim_simo and mcspim_somi) when it is selected by an active control signal (mcspim_csx) and receives an SPI clock (mcspim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the MCSPI uses the edge of mcspim_csx to detect word length. For this reason, mcspim_csx must become inactive between each word.

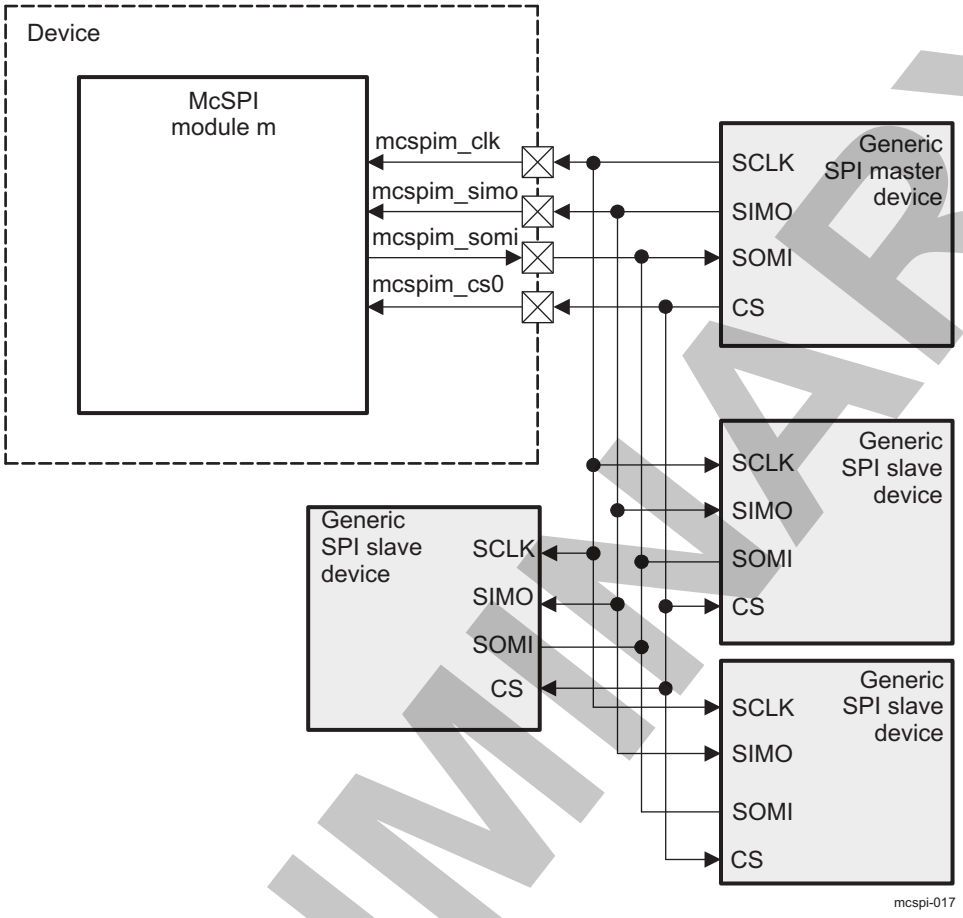
The MCSPI does not support mcspim_csx active between SPI words. It uses the edge to detect word length.

23.4.4.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section, register names such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL, where x = 0 (channel 0 control register).

Figure 23-92 shows an example of four slaves wired on a single master device.

Figure 23-92. Example of MCSPI Slave With One Master and Multiple Slave Devices on Channel 0



Channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI_CHxCTRL[0] EN bit (where x = 0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected on any of the mcspim_csx ports. This is programmable with the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field (where x = 0).
- Its own transmitter register, SPIm.MCSPI_TXx (where x = 0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the SPIm.MCSPI_CHxSTAT[1] TXS bit (where x = 0) is set. If MCSPI is selected by an external master (the active signal on the mcspim_csx port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before MCSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI_RXx (where x = 0), on top of the common receive shift register. If the MCSPI_RXx register is full, the SPIm.MCSPI_CHxSTAT[0] RXS bit (where x = 0) is set.

NOTE: The MCSPI_TXx and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm. MCSPI_CHxCONF register (where x = 0):
  - Transmit and receive modes, programmable with the TRM field
  - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)

- SPI word length, programmable with the WL bit
- mcspim_csx polarity, programmable with the EPOL bit
- mcspim_clk polarity, programmable with the POL bit
- mcspim_clk phase, programmable with the PHA bit

The mcspim_clk frequency of a transfer is controlled by the external SPI master connected to the MCSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD bit field (where x = 0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (where x = 0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of MCSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (where x = 0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (where x = 0) for writing.
- Four interrupt events (see Section 23.4.4.5.2, *Interrupt Events in Slave Mode*)

23.4.4.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before MCSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When the SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register (see Section 23.4.4.5.2, *Interrupt Events in Slave Mode*).

23.4.4.3.3 Slave Transmit-Only Mode

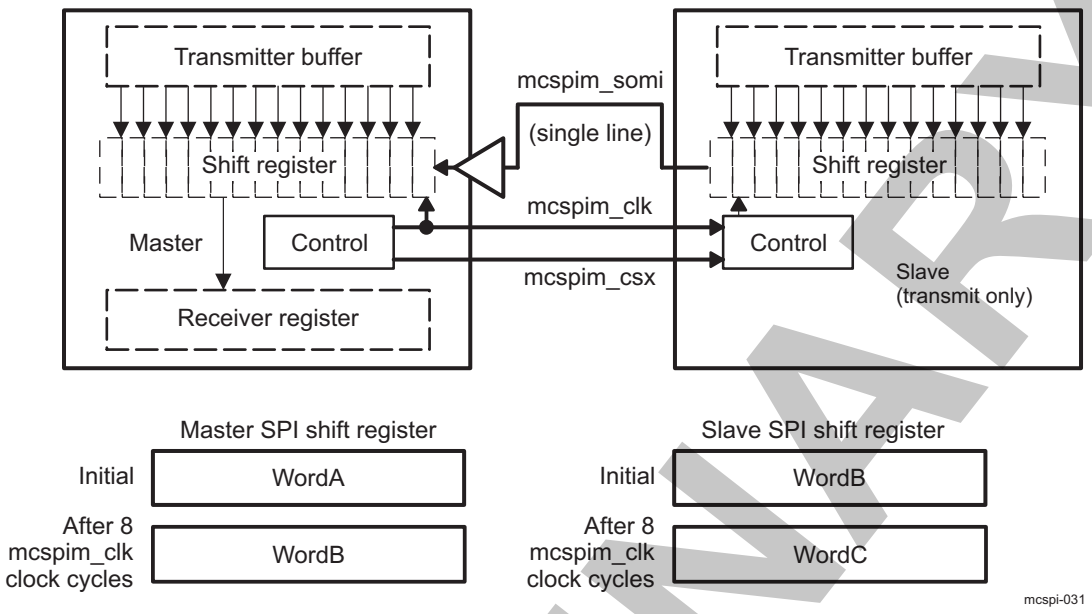
The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the MCSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the state of the MCSPI_RXx register.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (where x = 0).

Figure 23-93 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave, 1 bit transfers in the master. After eight cycles of the serial clock mcspim_clk, WordB transfers from the slave to the master.

Figure 23-93. SPI Half-Duplex Transmission (Transmit-Only Slave)



23.4.4.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM bit field [where x = 0] to 0x1).

In receive-only mode, the MCSPI_TXx register must be loaded before the MCSPI is selected by an external SPI master device. The MCSPI_TXx register content is always loaded into the shift register whether it is updated or not. The TXx_UNDERFLOW event is activated accordingly and does not prevent transmission.

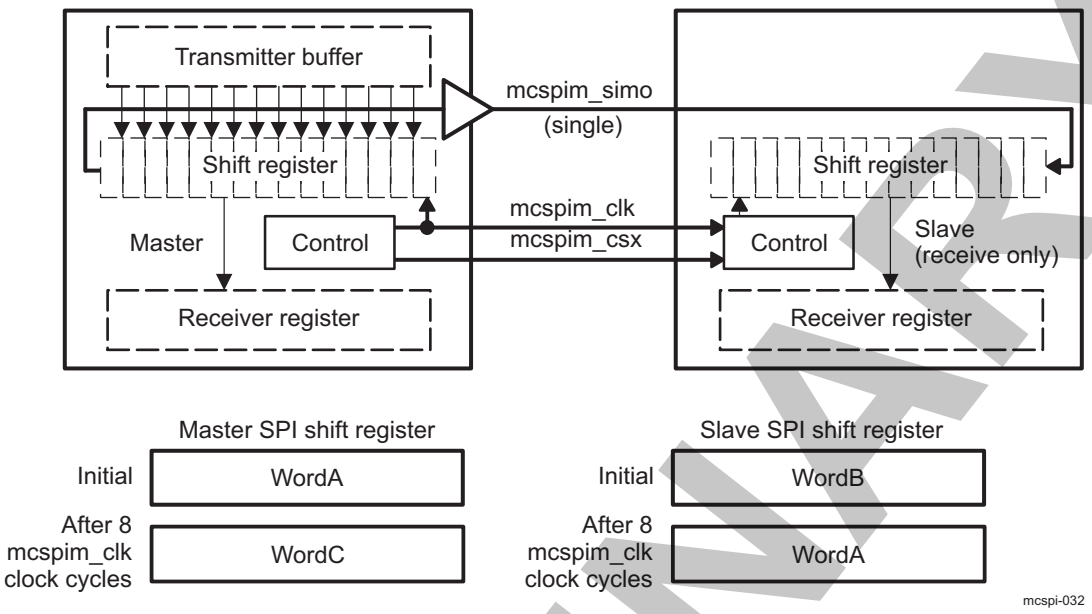
When the SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit [where x = 0] is set to 1), the received data is transferred to the channel receive register.

To use the MCSPI as a slave receive-only device, the TXx_EMPTY and TXx_UNDERFLOW interrupts and the DMA write requests must be disabled due to the state of the MCSPI_TXx register.

For a full-duplex transmission, the serial clock (mcspim_clk) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If mcspim_clk synchronizes on a single serial data line, the data line should be half-duplex.

Figure 23-94 shows a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock mcspim_clk, WordA transfers from the master to the slave.

Figure 23-94. SPI Half-Duplex Transmission (Receive-Only Slave)



23.4.4.4 FIFO Buffer Management

The MCSPI controller has a built-in 64-byte buffer to unload the DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at a time and is selected by setting the SPIm.MCSPI_CHxCONF[28] FFER or SPIm.MCSPI_CHxCONF[27] FFEW bit to 1. If several channels are selected and several FIFO enable bit fields are set to 1, the controller forces the buffer not to be used; the driver must set only one FIFO enable bit field.

The buffer can be used in the following modes:

- Master or slave mode
- Transmit-only, receive-only, or transmit-and-receive mode
- Single channel or turbo mode, or normal round-robin mode. In round-robin mode the buffer is used by only one channel.

Every word length (SPIm.MCSPI_CHxCONF[11:7] WL) is supported.

In transmit-and-receive mode, the buffer can be used in transmit (see Figure 23-95) or receive (see Figure 23-96) directions, or in both directions. If only one direction is chosen in transmit-and-receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction (see Figure 23-97).

Figure 23-95. Buffer Used in Transmit Direction Only

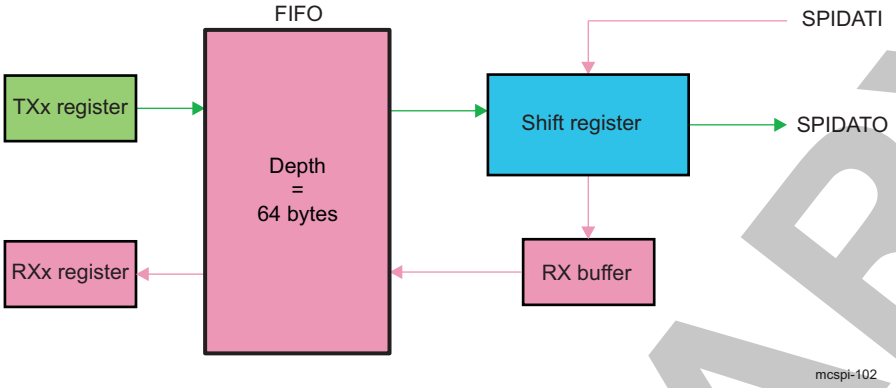


Figure 23-96. Buffer Used in Receive Direction Only

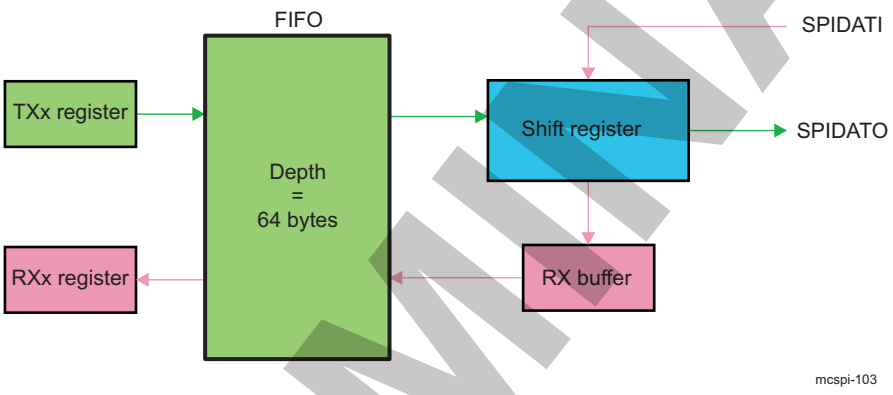

Figure 23-97. Buffer Used for Transmit and Receive Directions

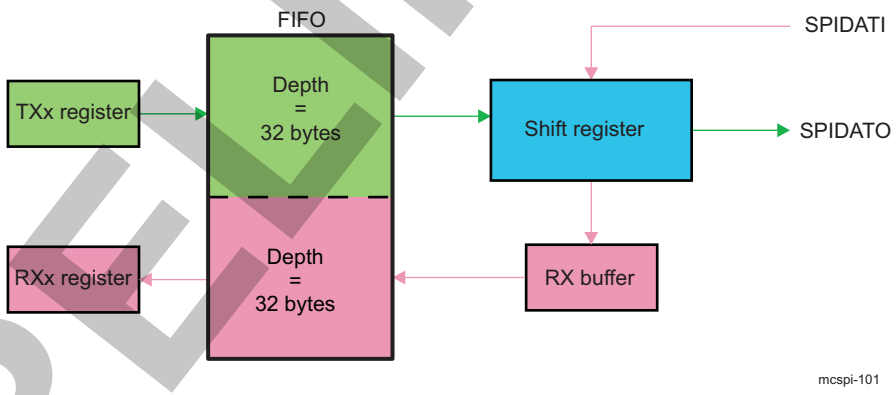


Two levels (SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL) rule the buffer management. The granularity of these levels is 1 byte; it is not aligned with the SPI word length. The driver must set these values as a multiple of the SPI word length defined in WL. Table 23-274 lists the number of bytes written in the FIFO, depending on the word length.

Table 23-274. FIFO Writes, Word Length Relationship

SPI Word Length WL	3 <= WL<= 7	8 <= WL <= 15	16 <= WL <= 31
Number of bytes written in the FIFO	1 byte	2 bytes	4 bytes

The FIFO buffer pointers are reset when the corresponding channel is enabled or the FIFO configuration changes.

23.4.4.4.1 Buffer Almost Full

The MCSPI_XFERLEVEL[15:8] AFL bit field is needed when the buffer is used to receive an SPI word from a slave (the MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the almost-full buffer status. See Figure 23-98.

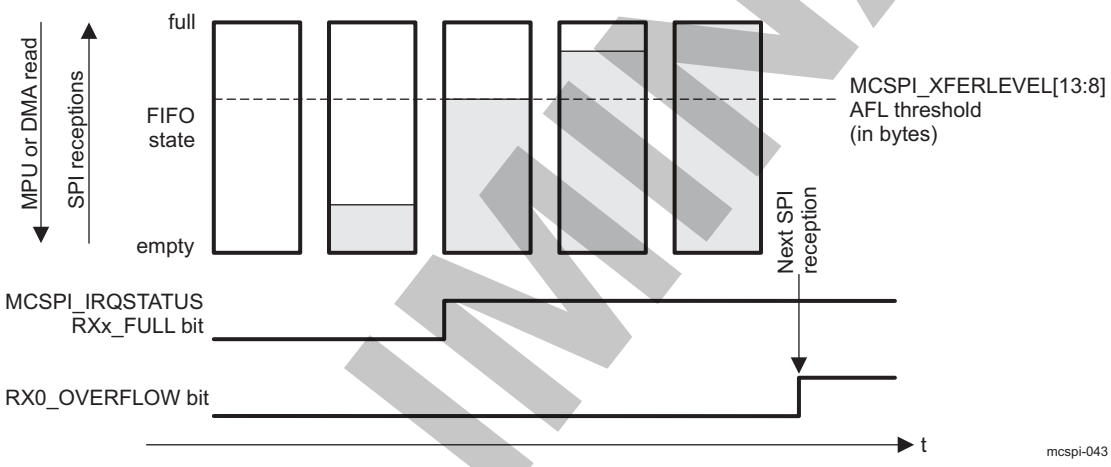
When the FIFO pointer reaches this level, an interrupt or a DMA request is sent to the MPU to enable the system to read AFL + 1 bytes from the receive register.

NOTE: AFL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first receive register read.

No new request is asserted again as long as the system has not performed the correct number of read accesses.

Figure 23-98. Buffer Almost Full Level (AFL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RXx request is asserted on the same conditions as the MCSPI_IRQSTATUS RXx_FULL flag.

23.4.4.4.2 Buffer Almost Empty

The MCSPI_XFERLEVEL[7:0] AEL bit field is needed when the buffer is used to transmit an SPI word to a slave (the MCSPI_CHxCONF[27] FFEW bit must be set to 1). It defines the almost-empty buffer status. See Figure 23-99.

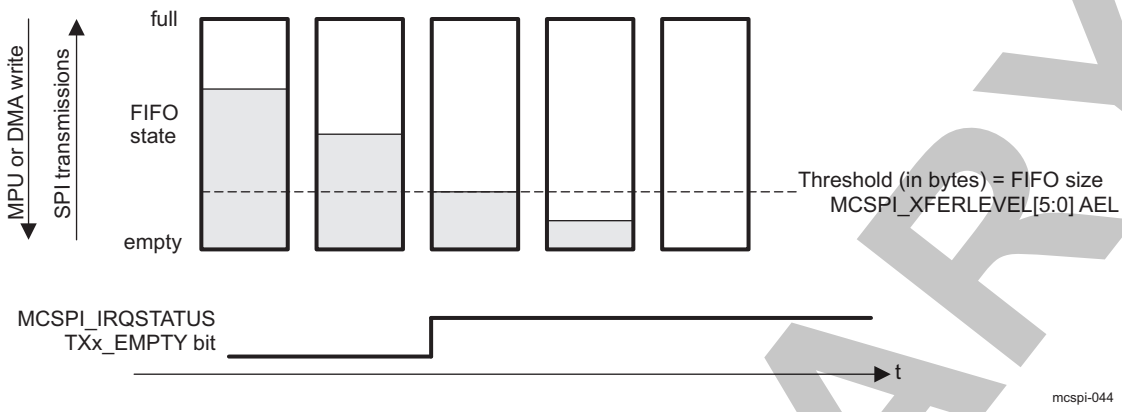
When the FIFO pointer does not reach this level, an interrupt or a DMA request is sent to the MPU to enable the system to write AEL + 1 bytes to the transmit register.

NOTE: AEL + 1 must correspond to a multiple value of the MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is deasserted after the first transmit register write.

No new request is asserted again as long as the system has not performed the correct number of write accesses.

Figure 23-99. Buffer Almost Empty Level (AEL)



NOTE: The MCSPI_IRQSTATUS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_TXx request is asserted on the same conditions as the MCSPI_IRQSTATUS TXx_EMPTY flag.

23.4.4.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user must previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter lets the controller stop the transfer correctly after a defined number of SPI word transfers. If WNCT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel; in this case, the user does not know how many SPI transfers have been done. For received words, software must poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx receive register to empty the FIFO buffer.

When the end-of-word count interrupt is generated (the MCSPI_IRQSTATUS[17] EOW bit is set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know the last SPI words in the FIFO buffer and read them.

No new request is asserted as long as the system has not performed the correct number of write accesses.

23.4.4.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, etc.) (where x = 0, 3) that indicate whether service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, etc.).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The MCSPI supports interrupt-driven and polling operations.

23.4.4.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the state of the MCSPI_RXx register is RXx_FULL.

23.4.4.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 23.4.4.2.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in the buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the MPU has not performed the number of writes into the MCSPI_TXx register defined by the MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the correct number of writes.

23.4.4.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the MCSPI_TXx register or the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register, because the channel is enabled. To avoid having a TXx_UNDERFLOW event, the MCSPI_TXx register must seldom be loaded.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

23.4.4.5.1.3 RXx_ FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register becomes filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_ FULL is asserted as soon as the number of bytes held in the FIFO to be read reaches the MCSPI_XFERLEVEL[13:8] AFL threshold.

The MCSPI_RXx register must be read to remove the source of the interrupt; the MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the correct number of reads.

23.4.4.5.1.4 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as MCSPI_XFERLEVEL[31:16] WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

23.4.4.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the state of the MCSPI_TXx register are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the state of the MCSPI_RXx are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the MCSPI_IRQSTATUS register.

23.4.4.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled (the MCSPI_CHxCONF[27] FFEW bit is set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event is asserted as long as the MPU has not performed the number of writes into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. The MPU must perform the correct number of writes.

23.4.4.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the MCSPI_TXx register is empty (not updated with new data) when an external master device starts a data transfer with the MCSPI (transmit and receive).

When FIFO is enabled, the data emitted while the underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data in the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when no data has been loaded into the MCSPI_TXx register because the channel is enabled.

The SPIm.MCSPI_IRQSTATUS TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

23.4.4.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the MCSPI_RXx register is being filled (transient event). When the FIFO buffer is enabled (the MCSPI_CHxCONF[28] FFER bit is set to 1), RXx_FULL is asserted as soon as the number of bytes held in the buffer to read defined by the MCSPI_XFERLEVEL[13:8] AFL bit field.

The MCSPI_RXx register must be read to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event is asserted as long as the MPU has not performed AFL + 1 reads into MCSPI_RXx. The MPU must perform the correct number of reads.

23.4.4.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in transmit-and-receive mode or receive-only mode when a channel is enabled and the MCSPI_RXx register or FIFO is full when a new SPI word is received. The MCSPI_RXx register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO are overwritten; it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW event indicates an error (data loss) in slave mode.

The MCSPI_IRQSTATUS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

23.4.4.5.2.5 End Of Word Count

The MCSPI_IRQSTATUS[17] EOW event (end of word count) is activated when the channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller performs the number of transfers defined in the MCSPI_XFERLEVEL[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The end of word count interrupt also indicates that the SPI transfer is halted on the channel using the FIFO buffer as soon as WCNT is not reloaded and the channel is not re-enabled.

The MCSPI_IRQSTATUS[17] EOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

23.4.4.5.3 Interrupt-Driven Operation

An interrupt enable bit in the SPIm.MCSPI_IRQENABLE register can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

1. Read the SPIm.MCSPI_IRQSTATUS register to identify which event occurred.
2. Read the MCSPI_RXx register that corresponds to the event to remove the source of an RXx_FULL event or write into the MCSPI_TXx register that corresponds to the event to remove the source of a TXx_EMPTY event. No action is required to remove the source of the WKS (wake-up), TXx_ UNDERFLOW, and RX0_OVERFLOW events.
3. Set the corresponding bit of the SPIm.MCSPI_IRQSTATUS register to 1 to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

23.4.4.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.MCSPI_IRQENABLE register, the interrupt line is not asserted, but the status bits in the SPIm.MCSPI_IRQSTATUS register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- RXx_FULL: To remove the source of the event, the MPU must read the corresponding MCSPI_RXx register.
- TXx_EMPTY: To remove the source of the event, the MPU must write into the corresponding MCSPI_TXx register.
- WKS (wake-up), TXx_UNDERFLOW, and RX0_OVERFLOW: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.MCSPI_IRQSTATUS register to 1. This does not affect the interrupt line state.

23.4.4.6 DMA Requests

The DMA_SYSTEM controller module manages DMA accesses. The DMA_SYSTEM controller reduces the MPU charge for data transfers.

Each MCSPI channel, if enabled, can issue DMA requests. There are two DMA request lines per MCSPI channel (one for read and one for write).

The DMA read request line is asserted when the MCSPI channel is enabled and new data is available in the receive register of the MCSPI channel. A DMA read request can be individually masked with the SPI1.MCSPI_CHxCONF[15] DMAR bit. The DMA read request line is deasserted when reading of the MCSPI_RXx register of the MCSPI channel completes.

The DMA write request line is asserted when the MCSPI channel is enabled and the MCSPI_TXx register of the MCSPI channel is empty. A DMA write request can be individually masked with the SPI1.MCSPI_CHxCONF[14] DMAW bit. The DMA write request line is deasserted when loading of the MCSPI_TXx register of the channel completes.

23.4.4.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The MCSPI is compliant with the idle and wake-up system handshake protocol.

23.4.4.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogated) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.MCSPI_SYSCONFIG[0] AUTOIDLE bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the MCSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the MCSPI is selected by the external master.

23.4.4.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clock, the PRCM module automatically launches a hardware handshake protocol to ensure that the MCSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the MCSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the MCSPI module acknowledges the PRCM IDLE request is configurable through the MCSPI.SYSCONFIG[4:3] SIDLEMODE bit field.

The settings of the SIDLEMODE bit field and the related acknowledgment modes are:

- Force-idle mode (the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0): The MCSPI module acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit field is set to 0x1): The MCSPI never acknowledges an IDLE request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit field is set to 0x2): The MCSPI acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for efficient system power management.

When configured in smart-idle mode, the MCSPI also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, CORE_L4_ICLK, neither clock, or both clocks).

The setting of the CLOCKACTIVITY bit field is used internally to the MCSPI to determine on which part of the module the conditions to acknowledge the PRCM IDLE request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM IDLE request, the MCSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some MCSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if the MCSPI acknowledges an IDLE request.

The settings of the CLOCKACTIVITY bit field and the associated features are:

- CLOCKACTIVITY set to 00: ICLK off and FCLK off, ICLK and FCLK are considered for generating the acknowledge. This setting also means that FCLK and ICLK are likely to be shut down on a PRCM IDLE request.
- CLOCKACTIVITY set to 01: ICLK on and FCLK off, ICLK is not shut down on a PRCM IDLE request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK off and FCLK on, FCLK is not shut down on a PRCM IDLE request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK on and FCLK on, none of the clocks are shut down. This means the MCSPI can potentially acknowledge the IDLE request without checking the internal functions linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, software must ensure consistent programming between CLOCKACTIVITY and the CORE_48M_FCLK and CORE_L4_ICLK control bits in the PRCM module. If the MCSPI is disabled in the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the MCSPI clocks. This can lead to unpredictable behavior.

23.4.4.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch back the interface clock and the functional clock. A wakeup is requested when channel 0 is enabled and an asynchronous selection occurs on the mcspim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF[22:21] SPIENSLV bit field [where x = 0] in the register table description).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- Before the beginning of the second SPI word serialization when the McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- Before the end of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (where x = 0) before the completion of the second SPI word serialization.

Table 23-275 lists the supported cases in smart-idle mode.

Table 23-275. Smart-Idle Mode and Wake-Up Capabilities

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Master	Must be maintained	Must be maintained	Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode	No wake-up event

Table 23-275. Smart-Idle Mode and Wake-Up Capabilities (continued)

Mode	Interface Clock	SPI Clock Ref	Functionality	Wake-Up Event
Slave	Can be switched off	Can be switched off	An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode.	The module asynchronously sends a wake-up request if an event on the mcspim_csx port associated with channel 0 is detected.

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

23.4.4.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The MCSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wakeup; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable and disable controls, accessible through the SPIm.MCSPI_IRQENABLE and SPIm.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSPI_IRQSTATUS is updated with the event causing the wakeup; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

23.4.4.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.
  - In force-idle mode, the MCSPI responds unconditionally to the IDLE request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set.
  - The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSPI_IRQSTATUS register.
  - In force-idle mode, because the module must be disabled, the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the MCSPI can be switched off.
  - An IDLE request during an SPI data transfer can lead to an unexpected and unpredictable result. Software must avoid such a request.
- The module exits force-idle mode through the idle and wake-up hardware handshake protocol.

  The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

23.4.5 MCSPI Programming Guide

23.4.5.1 MCSPI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the MCSPI module.

23.4.5.1.1 Global Initialization

23.4.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the I^2C module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the I^2C. For further information, see Section 23.1.2, *HS I^2C Environment* Section 23.1.3, *and HS I^2C Integration*.

For more information, see Section 23.4.3, *MCSPI Integration*.

Table 23-276 lists the information on the global initialization of the surrounding modules.

Table 23-276. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	MCSPI_FCLK functional clock must be enabled. See Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
L4 Interconnect	For information about L4_PER interconnect configuration, see Section 14.3, *L4 Interconnects*, in Chapter 14, *Interconnect*.
DMA_SYSTEM	DMA configuration must be done to enable the module DMA channel requests. See Chapter 16, *DMA_SYSTEM*.
MPU INTC	Cortex-A15 MPU, Cortex-M4 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A15 MPU or Cortex-M4 MPU, or in Section 5.3.2.6, *DSP INTC*, in Chapter 5, *DSP Subsystem*.

23.4.5.1.1.2 MCSPI Global Initialization

23.4.5.1.1.2.1 Main Sequence – MCSPI Global Initialization

This procedure initializes the MCSPI module after a POR or software reset.

Table 23-277. MCSPI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset.	SPIm.MCSPI_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished?	SPIm.MCSPI_SYSSTATUS[0] RESETDONE	=0x1

23.4.5.1.2 Operational Mode Configuration

23.4.5.1.2.1 MCSPI Operational Modes

The selection of the working mode is done with the SPIm.MCSPI_CHxCONF register. Table 23-278 through Table 23-280 list the possible operating modes and their configurations.

Table 23-278. MCSPI Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set receive mode.	SPIm.MCSPI_CHxCONF[13:12] TRM	0x1
Set the word length.	SPIm.MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	SPIm.MCSPI_MODULCTRL[2] MS SPIm.MCSPI_CHxCTRL[0] EN	0x0 0x1

Table 23-278. MCSPI Receive Mode Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Channels activated low during ACTIVE state	SPIm.MCSPI_CHxCONF[6] EPOL	0x1
Clock held low during INACTIVE state	SPIm.MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	SPIm.MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	SPIm.MCSPI_IRQSTATUS	0x0

Table 23-279. MCSPI Transmit Mode Initialization

Step	Register/Bit Field/Programming Model	Value

Reset the status bits.	SPIm.MCSPI_IRQSTATUS	0x0

Table 23-280. MCSPI Transmit-and-Receive Mode Initialization

Step	Register/Bit Field/Programming Model	Value
Set transmit and receive mode.	SPIm.MCSPI_CHxCONF[13:12] TRM	0x0
Set the word length.	SPIm.MCSPI_CHxCONF[11:7] WL	0x8
Clock initialization and channel enabling	SPIm.MCSPI_MODULCTRL[2] MS SPIm.MCSPI_CHxCTRL[0] EN	0x0 0x1
Channels activated low during ACTIVE state	SPIm.MCSPI_CHxCONF[6] EPOL	0x1
Clock held low during INACTIVE state	SPIm.MCSPI_CHxCONF[1] POL	0x0
Data latched on odd-numbered edges of the SPI clock	SPIm.MCSPI_CHxCONF[0] PHA	0x0
Reset the status bits.	SPIm.MCSPI_IRQSTATUS	0x0

23.4.5.1.2.1.1 Common Transfer Procedures Without FIFO – Polling Method

23.4.5.1.2.1.1.1 Receive-Only Procedure – Polling Method

Table 23-281 lists the receive-only procedure using the polling method. The MCSPI is acting as slave.

Table 23-281. Receive-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode	See Table 23-278.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until receive register is full?	SPIm.MCSPI_RXx	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

23.4.5.1.2.1.1.2 Receive-Only Procedure – Interrupt Method

Table 23-282 lists the receive-only procedure using the interrupt method. The MCSPI is acting as slave.

Table 23-282. Receive-Only Procedure – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-278.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x1
Read the status register.	SPIm.MCSPI_IRQSTATUS[2] RX_FULL	0x0
Disable the interrupt.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read the receiver register.	SPIm.MCSPI_RXx	xxxx

23.4.5.1.2.1.1.3 Transmit-Only Procedure – Polling Method

Table 23-283 lists the transmit-only procedure using the polling method. The MCSPI is acting as master.

Table 23-283. Transmit-Only Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-279	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2:1]	=0x2
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

23.4.5.1.2.1.1.4 Transmit-and-Receive Procedure – Polling Method

Table 23-283 lists the transmit-and-receive procedure using the polling method. The MCSPI is acting as master and slave.

Table 23-284. Transmit-and-Receive Procedure – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-280.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until transmit/receive word?	SPIm.MCSPI_CHxSTAT[2:0]	=0x3
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

23.4.5.1.3 Common Transfer Procedures With FIFO – Polling Method

When using FIFO the MCSPI module can start the transfer only after the first write request is released by writing the MCSPI_TXx register. The first write request can be managed by the IRQ routine or DMA handler. The end of transfer is more complex and depends on the transfer type. See Table 23-283 through Table 23-290.

23.4.5.1.3.1 Receive-Only Procedure With Word Count – Polling Method

Table 23-285. Receive-Only Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-278.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

23.4.5.1.3.2 Transmit-Only Procedure With and Without Word Count – Polling Method

Table 23-286. Transmit-Only Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-279.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

23.4.5.1.3.3 Transmit-Only Procedure With and Without Word Count – Interrupt Method

Table 23-287. Transmit-Only Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-279.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count.	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
End of transfer	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0
Disable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0

23.4.5.1.3.4 Transmit-and-Receive Procedure With Word Count – Polling Method

Table 23-288. Transmit-and-Receive Procedure With Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-280.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

23.4.5.1.3.5 Transmit-and-Receive Procedure With Word Count – Interrupt Method

Table 23-289. Transmit-and-Receive Procedure With Word Count – Interrupt Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-280.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Enable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x1
Enable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x1
End of word count?	SPIm.MCSPI_IRQSTATUS[17] EOW	=0x1
Clear the interrupt.	SPIm.MCSPI_IRQENABLE[17] EOW_ENABLE	=0x0

Table 23-289. Transmit-and-Receive Procedure With Word Count – Interrupt Method (continued)

Step	Register/Bit Field/Programming Model	Value
Disable the interrupt for the receiver register.	SPIm.MCSPI_IRQENABLE[4] TX_EMPTY_ENABLE	0x0
Disable the interrupt for the transmit register.	SPIm.MCSPI_IRQENABLE[2] RX_FULL_ENABLE	0x0
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

23.4.5.1.3.6 Transmit-and-Receive Procedure Without Word Count – Polling Method

Table 23-290. Transmit-and-Receive Procedure Without Word Count – Polling Method

Step	Register/Bit Field/Programming Model	Value
Configure the channel according to the mode.	See Table 23-280.	
Start the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x1
Wait until end of transfer?	SPIm.MCSPI_CHxSTAT[2] EOT SPIm.MCSPI_CHxSTAT[3] TXFFE	=0x1 =0x1
Stop the channel.	SPIm.MCSPI_CHxCTRL[0] EN	0x0
Read from the receiver register.	SPIm.MCSPI_RXx	xxxx

Description	Clock management configuration		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD																												IDLEMODE		FREEEMU	SOFTRESET

Bits	Field Name	Description	Type	Reset
31:4	RSVD		R	0x0000000
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's IDLE state follows (acknowledges) the system's IDLE requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only. 0x1: No-idle mode: local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wake-up events. 0x3: Smart-idle wake-up-capable mode: local target's IDLE state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. Mode is relevant only if the appropriate IP module "swake-up" output(s) is (are) implemented.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. 0x0: IP module is sensitive to emulation suspend. 0x1: IP module is not sensitive to emulation suspend.	RW	0
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Read 0x0: Reset done, no pending action Read 0x1: Reset (software or other) ongoing Write 0x1: Initiate software reset	RW	0

Table 23-301. MCSPI_SYSCONFIG

Address Offset	0x110		
Physical Address	0x4809 8110 0x4809 A110 0x480B 8110 0x480B A110	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register allows controlling various parameters of the OCP interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						CLOCKACTIVITY		RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reads returns 0	RW	0x000000
9:8	CLOCKACTIVITY	Clocks activity during wake-up mode period 0x0: OCP and functional clocks may be switched off. 0x1: OCP clock is maintained. Functional clock may be switched off. 0x2: Functional clock is maintained. OCP clock may be switched off. 0x3: OCP and functional clocks are maintained.	RW	0x0
7:5	RESERVED	Reads returns 0	RW	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the McSPI acknowledges it unconditionally and goes in inactive mode. Interrupt, DMA requests and wake-up lines are unconditionally deasserted and the module wake-up capability is deactivated even if the MCSPI_SYSCONFIG[EnaWakeUp] bit is set. 0x1: If an IDLE request is detected, the request is ignored and the module does not switch to wake-up mode, and keeps on behaving normally. 0x2: If an IDLE request is detected, the module will switch to wake-up mode based on its internal activity, and the wake-up capability can be used if the bit MCSPI_SYSCONFIG[EnaWakeUp] is set. 0x3: Reserved - do not use.	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled. 0x1: Wake-up capability is enabled.	RW	1
1	SOFTRESET	Software reset. During reads it always returns 0. 0x0: (write) Normal mode 0x1: (write) Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware.	RW	0
0	AUTOIDLE	Internal OCP clock-gating strategy 0x0: OCP clock is free-running. 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity.	RW	1

Table 23-311. MCSPI_SYST

Address Offset	0x124		
Physical Address	0x4809 8124 0x4809 A124 0x480B 8124 0x480B A124	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register is used to check the correctness of the system interconnect either internally to peripheral bus, or externally to device I/O pads, when the module is configured in system test (SYSTEST) mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																				SSB	SPIENDIR	SPIDATDIR1	SPIDATDIR0	WAKD	SPICLK	SPIDAT_1	SPIDAT_0	SPIEN_3	SPIEN_2	SPIEN_1	SPIEN_0

Bits	Field Name	Description	Type	Reset
31:12	RESERVED	Reads returns 0.	RW	0x00000
11	SSB	Set status bit 0x0: No action. Writing 0 does not clear already set status bits. This bit must be cleared before trying to clear a status bit of the <MCSPI_IRQSTATUS> register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits in the <MCSPI_IRQSTATUS> register.	RW	0
10	SPIENDIR	Set the direction of the SPIEN[3:0] lines and SPICLK line. 0x0: Output (as in master mode) 0x1: Input (as in slave mode)	RW	0
9	SPIDATDIR1	Set the direction of the SPIDAT[1]. 0x0: Output 0x1: Input	RW	0
8	SPIDATDIR0	Set the direction of the SPIDAT[0]. 0x0: Output 0x1: Input	RW	0
7	WAKD	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high.	RW	0
6	SPICLK	SPICLK line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.	RW	0

Bits	Field Name	Description	Type	Reset
5	SPIDAT_1	SPIDAT[1] line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.	RW	0
4	SPIDAT_0	SPIDAT[0] line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.	RW	0
3	SPIEN_3	SPIEN[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.	RW	0
2	SPIEN_2	SPIEN[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.	RW	0
1	SPIEN_1	SPIEN[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.	RW	0
0	SPIEN_0	SPIEN[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.	RW	0

Table 23-313. MCSPI_MODULCTRL

Address Offset	0x128		
Physical Address	0x4809 8128 0x4809 A128 0x480B 8128 0x480B A128	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register is dedicated to the configuration of the serial port interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							FDAA	MOA	INITDLY			SYSTEM_TEST	MS	PIN34	SINGLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reads returns 0.	RW	0x000000
8	FDAA	FIFO DMA address 256-bit aligned This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256-bit aligned address. If this bit is set the enabled channel which uses the FIFO has its data managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers. 0x0: FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers. 0x1: FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.	RW	0
7	MOA	Multiple word OCP access: This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16. 0x0: Multiple word access disabled 0x1: Multiple word access enabled with FIFO	RW	0
6:4	INITDLY	Initial SPI delay for first transfer: This register is an option only available in SINGLE master mode. The controller waits for a delay to transmit the first SPI word after channel enabled and corresponding TX register filled. This delay is based on SPI output frequency clock. No clock output provided to the boundary and chip select is not active in 4-pin mode within this period. 0x0: No delay for first spi transfer. 0x1: The controller wait 4 SPI bus clock 0x2: The controller wait 8 SPI bus clock 0x3: The controller wait 16 SPI bus clock 0x4: The controller wait 32 SPI bus clock	RW	0x0
3	SYSTEM_TEST	Enables the system test mode 0x0: Functional mode 0x1: System test mode (SYSTEST)	RW	0
2	MS	Master/slave 0x0: Master - The module generates the SPICLK and SPIEN[3:0]. 0x1: Slave - The module receives the SPICLK and SPIEN[3:0].	RW	1
1	PIN34	Pin mode selection: This register is used to configure the SPI pin mode, in master or slave mode. If asserted the controller only use SIMO, SOMI, and SPICLK clock pin for SPI transfers. 0x0: SPIEN is used as a chip-select. 0x1: SPIEN is not used. In this mode all related options to chip-select have no meaning.	RW	0

Bits	Field Name	Description	Type	Reset
0	SINGLE	Single channel/Multi Channel (master mode only) 0x0: More than one channel will be used in master mode. 0x1: Only one channel will be used in master mode. This bit must be set in Force SPIEN mode.	RW	0

Table 23-315. MCSPI_CHxCONF

Address Offset	0x12C + (0x14 * x)	**Index**	x= 0 to 3 for MCSPI1. x= 0 to 1 for MCSPI2 . x= 0 for MCSPI4 and MCSPI3.
Physical Address	0x4809 812C + (0x14 * x) 0x4809 A12C + (0x14 * x) 0x480B 812C + (0x14 * x) 0x480B A12C + (0x14 * x)	**Instance**	MCSPI1 MCSPI2 MCSPI3 MCSPI4
Description	This register is dedicated to the configuration of the channel 0		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		CLKG	FFER	FFEW	TCS0		SBPOL	SBE	SPIENSLV		FORCE	TURBO	IS	DPE1	DPE0	DMAR	DMAW	TRM		WL				EPOL	CLKD					POL	PHA

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Read returns 0.	R	0x0
29	CLKG	Clock divider granularity This register defines the granularity of channel clock divider: power of 2 or one clock cycle granularity. When this bit is set the register MCSPI_CHCTRL[EXTCLK] must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHCONF[CLKD] and MCSPI_CHCTRL[EXTCLK] values 0x0: Clock granularity of power of 2 0x1: One clock cycle granularity	RW	0
28	FFER	FIFO enabled for receive: Only one channel can have this bit field set. 0x0: The buffer is not used to receive data. 0x1: The buffer is used to receive data.	RW	0
27	FFEW	FIFO enabled for transmit: Only one channel can have this bit field set. 0x0: The buffer is not used to transmit data. 0x1: The buffer is used to transmit data.	RW	0

Bits	Field Name	Description	Type	Reset
26:25	TCS0	Chip-select time control This 2-bit field defines the number of interface clock cycles between CS toggling and first or last edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles	RW	0x0
24	SBPOL	Start-bit polarity 0x0: Start-bit polarity is held to 0 during SPI transfer. 0x1: Start-bit polarity is held to 1 during SPI transfer.	RW	0
23	SBE	Start-bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer polarity is defined by MCSPI_CH0CONF[SBPOL]	RW	0
22:21	SPIENSLV	Channel 0 only and slave mode only: SPI slave select signal detection. Reserved bits for other cases. 0x0: Detection enabled only on SPIEN[0] 0x1: Detection enabled only on SPIEN[1] 0x2: Detection enabled only on SPIEN[2] 0x3: Detection enabled only on SPIEN[3]	RW	0x0
20	FORCE	Manual SPIEN assertion to keep SPIEN active between SPI words (single channel master mode only). 0x0: Writing 0 into this bit drives low the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it high when MCSPI_CHCONF(i)[EPOL]=1. 0x1: Writing 1 into this bit drives high the SPIEN line when MCSPI_CHCONF(i)[EPOL]=0, and drives it low when MCSPI_CHCONF(i)[EPOL]=1.	RW	0
19	TURBO	Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer). 0x1: Turbo is activated to maximize the throughput for multiple SPI words transfer.	RW	0
18	IS	Input Select 0x0: Data line 0 (SPIDAT[0]) selected for reception 0x1: Data line 1 (SPIDAT[1]) selected for reception	RW	1
17	DPE1	Transmission enable for data line 1 (SPIDATAGZEN[1]) 0x0: Data line 1 (SPIDAT[1]) selected for transmission 0x1: No transmission on Data Line1 (SPIDAT[1])	RW	1
16	DPE0	Transmission Enable for data line 0 (SPIDATAGZEN[0]) 0x0: Data Line0 (SPIDAT[0]) selected for transmission 0x1: No transmission on data line 0 (SPIDAT[0])	RW	0
15	DMAR	DMA read request The DMA read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled	RW	0

Bits	Field Name	Description	Type	Reset
14	DMAW	DMA write request. The DMA write request line is asserted when The channel is enabled and the transmitter register of the channel is empty. The DMA write request line is deasserted on load completion of the transmitter register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled	RW	0
13:12	TRM	Transmit/receive modes 0x0: Transmit-and-receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved	RW	0x0
11:7	WL	SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4 bits long 0x4: The SPI word is 5 bits long 0x5: The SPI word is 6 bits long 0x6: The SPI word is 7 bits long 0x7: The SPI word is 8 bits long 0x8: The SPI word is 9 bits long 0x9: The SPI word is 10 bits long 0xA: The SPI word is 11 bits long 0xB: The SPI word is 12 bits long 0xC: The SPI word is 13 bits long 0xD: The SPI word is 14 bits long 0xE: The SPI word is 15 bits long 0xF: The SPI word is 16 bits long 0x10: The SPI word is 17 bits long 0x11: The SPI word is 18 bits long 0x12: The SPI word is 19 bits long 0x13: The SPI word is 20 bits long 0x14: The SPI word is 21 bits long 0x15: The SPI word is 22 bits long 0x16: The SPI word is 23 bits long 0x17: The SPI word is 24 bits long 0x18: The SPI word is 25 bits long 0x19: The SPI word is 26 bits long 0x1A: The SPI word is 27 bits long 0x1B: The SPI word is 28 bits long 0x1C: The SPI word is 29 bits long 0x1D: The SPI word is 30 bits long 0x1E: The SPI word is 31 bits long 0x1F: The SPI word is 32 bits long	RW	0x00
6	EPOL	SPIEN polarity 0x0: SPIEN is held high during the ACTIVE state. 0x1: SPIEN is held low during the ACTIVE state.	RW	0

Bits	Field Name	Description	Type	Reset
5:2	CLKD	Frequency divider for SPICLK (only when the module is a Master SPI device). A programmable clock divider divides the SPI reference clock (CLKSPIREF) with a 4-bit value, and results in a new clock SPICLK available to shift-in and shift-out data. By default the clock divider ratio has a power of 2 granularity when MCSPI_CHCONF[CLKG] is cleared. Otherwise this register is the 4-LSB bit of a 12-bit register concatenated with clock divider extension MCSPI_CHCTRL[EXTCLK] register. The value description below defines the clock ratio when MCSPI_CHCONF[CLKG] is set to 0. 0x0: 1 0x1: 2 0x2: 4 0x3: 8 0x4: 16 0x5: 32 0x6: 64 0x7: 128 0x8: 256 0x9: 512 0xA: 1024 0xB: 2048 0xC: 4096 0xD: 8192 0xE: 16384 0xF: 32768	RW	0x0
1	POL	SPICLK polarity, see Section 23.4.2.1.3.1, *Transfer Format*. 0x0: SPICLK is held low during the INACTIVE state 0x1: SPICLK is held high during the INACTIVE state	RW	0
0	PHA	SPICLK phase, see Section 23.4.2.1.3.1, *Transfer Format*. 0x0: Data are latched on odd-numbered edges of SPICLK. 0x1: Data are latched on even-numbered edges of SPICLK.	RW	0

	0x4809 A17C		MCSPI2
	0x480B 817C		MCSPI3
	0x480B A17C		MCSPI4
Description	This register provides transfer levels needed while using FIFO buffer during transfer.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WCNT																AFL								AEL							

Bits	Field Name	Description	Type	Reset
31:16	WCNT	SPI word counter. This register holds the programmable value of number of SPI word to be transferred on channel which is using the FIFO buffer. When transfer had started, a read back in this register returns the current SPI word transfer index. 0x0: Counter not used 0x1: One word 0xFFFE: 65534 SPI word 0xFFFF: 65535 SPI word	RW	0x0000

Bits	Field Name	Description	Type	Reset
15:8	AFL	Buffer almost full This register holds the programmable almost full level value used to determine almost full buffer condition. If the user wants an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least n bytes, then the buffer MCSPI_XFERLEVEL[AFL] must be set with n–1.The size of this register is defined by the generic parameter FFNBYTE. 0x0: 1 byte 0x1: 2 bytes 0xFE: 255bytes 0xFF: 256bytes	RW	0x00
7:0	AEL	Buffer almost empty. This register holds the programmable almost empty level value used to determine almost empty buffer condition. If the user wants an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive n bytes, then the buffer MCSPI_XFERLEVEL[AEL] must be set with – 1. 0x0: 1 byte 0x1: 2 bytes 0xFE: 255 bytes 0xFF: 256bytes	RW	0x00

23.5 Multichannel Buffered Serial Port (MCBSP)

This section introduces the multichannel buffered serial port (MCBSP)

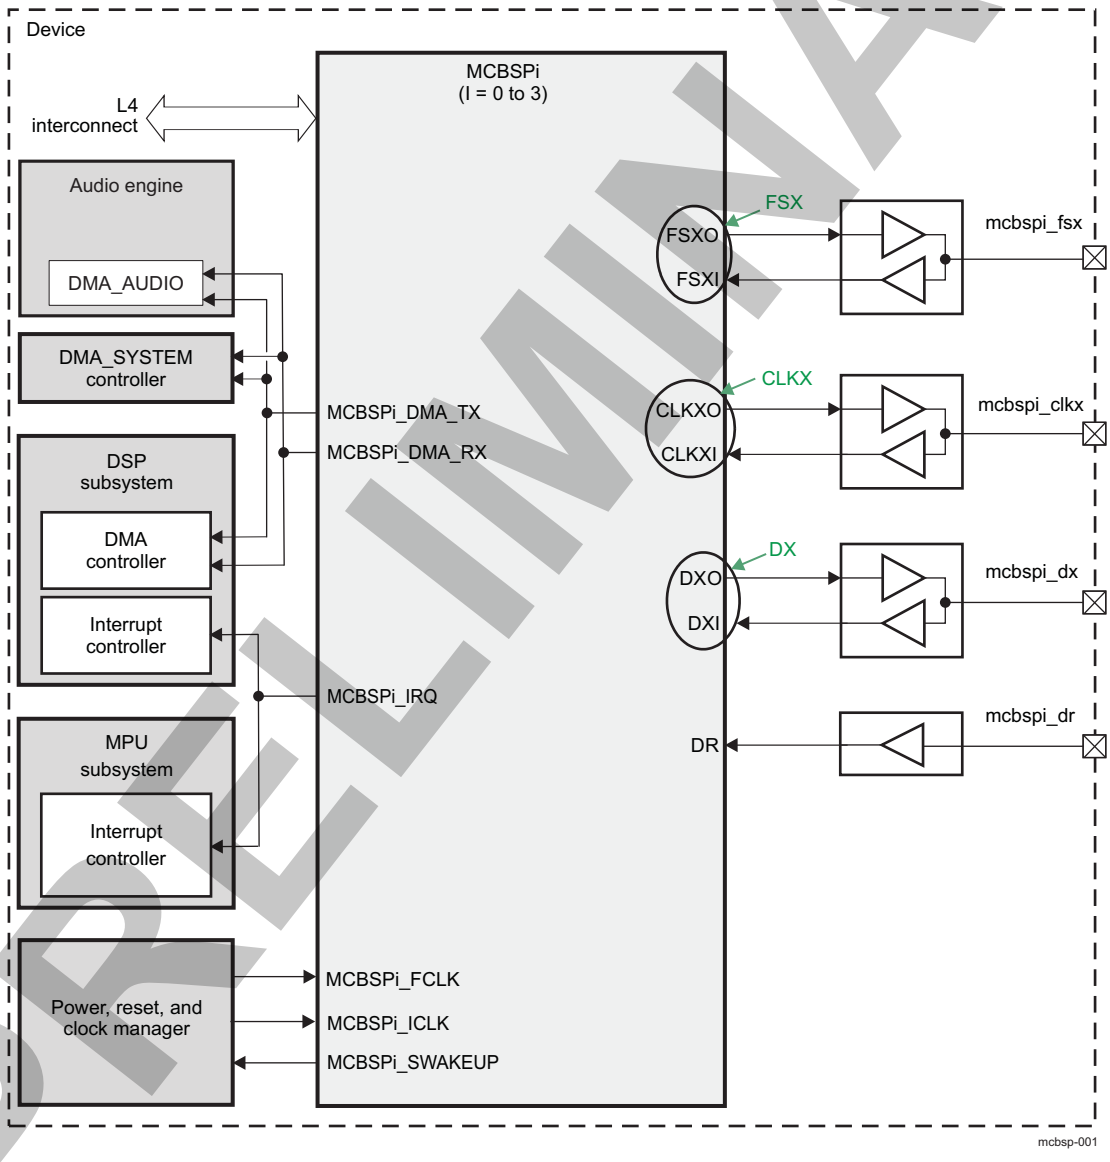
23.5.1 MCBSP Overview

The MCBSP provides a full-duplex direct serial interface between the device and other devices in a system such as other application devices (digital base band), audio and voice codec, etc. Because of its high level of versatility, it can accommodate a wide range of peripherals and clocked frame oriented protocols (for more information, see Section 23.5.1.1, *MCBSP Features*).

The device provides three instances of the MCBSP module.

Figure 23-100 is an overview of the MCBSP in the device.

Figure 23-100. MCBSP Highlight



23.5.1.1 MCBSP Features

The main features of the MCBSP modules are:

- L4 interconnect slave interface supports:

  - 32-bit data bus width
  - 32-bit access supported
  - 16-/8-bit access not supported
  - 10-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations
- Transmit and receive direct memory access (DMA) requests triggered with programmable FIFO thresholds
- Serial interface description
  - 4-pin configuration
  - Full-duplex communication
  - Multichannel selection modes
    - Support to enable or block transfers in each channel
    - 128 channels for transmission and reception
  - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
    - Inter-IC sound (I2S™) compliant devices
    - Pulse code modulation (PCM) devices
    - Time division multiplexed (TDM) bus devices

CAUTION

MCBSP modules do not offer support for μ-law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

  - A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
  - Bit reordering (send/receive least-significant bit [LSB])
- Clock and frame-synchronization generation support:
  - Independent clocking and framing for reception and for transmission up to 48 MHz
  - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
  - A programmable sample rate generator (SRG) for internal generation and control of clock signals and frame-sync signals
  - Programmable polarity for frame-sync pulses and clock signals

NOTE:

- MCBSP modules do not support features such as retransmit or re-receive of an erroneous frame or word.
- MCBSP modules support dual-phase frames to provide I2S fully compliant capabilities. This dual-phase mode, however, is limited to one channel (or word) for each phase instead of 128 channels maximum for single-phase mode.

23.5.2 MCBSP Environment

This section describes the intended functions for the MCBSP module from an environment point of view (that is, external connections). It presents the MCBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

23.5.2.1 MCBSP Functions

The device provides four instances of the MCBSP module called MCBSP1, MCBSP2 and MCBSP3.

The recommended use (nonexhaustive) for each MCBSP module in the device is:

- MCBSP1: Digital baseband (DBB) data
- MCBSP2: Audio data
- MCBSP3: Bluetooth® voice data

Table 23-331 describes the functions and the corresponding application fields.

Table 23-331. Functions Description

Function	Application Field	Recommended MCBSP Module	Description
Control and data	DBB data	MCBSP1	Serial interface to transfer data
Audio data	Audio data without audio buffer and sidetone feature	MCBSP2	Audio interface to transfer audio data with I2S
Voice data	Bluetooth voice data without sidetone feature	MCBSP3	Voice interface to transfer voice data with PCM

23.5.2.2 MCBSP Signals Descriptions

The MCBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 4-pin configuration.

The internal multiplexers are controlled through the system control module on the device (see Section 23.5.3, *MCBSP Integration*). Table 23-332 describes the inputs/outputs (I/Os).

Table 23-332. I/O Description

Pin Name	I/O	Description	Internal Signal Name	Reset Value[1]	Control and Data	Audio Data	Voice Data
abe_MCBSPi_dr	I	Receive serial data	DR	Hi-Z	✓	✓	✓
abe_MCBSPi_dx	(I)O[2]	Transmit serial data	DX	Hi-Z	✓	✓	✓
abe_MCBSPi_clkx	I/O [3]	Transmit clock[4]	CLKX	Hi-Z	✓	✓	✓
abe_MCBSPi_fsx	I/O [3]	Transmit frame synchronization [5]	FSX	Hi-Z	✓	✓	✓

(1) Hi-Z = High Impedance
(2) i = 1 to 3; I = Input, O = Output; I/O = Bidirectional
(3) For details of the I/O selection, see Section 23.5.2.3.1, *MCBSP Modes*.
(4) This signal is also used as CLKR when it is configured as output.
(5) This signal is also used as FSR when it is configured as output.

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

- The abe_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see Section 23.5.4.9, *MCBSP SRG*). The CLKS signal of the MCBSP modules is linked to an external signal through the abe_clks pin, but the CLKS signal can also be linked to an internal clock provided by the power, reset, and clock management (PRCM) module of the device. For more information, see Section 23.5.3, *MCBSP Integration*.
- Data are transmitted to external devices interfacing with MCBSP modules through the MCBSPi_dx pin. Data from those devices are received on the MCBSPi_dr pin.

NOTE: The MCBSPi_dx pin is an I/O signal to use the MCBSP module in half-duplex mode.

- Control information is communicated by the following pins:
  - MCBSPi_clkx (transmit clock)
  - MCBSPi_fsx (transmit frame-sync)

CAUTION

There is a light restriction on MCBSP modules when used in full-duplex mode. Reception and transmission use the same clock signal and the same frame-sync signal.

23.5.2.3 MCBSP Functions Description

23.5.2.3.1 MCBSP Modes

For all MCBSP functions, MCBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of MCBSP clocks and MCBSP frames synchronization:

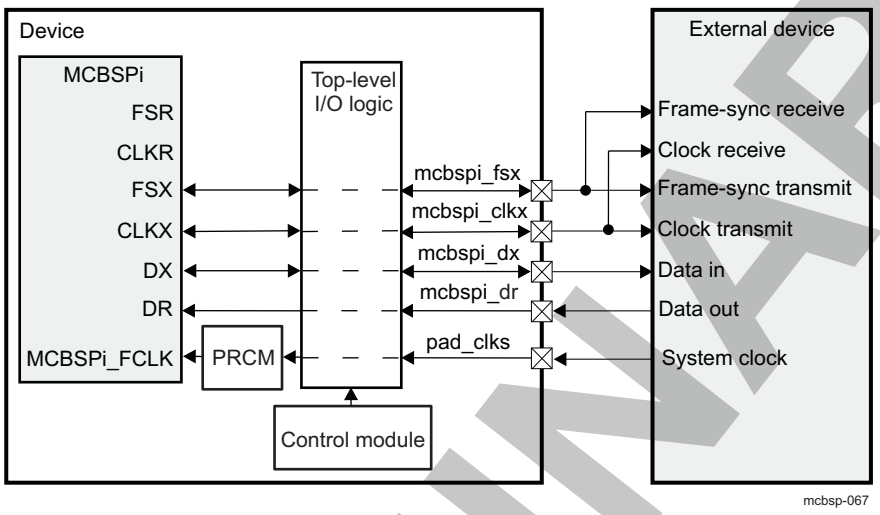
- Master mode: MCBSP module provides them to the external device
- Slave mode: MCBSP module receives them from the external device

The choice between the two modes depends on technical data of the external device and the type of interface (protocols and data formats). For one MCBSP module, there are four possible functions:

- Transmit-and-receive master mode
- Transmit-and-receive slave mode

Figure 23-101 shows the connection between the MCBSPi module, where i = 1, 2, or 3 (4-pin configuration) and an external device in transmit and receive master mode.

Figure 23-101. Mode Overview of MCBSPi



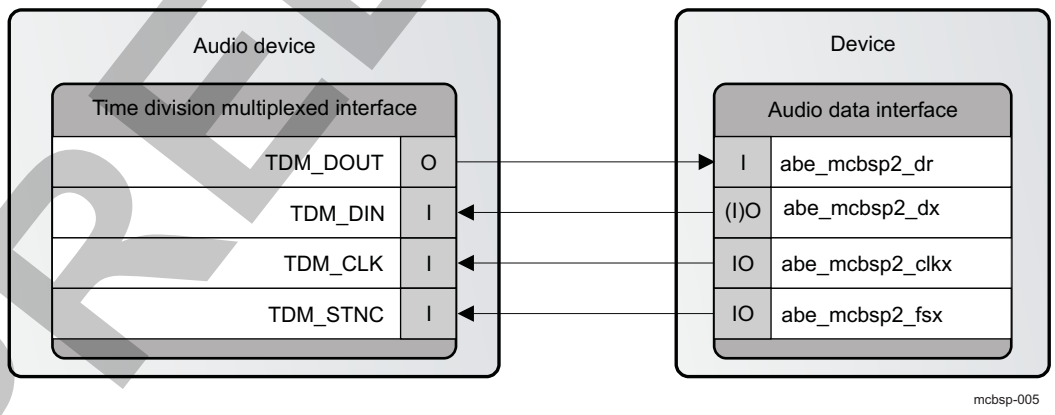
23.5.2.3.2 MCBSP Functions

23.5.2.3.2.1 MCBSP Function 1: Audio Data

The MCBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot-based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 23-102 shows typical connections between a device and a typical device of analog audio interface to show the audio data application. The typical device contains several audio analog inputs and outputs and digital microphone inputs.

Figure 23-102. Audio Data Application



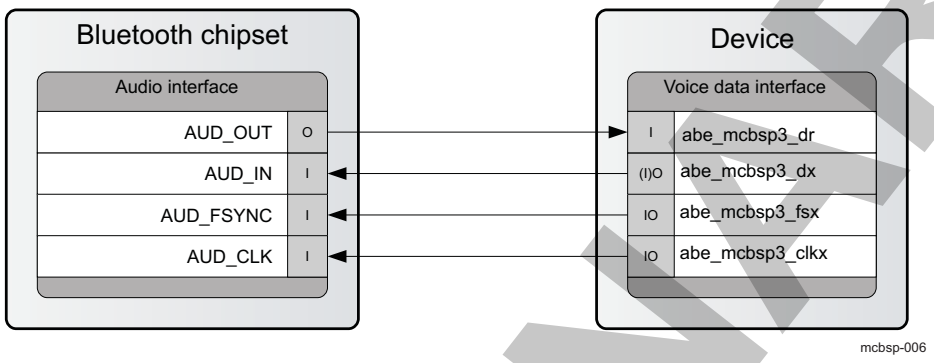
In Figure 23-102, MCBSP2 is configured in transmit-and-receive master mode.

23.5.2.3.2.2 MCBSP Function 2: Voice Data

The MCBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot-based serial interface that is used to transfer voice data. The voice devices can be modem chipsets, Bluetooth chipsets, or other devices with voice data interface.

Figure 23-103 shows typical connections between a device and a Bluetooth chipset (TI BRF6300 or TI BRF6350) to show voice data application.

Figure 23-103. Voice Data Application



In Figure 23-103, MCBSP3 is configured in transmit-and-receive master mode.

23.5.2.4 MCBSP Protocols and Data Formats

The MCBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The MCBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

23.5.2.4.1 Words, Frames, and Phases Definitions

23.5.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable through bit fields (MCBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and MCBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2, MCBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and MCBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2) and can be 8, 12, 16, 20, 24, or 32 bits (see Section 23.5.4.8.3, *Clocking and Framing Data*). The MCBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on the rising or falling edge of clock signals. This clock polarity is programmable through bit fields of the pin-control register (MCBSPi.MCBSPLP_PCR_REG).

For more information, see Section 23.5.4.8.4, *Frame Phases (Dual-Phase Frame I2S Support)*.

23.5.2.4.1.2 Frames

One or more words (maximum 128) are transferred in a group called a frame. The MCBSP module can transmit and receive a maximum of 128 words per frame, programmable through bit fields of transmit-and-receive control registers (MCBSPi.MCBSPLP_XCR1_REG/MCBSPi.MCBSPLP_XCR2_REG and MCBSPi.MCBSPLP_RCR1_REG/MCBSPi.MCBSPLP_RCR2_REG). For more details, see Section 23.5.4.8.3, *Clocking and Framing Data*.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The MCBSP module uses frame-sync signals to determine when each frame is received or transmitted. When a pulse occurs on a frame-sync signal, the MCBSP module begins receiving or transmitting a frame of data. When the next pulse occurs, the MCBSP module receives or transmits the next frame, and so on. The frame-sync pulse is active high or low. This pulse polarity is programmable through bit fields of the pin control register (MCBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (MCBSPi.MCBSPLP_XCR2_REG and MCBSPi.MCBSPLP_RCR2_REG). For more information, see Section 23.5.4.10.6.3, *Preventing Unexpected Transmit Frame-sync Pulses* and Section 23.5.4.10.3.3, *Preventing Unexpected Receive Frame-sync Pulses*.

23.5.2.4.1.3 Phases

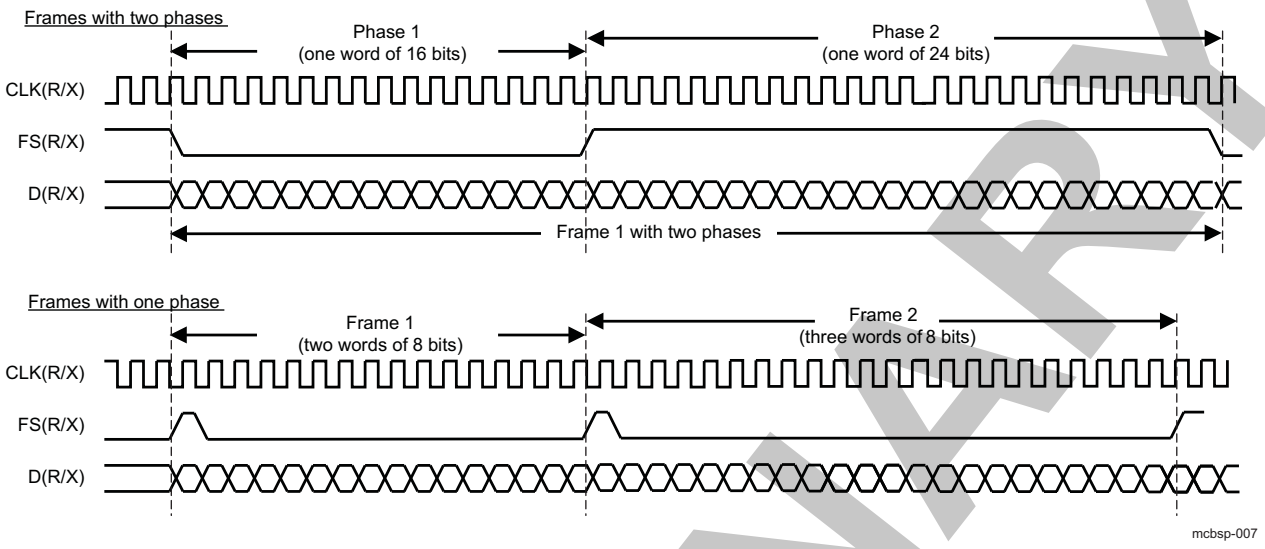
The MCBSP module allows configuring of each frame to contain one or two phases. The MCBSP module supports dual-phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual-phase frame is that the number of words per phase must be set to 1 for both first and second phases. The number of bits per word, however, can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see Section 23.5.4.8.4, *Frame Phases (Dual-Phase Frame I2S Support)*.

Figure 23-104 shows signal activity for two possible reception/transmission scenarios.

Figure 23-104. MCBSP Reception/Transmission Signal Activity



23.5.2.4.2 Serial Protocol and Data Formats

23.5.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows the MCBSP module to accommodate all serial devices and their protocols.

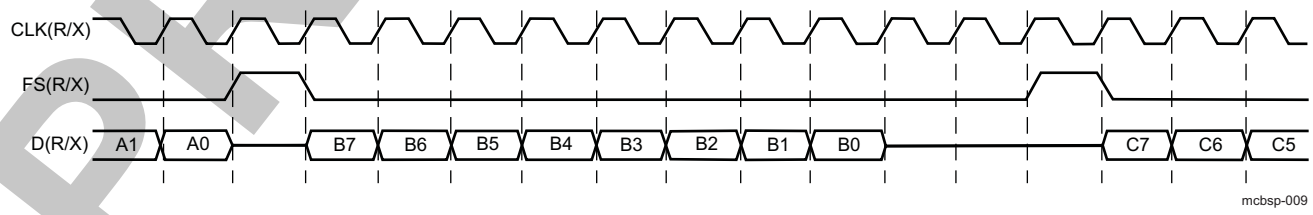
23.5.2.4.2.2 Data Format

Figure 23-105 shows typical operation of the MCBSP clock and frame-sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The MCBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0- , 1- , or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see Section 23.5.4, *MCBSP Functional Description*, and Section 23.5.5, *MCBSP Basic Programming Model*.

Figure 23-105. Serial Data Formats



23.5.2.4.3 Audio Protocol and Data Formats

23.5.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8-kHz to 48-kHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (two standard sample rate groups that are used in audio applications are supported: 48 and 44.1 KHz). The 48-KHz sample rate group includes 8, 16, 24, 32 and 48 KHz frequencies. The 44.1-KHz sample rate group includes 11.025, 22.05, and 44.1 KHz frequencies.

Based on required sample rate, it is recommended the I2S clock to be configured as multiple of 44.1 or 96 KHz (48KHz × 2).

For example:

The McBSP clock is provided by the system clock and is set to 12.288 MHz (48KHz × 256) for the first group and 11.2896 MHz (44.1 × 256) for the second group. In this case, 256 is the value for Sample Rate Generator Clock Divider, which should be set in the MCBSPLP_SRGR1_REG[7:0] CLKGDIV bit field.

The frame-sync signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-sync signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-sync signal is synchronous to the falling edge of the clock signal.

23.5.2.4.3.2 Data Formats

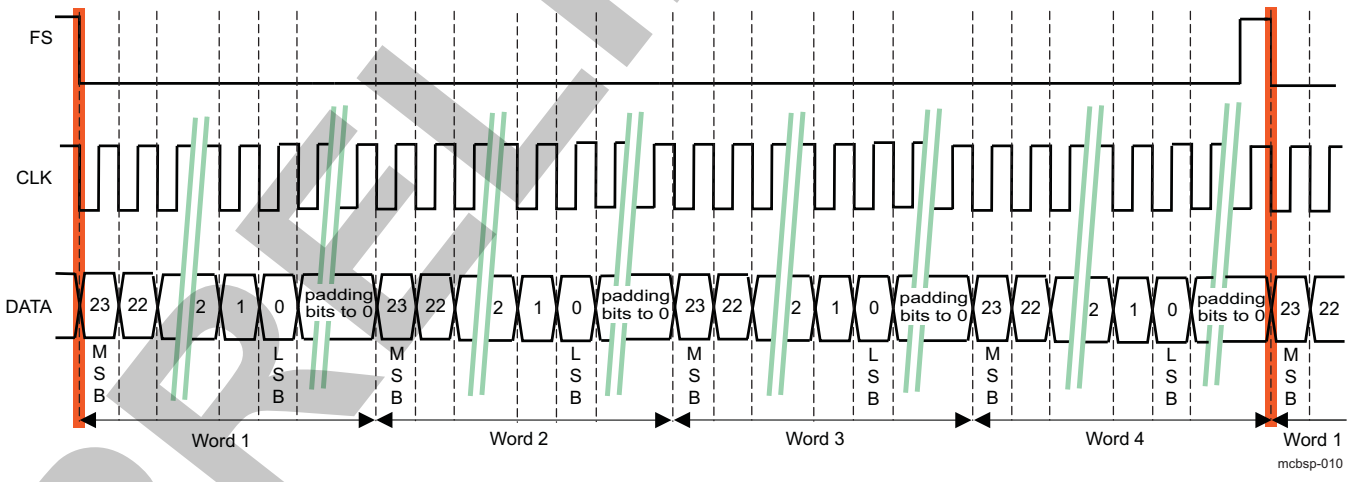
The I2S protocol supports TDM, I2S, left-justified, and right-justified data formats.

Bits of each word (sample) are clocked using the clock signal. For each word, the most-significant bit (MSB) is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

23.5.2.4.3.2.1 TDM Data Format

Figure 23-106 shows that each frame of TDM data format is composed of four words (or channels).

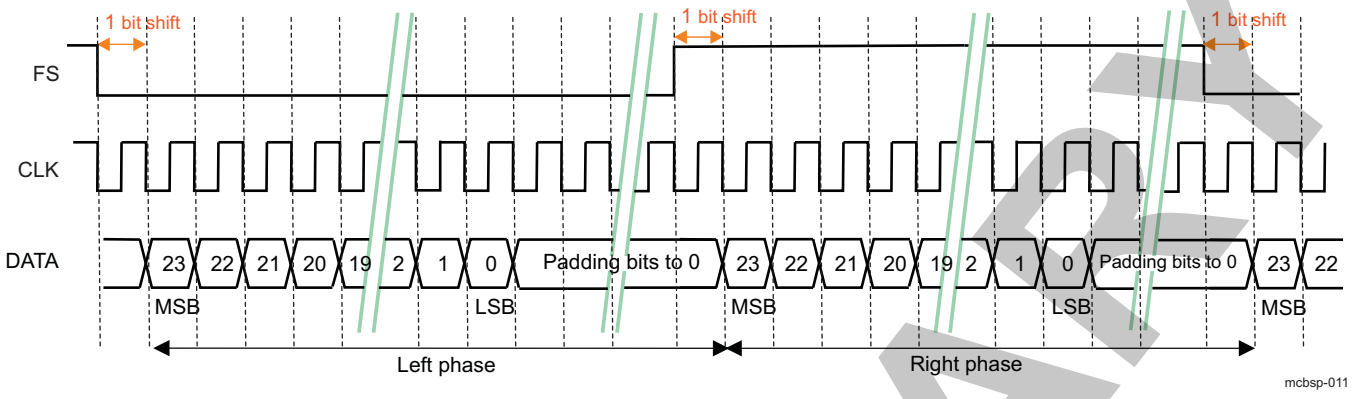
Figure 23-106. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits



23.5.2.4.3.2.2 I2S Data Format

Figure 23-107 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

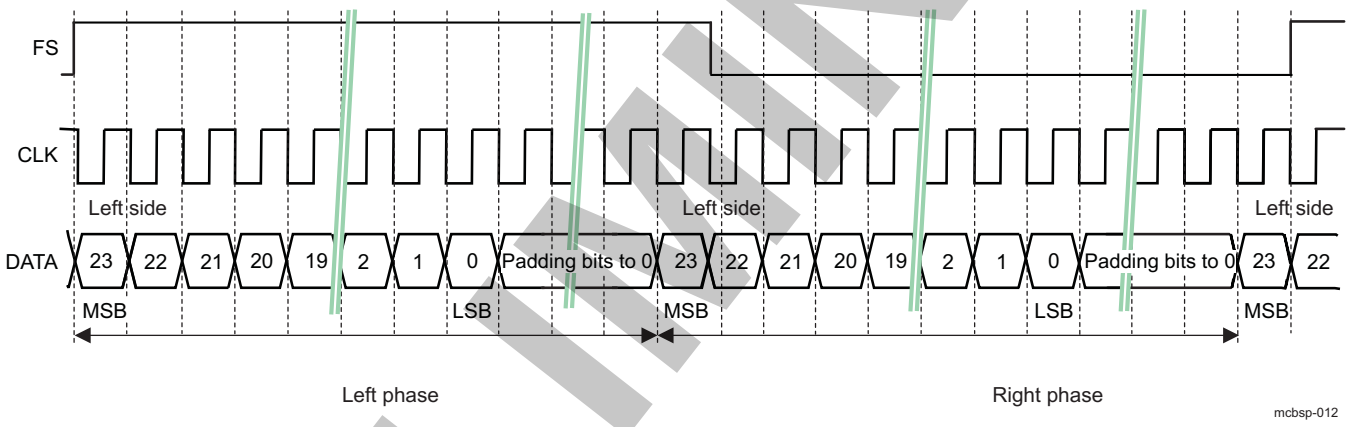
Figure 23-107. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits



23.5.2.4.3.2.3 Left-Justified Data Format

Figure 23-108 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

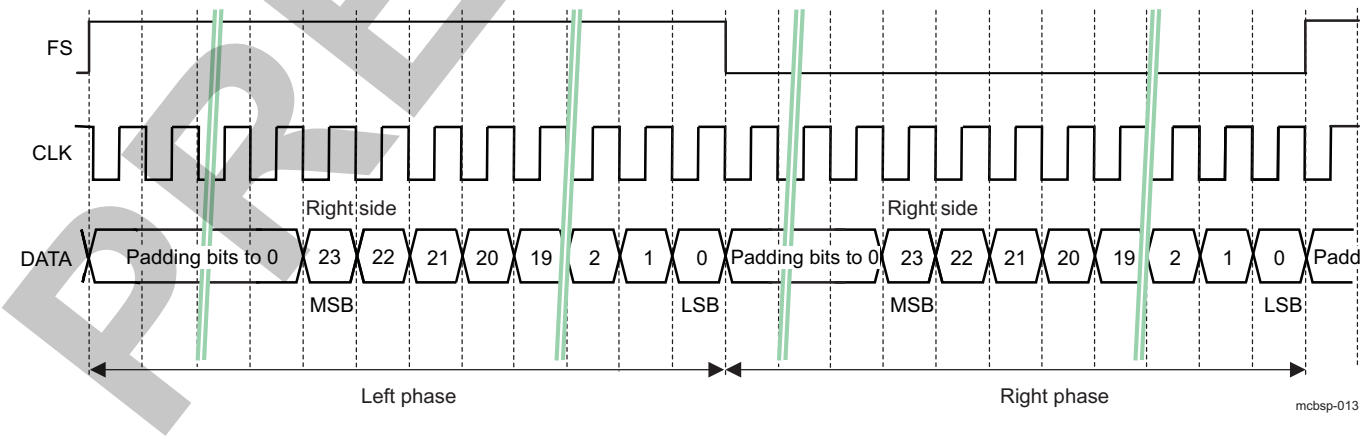
Figure 23-108. Left-Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits



23.5.2.4.3.2.4 Right-Justified Data Format

Figure 23-109 shows an example with 24-bit data (MSB first) and 8 padding bits at 0.

Figure 23-109. Right-Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits



23.5.2.4.4 Voice Protocol and Data Formats

23.5.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8-kHz (default narrowband mode) or 16-kHz (wideband mode) sample rate (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame synchronization defines the frame length in the PCM protocol. Bits are clocked using the PCM clock signal, with the MSB first.

23.5.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. Both modes have two types of operations: mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way in which they use the rising or the falling edge of the clock signal, and the frame-sync polarity.

- PCM mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. The frame-sync pulse is active high.
- PCM mode 2: Input data is latched on the rising edge of the clock, and the transmitted data starts on the falling edge of the clock. The frame-sync pulse is active low.

Figure 23-110 and Figure 23-111 show an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed of one word (32 bits wide) with 16 bits of data.

Figure 23-110. PCM Protocol – Mode 1 Data Format

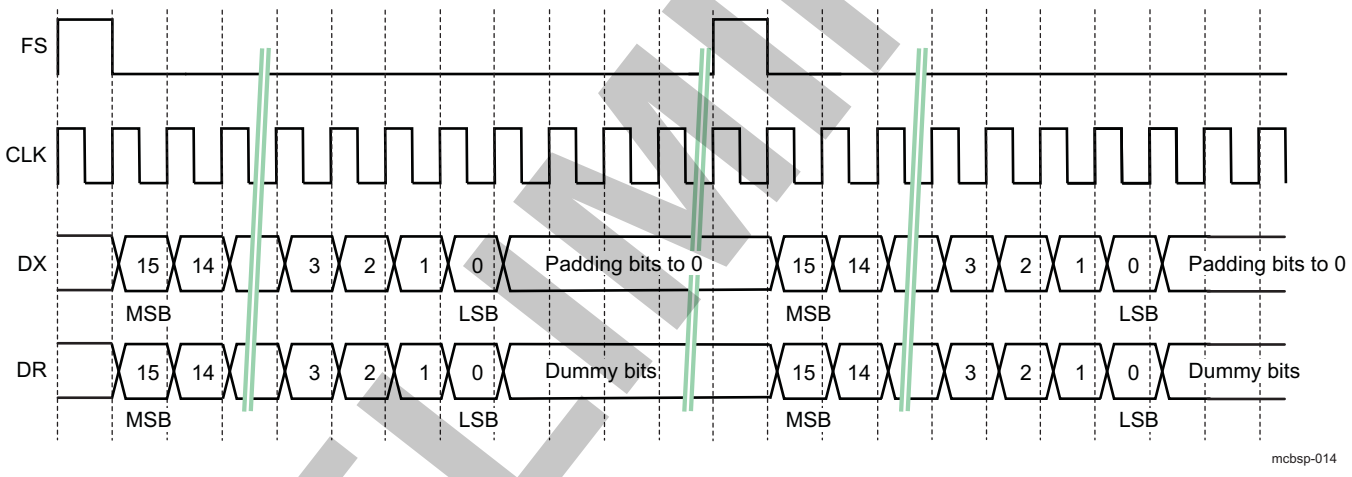


Figure 23-111. PCM Protocol – Mode 2 Data Format

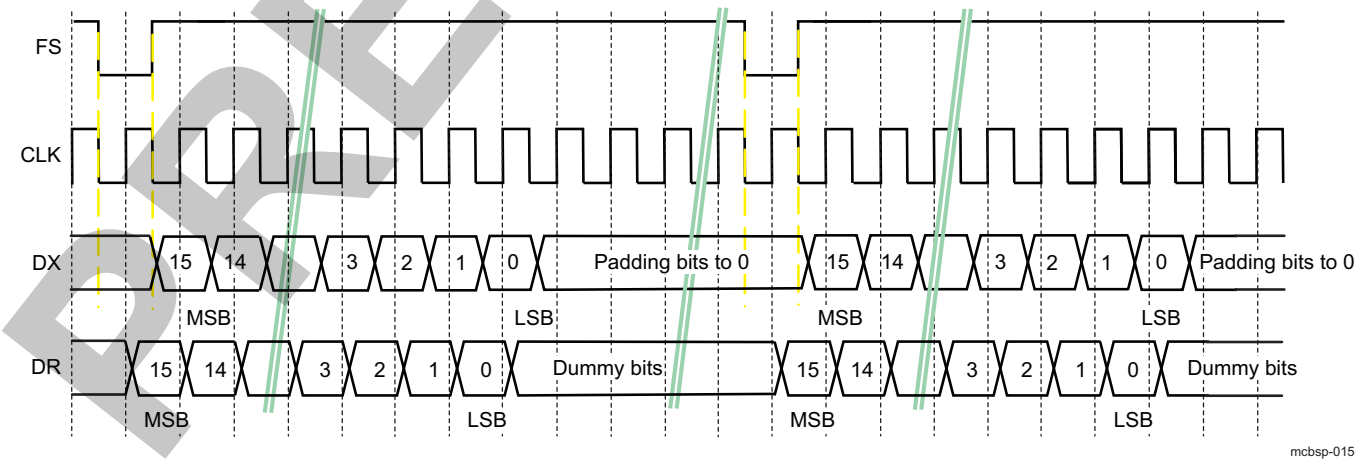

23.5.3 MCBSP Integration

This section describes the integration of the MCBSP module in the device, including information about clocks, resets, and hardware requests.

MCBSP modules are divided into two families: MCBSP modules that are gated in the AUDIO power domain (MCBSP1, 2, and 3).

Figure 23-112 shows the integration of the MCBSP modules in the device, including interrupt handlers, DMA requests, clock generators, and interconnections.

The features of the MCBSP modules are:

- Wake-up request
- Two DMA requests
- One IRQ
- One functional clock
- One interface clock

Figure 23-112. MCBSPi Integration

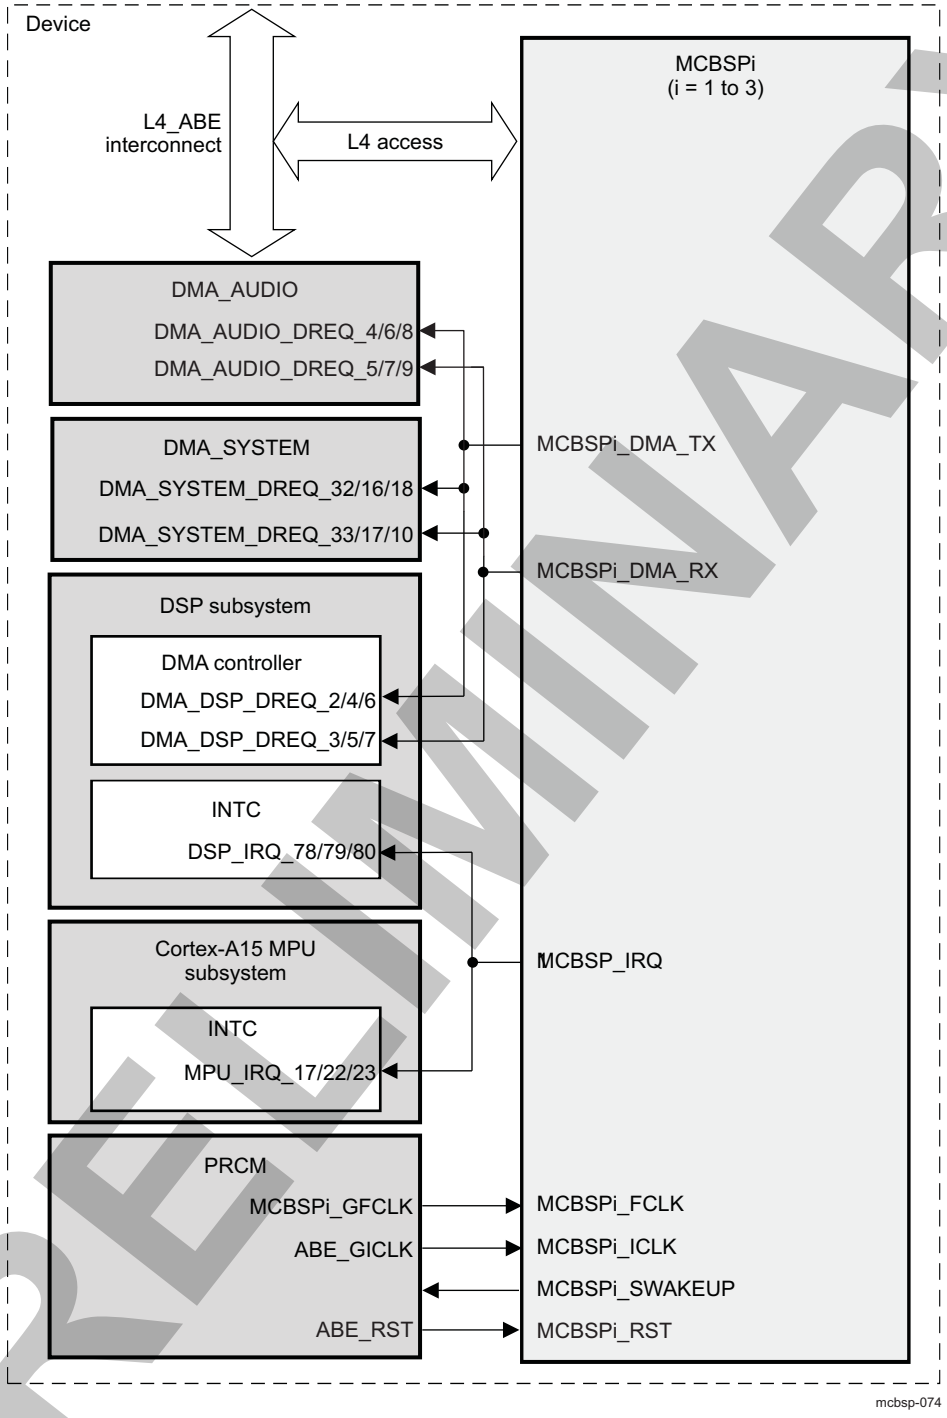

Table 23-333 through Table 23-335 summarize the integration of the module in the device.

Table 23-333. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MCBSP1	PD_ABE	Yes	L4_ABE
MCBSP2	PD_ABE	Yes	L4_ABE

Table 23-333. Integration Attributes (continued)

MCBSP3	PD_ABE	Yes	L4_ABE

	MCBSP3_DMA_RX	DMA_DSP_DREQ_7	DMA_DSP	Receive DMA request

NOTE:

- For more information about the interrupt source, see Section 23.5.4.6, *Interrupt Requests*.
- For more information about the DMA source, see Section 23.5.4.7, *DMA Requests*.

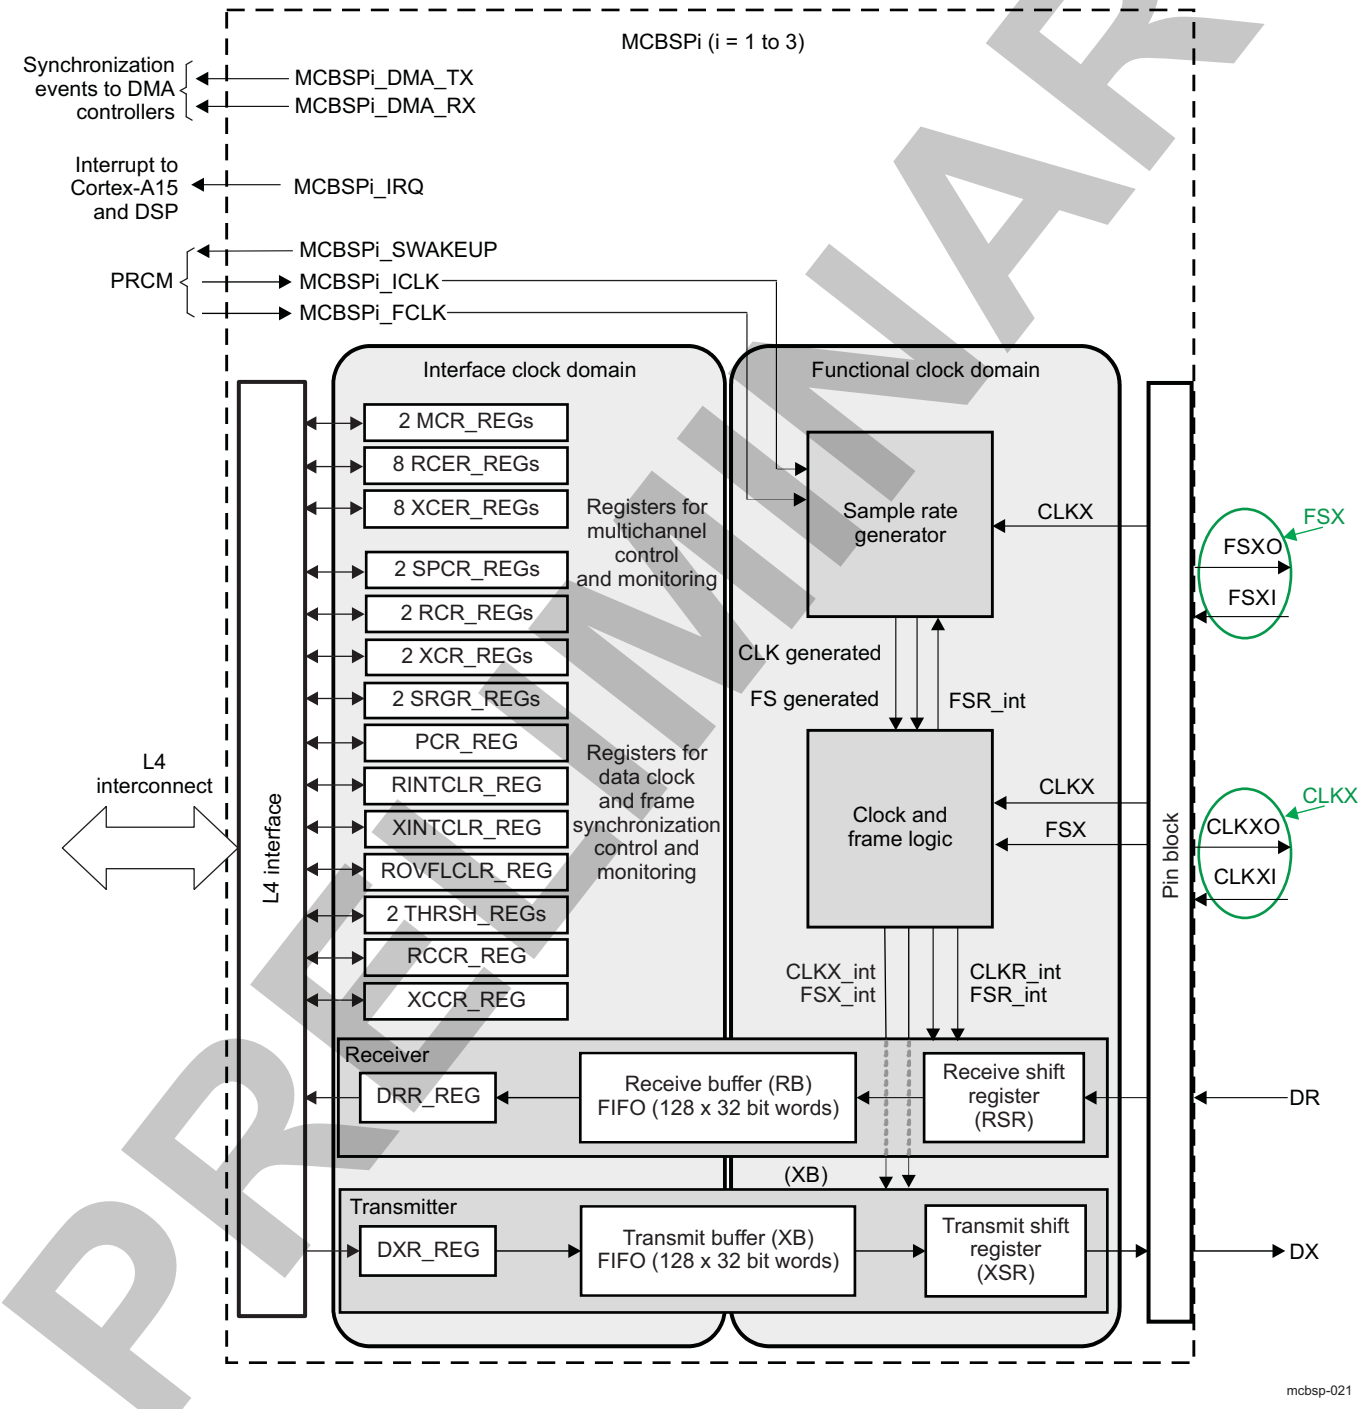
23.5.4 MCBSP Functional Description

This section is a functional description of the MCBSP module.

23.5.4.1 Block Diagram

Figure 23-113 shows the functional block diagram of the four instances of the MCBSP modules.

Figure 23-113. MCBSPi Block Diagram



23.5.4.2 Signal Source Control

The sources of the CLKX, DX, DR, FSX signals are defined by the system control module. The control registers of the system control module are used to select these signal sources. For more information, see Section 18.4.12.7.5, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*.

23.5.4.3 MCBSP Clock Configuration

23.5.4.3.1 MCBSP1 Clocks

MCBSP1 is clocked by a functional clock (MCBSP1_FCLK and CLKX) and an interface clock (MCBSP1_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 23.5.4, *MCBSP Functional Description*). For MCBSP1, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP1.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP1.MCBSPLP_SRGR2_REG[13] CLKSM bit.

  The CLKS signal of MCBSP1 is linked to an internal clock (MCBSP1_FCLK) provided by the PRCM module. The CLKS signal can also be linked to an external signal through the abe_clks pin of the device boundary.

  NOTE: When MCBSP1 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM1_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At the PRCM level, when all the conditions to shut off the MCBSP1_FCLK clock are met, the PRCM module automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

  Only the CLKX signal is connected by MCBSP1_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.
- The MCBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the MCBSP1 L4 interface and MCBSP1 configuration interface through the Cortex-A15 MPU/DSP shared bus. It can also be an input clock for the MCBSP SRG (clock divider), depending on the module configuration (see Section 23.5.4.9, *MCBSP SRG*). Its source is the ABE_GICLK signal.

  NOTE: When MCBSP1 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_ABE_MCBSP1_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

  At the PRCM level, when all the conditions to shut off the ABE_GICLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

23.5.4.3.2 MCBSP2 Clocks

MCBSP2 is clocked by a functional clock (MCBSP2_FCLK or CLKX) and an interface clock (MCBSP2_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 23.5.4, *MCBSP Functional Description*). For MCBSP2, the functional clock comes from the MCBSP2_FCLK and CLKX signals. The choice between these two clocks is defined by the MCBSP2.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP2.MCBSPLP_SRGR2_REG[13]

CLKSM bit.

NOTE: When MCBSP2 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP2_GFCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

Only the CLKX signal is connected by MCBSP2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The MCBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the MCBSP2 L4 interface and MCBSP2 configuration interface through the Cortex-A15 MPU/DSP shared bus. It can also be an input clock for the MCBSP SRG (clock divider), depending on the module configuration (see Section 23.5.4.9, *MCBSP SRG*). Its source is the ABE_GICLK signal.

NOTE: When MCBSP2 no longer requires the interface clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_ABE_MCBSP2_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the ABE_ICLK2 clock are met the PRCM module automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

23.5.4.3.3 MCBSP3 Clocks

MCBSP3 is clocked by a functional clock (MCBSP3_FCLK or CLKX) and an interface clock (MCBSP3_ICLK).

- The functional clock is used to generate control signals depending on the internal configuration of the module (see Section 23.5.4, *MCBSP Functional Description*). For MCBSP3, the functional clock comes from the CLKS and CLKX signals. The choice between these two clocks is defined by the MCBSP3.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSP3.MCBSPLP_SRGR2_REG[13] CLKSM bit.

NOTE: When MCBSP3 no longer requires the functional clock, software can disable it at the PRCM level by configuring the MODULEMODE bit field to 0x0 (PRCM.CM_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At the PRCM level, when all the conditions to shut off the MCBSP3_FCLK clock are met the PRCM module automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM module asserts an IDLE request to the MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

Only, the CLKX signal is connected by MCBSP3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The MCBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the MCBSP3 L4 interface and MCBSP3 configuration interface via the Cortex-A15 MPU/DSP shared bus. It can also be an input clock for the MCBSP sample-rate generator (clock divider), depending on the module configuration (see Section 23.5.4.9, *MCBSP SRG*). Its source is either the ABE_GICLK signal.

NOTE: When the MCBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by configuring the MODULEMODE bit field (PRCM.CM_ABE_MCBSP3_CLKCTRL[1:0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it.

At PRCM level, when all the conditions to shut-off ABE_GICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure MCBSP is ready to have this clock switched off. Namely, the PRCM asserts an IDLE request to MCBSP module. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, MCBSP3_ICLK follows the AUDIO_L4 clock domain behavior on the device. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

23.5.4.4 MCBSP Software Reset

The MCBSP1, 2, and 3 modules belong to the AUDIO domain and their reset signal is AUDIO_RST from the PRCM module. Table 23-336 lists the software reset signals to all MCBSP modules.

Table 23-336. Software Reset Signals to All MCBSP Modules

Type	Bit Field	Register Source	Activation	Description
Software	SOFTRESET	MCBSPi.MCBSPLP_SYSCONFIG_REG[1]	Active high	MCBSP global software reset
	RRST	MCBSPi.MCBSPLP_SPCR1_REG[0]	Active low	This resets and disables the receiver, including the RB.
	XRST	MCBSPi.MCBSPLP_SPCR2_REG[0]		This resets and disables the transmitter, including the XB.
	GRST	MCBSPi.MCBSPLP_SPCR2_REG[6]		SRG is reset.
	FRST	MCBSPi.MCBSPLP_SPCR2_REG[7]		Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG.

For a complete description of the MCBSP initialization procedure, see Section 23.5.5.1, *MCBSP Initialization Procedure*.

23.5.4.5 MCBSP Power Management

23.5.4.5.1 MCBSP Operating States

Two operating states are defined for all the MCBSP modules:

- ACTIVE state: The module is running synchronously on the interface and functional clocks. Interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- IDLE state: As part of the system power management, the PRCM module can request the MCBSP modules to enter IDLE state. Depending on the configured acknowledgment mode (force-idle, no-idle and smart-idle modes), a MCBSP module effectively enters IDLE state or not. As soon as a MCBSP module enters IDLE state, its only activities are those unrelated to clock activity (for example, wake-up features) and its clocks are likely to be switched off at the PRCM level.

NOTE: IDLE request and IDLE acknowledge are only internal signals, with no means to observe or to control. The generation and control of the signals is purely hardware (managed automatically by the PRCM module and the MCBSP depending on the SIDLEMODE settings).

23.5.4.5.2 MCBSP Acknowledgment Modes

During initialization or configuration of the MCBSP module, software must configure how the MCBSP module will answer an IDLE solicitation from the PRCM module (that is, the way IDLE acknowledge is asserted following assertion of an idle request).

Each MCBSP module can be configured through the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE bit = 0x0): An IDLE request is acknowledged unconditionally, regardless of the internal state of the module. The MCBSP module immediately enters IDLE state (no activity), interface and PRCM functional clocks can be stopped, and no interrupts and DMA requests can be generated. In this mode, the MCBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In force-idle mode, the wake-up feature is inhibited.

CAUTION

If the MCBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the MCBSP module will not be idle (FSM states, processes, etc.), and when the MCBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No-idle mode (SIDLEMODE bit = 0x1): An IDLE request is never acknowledged, meaning it prevents the PRCM module from switching off its related clocks and from putting in a lower power state than the power domain to which it belongs. The MCBSP module never enters IDLE state (is active).
- Smart-idle mode (SIDLEMODE bit = 0x2): Acknowledgement to an IDLE request is given based on the internal activity of the MCBSP module. The MCBSP module is in a waiting state, interface and functional clocks can be stopped, no interrupts can be generated, and a wake-up signal can be generated according to the configuration (see Section 23.5.4.5.4, *Analysis of the Receiver Smart-Idle Behavior*) and external signals.

NOTE: The value MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field = 0x3 must not be used.

When configured in smart-idle mode, the MCBSP module also offers an additional granularity on MCBSPi_FCLK and MCBSPi_ICLK gating. The MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (MCBSPi_FCLK, MCBSPi_ICLK, none of them, or both of them).

CLOCKACTIVITY setting is used in the MCBSP module to determine on which part of the module the conditions to acknowledge the PRCM IDLE request will be tested. As an example, if MCBSPi_FCLK is said not to be shut down upon a PRCM IDLE request, this means the MCBSP module will consider only MCBSPi_ICLK and the associated pending activities before acknowledging the request.

NOTE: Some MCBSP features are associated with MCBSPi_ICLK and others with MCBSPi_FCLK. Using CLOCKACTIVITY along with the smart-idle mode ensures that the features associated with the clock that remain active are always enabled, even if the MCBSP has acknowledged an IDLE request. For more information, see Section 23.5.4.5.4, *Analysis of the Receiver Smart-Idle Behavior*.

Table 23-337 lists the value of the bit field and indicates whether the interface (MCBSPi_ICLK) and PRCM functional (MCBSPi_FCLK) clocks can be switched off or not when an IDLE request is received by the MCBSP module.

Table 23-337. State of Clocks When the Module is in Idle State

CLOCKACTIVITY Value	Interface Clock (MCBSPi_ICLK)	PRCM Functional Clock
0b00	Off	Off
0b01	Off	On
0b10	On	Off
0b11	On	On

NOTE: Off means this clock can be switched off.

On means this clock must be maintained during the wake-up period.

CAUTION

The PRCM module does not have any hardware means to read CLOCKACTIVITY settings. Software must ensure a consistent programming between the MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8] CLOCKACTIVITY bit field and the PRCM MCBSPi_GFCLK and L4_ICLK control bits (see notes in Section 23.5.4.3, *MCBSP Clock Configuration*). If the MCBSP module is disabled while CLOCKACTIVITY is set to 0x3, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the MCBSP clocks. This may lead to unpredictable behaviors.

23.5.4.5.3 Wake-Up Capability

When configured in smart-idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake-up sources are enabled by setting the MCBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake-up feature control):

- Set to 0, wake-up capability is disabled.
- Set to 1, wake-up capability is enabled.

The MCBSPi_SWAKEUP signal is the MCBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake-up configurations are defined by setting the corresponding bits in the MCBSPi.MCBSPLP_WAKEUPEN_REG register.

23.5.4.5.3.1 Receive Wakeup

There are four receive possible wake-up configurations:

- MCBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the MCBSPi.MCBSPLP_THRSH1_REG register. If the MCBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt will be asserted once the MCBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from 0 to 1, indicating that received data is ready to be read).
- MCBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request at the end of the frame. If the MCBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.

- MCBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The MCBSP module sends a MCBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the MCBSP module is in idle mode. If the MCBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- MCBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the MCBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the MCBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from 0 to 1, indicating that a receive error occurred).

23.5.4.5.3.2 Transmit Wakeup

For transmit, there are five possible wake-up configuration scenarios:

- MCBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the MCBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- MCBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the MCBSPi.MCBSPLP_THRSH2_REG register. If the MCBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting from idle mode (interrupt is asserted once the MCBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from 0 to 1, indicating that transmit buffer data is ready to accept new data).
- MCBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request at the end of the frame. If the MCBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- MCBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The MCBSP module sends a MCBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the MCBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode.
- MCBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The MCBSP module asserts the MCBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the MCBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the MCBSP module sends an interrupt (MCBSPi_IRQ) request to the MPU or DSP subsystems when exiting idle mode (interrupt is asserted once the MCBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from 0 to 1, indicating that a transmit error occurred).

23.5.4.5.3.3 Notes

The module does not implement interrupt request (IRQ) assertion when configured as GPIO (pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake-up capability in this mode is not available.

23.5.4.5.4 Analysis of the Receiver Smart-Idle Behavior

Table 23-338 provides an analysis of the power mode behavior.

In this table, the CLKRM bit is in the MCBSPi.MCBSPLP_PCR_REG register on position 8, the CLKXM bit is in the MCBSPi.MCBSPLP_PCR_REG[9] register, and the CLOCKACTIVITY bit is in the MCBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X indicates that the bit value is not significant.

Table 23-338. MCBSP Smart-Idle Mode Configuration Behavior

CLKRM Bit	CLKXM Bit	MCBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
0	0	Slave	Outside	0bXX	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity.
0	1	Transmit master	MCBSPi_ICLK	0b0X	The MCBSP does not acknowledge the IDLE request unless: • The transmit part is disabled (XDISABLE) or under software reset (XRST). • Transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			MCBSPi_FCLK	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached).
			MCBSPi_FCLK	0bX1	
			CLKR (outside)	0bXX	The module acknowledges the idle request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.
1	0	Receive master	MCBSPi_ICLK	0b0X	The MCBSP does not acknowledge the IDLE request unless the receive part is disabled (RDISABLE) or under software reset (RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.
			MCBSPi_FCLK	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached).
			MCBSPi_FCLK	0bX1	
			CLKX	0bXX	When CLKX is used as source (the functional clock is provided from outside), the module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached), regardless of the CLOCKACTIVITY settings.

Table 23-338. MCBSP Smart-Idle Mode Configuration Behavior (continued)

CLKRM Bit	CLKXM Bit	MCBSP Mode	Source of Functional Clock	CLOCKACTIVITY Bit	Behavior
1	1	Transmit and receive master	MCBSPi_ICLK	0b0X	The MCBSP does not acknowledge the IDLE request unless transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST). The IDLE acknowledge is asserted as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. No wake-up event is available in this mode, because the entire MCBSP and remote device activity is frozen.
			MCBSPi_FCLK	0bX0	
			MCBSPi_ICLK	0b1X	The module acknowledges the IDLE request as soon as there is no pending DMA, interrupt request, or transmit/receive buffer threshold synchronization (only when the wake-up event is set on transmit/receive threshold reached).
			MCBSPi_FCLK	0bX1	

NOTE: The RSYNCERREN/XSYNCERREN mode can be used to wake up the MCBSP module only by a remote module implementing such a feature to trigger a wakeup. In this mode, the functional clock must be active.

23.5.4.6 MCBSP Interrupt Requests

Each of the four MCBSP modules can generate one common interrupt (MCBSPi_IRQ), shared between the Cortex-A15 MPU subsystem and DSP subsystem interrupt controllers (INTCs).

An event can generate an interrupt request when the corresponding mask bit in the MCBSPi.MCBSPLP_IRQENABLE_REG register is set to 1.

Once an interrupt request is generated, software must read the MCBSPi.MCBSPLP_IRQSTATUS_REG register to check which event has caused the interrupt request generation, and acknowledge each processed event by setting the corresponding bit in the MCBSPi.MCBSPLP_IRQSTATUS_REG register to 1.

23.5.4.7 MCBSP DMA Requests

The DMA requests are shared between the DSP subsystem DMA (DMA_DSP) controller, system DMA (DMA_SYSTEM) controller, and audio engine DMA (DMA_AUDIO) controller. Each of the four MCBSP modules can generate two DMA events:

- MCBSPi_DMA_TX: MCBSPi module transmit DMA request
- MCBSPi_DMA_RX: MCBSPi module receive DMA request

Table 23-335 summaries the DMA events with the mapping on both DMA controllers.

The receive and transmit DMA requests can be individually disabled by setting the MCBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and MCBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

For more information, see Section 23.5.4.11, *MCBSP DMA Configuration*.

23.5.4.8 MCBSP Data Transfer Process

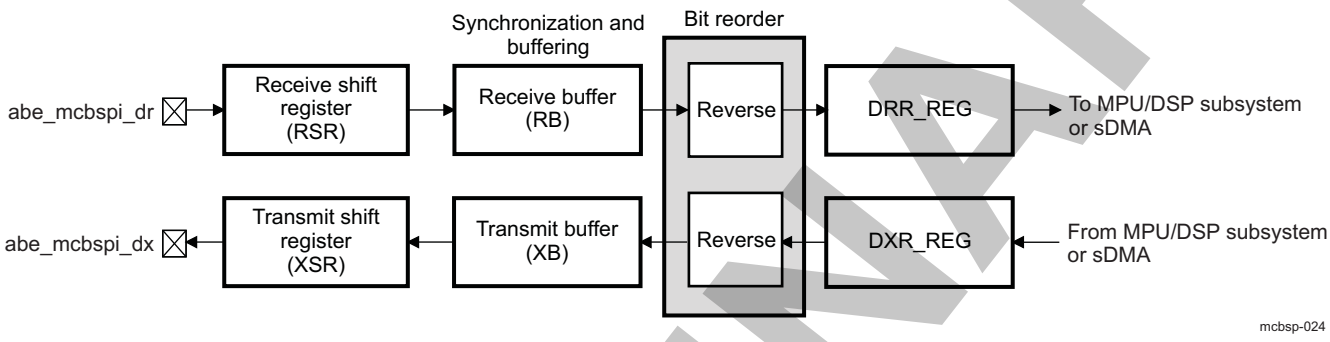
For MCBSP modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

All registers of MCBSP data transfer paths are 32 bits wide. Figure 23-114 shows the MCBSP data transfer paths.

CAUTION

The MCBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect); 16-and 8-bit accesses are not allowed and can corrupt register content.

Figure 23-114. MCBSP Data Transfer Paths



23.5.4.8.1 Data Transfer Process for 8-/12-/16-/20-/24-/32-Bit-Long Words

NOTE: For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the MCBSPi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the threshold of the RB is reached, the MCBSP module asserts DMA or interrupt request and the content of the RB is then transferred (the DMA_SYSTEM or the DMA_DSP controller reads the data receive register MCBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, DSP subsystem, or the DMA controller to the data transmit register (MCBSPi.MCBSPLP_DXR_REG) using the MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory contains the previous written value). If there is no previous data in the transmit shift register (XSR), the value from the transmit buffer (XB) is copied to the XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the MCBSPi_dx pin.

23.5.4.8.2 Bit Reordering (Option to Transfer LSB First)

Generally, the MCBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

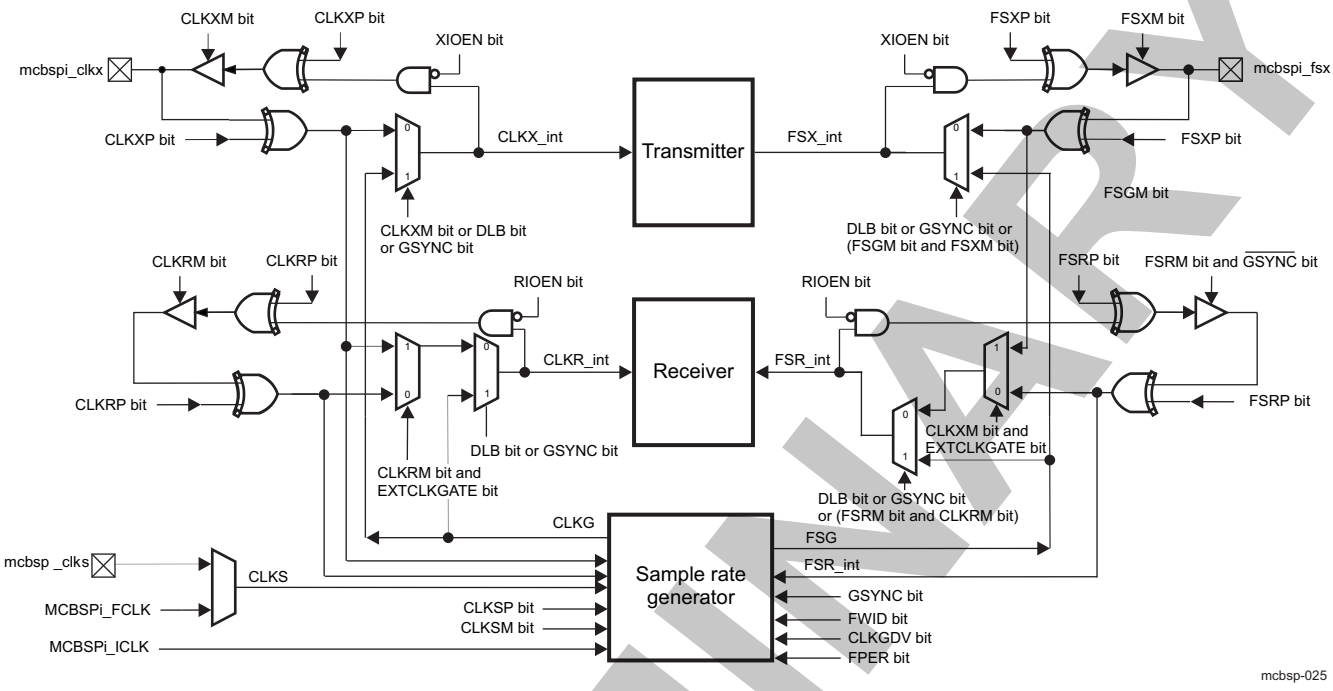
If the MCBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If MCBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field is set to 0b01, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8- to 32-bit data length.

23.5.4.8.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how MCBSP data transfers are timed and delimited.

Figure 23-115. Conceptual Block Diagram for Clock and Frame Generation When MCBSPLP_SPCR1_REG[15] ALB = 0



The CLKR_int clock signal can be derived from three sources:

- The sample rate generator (CLKG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- MCBSP1_clkr pin (CLKR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0)
- MCBSPi_clkx pin (CLKX) : When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1 and (MCBSPLP_XCCR_REG[5]DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0)

The CLKX_int clock signal can be derived from two sources:

- The sample rate generator (CLKG): When MCBSPLP_PCR_REG[9] CLKXM = 1 or MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1
- MCBSPi_clkx pin (CLKX) – when MCBSPLP_PCR_REG[9] CLKXM = 0 or MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0

The FSR_int frame-sync signal can be derived from three sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1 or (MCBSPLP_PCR_REG[10] FSRM = 1 and MCBSPLP_PCR_REG[8] CLKRM = 1)
- MCBSP1_fsr pin (FSR): When MCBSPLP_PCR_REG[9] CLKXM = 0 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 0 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0))
- MCBSPi_fsx pin (FSX): When MCBSPLP_PCR_REG[9] CLKXM = 1 and MCBSPLP_XCCR_REG[15] EXTCLKGATE = 1 and (MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_PCR_REG[10] FSRM = 0 and MCBSPLP_PCR_REG[8] CLKRM = 0))

The FSX_int frame-sync signal can be derived from two sources:

- The sample rate generator (FSG): When MCBSPLP_XCCR_REG[5] DLB = 1 or MCBSPLP_SRGR2_REG[15] GSYNC = 1 or (MCBSPLP_SRGR2_REG[12] FSGM = 1 and MCBSPLP_PCR_REG[11] FSXM = 1)

- MCBSPi_fsx pin (FSX): When MCBSPLP_XCCR_REG[5] DLB = 0 or MCBSPLP_SRGR2_REG[15] GSYNC = 0 or (MCBSPLP_SRGR2_REG[12] FSGM = 0 and MCBSPLP_PCR_REG[11] FSXM = 0)

23.5.4.8.3.1 Clocking

Data is shifted 1 bit at a time from the MCBSPi_dr pin to the RSRs or from the XSRs to the MCBSPi_dx pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (CLKR_int) controls bit transfers from the MCBSPi_dr pin to the RSRs. The transmit clock signal (CLKX_int) controls bit transfers from the XSRs to the MCBSPi_dx pin. The CLKR_int and CLKX_int signals can be derived from inside the MCBSP module (see Figure 23-115). The clock source is selected by programming the MCBSPi.MCBSPLP_PCR_REG[9] CLKXM and MCBSPi.MCBSPLP_PCR_REG[8] CLKRM bits, respectively.

When the MCBSPi.MCBSPLP_PCR_REG[9] CLKXM bit (transmitter clock mode) is set to:

- 0: CLKX_int is driven by an external clock and MCBSPi_clkx is an input pin.
- 1: CLKX_int is driven by the internal SRG and MCBSPi_clkx is an output pin.

For the MCBSPi.MCBSPLP_PCR_REG[8] CLKRM bit (receiver clock mode), see .

The polarities of CLKR and CLKX signals are configured in MCBSPi.MCBSPLP_PCR_REG register.

The MCBSPi.MCBSPLP_PCR_REG[1] CLKXP bit defines the transmit clock polarity:

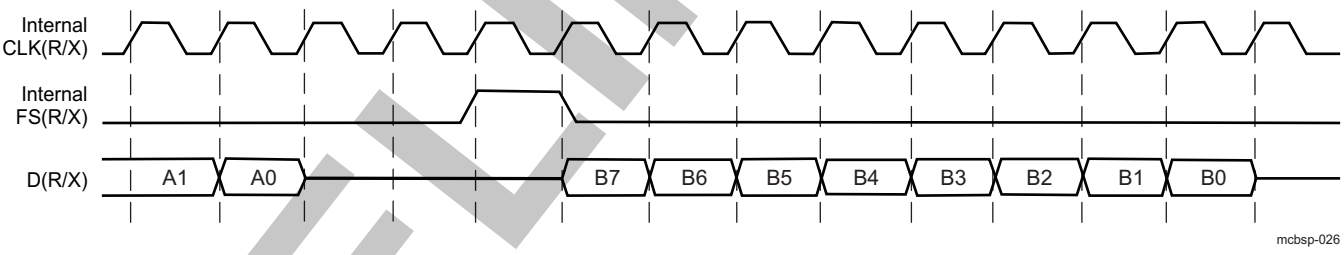
- When set to 0, transmit data is driven on the rising edge of the CLKX signal.
- When set to 1, transmit data is driven on the falling edge of the CLKX signal.

The MCBSPi.MCBSPLP_PCR_REG[0] CLKRP bit defines the receive clock polarity:

- When set to 0, receive data is sampled on the falling edge of the CLKX signal.
- When set to 1, transmit data sampled on the rising edge of the CLKX signal.

Figure 23-116 shows an example in which the clock signal controls the timing of each bit transfer on the pin.

Figure 23-116. Clock Signal Control of Bit Transfer Timing



NOTE: The MCBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal SRG for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the MCBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

23.5.4.8.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (MCBSPi_dr or MCBSPi_dx) are transferred in a group called a serial word. Software defines how many bits are in a word by programming:

- For the receiver: The MCBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and MCBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields
- For the transmitter: The MCBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and MCBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields

The difference of use is explained in Section 23.5.4.8.4.1, *Number of Phases, Words, and Bits per Frame*.

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see Section 23.5.6, *MCBSP Register Manual*)

Bits coming from the MCBSPi_dr pin are held in the RSR until it holds a full serial word, and then the word is passed to the RB and the MCBSPi.MCBSPLP_DRR_REG register.

During transmission, the XSR accepts new data from the XB after a full serial word has been passed from the XSR to the MCBSPi_dx pin.

In the example in Figure 23-119, an 8-bit word size was defined (see the transfer of the 8-bit word B).

23.5.4.8.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. Software defines how many words are in a frame by programming:

- For the receiver: The MCBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 and MCBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit fields
- For the transmitter: The MCBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and MCBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields

The difference between these registers is explained in Section 23.5.4.8.4.1, *Number of Phases, Words, and Bits per Frame*. For the corresponding field values and number of words, see Section 23.5.6, *MCBSP Register Manual*.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The MCBSP module uses frame-sync signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-sync signal, the MCBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the MCBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-sync (FSR_int) signal initiate frame transfers on MCBSPi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on MCBSPi_dx. FSR_int or FSX_int signals can be derived from inside the MCBSP module (see Figure 23-114). The frame-sync source is selected by programming the MCBSPi.MCBSPLP_PCR_REG[11] FSXM and MCBSPi.MCBSPLP_PCR_REG[10] FSRM bits, respectively.

When the MCBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- 0: FSX_int is derived from an external source and MCBSPi_fsx is an input pin.
- 1: FSX_int is determined by the MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and MCBSPi_fsx is an output pin.

For the MCBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- 0: Reserved.
- 1: FSR_int is generated internally by the SRG.

In the example in Figure 23-115, a one-word frame is transferred when a frame-sync pulse occurs. The polarities of FSR and FSX signals are programmable by bits in the MCBSPi.MCBSPLP_PCR_REG register.

The MCBSPi.MCBSPLP_PCR_REG[3] FSXP bit defines the transmit frame-sync polarity:

- When set to 0, frame-sync pulse FSX is active high.
- When set to 1, frame-sync pulse FSX is active low.

The MCBSPi.MCBSPLP_PCR_REG[2] FSRP bit defines the receive frame-sync polarity:

- When set to 0, frame-sync pulse FSR is active high.
- When set to 1, frame-sync pulse FSR is active low.

In MCBSP operation, the inactive-to-active transition of the frame-sync signal indicates the start of the next frame. For this reason, the frame-sync signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

23.5.4.8.3.4 Detecting Frame-Sync Pulses, Even in Reset State

The MCBSP module can generate receive and transmit interrupts to the Cortex-A15 MPU/DSP subsystems to indicate specific events in the MCBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-sync pulses (see Section 23.5.5, *MCBSP Basic Programming Model* for more information).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, the MCBSPi.MCBSPLP_PCR_REG[0] FSRM/MCBSPi.MCBSPLP_PCR_REG[1] FSXM bit and the MCBSPi.MCBSPLP_PCR_REG[2] FSRP/MCBSPi.MCBSPLP_PCR_REG[3] FSXP bit still selects the appropriate source and polarity of frame synchronization. Thus, even when the serial port is in reset state, these signals are synchronized to the interface clock (MCBSPi_ICLK) and then sent to the Cortex-A15 MPU/DSP subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-sync pulse can be detected, and then the Cortex-A15 MPU/DSP subsystem can take the serial port out of reset safely.

23.5.4.8.3.5 Ignoring Frame-Sync Pulses

The MCBSP module ignores transmit and/or receive frame-sync pulses if the frame transfer was started by a previous frame-sync pulse (unexpected frame-sync pulses). The MCBSP module does not support features such as retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-sync pulses until the desired frame length or number of words is reached. For more information about unexpected frame-sync pulses, see Section 23.5.4.10.3, *Unexpected Receive Frame-Sync Pulse*, or Section 23.5.4.10.6, *Unexpected Transmit Frame-Sync Pulse*.

23.5.4.8.3.6 Frame Frequency

The frame frequency is determined by the period between frame-sync pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency/(number of clock cycles between two rising edges [or falling edges] of two consecutive frame-sync pulses)

The frame frequency can be increased by decreasing the time between frame-sync pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

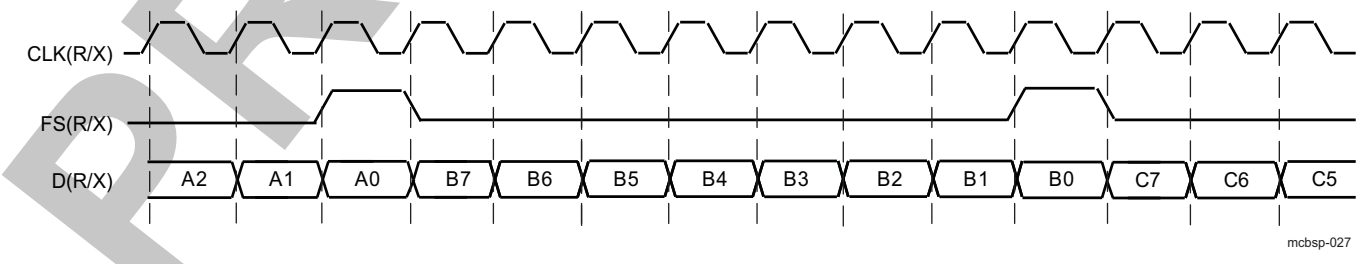
23.5.4.8.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame-sync pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = Clock frequency/number of bits per frame

Figure 23-117 shows the MCBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 23-117. MCBSP Operating at Maximum Packet Frequency



If there is a 1-bit data delay as shown in Figure 23-117, the frame-sync pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: When the MCBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field is se to 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more information, see Table 23-387.

23.5.4.8.4 Frame Phases (Dual-Phase Frame I2S Support)

The MCBSP module allows configuration of each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phases. It is the only possible value for word per frame when using the dual-phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user may define a frame as consisting of one phase containing one 16-bit word, followed by a second phase consisting of one 32-bit word. This configuration allows the user to compose frames for custom applications such as I2S protocol.

23.5.4.8.4.1 Number of Phases, Words, and Bits per Frame

Table 23-339 shows which bit fields in the receive control registers (MCBSPi.MCBSPLP_RCR1_REG and MCBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (MCBSPi.MCBSPLP_XCR1_REG and MCBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to Table 23-339:

- RPHASE => MCBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE => MCBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFRLEN1 => MCBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 bit field
- RFRLEN2 => MCBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2 bit field
- XFRLEN1 => MCBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit field
- XFRLEN2 => MCBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit field
- RWDLEN1 => MCBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field
- RWDLEN2 => MCBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit field
- XWDLEN1 => MCBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field
- XWDLEN2 => MCBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit field

Table 23-339. Phases, Words and Bits per Frame Control Bit

Operation	Number of Phases	Words per Frame Set With	Bits per Word Set With
Reception	1 (RPHASE = 0)	RFRLEN1	RWDLEN1
Reception	2 (RPHASE = 1)	RFRLEN1 = 0x0 and RFRLEN2 = 0x0	RWDLEN1 for phase 1 RWDLEN2 for phase 2
Transmission	1 (XPHASE = 0)	XFRLEN1	XWDLEN1
Transmission	2 (XPHASE = 1)	XFRLEN1 = 0x0 and XFRLEN2 = 0x0	XWDLEN1 for phase 1 XWDLEN2 for phase 2

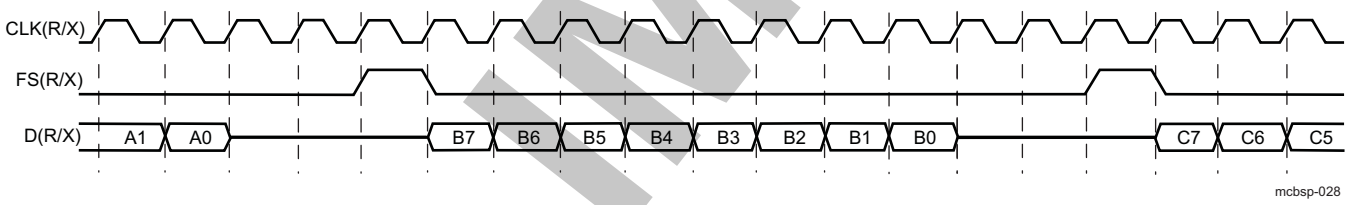
23.5.4.8.4.2 Single-Phase Frame Example

Figure 23-118 shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the MCBSPi_dx and MCBSPi_dr pins are available one clock cycle after FS(R/X) goes active. Table 23-340 lists the assumptions used in the example in Figure 23-118.

Table 23-340. Assumptions for the Single-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	0	MCBSPi.MCBSPLP_RCR2_REG[15] RPHASE
		MCBSPi.MCBSPLP_XCR2_REG[15] XPHASE
One word per frame	0x0	MCBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1
		MCBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1
8-bit word length	0x0	MCBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1
		MCBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1
Word length in register2	Ignored	MCBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2
		MCBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2
Receive data clocked on falling edge	0	MCBSPi.MCBSPLP_PCR_REG[0] CLKRP
Transmit data clocked on rising edge		MCBSPi.MCBSPLP_PCR_REG[1] CLKXP
Active-high frame-sync signals	0	MCBSPi.MCBSPLP_PCR_REG[2] FSRP
		MCBSPi.MCBSPLP_PCR_REG[3] FSXP
1-bit data delay	01b	MCBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY
		MCBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY

Figure 23-118. Single-Phase Frame for a MCBSP Data Transfer



23.5.4.8.4.3 Dual-Phase Frame Example

Figure 23-119 shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bitstream in the frame is contiguous. There are no gaps between words/phases. Table 23-341 lists the assumptions used in the example in Figure 23-119.

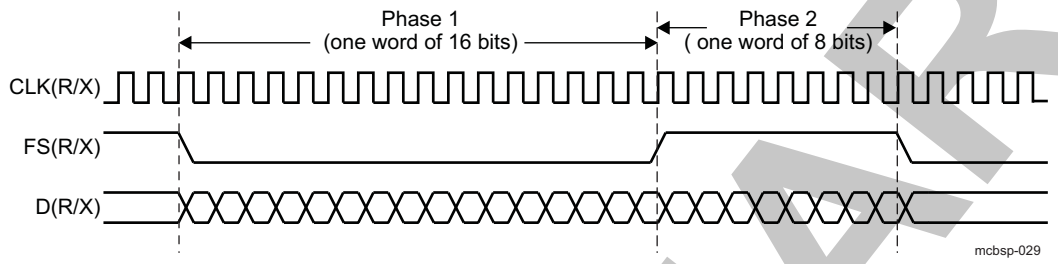
Table 23-341. Assumptions for the Dual-Phase Frame Example

Assumption	Value	Bit or Field Name
Single-phase frame	1	MCBSPi.MCBSPLP_RCR2_REG[15] RPHASE
		MCBSPi.MCBSPLP_XCR2_REG[15] XPHASE
One word per frame	0x0	MCBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1
		MCBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1
16-bit word length	0x0	MCBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1
		MCBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1
8-bit word length	0x2	MCBSPi.MCBSPLP_RCR2_REG[14:8] RFRLEN2
		MCBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2
Receive data clocked on falling edge	0	MCBSPi.MCBSPLP_PCR_REG[0] CLKRP
Transmit data clocked on rising edge		MCBSPi.MCBSPLP_PCR_REG[1] CLKXP
Active-high frame-sync signals	0	MCBSPi.MCBSPLP_PCR_REG[2] FSRP
		MCBSPi.MCBSPLP_PCR_REG[3] FSXP

Table 23-341. Assumptions for the Dual-Phase Frame Example (continued)

Assumption	Value	Bit or Field Name
0-bit data delay	00b	MCBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY
		MCBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY

Figure 23-119. Dual-Phase Frame for a MCBSP Data Transfer



23.5.4.8.5 MCBSP Reception

This section explains the fundamental process of reception in the MCBSP module. For information about how to program the MCBSP receiver, see Section 23.5.5, *MCBSP Basic Programming Model*, Section 23.5.5.4, *Interrupt Configuration*, and Section 23.5.5.5, *Receiver Configuration*.

Figure 23-120 and Figure 23-121 show how reception occurs in the MCBSP module. A description of the process follows the figures. Figure 23-120 shows the physical path for the data.

Figure 23-120. MCBSP Reception Physical Data Path

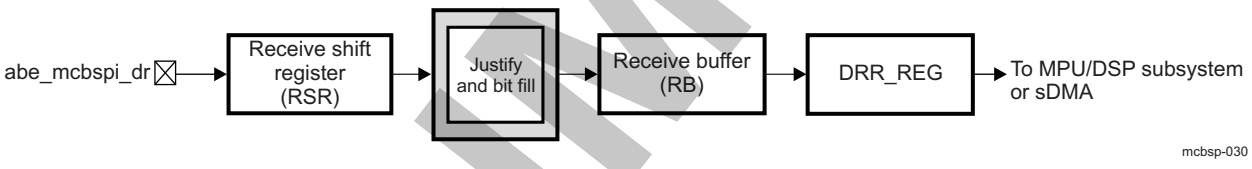


Figure 23-121 is a timing diagram showing signal activity for one possible reception scenario.

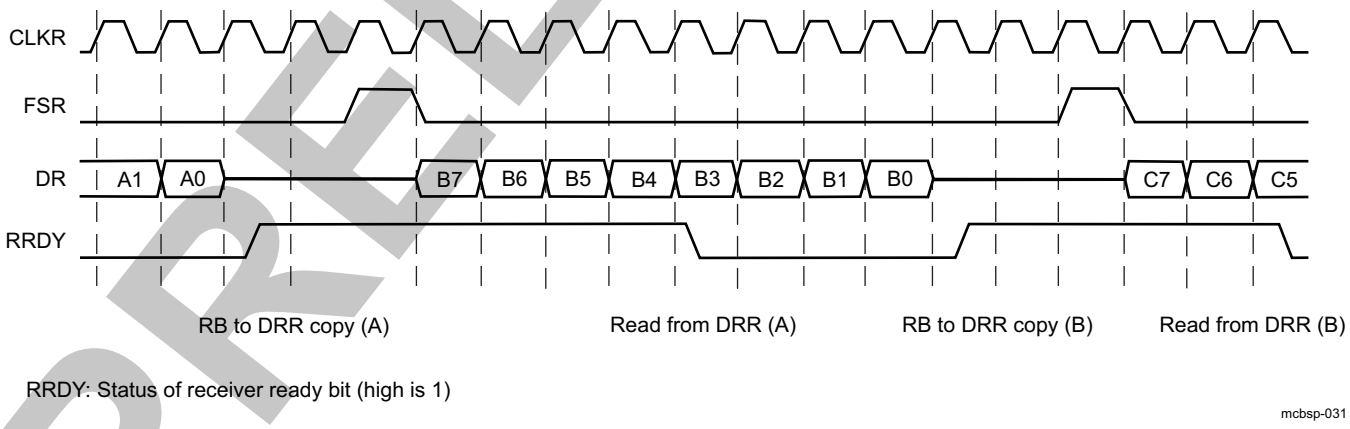
Figure 23-121. MCBSP Reception Signal Activity



The following process describes how data travels from the MCBSPi_dr pin to the MPU/DSP subsystem or to the sDMA controller:

1. The MCBSP module waits for a receive frame-sync pulse on FSR_int.
2. When the pulse arrives, the MCBSP module inserts the appropriate data delay that is selected with the MCBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. In the preceding timing diagram a 1-bit data delay is selected.

3. The MCBSP module accepts data bits on the MCBSPi_dr pin and shifts them into the RSR. For information about choosing a word length, see Section 23.5.5.6, *Transmitter Configuration*.
4. When a full word is received, the MCBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (MCBSPi.MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD bit field), the MCBSP module asserts the receiver ready bit (MCBSPi.MCBSPLP_SPCR1_REG[1] RRDY). This indicates that receive data is ready to be read by the Cortex-A15 MPU/DSP subsystem or the sDMA controller by accessing the MCBSPi.MCBSPLP_DRR_REG register.

   The data copied from RB to MCBSPi.MCBSPLP_DRR_REG is justified and bit-filled according to the MCBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field.
6. The Cortex-A15 MPU/DSP subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, the MCBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

23.5.4.8.6 MCBSP Transmission

This section explains the fundamental process of transmission in the MCBSP module. For information about how to program the MCBSP transmitter, see Section 23.5.5, *MCBSP Basic Programming Model* and Section 23.5.5.6, *Transmitter Configuration*.

Figure 23-122 and Figure 23-123 show how transmission occurs in the MCBSP module. A description of the process follows the figures. Figure 23-122 shows the physical path for the data.

Figure 23-122. MCBSP Transmission Physical Data Path

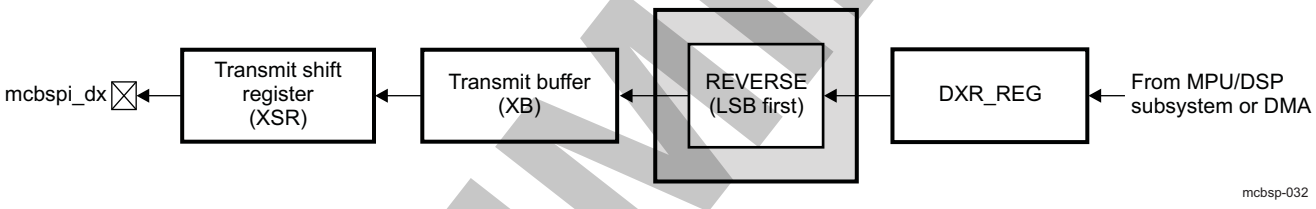


Figure 23-123 is a timing diagram showing signal activity for one possible transmission scenario.

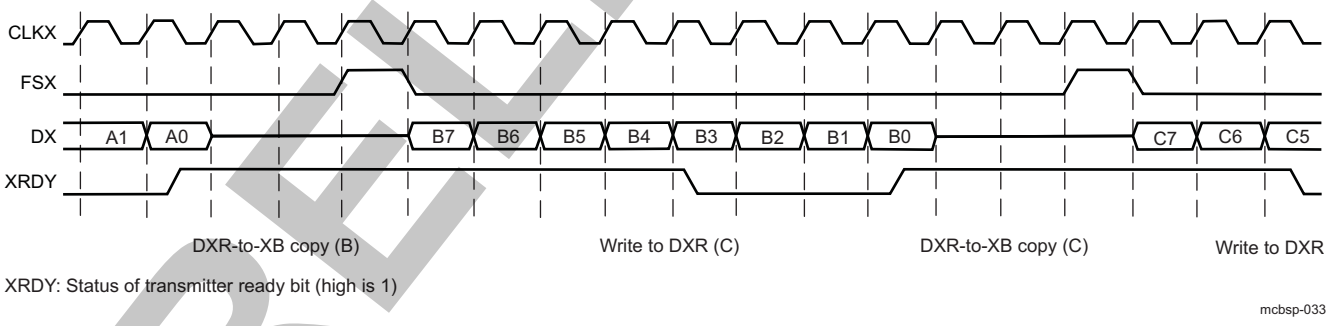
Figure 23-123. MCBSP Transmission Signal Activity



1. The Cortex-A15 MPU/DSP subsystem or the sDMA controller writes data to the data transmit register (MCBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is cleared to indicate that the transmitter is not ready for new data. For information about choosing a word length, see Table 23-383.
2. When new data arrives in the MCBSPi.MCBSPLP_DXR_REG register, the MCBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY) is set as long as the buffer contains at least the transmit threshold number of free locations (the MCBSPi.MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD bit field). This indicates that the transmitter is ready to accept new data from the MPU/DSP subsystem or the sDMA controller.
3. The MCBSP module waits for a transmit frame-sync pulse on FSX_int.
4. When the pulse arrives, the MCBSP module inserts the appropriate data delay that is selected with the

MCBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field.

In the preceding timing diagram, a 1-bit data delay is selected.

5. The MCBSP module shifts data bits from the XSR to the MCBSPi_dx pin.

23.5.4.8.7 Enable/Disable the Transmit and Receive Processes

The MCBSP module has the option to stop and resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (MCBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/MCBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the MCBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when the FSR signal is asserted while receive disable) by the remote device are lost, and the receive buffer overflow status bit (MCBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while the MCBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when the FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (MCBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization while transmit/receive process is disabled can be checked by reading the transmit/receive frame-sync interrupt status: MCBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX/MCBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the MCBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/MCBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (MCBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/MCBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT bit field indicating the occupied/available buffer locations), because this register is an interface clock (MCBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available in the functional clock domain.

23.5.4.8.8 MCBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (MCBSPi.MCBSPLP_PCR_REG[1] CLKXP = 0x0) and the configured CLKR edge is the falling edge (MCBSPi.MCBSPLP_PCR_REG[0] CLKRP = 0x0). These are the reset values.

In the following timing diagrams, a 1-bit data delay is selected (MCBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY = 0x01 and MCBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x01), because data often follows a 1-cycle active frame-synchronization.

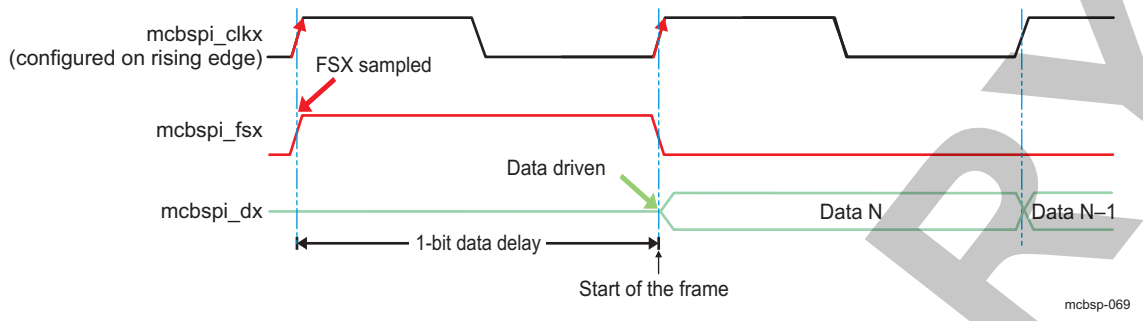
MCBSP modules can support two edge selection modes for transmit and receive data transfer at the system level:

- The full-cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later)
- The half-cycle mode, for which one-half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one-half clock period later). New data are generated only every clock period, which ensures the required hold time.

23.5.4.8.8.1 Transmit Full-Cycle Mode

When configured in full-cycle mode (MCBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 23-124.

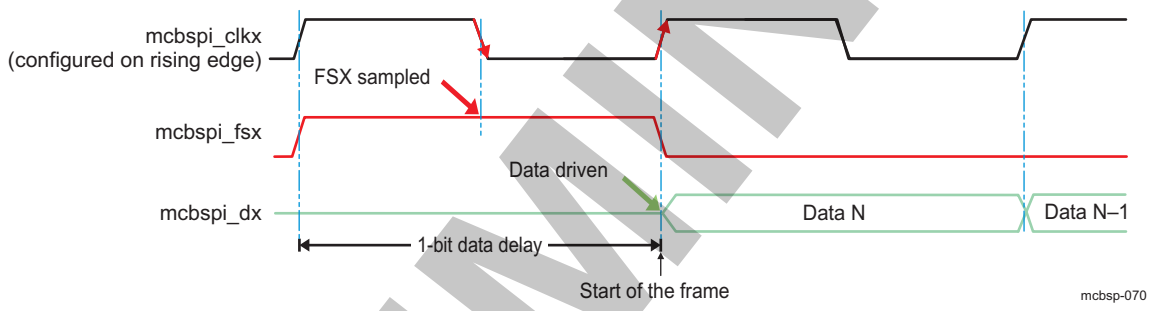
Figure 23-124. Transmit Full-Cycle Timing Diagram



23.5.4.8.8.2 Transmit Half-Cycle Mode

When configured in half-cycle mode (MCBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 23-125.

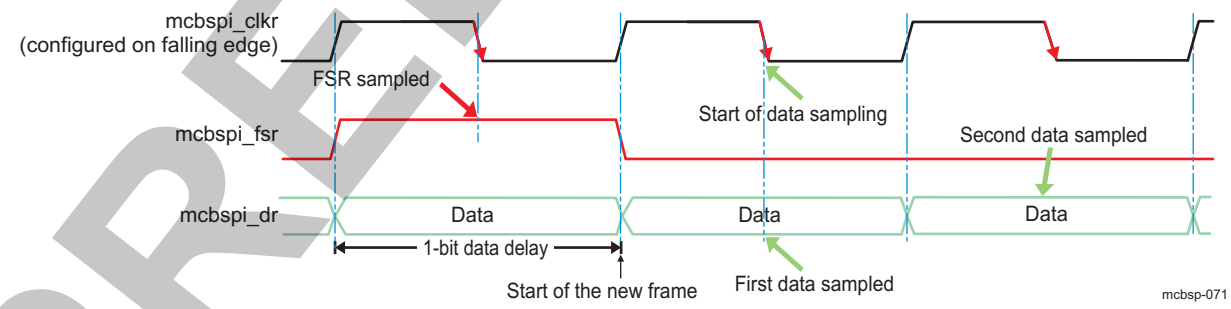
Figure 23-125. Transmit Half-Cycle Timing Diagram



23.5.4.8.8.3 Receive Full-Cycle Mode

When configured in full-cycle mode (MCBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 23-126.

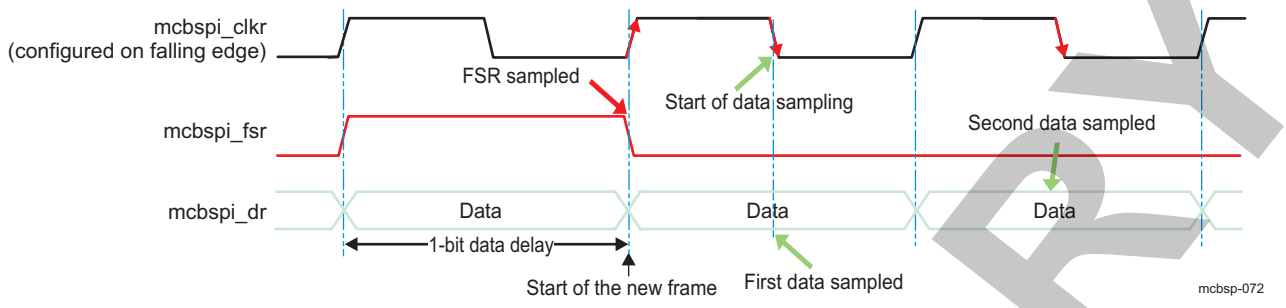
Figure 23-126. Receive Full-Cycle Timing Diagram



23.5.4.8.8.4 Receive Half-Cycle Mode

When configured in half-cycle mode (MCBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 23-127.

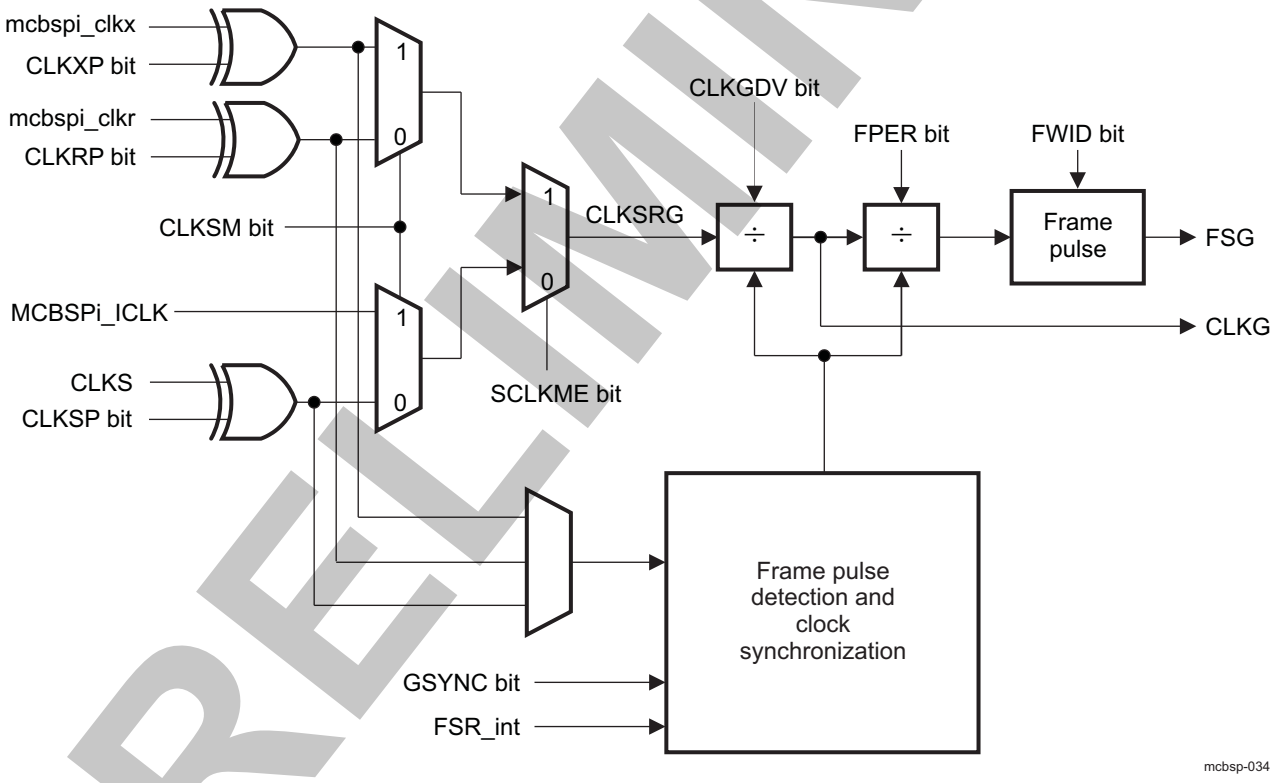
Figure 23-127. Receive Half-Cycle Timing Diagram



23.5.4.9 MCBSP SRG

The MCBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-sync signal (FSG). CLKG can be used for bit shifting on the data receive pin (MCBSPi_dr) and/or the data transmit pin (MCBSPi_dx). FSG can be used to initiate frame transfers on the MCBSPi_dr pin and/or MCBSPi_dx pin. Figure 23-128 is a conceptual block diagram of the SRG.

Figure 23-128. Conceptual Block Diagram of the SRG



The source clock for the SRG (labeled CLKSRG in the diagram) can be supplied by the interface clock (MCBSPi_ICLK) or the functional clock (MCBSPi_FCLK input), or by an external pin (MCBSPi_clkx). The source is selected with the MCBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the MCBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (MCBSPi.MCBSPLP_SRGR2_REG[14] CLKSP, MCBSPi.MCBSPLP_PCR_REG[1] CLKXP, or MCBSPi.MCBSPLP_PCR_REG[0] CLKRP).

The SRG has a 3-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKSRG) is divided according to the MCBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field to produce the CLKG signal.
- Frame period divide-down: CLKG is divided according to the MCBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field to control the period from the start of a frame-pulse to the start of the next pulse.
- Frame-sync pulse-width countdown: CLKG cycles are counted according to the MCBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field to control the width of each frame-sync pulse.

NOTE: The MCBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a MCBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

CLKG is used as source to generate the output clocks CLKX and CLKR when the MCBSPi.MCBSPLP_PCR_REG[9] CLKXM/MCBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see Figure 23-115).

For information about preparing the SRG for operation, see Section 23.5.5, *MCBSP Basic Programming Model*.

23.5.4.9.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (MCBSPi.MCBSPLP_PCR_REG[9] CLKXM and MCBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (MCBSPi.MCBSPLP_PCR_REG[1] CLKXP and MCBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM = 1 for reception, CLKXM = 1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the MCBSP module are partially affected by use of the digital loopback (DLB) mode, the analog loopback (ALB) mode, and by the synchronous receive/transmit setting, respectively, as described in Table 23-342. ALB mode is selected with the MCBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. DLB mode is selected with the MCBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the control module (for more information, see Section 18.4.8*Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*).

When using the SRG as a clock source, ensure that the SRG is enabled (the MCBSPi.MCBSPLP_SPCR2_REG[6] GRST bit is set to1).

Table 23-342. Effects of DLB and ALB Bits on Clock Modes

Mode Bit Settings		Effect
CLKRM=1	DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled)	MCBSP1_clkr is an output pin driven by the SRG output clock (CLKG).
	DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled)	MCBSP1_clkr is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by the CLKX input signal provided by the MCBSPi_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by the FSX input signal provided by the MCBSPi_fsx pin. The receive data is driven by the DX input loopback pin (MCBSPi_dx).
	DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled)	The SRG and the frame-sync generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. In digital loopback mode, no serial link activity is seen by the remote device.
	DLB = 1 and ALB = 1 (Reserved mode)	Undefined functionality.
CLKXM=1	DLB = 0 and ALB = 0 (Digital and analog loopback mode disabled)	MCBSPi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB = 0 and ALB = 1 (Digital loopback mode disabled and analog loopback mode enabled)	MCBSPi_clkx is an output pin driven by the SRG output clock (CLKG).
	DLB = 1 and ALB = 0 (Digital loopback mode enabled and analog loopback mode disabled)	The SRG and the frame-sync generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame-sync signals are driven by the FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. In digital loopback mode, no serial link activity is seen by the remote device.
	DLB = 1 and ALB = 1 (Reserved mode)	Undefined functionality
	CONTROL_MCBSPLP[30] ALBCTRLRX_CLKX bit = 1 (synchronous setting and DLB = 0 and ALB = 0)	CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX.

23.5.4.9.2 Frame-Sync Generation in the SRG

The SRG can produce a frame-sync signal (FSG) for use by the receiver, the transmitter, or both.

For the receiver to use FSG for frame synchronization, make sure the MCBSPi.MCBSPLP_PCR_REG[10] FSRM bit is set to 1.

For the transmitter to use FSG for frame synchronization, the following bits must be set:

- MCBSPi.MCBSPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the MCBSP module rather than from the MCBSPi_fsx pin.
- MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1: This indicates that when FSXM is set to 1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM = 0 and FSXM = 1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, the MCBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and MCBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (the MCBSPi.MCBSPLP_SPCR2_REG[6] GRST bit is set to 1) and the frame-sync logic in the SRG must be enabled (the MCBSPi.MCBSPLP_SPCR2_REG[7] FRST bit is set to 0).

23.5.4.9.2.1 Choosing the Width of the Frame-Sync Pulse

Each pulse on FSG has a programmable width. Program the MCBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit field, and the resulting pulse width is (FWID + 1) CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

23.5.4.9.2.2 Controlling the Period Between the Starting Edges of Frame-Sync Pulses

The user can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- Software programs the MCBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field, and the resulting frame-sync period is (FPER + 1) CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

23.5.4.9.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and an FSG based on an input clock signal that is either:

- The interface clock signal (MCBSPi_ICLK)
- The functional clock signal (MCBSPi_FCLK)
- The MCBSPi_clkx pin

If the MCBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 0, the CLKG signal runs freely and is not resynchronized, and the frame-sync period on the FSG signal is determined by the MCBSPi.MCBSPLP_SRGR2_REG[11:0] FPER bit field.

23.5.4.9.3.1 Operating the Transmitter Synchronously With the Receiver

When the MCBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is set to 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by the FSG signal (MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1 and MCBSPi.MCBSPLP_PCR_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of the CLKG signal, it can be used, instead, by setting the MCBSPi.MCBSPLP_PCR_REG[11] FSXM bit to 0 and connecting the FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (the MCBSPi.MCBSPLP_PCR_REG[8] CLKRM and MCBSPi.MCBSPLP_PCR_REG[9] CLKXM bits are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

23.5.4.10 MCBSP Exception/Error Conditions

23.5.4.10.1 Introduction

Several serial port events can constitute a system error. Any error condition can be a source of an interrupt:

- Receiver overrun (the MCBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and the legacy mode MCBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1)

  This occurs when the RB is full and the RSR is full with another new word shifted in from MCBSPi_dr. Therefore, the MCBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit (MCBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on MCBSPi_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on MCBSPi_dr and the MCBSPi.MCBSPLP_DRR_REG register is not read. For more information about overrun in the receiver, see Section 23.5.4.10.2, *Overrun in the Receiver*.
- Unexpected receive frame-sync pulse (the MCBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit

is set to 1, and the legacy mode MCBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to 1)

This occurs during reception when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are received. Such a pulse is ignored by the receiver, but sets the MCBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more information about receive frame-sync errors, see Section 23.5.4.10.3, *Unexpected Receive Frame-Sync Pulse*.

- Receiver underflow (the MCBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to 1)

  This occurs when the sDMA controller or MPU/DSP subsystem reads data from an empty receive buffer. For more information about underflow in the receiver, see Section 23.5.4.10.4, *Underflow in the Receiver*.

- Transmitter underflow (the MCBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to 1, and the legacy mode MCBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0)

  If a new frame-sync signal arrives when the XB is empty, the previous data in the XSR is re-sent. This procedure continues for every new frame-sync pulse that arrives until the MCBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more information about underflow in the transmitter, see Section 23.5.4.10.5, *Underflow in the Transmitter*.

- Unexpected transmit frame-sync pulse (the MCBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit is set to 1, and the legacy mode MCBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERRbit is set to 1)

  This occurs during transmission when an unexpected frame-sync pulse arrives. An unexpected frame-sync pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame are transferred. Such a pulse is ignored by the transmitter, but sets the MCBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more information, see Section 23.5.4.10.6, *Unexpected Transmit Frame-Sync Pulse*.

- Transmitter overflow (the MCBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to 1)

  This occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB. For more information about underflow in the receiver, see Section 23.5.4.10.7, *Overflow in the Transmitter*.

23.5.4.10.2 Overrun in the Receiver

When the MCBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and the MCBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1 (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. MCBSPi.MCBSPLP_DRR_REG is not read even if the MCBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full.
3. RSR is full.

As previously described, data arriving on MCBSPi_dr is continuously shifted into the RSR. Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode MCBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

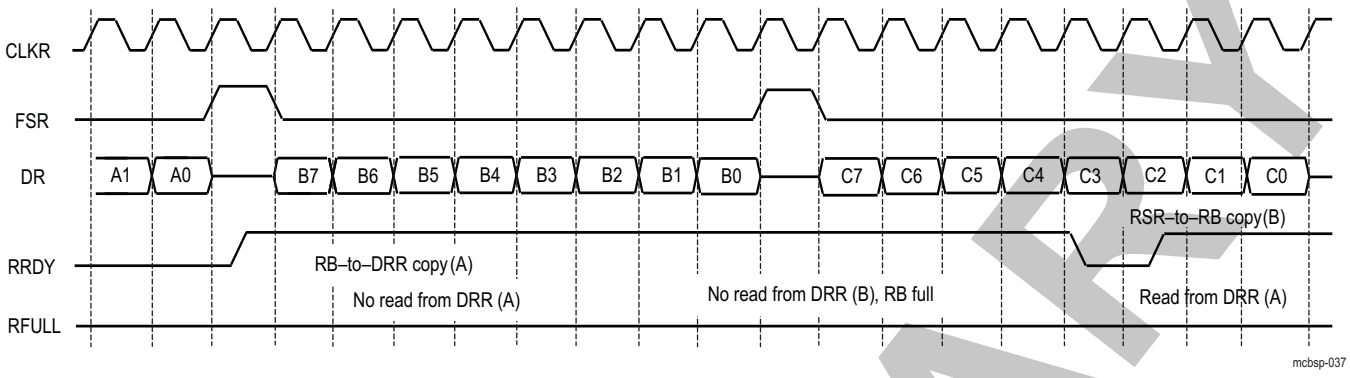
- The MPU/DSP subsystems or sDMA controller reads the MCBSPi.MCBSPLP_DRR_REG register.
- The receiver is reset individually (the MCBSPi.MCBSPLP_SPCR1_REG[0] RRST bit is set to 0) or as part of a global reset.

Another frame-sync pulse is required to restart the receiver.

According to the MCBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the MCBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

Figure 23-129 shows the receive overrun condition.

Figure 23-129. Overrun in the MCBSP Receiver



23.5.4.10.3 Unexpected Receive Frame-Sync Pulse

23.5.4.10.3.1 Possible Responses to Receive Frame-Sync Pulses

If a frame-sync pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-sync pulse, and the receiver sets the receive frame-sync error bit MCBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR (and the legacy MCBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit).

According to the settings of the MCBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the MCBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

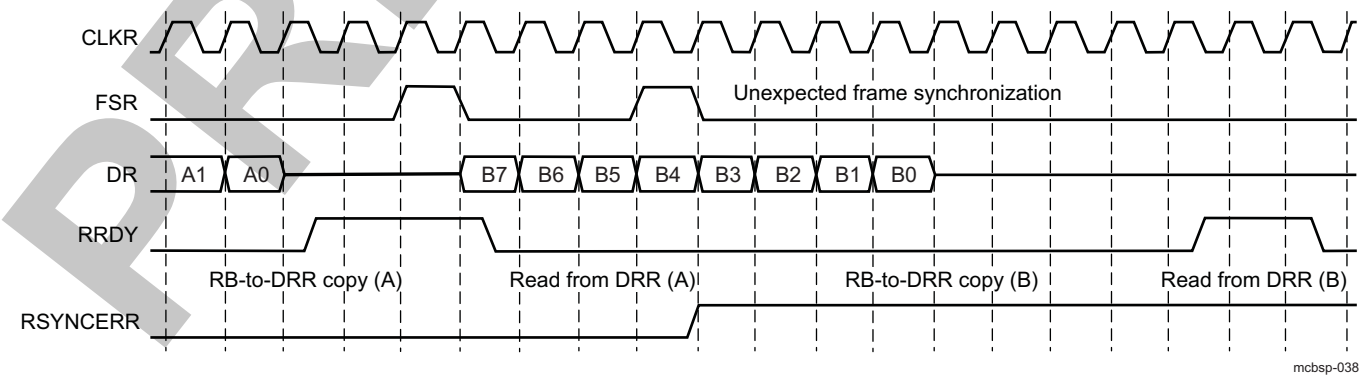
Using the legacy mode, the MCBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit can be cleared only by a receiver reset or by setting this bit to 0. For the MCBSP module to notify the MPU/DSP subsystem of receive frame-sync errors, set the legacy mode receive interrupt with the MCBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field. When RINTM is set to 0b11, the MCBSP module sends a receive interrupt (legacy mode) request to the MPU/DSP subsystems each time that RSYNCERR is set.

23.5.4.10.3.2 Example of an Unexpected Receive Frame-Sync Pulse

Figure 23-130 shows an unexpected receive frame-sync pulse during normal operation of the serial port with time intervals between data packets.

NOTE: The unexpected receive frame-sync pulse does not influence the data receive process, being ignored by the data receive state-machine.

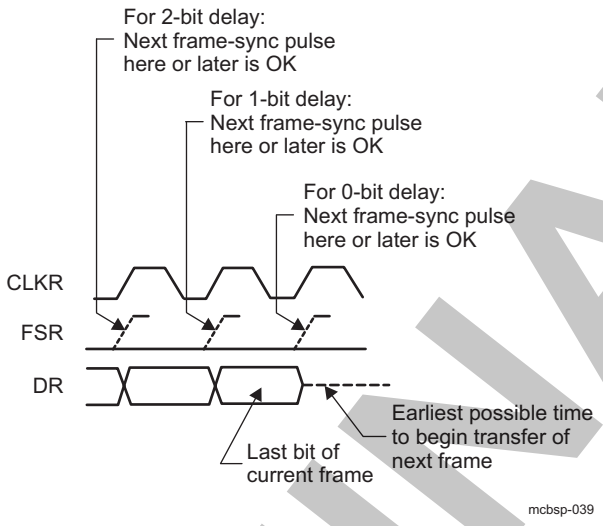
Figure 23-130. Unexpected Frame-Sync Pulse During a MCBSP Reception



23.5.4.10.3.3 Preventing Unexpected Receive Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the MCBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field. For each possible data delay, Figure 23-131 shows when a new frame-sync pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 23-131. Proper Positioning of Receive Frame-Sync Pulses



23.5.4.10.4 Underflow in the Receiver

The MCBSP module indicates a receiver underflow condition by setting the MCBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit. This error occurs when sDMA controller or MPU/DSP subsystem reads data from an empty RB this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the MCBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in MCBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

23.5.4.10.5 Underflow in the Transmitter

The MCBSP module indicates a transmitter empty (or underflow) condition by setting the MCBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit. The legacy mode MCBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is also cleared. Either of the following events activates the XEMPTY bit (XEMPTY = 0):

- The MCBSPi.MCBSPLP_DXR_REG register has not been loaded and the XB is empty, and all bits of the data word in the XSR have been shifted out on the MCBSPi_dx pin.
- The transmitter is reset (by forcing MCBSPi.MCBSPLP_SPCR2_REG[0] XRST to 0, or by a global reset) and is then restarted.

The XEMPTY bit is deactivated (XEMPTY = 1) when a new word in the MCBSPi.MCBSPLP_DXR_REG register is transferred to the XB. If the MCBSPi.MCBSPLP_PCR_REG[11] FSXM bit is set to 1 and the MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the FSX signal is generated when the XB is not empty. When the MCBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit is set to 0, the MCBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and MCBSPi.MCBSPLP_SRGR1_REG[15:8] FWID bit fields are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-sync pulse before sending the next frame on the MCBSPi_dx pin.

When the transmitter is taken out of reset (the cBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is set to 1), it is in a transmitter ready state (the MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is set to 1) and transmitter empty (the MCBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to 0) state. If the MCBSPi.MCBSPLP_DXR_REG register is loaded by the MPU/DSP subsystem or the sDMA controller before internal the FSX goes active high, a valid XB-to-XSR transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-sync pulse is generated or detected. Alternatively, if a transmit frame-sync pulse is detected before MCBSPi.MCBSPLP_DXR_REG is loaded, zeros are output on the MCBSPi_dx pin.

The MCBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during the transmit process. According to the settings of the MCBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in MCBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

23.5.4.10.6 Unexpected Transmit Frame-Sync Pulse

23.5.4.10.6.1 Possible Responses to Transmit Frame-Sync Pulses

If a frame-sync pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-sync pulse, and the transmitter sets the transmit frame-sync error bit MCBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy MCBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the settings of the MCBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

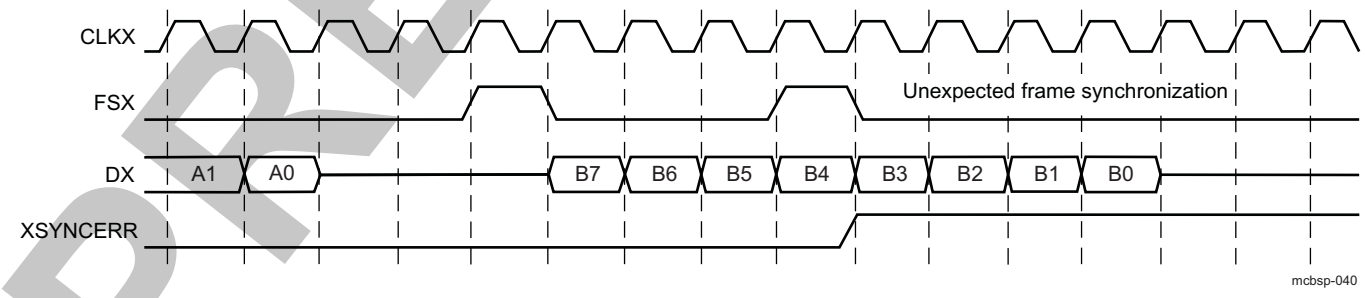
Using the legacy mode, the MCBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by setting this bit to 0. For the MCBSP module to notify the MPU/DSP subsystem of frame-sync errors, set a special transmit interrupt mode with the MCBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field. When XINTM is set to 0b11, the MCBSP module sends a transmit interrupt request to the MPU/DSP subsystem each time XSYNCERR is set.

23.5.4.10.6.2 Example of Unexpected Transmit Frame-Sync Pulse

Figure 23-132 shows an unexpected transmit frame-sync pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-sync pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

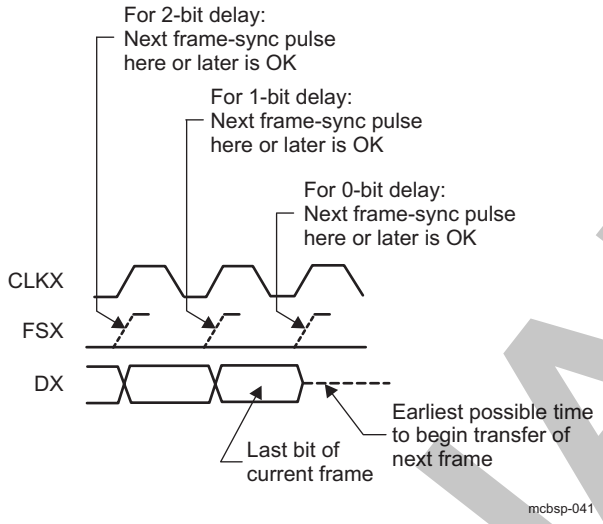
Figure 23-132. Unexpected Frame-Sync Pulse During a MCBSP Transmission



23.5.4.10.6.3 Preventing Unexpected Transmit Frame-Sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the MCBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field. For each possible data delay, Figure 23-133 shows when a new frame-sync pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 23-133. Proper Positioning of Transmit Frame-Sync Pulses



23.5.4.10.7 Overflow in the Transmitter

The MCBSP module indicates a transmitter overflow condition by setting the MCBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit. This error occurs when the sDMA controller or MPU/DSP subsystem writes data to a full XB (this happens only if the MPU/DSP subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before writing data). According to the settings of the MCBSPi.MCBSPLP_IRQENABLE_REG register, this condition can generate the MCBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in the status register clears the interrupt.

23.5.4.11 MCBSP DMA Configuration

The MCBSP receive and transmit data DMA requests are active after the receive MCBSPi.MCBSPLP_SPCR1_REG[0] RRST and transmit MCBSPi.MCBSPLP_SPCR2_REG[0] XRST bits are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the MCBSPi.MCBSPLP_RCCR_REG[3] RDMAEN and MCBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bits to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through the MCBSPi.MCBSPLP_THRSH1_REG and MCBSPi.MCBSPLP_THRSH2_REG registers as follows:

- (THRSH1_REG + 1) value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the RB occupied locations level is greater than or equal to the THRSH1_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG + 1) number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- (THRSH2_REG + 1) value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus 1). As long as the XB free locations level is greater than or equal to the THRSH2_REG value + 1, the DMA request is asserted. After transferring the configured (THRSH2_REG + 1) number of words, the transmit DMA request is deasserted and reasserted as soon as the conditions are met.

NOTE: The MPU/DSP subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/DSP subsystem) and the common interrupt line (MCBSPi_IRQ) can be used. The MCBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and the MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit indicate when the threshold values are reached. Also, by reading the receive buffer status MCBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status MCBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/DSP subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on the receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/DSP subsystem needs to read this data. Because no interrupt or DMA request is asserted, the only option in this case is to read the value of the RB status register and to transfer the remaining data without using the DMA or interrupt indication.

23.5.4.12 Multichannel Selection Modes

23.5.4.12.1 Channels, Blocks and Partitions

A MCBSP channel is a time slot for shifting in/out the bits of one serial word. The MCBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each (see Table 23-343).

Table 23-343. MCBSP Channels

Block 0: Channels 0–15	**Block 4: Channels 64–79**
Block 1: Channels 16–31	**Block 5: Channels 80–95**
Block 2: Channels 32–47	**Block 6: Channels 96–111**
Block 3: Channels 48–63	**Block 6: Channels 112–127**

The blocks are assigned to partitions according to the selected partition mode. In the 2-partition mode described in Section 23.5.4.12.6, *Using Two Partitions (Legacy Only)*, assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) block to partition B. In the 8-partition mode described in Section 23.5.4.12.4, *Using Eight Partitions*, blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of one another. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

23.5.4.12.2 Multichannel Selection

When a MCBSP module uses a time-division multiplexed (TDM) data stream while communicating with other MCBSP modules or serial devices, the MCBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The MCBSP module has one receive multichannel selection mode (see Section 23.5.4.12.5, *Receive Multichannel Selection Mode*) and three transmit multichannel selection modes (see Section 23.5.4.12.7, *Transmit Multichannel Selection Modes*).

23.5.4.12.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, ensure that the data frame is properly configured:

- Select a single-phase frame (the MCBSPi.MCBSPLP_RCR2_REG[15] RPHASE and MCBSPi.MCBSPLP_XCR2_REG[15] XPHASE bits are set to 0). Each frame represents a TDM data stream.
- Set a frame length (in the MCBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 and MCBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 bit fields) that includes the highest numbered channel to be used. For example, to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). In this case, If XFRLEN1= 39, the receiver creates 40 time slots per frame but receives data only during time slots 0, 15, and 39 of each frame.

23.5.4.12.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or transmitter, eight partitions or two partitions (as previously described) can be used. If 8-partition mode (MCBSPi.MCBSPLP_MCR1_REG[9] RMCME = 1 for reception, and MCBSPi.MCBSPLP_MCR2_REG[9] XMCME = 1 for transmission) is selected, MCBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions, in order, until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In 8-partition mode, the MCBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK/MCBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit fields, and the MCBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK/MCBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bit fields are ignored and the 16-channel blocks are assigned to the partitions as shown in Table 23-344 and Table 23-345. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 23-344. Eight Partitions – Receive Channel Assignment and Control

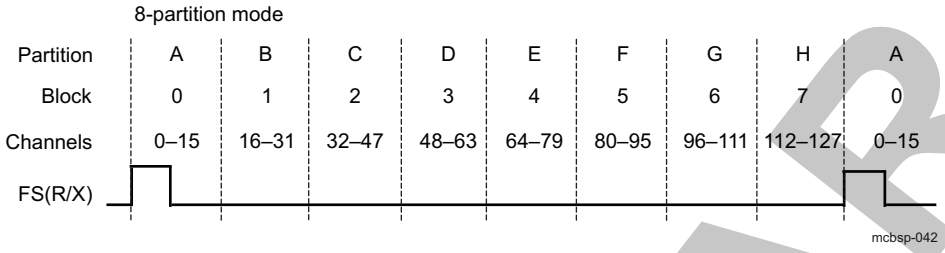
Receive Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0–15	MCBSPi.MCBSPLP_RCERA_REG
B	Block 1: Channels 16–31	MCBSPi.MCBSPLP_RCERB_REG
C	Block 2: Channels 32–47	MCBSPi.MCBSPLP_RCERC_REG
D	Block 3: Channels 48–63	MCBSPi.MCBSPLP_RCERD_REG
E	Block 4: Channels 64–79	MCBSPi.MCBSPLP_RCERE_REG
F	Block 5: Channels 80–95	MCBSPi.MCBSPLP_RCERF_REG
G	Block 6: Channels 96–111	MCBSPi.MCBSPLP_RCERG_REG
H	Block 7: Channels 112–127	MCBSPi.MCBSPLP_RCERH_REG

Table 23-345. Eight Partitions – Transmit Channel Assignment and Control

Transmit Partition	Assigned Block of Receive Channels	Register Used for Channel Control
A	Block 0: Channels 0–15	MCBSPi.MCBSPLP_XCERA_REG
B	Block 1: Channels 16–31	MCBSPi.MCBSPLP_XCERB_REG
C	Block 2: Channels 32–47	MCBSPi.MCBSPLP_XCERC_REG
D	Block 3: Channels 48–63	MCBSPi.MCBSPLP_XCERD_REG
E	Block 4: Channels 64–79	MCBSPi.MCBSPLP_XCERE_REG
F	Block 5: Channels 80–95	MCBSPi.MCBSPLP_XCERF_REG
G	Block 6: Channels 96–111	MCBSPi.MCBSPLP_XCERG_REG
H	Block 7: Channels 112–127	MCBSPi.MCBSPLP_XCERH_REG

Figure 23-134 shows an example of the MCBSP using 8-partition mode. In response to a frame-sync pulse, the MCBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 23-134. MCBSP Data Transfer in 8-Partition Mode



23.5.4.12.5 Receive Multichannel Selection Mode

The MCBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether all channels or only selected channels are enabled for reception.

- When RMCM = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCM = 1, the receive multichannel selection mode is enabled. In this mode:
  - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (MCBSPi.MCBSPLP_RCERA_REG/MCBSPi.MCBSPLP_RCERH_REG). The channels assigned to the MCBSPi.MCBSPLP_RCERA_REG/MCBSPi.MCBSPLP_RCERH_REG registers depend on the number of receive channel partitions (2 or 8), as defined by the MCBSPi.MCBSPLP_MCR1_REG[9] RMCME bit.
  - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (MCBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM = 0b00), no interrupt is generated.

As an example of how the MCBSP module behaves in the receive multichannel selection mode, suppose only channels 0, 15, and 39 are enabled and that the frame length is 40. The MCBSP module:

1. Accepts bits shifted in from the MCBSPi_dr pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the MCBSPi_dr pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the MCBSPi_dr pin in channel 39

23.5.4.12.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, two partitions or eight partitions can be used. If 2-partition mode (the MCBSPi.MCBSPLP_MCR1_REG[9] RMCME bit is set to 0 for reception, and the MCBSPi.MCBSPLP_MCR2_REG[9] XMCME bit is set to 0 for transmission) is selected, the MCBSP channels are activated using an alternating scheme. In response to a frame-sync pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame is transferred. When the next frame-sync pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the MCBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK bit field. In the receive multichannel selection mode,

the channels in this partition are controlled by receive channel enable register A (MCBSPi.MCBSPLP_RCERA_REG).

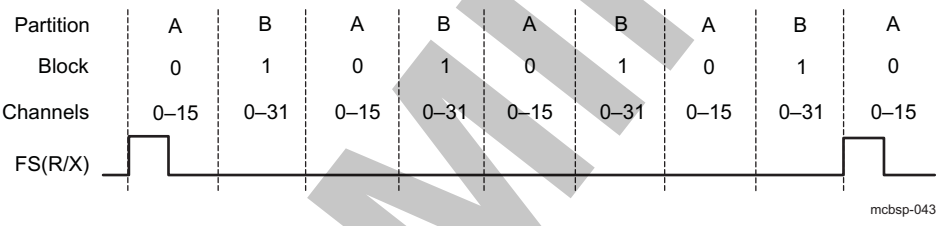
- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the MCBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK bit field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (MCBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the MCBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (MCBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the MCBSPi.MCBSPLP_MCR1_REG[8:7] XPBBLK bit field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (MCBSPi.MCBSPLP_XCERB_REG).

Figure 23-135 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-sync pulse, the MCBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 23-135. Alternating Between Partitions A and B Channels



23.5.4.12.7 Transmit Multichannel Selection Modes

The MCBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether all channels or only selected channels are enabled and unmasked for transmission. The MCBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 23-346.

Table 23-346. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

XMCM	Transmit Multichannel Selection Mode
0b00	No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked.
0b01	All channels are disabled unless they are selected in the appropriate transmit channel enable registers (MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The MCBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG registers.
0b10	All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG). The MCBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG registers.
0b11	This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (MCBSPi.MCBSPLP_RCERA_REG/MCBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG). The MCBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 or 128 channels are selectable in the MCBSPi.MCBSPLP_RCERA_REG/MCBSPi.MCBSPLP_RCERH_REG registers and the MCBSPi.MCBSPLP_XCERA_REG/MCBSPi.MCBSPLP_XCERH_REG registers.

As an example of how the MCBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that only channels 0, 15, and 39 are enabled. Suppose also that the frame length is 40. The MCBSP module:

1. Shifts data to the MCBSPi_dx pin in channel 0
2. Places the MCBSPi_dx pin in the high-impedance state in channels 1–14
3. Shifts data to the MCBSPi_dx pin in channel 15
4. Places the MCBSPi_dx pin in the high-impedance state in channels 16–38
5. Shifts data to the MCBSPi_dx pin in channel 39

23.5.4.12.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in Table 23-347 explain the channel control options:

Table 23-347. MCBSP Channel Control Options

Enabled channel	A channel that can begin transmission by passing data from the data transmit register (MCBSPi.MCBSPLP_DXR_REG) to the XSR through the XB.
Masked channel	A channel that cannot complete transmission. The MCBSPi_dx pin is held in high-impedance state; data cannot be shifted out on the MCBSPi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention.
Disabled channel	A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the MCBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (MCBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM = 00b), no interrupt is generated. The MCBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected.
Unmasked channel	A channel that is not masked. Data in the XSR(s) is shifted out on the MCBSPi_dx pin.

23.5.4.12.7.2 Activity on MCBSP Pins for Different Values of XMCM

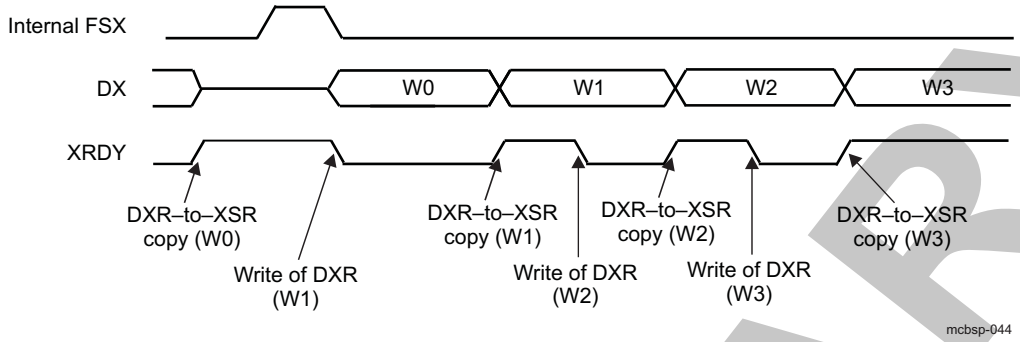
Figure 23-136 shows the activity on the MCBSP pins for the various values of the MCBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field. In all cases, the transmit frame is configured as follows:

- XPHASE = 0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1 = 0b0000011: 4 words per frame
- XWDLEN1 = 0b000: 8 bits per word
- XMCME = 0: 2-partition mode (only partitions A and B are used)

In the case where MCBSPi.MCBSPLP_MCR2_REG[1:0] XMCM = 0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

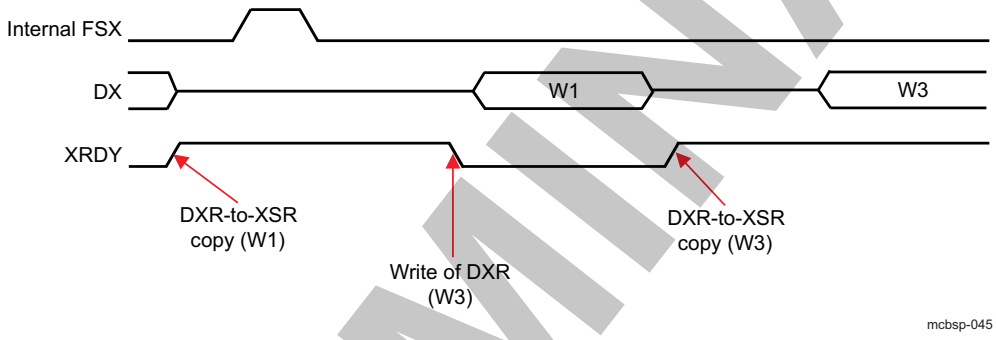
In Figure 23-136, the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 23-136. Activity on MCBSP Pins When XMCM = 0b00



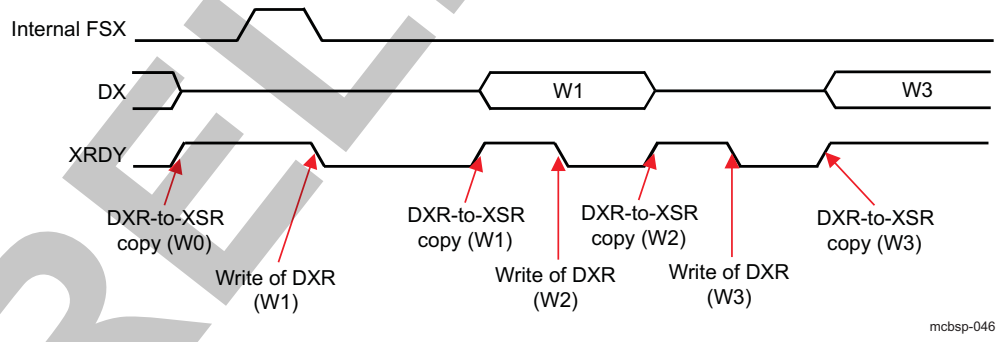
If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, and then, from the XB, they are transferred by MCBSPi_dx.

Figure 23-137. Activity on MCBSP Pins When XMCM = 0b01



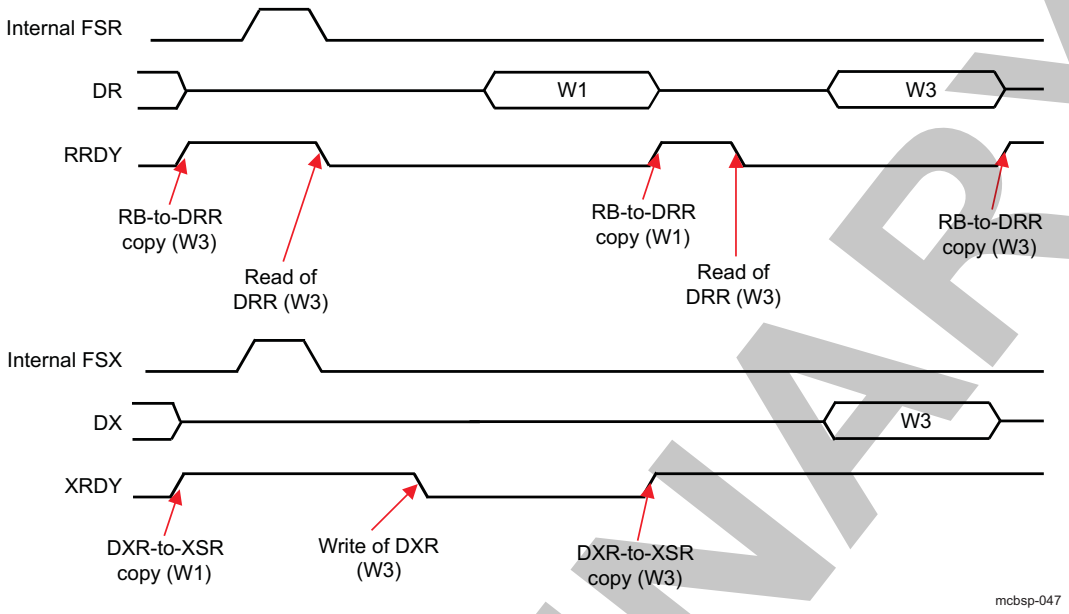
In Figure 23-137 if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, and then, from the XB, they are transferred by MCBSPi_dx.

Figure 23-138. Activity on MCBSP Pins When XMCM = 0b10



In Figure 23-138 if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, and only 1 and 3 are unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, are transferred by MCBSPi_dx.

Figure 23-139. Activity on MCBSP Pins When XMCM = 0b11



In Figure 23-139 if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010, and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 is unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, is transferred by MCBSPi_dx.

23.5.5 MCBSP Basic Programming Model

This section describes the programming model of a typical MCBSP module.

CAUTION

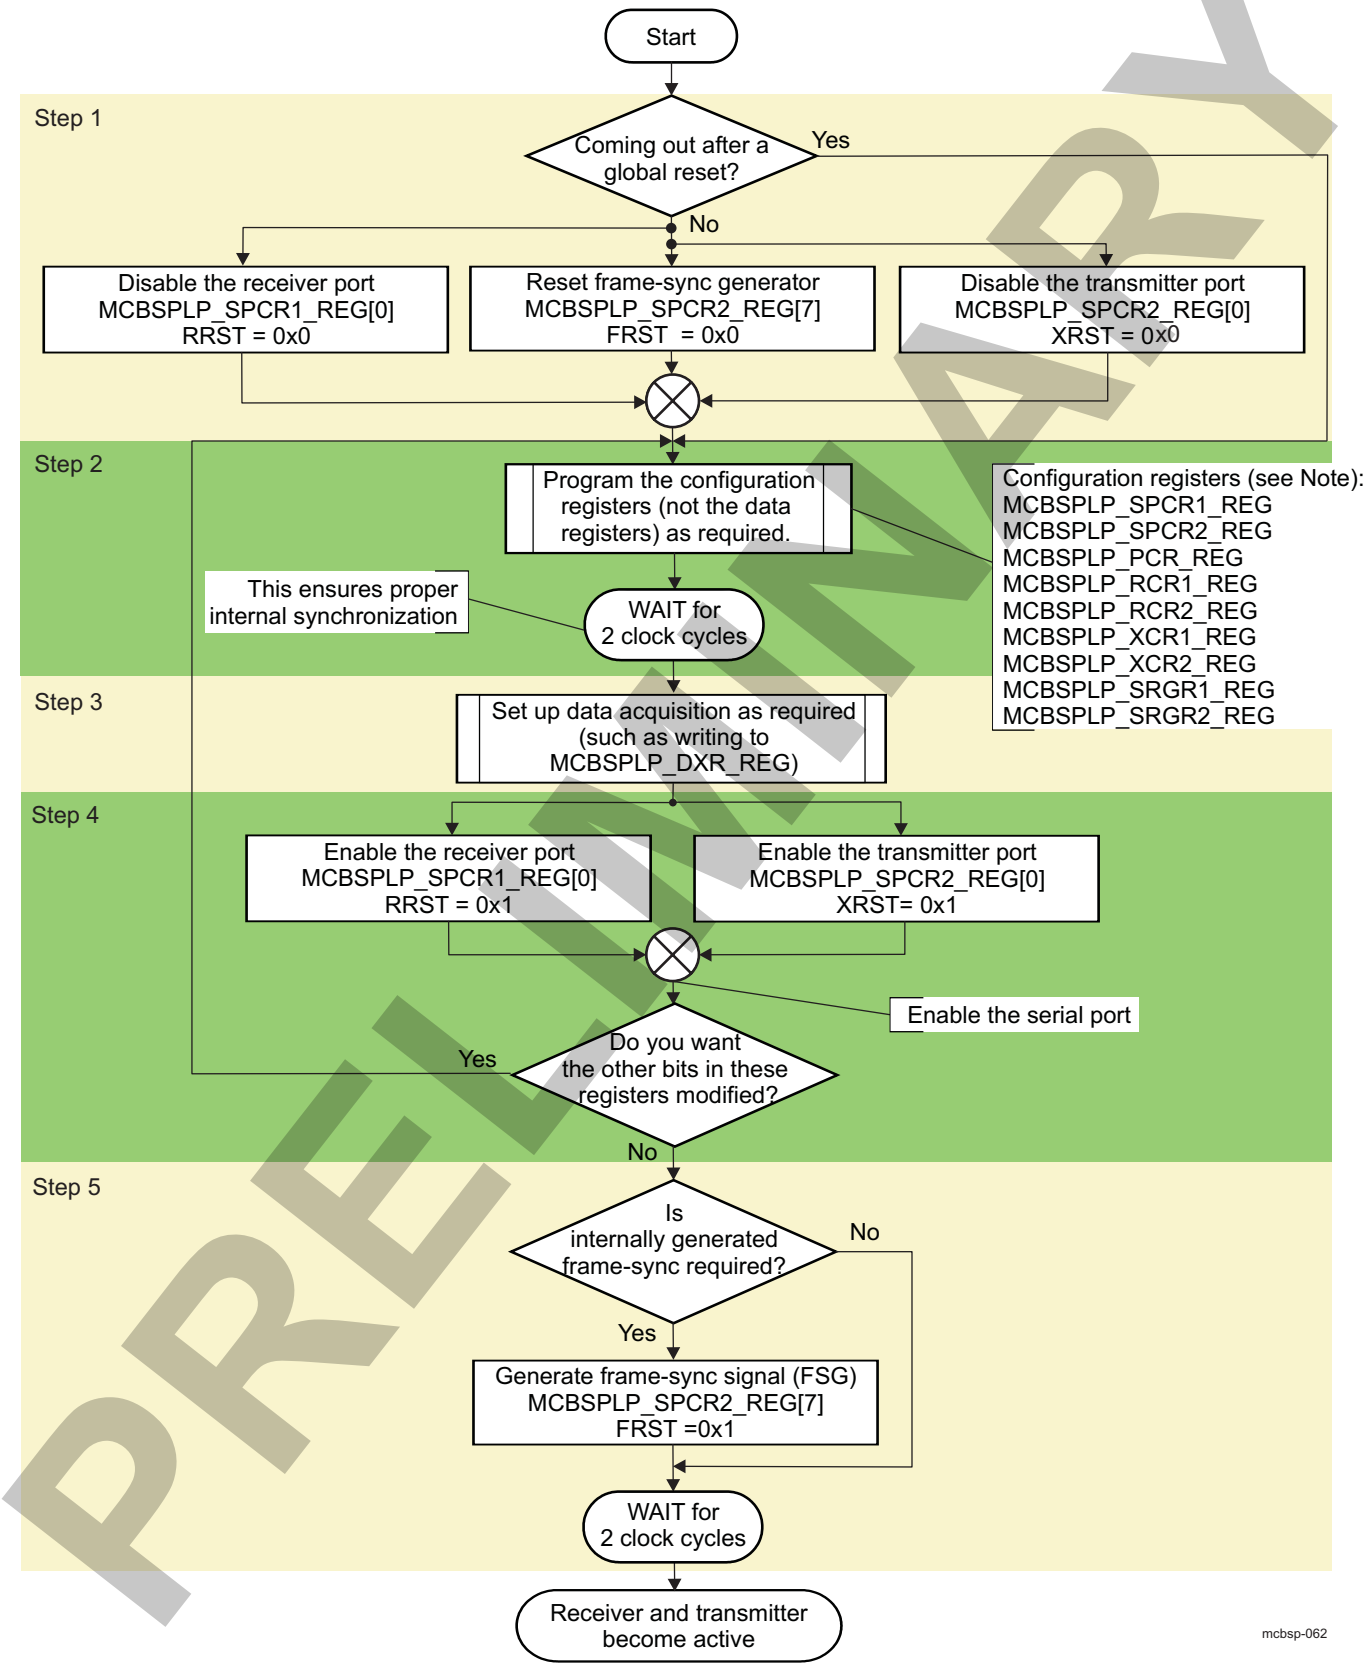
For all descriptions in this section, the MCBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE and MCBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bits are their reset value (XFULL_CYCLE is set to 0 and RFULL_CYCLE is set to 1).

23.5.5.1 MCBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the receiver or transmitter must be reset during its normal operation, and also when the SRG is not used for either operation.

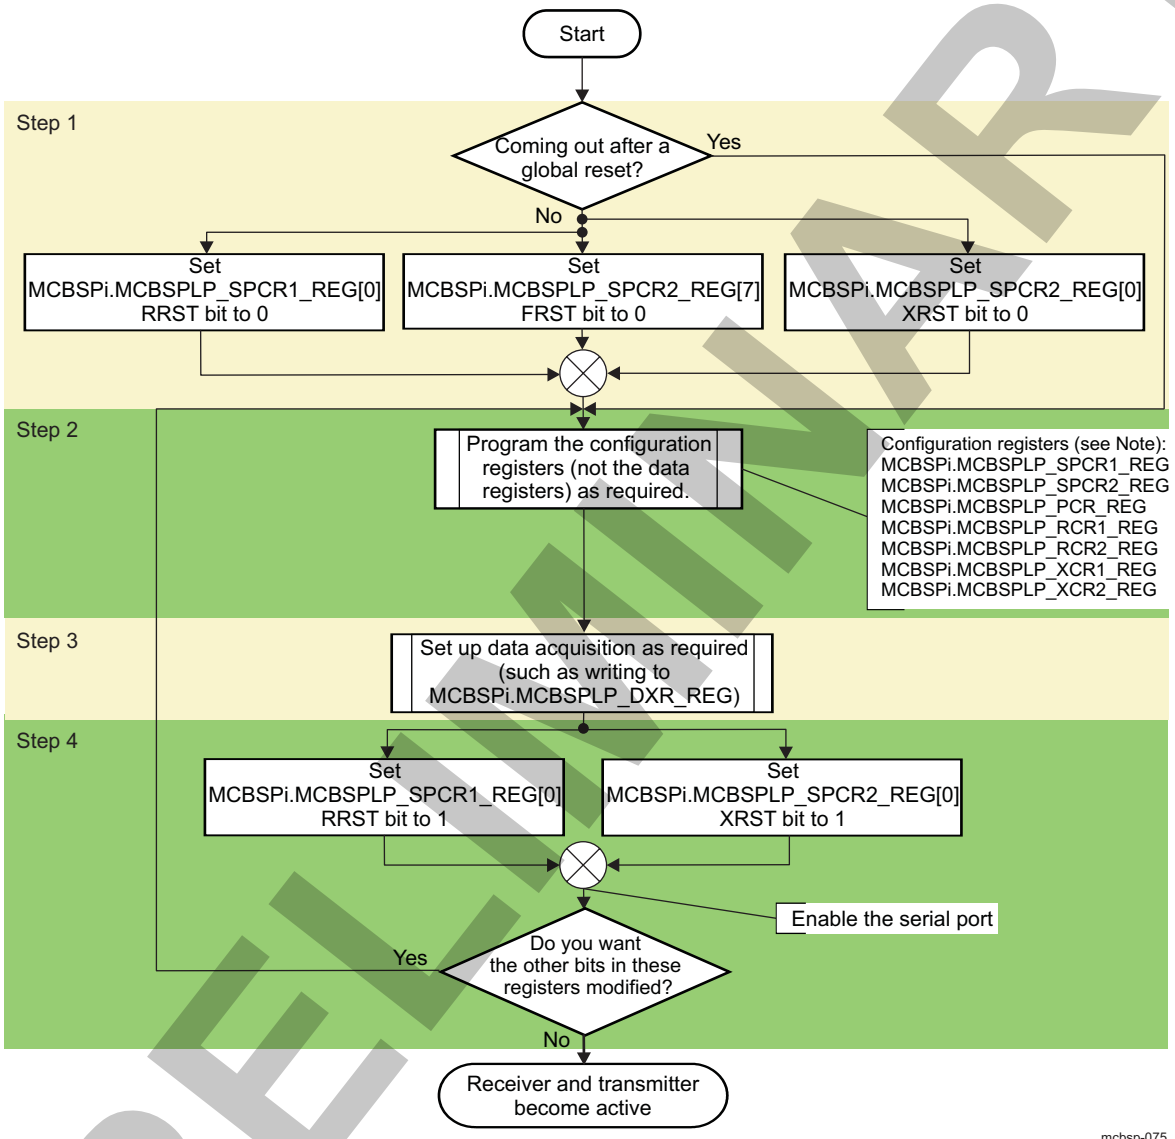
Figure 23-140 shows the serial port initialization procedure for master mode.

Figure 23-140. Flow Diagram of MCBSP Initialization Procedure for Master Mode



Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the MCBSPi.MCBSPLP_SPCR2_REG[0] XRST and MCBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.
Figure 23-141 shows the flow diagram of the MCBSP initialization procedure for slave mode.

Figure 23-141. Flow Diagram of MCBSP Initialization Procedure for Slave Mode



NOTE:

- Alternatively, on write (Step 1 or Step 4), the transmitter and receiver can be placed in or taken out of reset by modifying the MCBSPi.MCBSPLP_SPCR2_REG[0] XRST and MCBSPi.MCBSPLP_SPCR1_REG[0] RRST bits, respectively.
- The necessary duration of the active-low period of XRST or RRST is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (MCBSPi.MCBSPLP_SPCR1_REG, MCBSPi.MCBSPLP_SPCR2_REG, MCBSPi.MCBSPLP_PCR_REG, MCBSPi.MCBSPLP_RCR1_REG, MCBSPi.MCBSPLP_RCR2_REG, MCBSPi.MCBSPLP_XCR1_REG, MCBSPi.MCBSPLP_XCR2_REG, MCBSPi.MCBSPLP_THRSH2_REG, MCBSPi.MCBSPLP_XCCR_REG, MCBSPi.MCBSPLP_SYSCONFIG_REG, MCBSPi.MCBSPLP_SRGR1_REG and MCBSPi.MCBSPLP_SRGR2_REG) should be modified only when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (MCBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/DSP subsystem or the sDMA controller only when the transmitter is enabled (MCBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (MCBSPi.MCBSPLP_MCR1_REG, MCBSPi.MCBSPLP_MCR2_REG, MCBSPi.MCBSPLP_RCER{A-H}_REG and MCBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting the MCBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- The necessary duration of the active-low period of XRST or RRST is at least two
- Modification on-the-fly has no effect if a reset is not performed first.

Table 23-348. Register Call Summary for Flow Diagram of MCBSP Initialization Procedure

Register Name	Register Name	Register Name
MCBSPLP_SPCR1_REG	MCBSPLP_RCR1_REG	MCBSPLP_XCR2_REG
MCBSPLP_SPCR2_REG	MCBSPLP_RCR2_REG	MCBSPLP_SRGR1_REG
MCBSPLP_PCR_REG	MCBSPLP_XCR1_REG	MCBSPLP_SRGR2_REG

23.5.5.2 Reset and Initialization Procedure for the SRG

To reset and initialize the SRG:

1. Place the MCBSP SRG in reset.
2. Program the registers that affect the SRG.
3. Enable the SRG (take it out of reset).
4. If necessary, enable the receiver and/or the transmitter.
5. If necessary, remove the receiver and/or transmitter from reset

Figure 23-142 shows the flow diagram for programming the SRG registers.

Figure 23-142. Flow Diagram for the SRG Registers Programmation

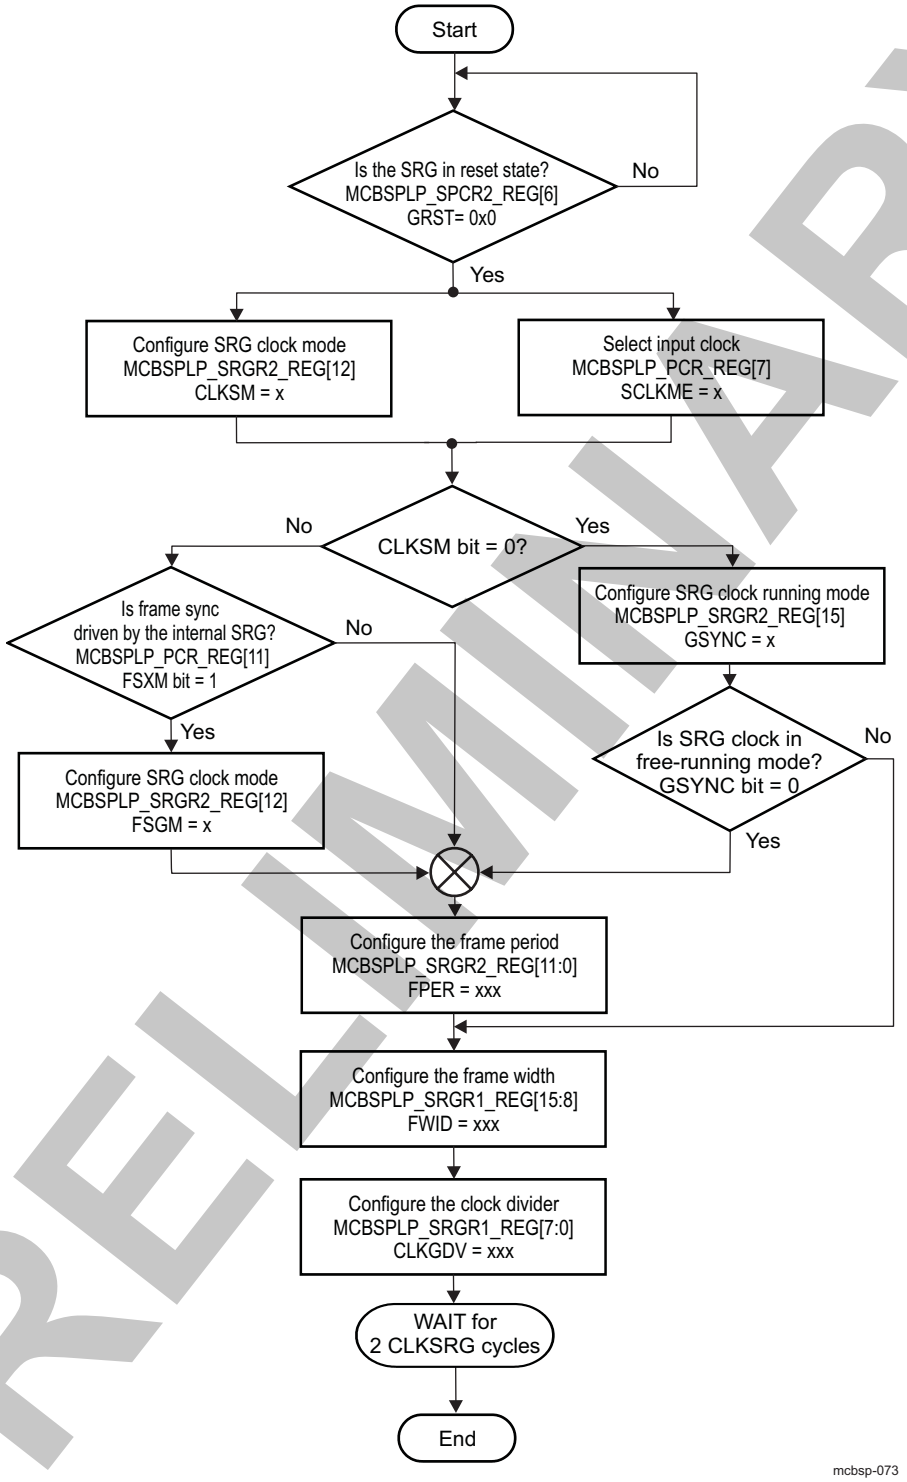


Table 23-349. Register Call Summary for Flow Diagram for the SRG Registers Programmation

Register Name	Register Name
MCBSPLP_SPCR2_REG	MCBSPLP_PCR_REG
MCBSPLP_SRGR2_REG	MCBSPLP_SRGR1_REG

23.5.5.3 Data Transfer DMA Request Configuration

This procedure configures the MCBSP receive/transmit data DMA requests (MCBSPi_DMA_RX and MCBSPi_DMA_TX) (see Table 23-350).

Table 23-350. Data Transfer DMA Request Configuration

Step	Register/Bit Field/Programming Model	Value
Write the required receive DMA request length.	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x
Write the required transmit DMA request length.	MCBSPLP_THRSH2_REG[6:0] RTHRESHOLD	x..x

NOTE:

- The length of the transfer is the same as the threshold value + 1
- In case of a number of transfers that exceed the number of the programmed DMA length, the MCBSP module will respond to the command and will perform the transfer regardless of the receive buffer empty condition.
- In case of a number of transfers that exceed the number of the programmed DMA length, the MCBSP module will respond to the command and will perform the transfer regardless of the transmit buffer full condition.

23.5.5.4 Interrupt Configuration

This procedure configures the common receive/transmit interrupt request line (see Table 23-351).

Table 23-351. Interruption Configuration

Step	Register/Bit Field/Programming Model	Value
Enable the required IRQ events.	MCBSPLP_IRQENABLE_REG	x..x

23.5.5.5 Receiver Configuration

To configure the MCBSP receiver, perform the following steps:

Step 1. Place the MCBSP receiver in reset.

Step 2. Program the MCBSP registers for the desired receiver operation.

Step 3. Take the receiver out of reset.

23.5.5.5.1 Place the Receiver in Reset (Step 1)

Table 23-352. Receiver Reset

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RST	0x0

23.5.5.5.2 Programming the MCBSP Registers for the Desired Receiver Configuration (Step 2)

This section describes the steps to be performed when software configures the MCBSP receiver.

Global Configuration

Table 23-353 describes the steps to perform the global configuration.

Table 23-353. Global Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receiver pins to operate as MCBSP pins.	MCBSPLP_PCR_REG[12] RIOEN	0x0
Enable/disable DLB mode(1).	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/disable ALB mode(1).	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Enable/disable the receive multichannel selection Mode(1).	MCBSPLP_MCR1_REG[0] RMCM	0x0 or 0x1

(1) Software decision

NOTE: In DLB mode the SRG and frame-sync generator must be enabled to generate the CLKX and FSX signals.

Data Configuration

Table 23-354 describes the steps to perform the data configuration.

Table 23-354. Data Configuration

Step	Register/Bit Field/Programming Model	Value
Select single/dual-phase frame (1).	MCBSPLP_RCR2_REG[15] RPHASE	0x0 or 0x1
Set the receive word length(s) for phase 1(1).	MCBSPLP_RCR1_REG[7:5] RWDLEN1	xxx
Set the receive word length(s) for phase 2(1).	MCBSPLP_RCR2_REG[7:5] XWDLEN2	xxx
Set the receive frame length*.	MCBSPLP_RCR1_REG[14:8] RFRLEN1 MCBSPLP_RCR2_REG[14:8] RFRLEN2	xxx
Set the receive reverse mode(1).	MCBSPLP_RCR2_REG[4:3] RREVERSE	xx
Set the receive data delay(1).	MCBSPLP_RCR2_REG[1:0] RDATLY	xx
Set the receive sign-extension and justification mode(1).	MCBSPLP_SPCR1_REG[14:13] RJUST	xx
Enable the serial receiver port.	MCBSPLP_SPCR1_REG[0] RRST	0x1
Configure the receive buffer threshold value(1).	MCBSPLP_THRSH1_REG[6:0] RTHRESHOLD	x..x

(1) Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame. If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

Frame-Sync Configuration

Table 23-355 describes the steps to perform the frame-sync configuration.

Table 23-355. Frame-Sync Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receive frame-sync mode(1).	MCBSPLP_PCR_REG[10] FSRM	0x0 or 0x1
Select SRG synchronization(1).	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1

(1) Software decision

Table 23-355. Frame-Sync Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Set the receive frame-sync polarity [(1)].	MCBSPLP_PCR_REG[2] FSRP	0x0 or 0x1
Set the SRG frame-sync period[(1)].	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG frame-sync pulse width[(1)].	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

Clock Configuration

Table 23-356 describes the steps to perform clock configuration.

Table 23-356. Clock Configuration

Step	Register/Bit Field/Programming Model	Value
Set the receive clock mode[(1)].	MCBSPLP_PCR_REG[8] CLKRM	0x0 or 0x1
Set the receive clock polarity[(1)].	MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1
Set the SRG clock divide-down value[(1)].	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG clock synchronization mode[(1)].	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG input clock mode[(1)].	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG input clock polarity[(1)].	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

(1) Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

23.5.5.5.3 Take the Receiver Out of Reset (Step 3)

Table 23-357. Take the Receiver Out of Reset

Step	Register/Bit Field/Programming Model	Value
Enable the receiver.	MCBSPLP_SPCR1_REG[0] RST	0x1

23.5.5.6 Transmitter Configuration

To configure the MCBSP transmitter, perform the following steps:

Step 1. Place the MCBSP transmitter in reset.

Step 2. Program the MCBSP registers for the desired transmitter operation.

Step 3. Take the transmitter out of reset.

23.5.5.6.1 Place the Transmitter in Reset (Step 1)

Table 23-358. Transmitter Reset

Step	Register/Bit Field/Programming Model	Value
Place the transmitter in reset.	MCBSPLP_SPCR2_REG[0] RST	0x0

23.5.5.6.2 Programming the MCBSP Registers for the Desired Transmitter Operation (Step 2)

This section describes the steps to be performed when software configures the MCBSP transmitter.

Global Configuration

Table 23-359 describes the steps to perform the global configuration.

Table 23-359. Global Configuration

Step	Register/Bit Field/Programming Model	Value
Set the transmitter pins to operate as MCBSP pins.	MCBSPLP_PCR_REG[13] XIOEN	0x0
Enable/disable DLB mode(1).	MCBSPLP_XCCR_REG[5] DLB	0x0 or 0x1
Enable/disable ALB mode(1).	MCBSPLP_SPCR1_REG[5] ALB	0x0 or 0x1
Enable/disable the transmit multichannel selection mode(1).	MCBSPLP_MCR1_REG[0] RMCM	0x0 or 0x1

(1) Software decision

Data Configuration

Table 23-360 describes the steps to perform the data configuration.

Table 23-360. Data Configuration

Step	Register/Bit Field/Programming Model	Value
Select single/dual-phase frame (1).	MCBSPLP_RCR2_REG[15] XPHASE	0x0 or 0x1
Set the transmit word length(s) for phase 1(1).	MCBSPLP_XCR1_REG[7:5] XWDLEN1	xxx
Set the transmit word length(s) for phase 2(1).	MCBSPLP_XCR2_REG[7:5] XWDLEN2	xxx
Set the transmit frame length(1).	MCBSPLP_XCR1_REG[14:8] XFRLEN1 MCBSPLP_XCR2_REG[14:8] XFRLEN2	xxx
Set the transmit reverse mode(1).	MCBSPLP_XCR2_REG[4:3] XREVERSE	xx
Set the transmit data delay(1).	MCBSPLP_XCR2_REG[1:0] XDATLY	xx
Set the extra delay (DX delay) mode(1).	MCBSPLP_SPCR1_REG[7] DXENA	xx
Select the inserted delay value(1).	MCBSPLP_XCCR_REG[13:12] DXENDLY	xx
Set the interrupt line.	MCBSPLP_IRQENABLE_REG	x..x
Configure the transmit buffer threshold value(1)	MCBSPLP_THRSH2_REG[6:0] XTHRESHOLD	x..x

(1) Software decision

NOTE:

- When dual-phase frame is selected, the number of words per phase must be set to 1.
- If a single-phase frame is selected, XWDLEN1 selects the length for every serial word transmit in the frame. If a dual–phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select both lengths. These bits can have different values.
- If a dual-phase frame is selected, the frame length must be two words.

The DXENA bit controls the delay enabler on the MCBSP_dx pin. Set DXENA to enable an extra delay for turn-on time. Because this bit does not control the data itself, only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay, 80 ps, 160 ps (default), 240 ps, or 320 ps, can be set using the MCBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY bit field. If the MCBSP_dx pins of multiple MCBSP modules are tied together, ensure that DXENA is set to 1 to avoid having more than one MCBSP at a time transmitting on the data line.

Frame-Sync Configuration

Table 23-361 describes the steps to perform the frame-sync configuration.

Table 23-361. Frame-Sync Configuration

Step	Register / Bit Field / Programming Model	Value
Set the transmit frame-sync mode(1).	MCBSPLP_PCR_REG[11] FSXM MCBSPLP_SRGR2_REG[12] FSGM	0x0 or 0x1
Set the transmit frame-sync polarity(1).	MCBSPLP_PCR_REG[3] FSXP	0x0 or 0x1
Set the SRG frame-sync period(1).	MCBSPLP_SRGR2_REG[11:0] FPER	x..x
Set the SRG frame-sync pulse width(1).	MCBSPLP_SRGR1_REG[15:8] FWID	x..x

(1) Software decision

Clock Configuration

Table 23-362 describes the steps to perform the clock configuration.

Table 23-362. Clock Configuration

Step	Register / Bit Field / Programming Model	Value
Set the transmit clock mode (1).	MCBSPLP_PCR_REG[9] CLKXM	0x0 or 0x1
Set the transmit clock polarity(1).	MCBSPLP_PCR_REG[1] CLKXP	0x0 or 0x1
Set the SRG clock divide-down value(1).	MCBSPLP_SRGR1_REG[7:0] CLKGDV	x..x
Set the SRG clock synchronization mode(1).	MCBSPLP_SRGR2_REG[15] GSYNC	0x0 or 0x1
Set the SRG input clock mode(1).	MCBSPLP_PCR_REG[7] SCKLME MCBSPLP_SRGR2_REG[13] CLKSM	0x0 or 0x1
Set the SRG input clock polarity(1)	MCBSPLP_SRGR2_REG[14] CLKSP MCBSPLP_PCR_REG[1] CLKXP MCBSPLP_PCR_REG[0] CLKRP	0x0 or 0x1

(1) Software decision

NOTE: CLKRP = CLKXP in a system in which the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

23.5.5.6.3 Take the Receiver Out of Reset (Step 3)

Table 23-363. Take the Receiver Out of Reset

Step	Register/Bit Field/Programming Model	Value
Enable the transmitter.	MCBSPLP_SPCR2_REG[0] RST	0x1

23.5.5.7 GPIO on the MCBSP Pins (Legacy Only)

To use MCBSP pins as GPIO pins rather than as serial port pins, follow these steps:

- **For the receive pins (MCBSP_clkr, MCBSP_fsr, and MCBSP_dr as)**

Table 23-364. Use Serial Receive Pins as GPIO Pins

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RRST	0x0
Enable GPIO for the serial port receiver.	MCBSPLP_PCR_REG[12] RIOEN	0x1

- **For the transmitter pins (MCBSP_clkx, MCBSP_fsx, and MCBSP_dx)**

Table 23-365. Use Serial Transmit Pins as GPIO Pins

Step	Register/Bit Field/ Programming Model	Value
Place the transmit in reset.	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enable GPIO for the serial port transmitter.	MCBSPLP_PCR_REG[12] XIOEN	0x1

- **For the external clock pins (abe_clks)**

  For the abe_clks pin (common to all MCBSP modules), all of the reset and I/O conditions must be met as follows:

Table 23-366. Use External Clock Pin as GPIO Pin

Step	Register/Bit Field/Programming Model	Value
Place the receiver in reset.	MCBSPLP_SPCR1_REG[0] RRST	0x0
Place the transmit in reset.	MCBSPLP_SPCR2_REG[0] XRST	0x0
Enable GPIO for the serial port receiver.	MCBSPLP_PCR_REG[12] RIOEN	0x1
Enable GPIO for the serial port transmitter.	MCBSPLP_PCR_REG[12] XIOEN	0x1

23.5.6 MCBSP Register Manual

Table 23-367 shows the base address and address space for the device module instances.

23.5.6.1 MCBSP Instance Summary

Table 23-367. MCBSP Instance Summary

Module Name	Base Address L3 Interconnect	Base Address Cortex-A15 Private Access	Base Address DSP Private Access	Size
MCBSP1	0x4902 2000	0x4012 2000	0x2 2000	4 KiB
MCBSP2	0x4902 4000	0x4012 4000	0x2 4000	4 KiB
MCBSP3	0x4902 6000	0x4012 6000	0x2 6000	4 KiB

NOTE: Private access is an access that does not use the L3/L4 interconnects.

23.5.6.2 MCBSP Registers

CAUTION

The MCBSP registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

23.5.6.2.1 MCBSP Register Summary

Table 23-368 through summarize the MCBSP1, MCBSP2 and MCBSP3 registers, respectively.

Table 23-368. MCBSP1 Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A15 Private Access	Physical Address DSP Private Access

Description	MCBSPLP serial port control register 2		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						FREE	SOFT	FRST	GRST	XINTM		XSYNCERR	XEMPTY	XRDY	XRST

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reserved	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0
8	SOFT	Soft Bit 0x0: SOFT mode is disabled: the module stops its activity immediately following MSuspend assertion 0x1: SOFT mode is enabled: the module freezes its state after completion of the current operation when MSuspend is asserted	RW	0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-sync logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; that is, all frame counters are loaded with their programmed values	RW	0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0

Bits	Field Name	Description	Type	Reset
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: XINT is driven by XRDY 0x1: XINT generated by end-of-frame 0x2: XINT generated by a new frame synchronization 0x3: XINT generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERR condition) 0x0: No synchronization error 0x1: Synchronization error detected by MCBSP	RW	0
2	XEMPTY	Transmit Shift Register XSR Empty Read 0x0: XSR is empty Read 0x1: XSR is not empty	R	0
1	XRDY	Transmitter ready Read 0x0: Transmitter is not ready. Read 0x1: Transmitter is ready for new data in DXR	R	0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0

RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER											

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	GSYNC	0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-sync signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse.	RW	0
14	CLKSP	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG.	RW	0
13	CLKSM	MCBSPLP Sample Rate Generator Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKRI pin. 0x1: SCLKME=0: SRG clock derived from the CPU clock. SCLKME=1: SRG clock derived from the CLKXI clock.	RW	1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty When FSGM=0, FPER and FWID are used to determine the frame-sync period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0
11:0	FPER	Frame Period. This field plus 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						XMCME	XPBBLK	XPABLK	RESERVED						XMCM

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Reserved	R	0x000000
9	XMCME	0x0: 2-partition mode: Only partitions A and B are used. You can control up to 32 channels in the transmit multichannel selection mode selected with the XMCM bits. If XMCM = 01b or 10b, assign 16 channels to partition A with the XPABLK bits. Assign 16 channels to partition B with the XPBBLK bits. If XMCM = 11b (for symmetric transmission and reception), assign 16 channels to receive partition A with the RPABLK bits. Assign 16 channels to receive partition B with the RPBBLK bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels in partition A XCERB: Channels in partition B 0x1: 8-partition mode: All partitions (A through H) are used. You can control up to 128 channels in the transmit multichannel selection mode selected with the XMCM bits. You control the channels with the appropriate transmit channel enable registers: XCERA: Channels 0 through 15 XCERB: Channels 16 through 31 XCERC: Channels 32 through 47 XCERD: Channels 48 through 63 XCERE: Channels 64 through 79 XCERF: Channels 80 through 95 XCERG: Channels 96 through 111 XCERH: Channels 112 through 127	RW	0

Bits	Field Name	Description	Type	Reset
8:7	XPBBLK	Transmit Partition B Block (legacy) 0x0: Block 1. Channel 16 to channel 31 0x1: Block 3. Channel 48 to channel 63 0x2: Block 5. Channel 80 to channel 95 0x3: Block 7. Channel 112 to channel 127	RW	0x0
6:5	XPABLK	Transmit Partition A Block (legacy) 0x0: Block 0. Channel 0 to channel 15 0x1: Block 2. Channel 32 to channel 47 0x2: Block 4. Channel 64 to channel 79 0x3: Block 6. Channel 96 to channel 111	RW	0x0
4:2	RESERVED	Reserved	R	0x0
1:0	XMCM	Transmit Multichannel Selection Enable 0x0: All channels enabled without masking (DX is always driven during transmission of data). 0x1: All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven. 0x2: All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked. 0x3: All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symetric transmit and receive operation.	RW	0x0

RESERVED																IDLE_EN	XIOEN	RIOEN	FSXM	FSRM	CLKXM	CLKRM	SCLKME	CLKS_STAT	DX_STAT	DR_STAT	FSXP	FSRP	CLKXP	CLKRP	

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Reserved	R	0x00000
14	IDLE_EN	Idle enable. This bit allows stopping all the clocks in the MCBSPLP. (legacy) 0x0: The MCBSP is running 0x1: The clocks in the MCBSP are shut off when both IDLE_EN=1 and peripheral domain is in idle mode	RW	0
13	XIOEN	Transmit General Purpose I/O Mode only when XRST=0 in SPCR[1,2] (legacy) 0x0: DX, FSX and CLKX are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DX pin is a general purpose output. FSX and CLKX are general purpose I/Os. These serial port pins do not perform serial port operation.	RW	0
12	RIOEN	Receive General Purpose I/O Mode when RRST=0 in SPCR[1,2] (legacy) 0x0: DR, FSR, CLKR and CLKS are configured as serial port pins and do not function as general-purpose I/Os. 0x1: DR and CLKS pins are general purpose inputs; FSR and CLKR are general purpose I/Os. These serial port pins do not perform serial port operation. The CLKS pin is affected by a combination of RRST and RIOEN signals of the receiver.	RW	0

Bits	Field Name	Description	Type	Reset
11	FSXM	Transmit Frame-Synchronization Mode 0x0: Frame-sync signal derived from an external source 0x1: Frame synchronization is determined by the SRG frame-sync mode bit FSGM in SRGR2.	RW	0
10	FSRM	Receive Frame-Synchronization Mode 0x0: Frame-sync pulses generated by an external device. FSR is an input pin. 0x1: Frame synchronization generated internally by SRG. FSR is an output pin except when GSYNC=1 in SRGR.	RW	0
9	CLKXM	Transmitter Clock Mode 0x0: Transmitter clock is driven by an external clock with CLKX as an input pin. 0x1: CLKX is an output pin and is driven by the internal sample rate generator.	RW	0
8	CLKRM	Receiver Clock Mode 0x0: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: Receive clock (CLKR) is an input driven by an externaal clock. Case 2: Digital loopback mode set (DLB=1) in SPCR1: Receive clock (not the CLKR pin) is driven by transmit clock (CLKX) which is based on the CLKXM bit in the PCR. CLKR pin is in high-impedance. 0x1: Case 1: Digital loopback mode not set (DLB=0) in SPCR1: CLKR is an output pin and is driven by the internal SRG. Case 2: Digital loopback mode set (DLB=1) in SPCR1: CLKR is an output pin and is driven by the transmit clock. The transmit clock is derived based on the CLKRM bit in the PCR.	RW	0
7	SCLKME	The frequency of CLKG is: CLKG frequency = (Input clock frequency) / (CLKGDV + 1) SCLKME is used in conjunction with the CLKSM bit to select the input clock: 0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: CPU clock 0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin	RW	0
6	CLKS_STAT	CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) Read 0x0: The signal on the CLKS pin is low Read 0x1: The signal on the CLKS pin is high	R	0
5	DX_STAT	DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) 0x0: Drive the signal on the DX pin low 0x1: Drive the signal on the DX pin high	RW	0
4	DR_STAT	DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) Read 0x0: The signal on DR pin is low Read 0x1: The signal on DR pin is high	R	0
3	FSXP	Transmit Frame-Synchronization Polarity 0x0: Frame-sync pulse FSX is active high 0x1: Frame-sync pulse FSX is active low	RW	0
2	FSRP	Receive Frame-Synchronization Polarity 0x0: Frame-sync pulse FSR is active high 0x1: Frame-sync pulse FSR is active low	RW	0
1	CLKXP	Transmit Clock Polarity 0x0: Transmit data driven on rising edge of CLKX 0x1: Transmit data driven on falling edge of CLKX	RW	0

Bits	Field Name	Description	Type	Reset
0	CLKRP	Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR	RW	0

Description	MCBSPLP transmit configuration control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																EXTCLKGATE	PPCONNECT	DXENDLY		XFULL_CYCLE	RESERVED			DLB	RESERVED	XDMAEN	RESERVED		XDISABLE		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	EXTCLKGATE	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable.	RW	0

Bits	Field Name	Description	Type	Reset
14	PPCONNECT	Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x0: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output 0x1: Pair to pair connection. When set the DXENO pin is always set to 0 regardless of the frame boundary, setting the tree state buffer as output	RW	0
13:12	DXENDLY	When DXENA bit in SPCR1 is set to 1 this field selects the added delay as follow: 0x0: 80 ps 0x1: 160 ps (default) 0x2: 240 ps 0x3: 320 ps	RW	0x1
11	XFULL_CYCLE	Transmit full-cycle mode select. 0x0: MCBSPLP operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data). 0x1: MCBSPLP operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data).	RW	0
10:6	RESERVED	Reserved	R	0x00
5	DLB	Digital Loop-Back 0x0: No DLB 0x1: DLB	RW	0
4	RESERVED	Reserved	R	0
3	XDMAEN	Transmit DMA Enable bit. When set to 0 this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset. 0x0: When set to 0 this bit will gate the external transmit DMA request, 0x1: When set to 1 this bit will NOT gate the external transmit DMA request,	RW	1
2:1	RESERVED	Reserved	R	0
0	XDISABLE	Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary. 0x0: The transmit process will NOT stop at the next frame boundary. 0x1: The transmit process will stop at the next frame boundary.	RW	0

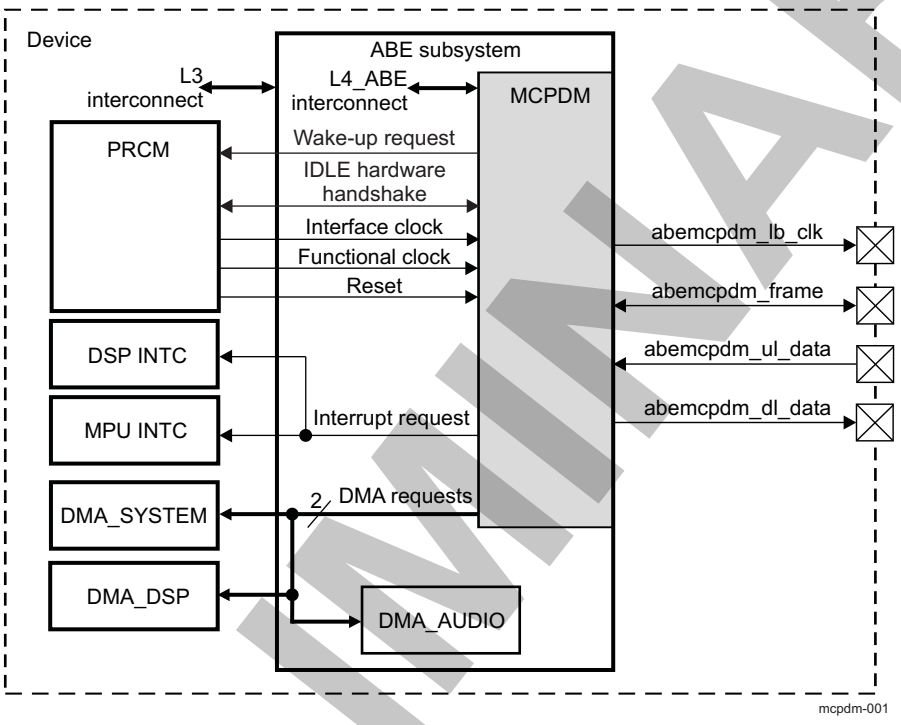
23.6 Multichannel PDM Controller

23.6.1 MCPDM Overview

The multichannel pulse density modulation (MCPDM) module consists of a proprietary audio module dedicated to mobile phone terminals and includes audio uplink and downlink paths communicating with an external audio companion chip through a dedicated interface.

Figure 23-143 shows an overview of the MCPDM module.

Figure 23-143. MCPDM Overview



The MCPDM module supports the following features:

- Full-duplex communication:
  - Five audio downlink channels with up to 3.84 Mbps each
  - Three audio uplink channels with up to 3.84 Mbps each
  - One command channel with up to 3.84 Mbps
  - One status channel with up to 3.84 Mbps
- Uplink and downlink FIFO operations:
  - 16 × 96-bit words for FIFO uplink, where a 96-bit word contains three 24-bit words for the audio uplink channels (one 24-bit word per audio uplink channel) and one 16-bit word for status information
  - 16 × 144-bit words for FIFO downlink, where a 144-bit word contains five 24-bit words for the audio downlink channels (one 24-bit word per audio downlink channel) and one 16-bit word for the command data.
- Interrupt request to MPU and DSP subsystems
- DMA requests with programmable FIFO thresholds:
  - One DMA request for downlink path
  - One DMA request for uplink path
- Upsampling and pulse-density modulators for each audio downlink channel (five channels)
- Offset cancellation feature for audio downlink channels 1 and 2

- Decimation filter and downsampling for each audio uplink channel (three channels)
- IDLE state hardware handshake
- Wake-up request

23.6.2 MCPDM Environment

This section describes the MCPDM application fields from an environmental point of view (external connections), the MCPDM connectivity options, the protocol and data format used in each case, and lists all possible interfaces.

23.6.2.1 MCPDM Modes

Table 23-457 describes the modes and application fields of the MCPDM module.

Table 23-457. Modes

Mode	Description
Normal mode	Up to five audio channels are transmitted to, and up to three audio channels are received from, the audio companion chip.
Command mode	In addition to the audio channels, commands are transmitted to the audio companion chip.
Status mode	In addition to the audio channels, status information is received from the audio companion chip.

23.6.2.2 MCPDM Signals

Table 23-458 describes the MCPDM module signals and specifies their links to modes.

Table 23-458. I/O

Signal	I/O[1]	Description	Reset Value[2]	Normal Mode	Command Mode	Status Mode
abeMCPDM_lb_clk	O	Clock loopback to the audio companion chip from the abe_clks clock signal. The frequency is the same as abe_clks frequency.[3]	Hi-Z	x	x	x
abeMCPDM_frame	I/O	Frame synchronization and command/status data	Hi-Z	x	x	x
abeMCPDM_ul_data	I	Audio uplink path data	Hi-Z	x	x	x
abeMCPDM_dl_data	O	Audio downlink path data	Hi-Z	x	x	x

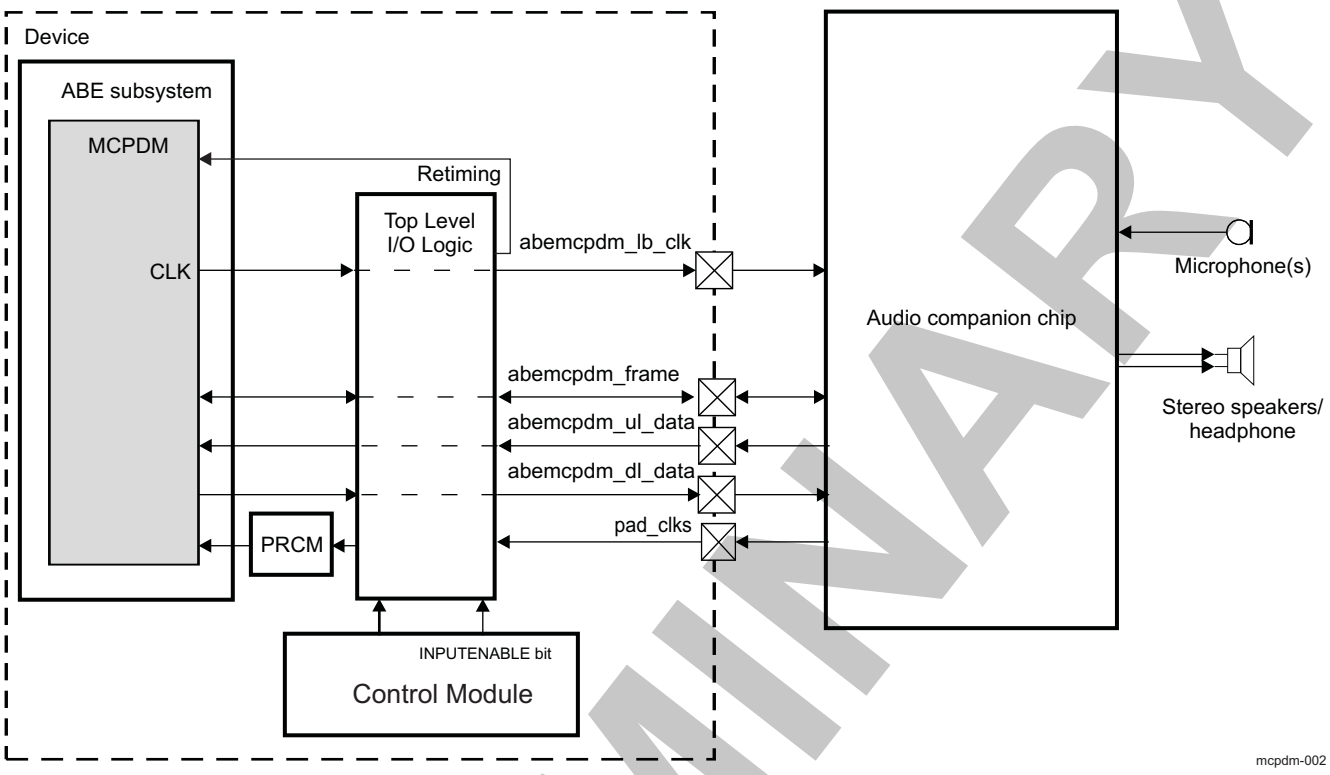
(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

23.6.2.3 MCPDM Configurations

Figure 23-144 shows the MCPDM generic configuration.

Figure 23-144. MCPDM Generic Configuration



23.6.2.4 Protocols and Data Formats

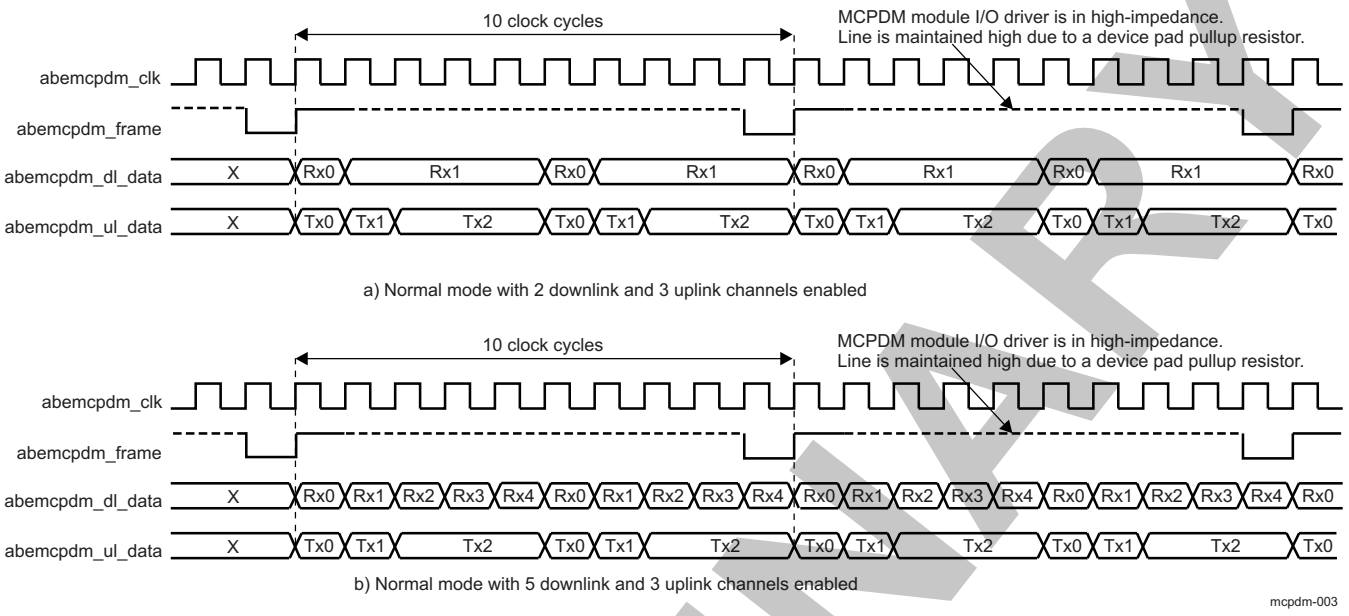
23.6.2.4.1 Protocols and Data Formats in Normal Mode

This section describes data transfer on the interface in normal mode. In this mode, the abeMCPDM_frame signal is used only for frame synchronization purposes. Figure 23-145 shows the protocols and data formats in normal mode for two examples:

(a) With two downlink and three uplink channels enabled

(b) With five downlink and three uplink channels enabled

Figure 23-145. Protocols and Data Formats in Normal Mode



In normal mode, the frequency ratio between the abeMCPDM_frame and abeMCPDM_lb_clk signals is 10. This ratio is static and the abeMCPDM_frame signal low-pulse width is one clock period longer than the abeMCPDM_lb_clk signal.

The abeMCPDM_frame signal is driven by the MCPDM module in the device to the external audio companion chip. The MCPDM module drives the abeMCPDM_frame signal low during one clock period of the abeMCPDM_lb_clk signal, and then drives it high during one clock period of the abeMCPDM_lb_clk signal before releasing the abeMCPDM_frame I/O driver in high-impedance state. The MCPDM module pad internal pullup resistor allows a high-level state to be maintained on the abeMCPDM_frame line when the abeMCPDM_frame I/O driver is in high-impedance state.

A maximum of two samples × five downlink channels (10 samples) can be transmitted by the MCPDM module to the external audio companion chip during a frame period.

A maximum of two samples × three uplink channels (six samples) can be received by the MCPDM module from the external audio companion chip during a frame period.

Each downlink and uplink channel can be independently enabled or disabled by setting to 1 or clearing to 0 the corresponding bit in the MCPDM_CTRL register.

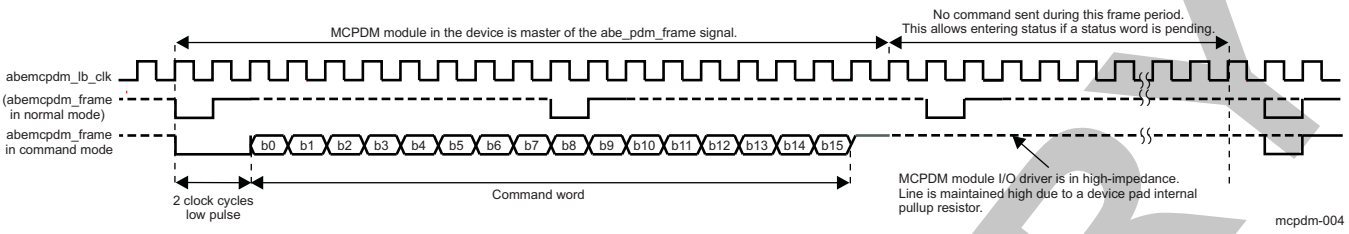
23.6.2.4.2 Protocols and Data Formats in Command Mode

This section describes data transfer on the interface in command mode. In this mode, the abeMCPDM_frame signal transmits command words to the external audio companion chip and allows audio registers to be configured in the external audio companion chip (that is, amplifier gains) without using the legacy I^2C interface, which can be busy and thus add latency to gain correction.

NOTE: In command mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip as in normal mode.

Figure 23-146 shows the protocols and data formats in command mode.

Figure 23-146. Protocols and Data Formats in Command Mode



23.6.2.4.2.1 Entering Command Mode

Command mode can be entered when command data are pending and no status mode is ongoing or detected.

If both conditions are met and the MCPDM_CTRL[9] CMD_INT bit is set to 1, the MCPDM module enters command mode automatically.

To enter command mode, the MCPDM module must drive the abeMCPDM_frame signal low during two periods of the abeMCPDM_lb_clk clock signal.

The external audio companion chip detects a command mode request from the MCPDM module when a low state is detected during two periods of the abeMCPDM_lb_clk clock signal. Once a command mode request is detected, the external audio companion chip enters command mode. In this mode, the status mode cannot be entered during at least four frame cycles.

If a status mode is detected or ongoing while a command is ready to be sent, the command data are stored in an internal register.

If one or more command data are written before the previous one is sent, the previous one is overwritten with the new one and only the last stored 16-bit command data are sent.

If new command data are available while the system is already in command mode, the current command completes normally and exits before re-entering command mode and transmitting the new command data a frame period later.

23.6.2.4.2.2 Command Data Transmission

The 16-bit command data are transmitted directly after the abeMCPDM_frame signal is driven low during two periods of the abeMCPDM_lb_clk clock signal.

When the MCPDM_CTRL[9] CMD_INT bit is set to 1, 16-bit command data must be written to the MCPDM_DN_DATA register. Only the 16 lower bits are significant. When no command must be transmitted on the abeMCPDM_frame line, a null word (0x00000000) must be written as the command data.

When the MCPDM_CTRL[9] CMD_INT bit is cleared to 0, no 16-bit command data must be written to the MCPDM_DN_DATA register.

23.6.2.4.2.3 Exiting Command Mode

After the 16-bit command data is sent, the MCPDM module drives the abeMCPDM_frame signal high during one period of the abeMCPDM_lb_clk clock signal before releasing the abeMCPDM_frame I/O driver in high-impedance state. The MCPDM module pad internal pullup resistor allows a high-level state to be maintained on the abeMCPDM_frame line when the abeMCPDM_frame I/O driver is in high-impedance state.

The MCPDM module exits automatically from command mode one period of the abeMCPDM_lb_clk clock signal after the last bit of the command data is transmitted on the abeMCPDM_frame line.

NOTE: Because of this protocol mechanism, frame synchronization is lost (and replaced by the ninth bit of the command data) during one frame period. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while receiving command data on the abeMCPDM_frame line.

23.6.2.4.2.4 Multiple Command Data Access

As shown in Figure 23-146, two consecutive command data can be sent every three frames. If no status mode is entered after a command data has been sent, the next command data is sent three frames after starting to send the current command data.

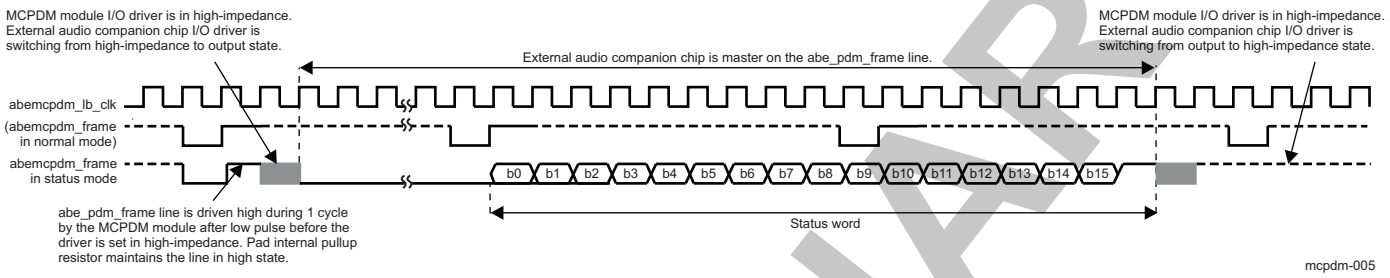
23.6.2.4.3 Protocols and Data Formats in Status Mode

This section describes data transfer on the interface in status mode. In this mode, the abeMCPDM_frame signal receives status information from the external audio companion chip.

NOTE: In status mode, as in normal mode, uplink channel samples are transmitted to and downlink channel samples are received from the external audio companion chip.

Figure 23-147 shows the protocols and data formats in status mode.

Figure 23-147. Protocols and Data Formats in Status Mode



23.6.2.4.3.1 Entering Status Mode

Status mode can be entered when no command mode is detected during the last frame low pulse and no command mode is ongoing.

If both conditions are met and the MCPDM_CTRL[10] STATUS_INT bit is set to 1, the MCPDM module enters status mode automatically when the command mode is complete.

In status mode, status information data are sent by the external audio companion chip to the MCPDM module and stored in an internal register.

If one or more status information packages are received before the previous status information is read, the status information stored in the internal register is overwritten with the new one.

In status mode, the external audio companion chip drives the abeMCPDM_frame line low until the next frame synchronization low pulse, and then sends the 16-bit status information data on the abeMCPDM_frame line. During transmission of the status information, the MCPDM module does not generate any frame-sync low pulse on the abeMCPDM_frame line for one frame period.

23.6.2.4.3.2 Status Information Data Reception

The 16-bit status information data are received directly after the second frame-sync low pulse on the abeMCPDM_frame line.

When the MCPDM_CTRL[10] STATUS_INT bit is set to 1, 16 bits of status information data must be read from the MCPDM_UP_DATA register. Only the 16 lower bits are significant. When the value of the status information is a null word (0x00000000), it means that no status information has been sent by the external audio companion chip.

When the MCPDM_CTRL[10] STATUS_INT bit is cleared to 0, no status information data must be read from the MCPDM_UP_DATA register.

23.6.2.4.3.3 Exiting Status Mode

After the 16-bit status information data is sent, the external audio companion chip drives the abeMCPDM_frame line high during one period of the abeMCPDM_lb_clk clock signal before releasing its I/O driver in high-impedance state.

The MCPDM module automatically exits status mode one period of the abeMCPDM_lb_clk clock signal after the last bit of the status information data is transmitted on the abeMCPDM_frame line. After exiting status mode, the MCPDM module generates frame-sync low pulses.

NOTE: Because of the protocol mechanism, frame synchronization is lost during three frame periods. The external audio companion chip must internally emulate a frame synchronization to send uplink channel samples and received downlink channel samples as in normal mode while transmitting status information data on the abeMCPDM_frame line.

23.6.2.4.3.4 Multiple Status Information Data Access

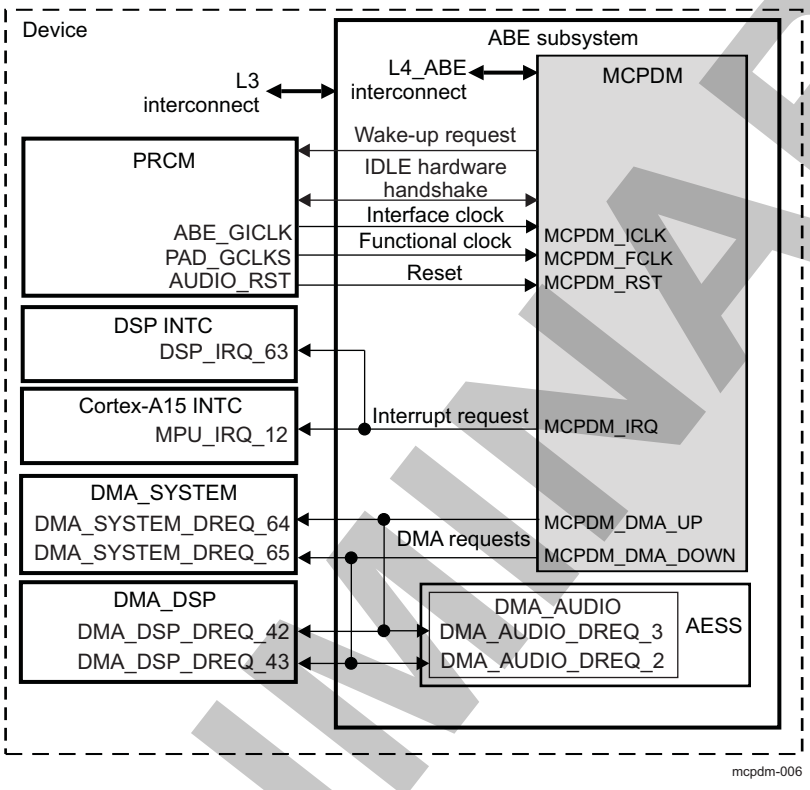
Multiple status information data can be sent by the external audio companion chip to the MCPDM module every four frames.

23.6.3 MCPDM Integration

This section describes the MCPDM module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-148 shows the MCPDM integration.

Figure 23-148. MCPDM Integration



NOTE: For more information about the IDLE state hardware handshake and the wake-up request, see Chapter 3, *Power, Reset, and Clock Management*.

Table 23-459 through Table 23-461 summarize the integration of the module in the device.

Table 23-459. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MCPDM	PD_AUDIO	Yes	L4_ABE

Table 23-460. Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
MCPDM	MCPDM_ICLK	ABE_GICLK	PRCM module	MCPDM interface clock
	MCPDM_FCLK	PAD_GCLKS	PRCM module	Common external functional clock
Resets				
MCPDM	MCPDM_RST	AUDIO_RST	PRCM module	MCPDM hardware reset

Table 23-461. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
MCPDM	MCPDM_IRQ	DSP_IRQ_63	DSP	MCPDM interrupt request to the DSP INTC
	MCPDM_IRQ	MPU_IRQ_112	Cortex-A15	MCPDM interrupt request to the Cortex-A15 MPU INTC
DMA Requests				
MCPDM	MCPDM_DMA_UP	DMA_SYSTEM_DREQ_64	DMA_SYSTEM	MCPDM uplink path DMA request to the DMA_SYSTEM
	MCPDM_DMA_DOWN	DMA_SYSTEM_DREQ_65	DMA_SYSTEM	MCPDM downlink path DMA request to the DMA_SYSTEM
	MCPDM_DMA_UP	DMA_DSP_DREQ_42	DMA_DSP	MCPDM uplink path DMA request to the DMA_DSP
	MCPDM_DMA_DOWN	DMA_DSP_DREQ_43	DMA_DSP	MCPDM downlink path DMA request to the DMA_DSP
	MCPDM_DMA_UP	DMA_AUDIO_DREQ_3	DMA_AUDIO	MCPDM uplink path DMA request to the DMA_AUDIO
	MCPDM_DMA_DOWN	DMA_AUDIO_DREQ_2	DMA_AUDIO	MCPDM downlink path DMA request to the DMA_AUDIO

NOTE:

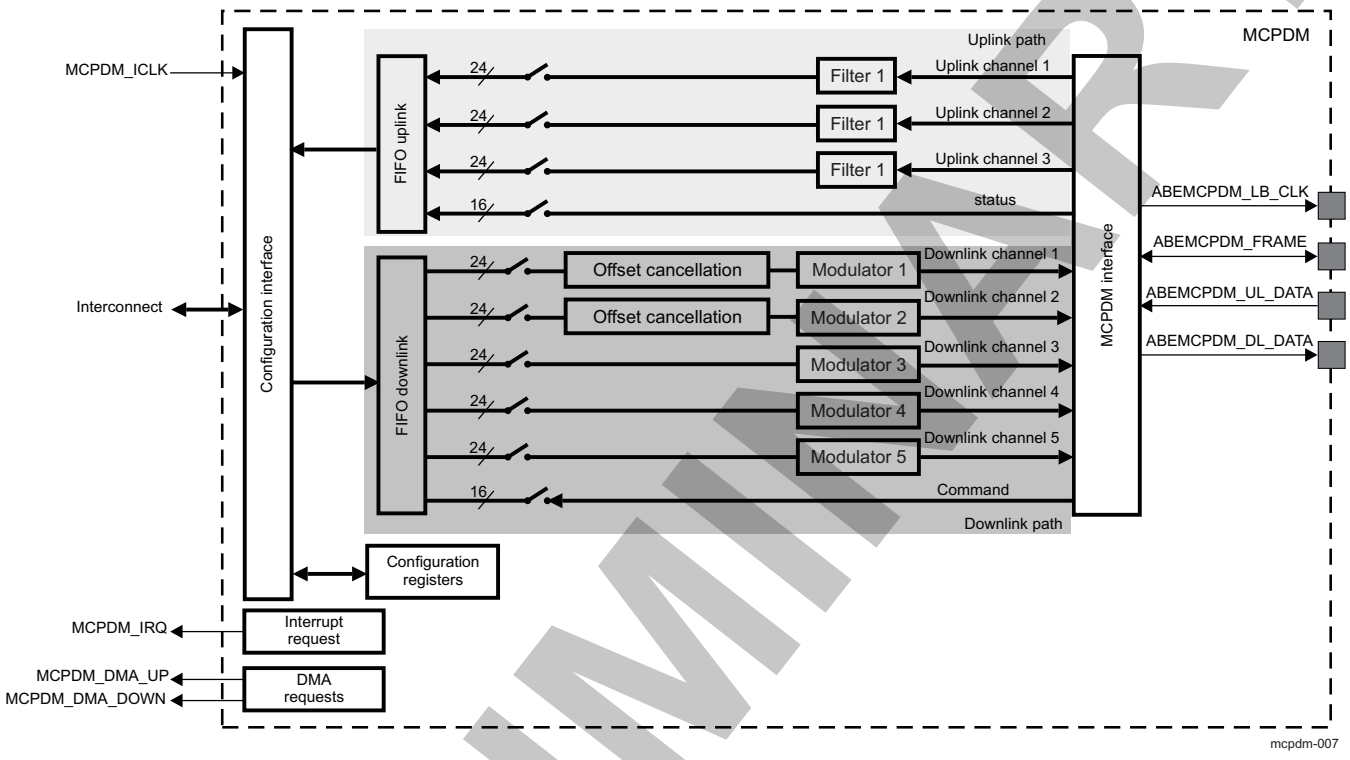
- For the description of the interrupt source, see Section 23.6.4.5, *Interrupt Requests*.
- For the description of the DMA source, see Section 23.6.4.6, *DMA Requests*.

23.6.4 MCPDM Functional Description

23.6.4.1 MCPDM Block Diagram

Figure 23-149 shows the MCPDM block diagram.

Figure 23-149. MCPDM Block Diagram



23.6.4.2 MCPDM Clock Configuration

The functional clock MCPDM_FCLK is provided by the external audio companion chip. Its frequency can be either 17.64 MHz (for a sampling frequency of 88.2/176.4 kHz) or 19.2 MHz (for a sampling frequency of 96/192 kHz).

For resynchronization purposes, the functional clock is also looped back to the audio companion chip through ABEMCPDM_LB_CLK.

23.6.4.3 MCPDM Software Reset

To perform a software reset of the MCPDM module, the MCPDM_SYSCONFIG[0] SOFTRESET bit must be set to 1. Reading the MCPDM_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: The software reset is ongoing.
- Read 0: The software reset is complete.

Software must ensure that the software reset completes before doing MCPDM operations. Moreover, uplink and downlink paths can be software reset independently by setting the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 1. The software reset is stopped by clearing the MCPDM_CTRL[11] SW_UP_RST bit for the uplink path, and the MCPDM_CTRL[12] SW_DN_RST bit for the downlink path to 0.

After completion, the software reset of the MCPDM module puts all MCPDM registers in their default state. The downlink/uplink reset resets only the downlink/uplink hardware logic (no registers are affected).

23.6.4.4 MCPDM Power Management

Table 23-462 describes the power-management features available to the MCPDM module.

Table 23-462. Local Power-Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	MCPDM_SYSCONFIG[3:2] IDLEMODE bit field	Force-idle, no-idle, smart-idle, and smart-idle wake-up capable modes are available for the interface clock.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers	Each register holds one active-high enable bit per event source able to generate wake-up signal.
Audio channel enable	MCPDM_CTRL[0] PDM_UP1_EN to MCPDM_CTRL[2] PDM_UP3_EN bits for audio uplink channels MCPDM_CTRL[3] PDM_DN1_EN to MCPDM_CTRL[7] PDM_DN5_EN bits for audio downlink channels	Each of these bits allows the corresponding audio channel to be enabled (set to 1) or disabled (cleared to 0).
Status channel enable	MCPDM_CTRL[10] STATUS_INT bit for the status channel	This bit allows the status channel to be enabled (set to 1) or disabled (cleared to 0).
Command channel enable	MCPDM_CTRL[9] CMD_INT bit for the command channel	This bit allows the command channel to be enabled (set to 1) or disabled (cleared to 0).

The MCPDM_ICLK interface clock is controlled though the PRCM module using the IDLE request and acknowledge signals. The MCPDM_SYSCONFIG[3:2] IDLEMODE bit field allows the interface clock gating to be controlled in idle mode.

For the uplink path, the interface clock can be put in idle after the uplink path is enabled. Wakeup is available based on the settings of the MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers and the FIFO uplink threshold configured in the MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field. The wake-up signal is asserted when the FIFO uplink level equals or is greater than the FIFO uplink threshold value.

For the downlink path, the interface clock can be put in idle after the FIFO downlink level reaches the FIFO downlink threshold at least once. Wakeup is available according to the settings of the MCPDM_IRQWAKEEN and MCPDM_DMAWAKEEN registers and the FIFO downlink threshold configured in the MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH bit field. The wake-up signal is asserted when the FIFO downlink level is below the FIFO downlink threshold value.

23.6.4.5 MCPDM Interrupt Requests

The MCPDM can generate interrupt requests to the Cortex-A15 MPU and DSP INTCs through the MCPDM_IRQ signal.

Table 23-463 lists the nonmaskable and maskable event flags and their mask that can cause the MCPDM module to generate interrupts.

Table 23-463. Interrupt Events

Nonmaskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MCPDM_IRQSTATUS_RAW[11] UP_IRQ_FULL	MCPDM_IRQSTATUS[11] UP_IRQ_FULL	MCPDM_IRQENABLE_CLR[11] UP_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK	FIFO-uplink-full event. This event occurs when the FIFO uplink is full and a new word is written to the FIFO uplink by the uplink part of the MCPDM module.
MCPDM_IRQSTATUS_RAW[10] UP_IRQ_ALST_FULL	MCPDM_IRQSTATUS[10] UP_IRQ_ALST_FULL	MCPDM_IRQENABLE_CLR[10] UP_IRQ_ALST_FULL_MASK	MCPDM_IRQENABLE_SET[10] UP_IRQ_ALST_FULL_MASK	FIFO-uplink-almost-full event. This event occurs when the FIFO uplink contains (FIFO uplink size – 1) words and a new word is written to the FIFO uplink by the uplink part of the MCPDM module.
MCPDM_IRQSTATUS_RAW[9] UP_IRQ_EMPTY	MCPDM_IRQSTATUS[9] UP_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[9] UP_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK	FIFO-uplink-empty event. This event occurs when the FIFO uplink is already empty and a new word is read from the FIFO uplink by software.
MCPDM_IRQSTATUS_RAW[8] UP_IRQ	MCPDM_IRQSTATUS[8] UP_IRQ	MCPDM_IRQENABLE_CLR[8] UP_IRQ_MASK	MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	FIFO-uplink-read-request event. This event occurs when the number of words stored in the FIFO uplink equals or is greater than the FIFO uplink threshold.
MCPDM_IRQSTATUS_RAW[3] DN_IRQ_FULL	MCPDM_IRQSTATUS[3] DN_IRQ_FULL	MCPDM_IRQENABLE_CLR[3] DN_IRQ_FULL_MASK	MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK	FIFO-downlink-full event. This event occurs when FIFO downlink is already full and a new word is written to the FIFO downlink by software.
MCPDM_IRQSTATUS_RAW[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQSTATUS[2] DN_IRQ_ALST_EMPTY	MCPDM_IRQENABLE_CLR[2] DN_IRQ_ALST_EMPTY_MASK	MCPDM_IRQENABLE_SET[2] DN_IRQ_ALST_EMPTY_MASK	FIFO-downlink-almost-empty event. This event occurs when FIFO downlink contains one word and a new word is read from the FIFO downlink by the downlink part of the MCPDM module.
MCPDM_IRQSTATUS_RAW[1] DN_IRQ_EMPTY	MCPDM_IRQSTATUS[1] DN_IRQ_EMPTY	MCPDM_IRQENABLE_CLR[1] DN_IRQ_EMPTY_MASK	MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK	FIFO-downlink-empty event. This event occurs when FIFO downlink is empty and a new word is read from the FIFO downlink by the downlink part of the MCPDM module.
MCPDM_IRQSTATUS_RAW[0] DN_IRQ	MCPDM_IRQSTATUS[0] DN_IRQ	MCPDM_IRQENABLE_CLR[0] DN_IRQ_MASK	MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	FIFO-downlink-write-request event. This event occurs when the number of words stored in the FIFO downlink is less than the FIFO downlink threshold.

(1) The MCPDM_IRQSTATUS_RAW register is used mainly for debug purposes.

CAUTION

Once an event generating the interrupt request is processed by software, the event must be cleared by writing a logical 1 to the corresponding bit of the MCPDM_IRQSTATUS register.

Writing a logical 1 in a bit of the MCPDM_IRQSTATUS register also clears the corresponding bit in the MCPDM_IRQSTATUS_RAW register to 0.

An event can generate an interrupt request when a logical 1 is written to the corresponding mask bit in the MCPDM_IRQENABLE_SET register. Events are reported in the MCPDM_IRQSTATUS and MCPDM_IRQSTATUS_RAW registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MCPDM_IRQENABLE_CLR register. Events are reported only in the MCPDM_IRQSTATUS_RAW register.

For the MCPDM_IRQSTATUS_RAW register, the event is reported in the corresponding bit, even if the interrupt request generation is disabled for this event.

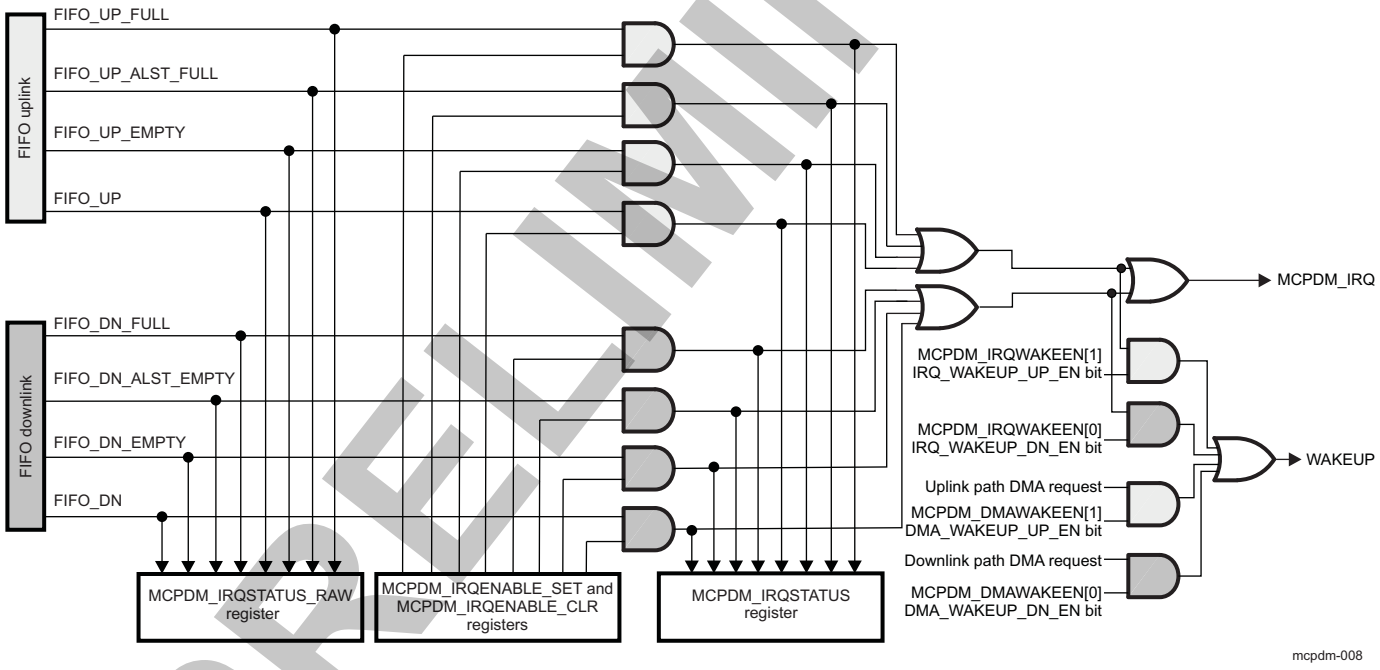
Writing a logical 1 in a bit of the MCPDM_IRQSTATUS_RAW register sets the corresponding bit in the MCPDM_IRQSTATUS register to 1.

The MCPDM_IRQSTATUS_RAW register is used primarily for debug purposes.

For more information about interrupt request signal mapping, see Table 23-461.

Figure 23-150 shows the interrupt tree of the MCPDM module.

Figure 23-150. Interrupt Tree



23.6.4.6 MCPDM DMA Requests

The MCPDM module can generate two DMA requests to the DMA_SYSTEM, DMA_AUDIO, and DMA_DSP controllers:

- The uplink path can generate a DMA request through the MCPDM_DMA_UP signal.
- The downlink path can generate a DMA request through the MCPDM_DMA_DOWN signal.

Table 23-464 lists the DMA requests of the MCPDM module.

Table 23-464. MCPDM DMA Requests

DMA Request Signal	DMA Request Generation Enabling Bit	DMA Request Generation Disabling Bit	Description
MCPDM_DMA_UP	MCPDM_DMAENABLE_SET [1] DMA_UP_ENABLE	MCPDM_DMAENABLE_CLR [1] DMA_UP_ENABLE	Uplink path DMA request. This request is generated when the number of words in the FIFO uplink equals or is above the FIFO uplink threshold.
MCPDM_DMA_DOWN	MCPDM_DMAENABLE_SET [0] DMA_DN_ENABLE	MCPDM_DMAENABLE_CLR [0] DMA_DN_ENABLE	Downlink path DMA request. This request is generated when the number of words in the FIFO downlink is below the FIFO downlink threshold.

To enable or disable the DMA request generation on the MCPDM_DMA_UP signal, one of the following actions must be performed:

- Write a logical 1 to the MCPDM_DMAENABLE_SET[1] DMA_UP_ENABLE bit to enable DMA request generation on the MCPDM_DMA_UP signal.
- Write a logical 1 to the MCPDM_DMAENABLE_CLR[1] DMA_UP_ENABLE bit to disable DMA request generation on the MCPDM_DMA_UP signal.

To enable or disable the DMA request generation on the MCPDM_DMA_DOWN signal, one of the following actions must be performed:

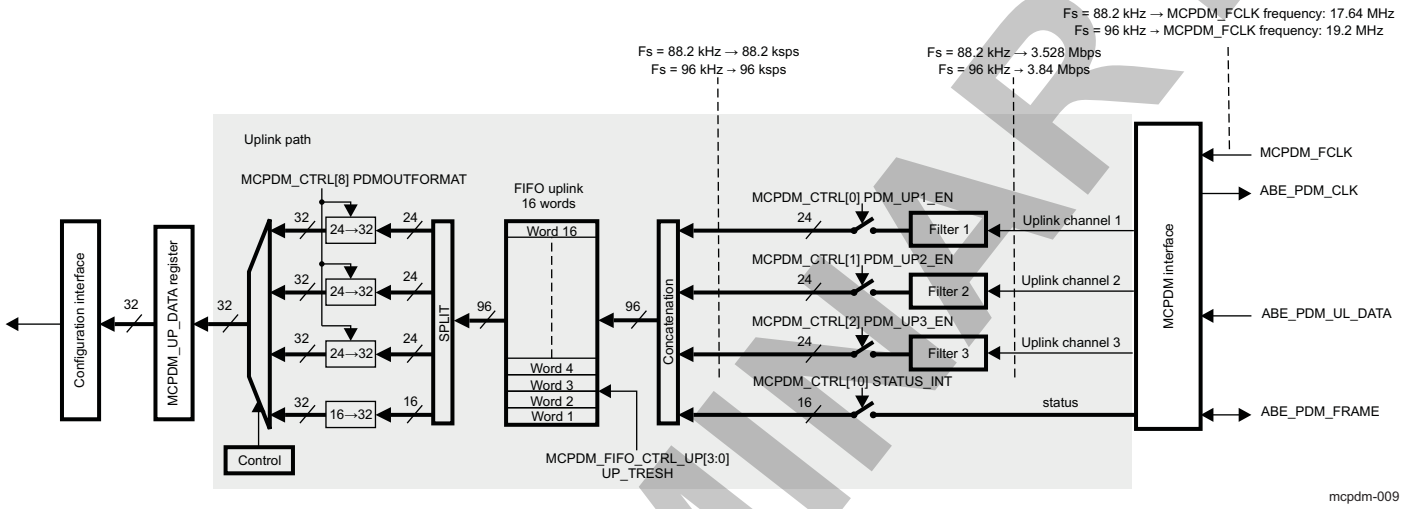
- Write a logical 1 to the MCPDM_DMAENABLE_SET[0] DMA_DN_ENABLE bit to enable DMA request generation on the MCPDM_DMA_DOWN signal.
- Write a logical 1 to the MCPDM_DMAENABLE_CLR[0] DMA_DN_ENABLE bit to disable DMA request generation on the MCPDM_DMA_DOWN signal.

For more information about DMA request signals mapping, see Table 23-461.

23.6.4.7 Uplink Path

Figure 23-151 shows a detailed block diagram of the uplink path in the MCPDM module.

Figure 23-151. Uplink Path Detailed Block Diagram



- The McPDM uplink input PDM data are provided by a 1-bit ADC Sigma-Delta (for each uplink channel).
- The McPDM uplink output PCM linear data format is equal to 24 bits signed format.
- It can be define 0dBpcm = maximum digital level allowed by the 24 bits data format is equal to amplitude peak ($2^{23} – 1$).
- McPDM uplink gain is product from filter decimation factor and filter gain → $G = 40^4 \times 4.89 = 12518400$ (decimal).
- 0dBpdm at McPDM uplink input (all PDM bits at '1' state) is not allowed on real silicon because it will overload the McPDM uplink output:
  - For 0dBpdm McPDM input follows McPDM uplink theoretical decimal output should be: 12518400 = +3.48 dBpcm. The result is calculated by → 20log (12518400 / ($2^{23} – 1$)).
- –4dBpdm level at McPDM input will produce a McPDM uplink output equal to 7898610 = –0.52 dBpcm.

23.6.4.7.1 Uplink Path Features

The uplink path has the following features:

- Three audio uplink channels
- One status channel
- Decimation filter for each audio uplink channel
- 16-word FIFO uplink with threshold setting
- Audio channel data formatting
- High-frequency sampling feature

23.6.4.7.2 Uplink Path Description

23.6.4.7.2.1 Uplink Data Received From the External Audio Companion Chip

The MCPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz (for a sampling frequency of 88.2 kHz) or 19.2 MHz (for a sampling frequency of 96 kHz). This low-frequency sampling feature is enabled by default. The uplink path supports a high-frequency sampling feature to work with an ultrasonic external microphone. This feature is enabled by setting the MCPDM_CTRL[13] DIV_SEL bit to 1. Thus, the MCPDM interface receives audio uplink channel data and status information data from the external audio companion chip at a clock rate of 17.64 MHz (for a sampling frequency of 176.4 kHz) or 19.2 MHz (for a sampling frequency of 192 kHz).

The MCPDM interface extracts each data bit related to audio and sends it to the decimation filter of the corresponding channel. Therefore, for each audio uplink channel, the MCPDM interface generates 1 bit data flow to the corresponding decimation filter at a rate of 3.528 Mbps (for a sampling frequency of 88.2 kHz) or 3.84 Mbps (for a sampling frequency of 96 kHz).

Moreover, when status information data are detected on the frame-sync signal (ABEMCPDM_FRAME), the status information data are recovered and sent to the status channel. When no status information data are detected on the frame-sync signal, a null word (0x0000) is sent on the status channel.

For more information about protocols and data formats in normal mode, see Section 23.6.2.4.1, *Protocols and Data Formats in Normal Mode*. For more information about protocols and data formats in status mode, see Section 23.6.2.4.3, *Protocols and Data Formats in Status Mode*.

23.6.4.7.2.2 Decimation Filter

Each bit data flow is related to an audio uplink channel and is provided by the MCPDM interface is processed by a decimation filter. The purpose of this filter is to band-limit the noise and downsample the incoming bit data flow to generate a 24-bit-wide signed data flow at a rate of 88.2 kbps (for a sampling frequency of 88.2 kHz) or 96 kbps (for a sampling frequency of 96 kHz).

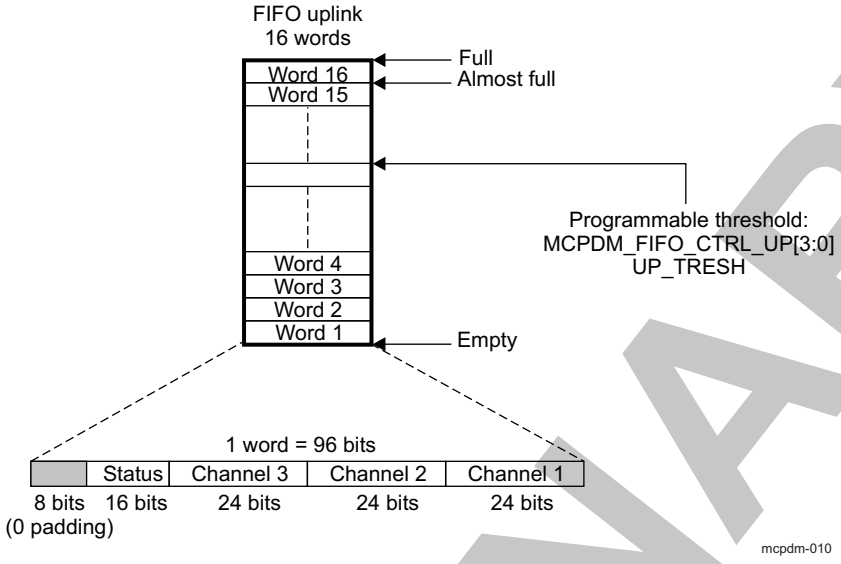
23.6.4.7.2.3 FIFO Uplink Management

23.6.4.7.2.3.1 General Description

The MCPDM module implements a FIFO for the uplink path for communication with the host processor in the device. The FIFO uplink can store up to 16 words. Each word is 96 bits wide and is a combination of 24-bit-wide signed audio uplink channel data coming from decimation filters and 16-bit-wide status information data coming from the MCPDM interface.

Figure 23-152 shows the FIFO uplink overview.

Figure 23-152. FIFO Uplink Overview



23.6.4.7.2.3.2 FIFO Operations

The FIFO uplink is filled with audio uplink channel data coming from decimation filters and status information data from the MCPDM interface. Once the FIFO uplink threshold (MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field) is reached, an event occurs (depending on conditions) and generates an interrupt or DMA request.

NOTE: For more information about events generating an interrupt request, see Section 23.6.4.5, *MCPDM Interrupt Requests*.

For more information about conditions for DMA request generation, see Section 23.6.4.6, *MCPDM DMA Requests*.

When an interrupt request on a FIFO uplink read-request event or an MCPDM_DMA_UP request occurs, the host processor or the DMA controller must read the words from the FIFO uplink (MCPDM_UP_DATA register). The number of read accesses from the host/DMA is determined by the following equation:

Num_read_access = (PDM_UP1_EN + PDM_UP2_EN + PDM_UP3_EN + STAT_INT) * (UP_THRESH), where the PDM_UP_THRESHOLD is programmed through the MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH bit field.

PDM_UP1_EN, PDM_UP2_EN, PDM_UP3_EN, and STAT_INT are boolean values representing whether or not the corresponding channel is enabled.

For example, if audio uplink channels 1 and 3 are enabled, audio uplink channel 2 is disabled, the status channel is enabled, and the uplink threshold is programmed for one line only (MCPDM_FIFO_CTRL_UP[3:0] UP_THRESH = 0x0):

- Num_read_access = 3 because two audio uplink and the status channels are enabled.
- The first reading of the MCPDM_UP_DATA register should correspond to the audio uplink channel 1 data.
- The second reading of the MCPDM_UP_DATA register should correspond to the audio uplink channel 3 data.
- The third reading of the MCPDM_UP_DATA register should correspond to the status information data.

NOTE: No status information is sent by the external audio companion chip if the status channel is enabled and the 16 lower bits of the corresponding data read from the MCPDM_UP_DATA register is 0x0000 .

The audio uplink and status channels cannot be enabled or disabled on the fly during uplink signaling. The uplink path must first be forced to reset by setting the MCPDM_CTRL[11] SW_UP_RST bit to 1 before enabling or disabling any channels.

Because the audio uplink channel data are 24 bits wide and the MCPDM_UP_DATA register is 32 bits wide, the MCPDM_CTRL[8] PDMOUTFORMAT bit allows the justification of the 24-bit audio uplink channel data in the MCPDM_UP_DATA register to be selected:

- When the MCPDM_CTRL[8] PDMOUTFORMAT bit is cleared to 0, the 24-bit-wide signed audio uplink channel data are left-justified with eight 0 padding bits for the lower bits (24 bits data Left Justified + 8 bits pad)..
- When the MCPDM_CTRL[8] PDMOUT FORMAT is set to 1, the 24-bit-wide signed audio uplink channel data are right-justified and sign-extended (8 bits Pad + 24 bits data Right Justified). For both cases (right or left-justified), 24 bits data transfer starts with MSB First format.

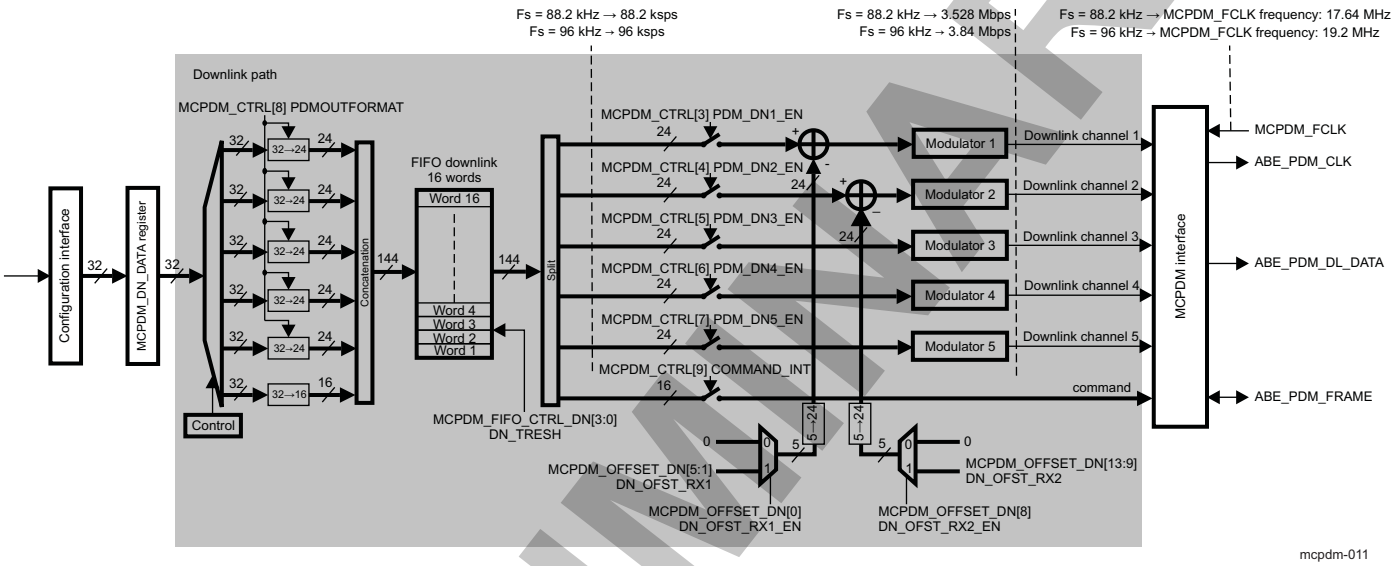
NOTE: The MCPDM_CTRL[8] PDMOUTFORMAT bit does not affect the status information format. When the status information data are read from the MCPDM_UP_DATA register, only the 16 lower bits are significant.

The setting of the MCPDM_CTRL[8] PDMOUTPUTFORMAT bit also affects the audio downlink channel data format.

23.6.4.8 Downlink Path

Figure 23-153 shows a detailed block diagram of the downlink path in the MCPDM module.

Figure 23-153. Downlink Path Detailed Block Diagram



- The McPDM downlink and dBpcm is relative to the 24 bits signed format (ABE data format): 0dBpcm amplitude peak is equal to (2^{23} – 1)
- dBpdm is defined by the gain provided by the McPDM total gain is equal to –6.35dB:
  - There is a –6dB attenuation at the input of the Sigma-Delta modulator.
  - The Sigma-Delta has an intrinsic gain of –0.35dB.
- Then the gain between McPDM PDM output and McPDM PCM linear input is constant and equal to –6.35dB.

23.6.4.8.1 Downlink Path Features

The downlink path has the following features:

- Five audio downlink channels
- Offset cancellation for audio downlink channels 1 and 2
- One command channel
- Delta-sigma modulator for each audio downlink channel
- 16-word FIFO downlink with threshold setting
- Audio channel data formatting

23.6.4.8.2 Downlink Path Description

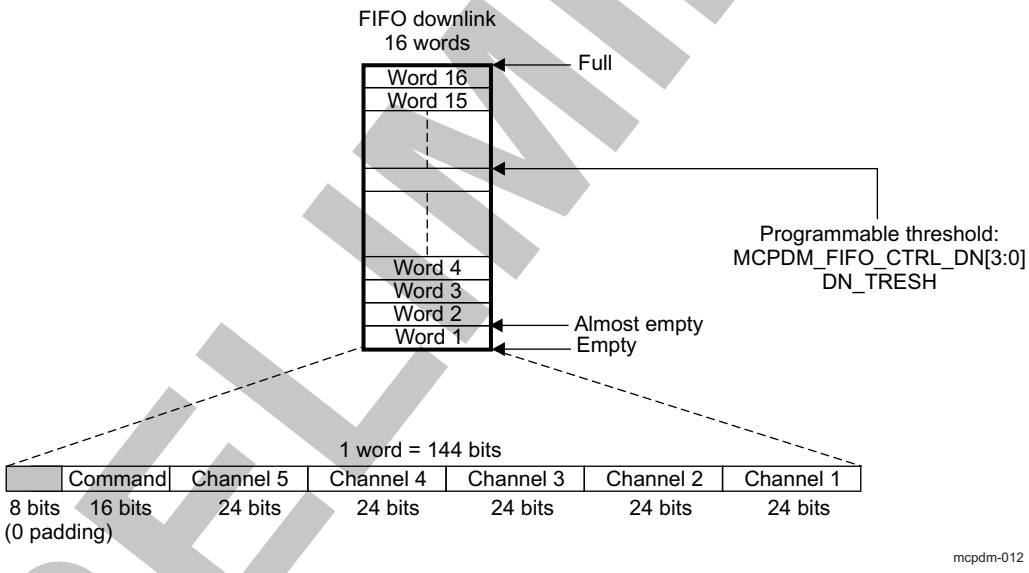
23.6.4.8.2.1 FIFO Downlink Management

23.6.4.8.2.1.1 General Description

The MCPDM module implements a FIFO for the downlink path to communicate with the host processor in the device. The FIFO downlink can store up to 16 words. Each word is 144 bits wide and is a combination of 24-bit-wide signed audio downlink channels data and 16-bit-wide command information data.

Figure 23-154 shows the FIFO downlink overview.

Figure 23-154. FIFO Downlink Overview



23.6.4.8.2.1.2 FIFO Operations

The FIFO downlink is read by the MCPDM module and data related to the audio downlink channels are sent to the delta-sigma modulators, while the data related to the command information is sent to the MCPDM interface. Once the FIFO pointer goes below the programmed threshold (the MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH bit field), a DMA or interrupt request is sent to the DMA or interrupt handler and, depending on conditions, an event occurs and generates an interrupt or DMA request.

NOTE: For more information about events generating an interrupt request, see Section 23.6.4.5, *MCPDM Interrupt Requests*.

For more information about conditions for DMA request generation, see Section 23.6.4.6, *MCPDM DMA Requests*.

When an interrupt request upon a FIFO downlink write-request event or a MCPDM_DMA_DOWN request occurs, it indicates that the next words are available to be written to the MCPDM_DN_DATA register. The minimum number of write accesses from the host/DMA is determined by the following equation:

Num_min_write_access = PDM_DN1_EN + PDM_DN2_EN + PDM_DN3_EN + PDM_DN4_EN + PDM_DN5_EN + CMD_INT

PDM_DN1_EN, PDM_DN2_EN, PDM_DN3_EN, PDM_DN4_EN, PDM_DN5_EN and CMD_INT are boolean values representing whether the corresponding channel is enabled or not.

The maximum number of write accesses (before overwriting the data in the FIFO still to be transmitted) from the host/DMA is determined by the following equation:

Num_max_write_access = (FIFO_SIZE – DN_THRESH + 1) * (PDM_DN1_EN + PDM_DN2_EN + PDM_DN3_EN + PDM_DN4_EN + PDM_DN5_EN +CMD_INT)

FIFO_SIZE is the size of the downlink FIFO and DN_THRESH is the downlink FIFO threshold, programmed through the MCPDM_FIFO_CTRL_DN[3:0] DN_THRESHOLD bit field.

For example, if audio downlink channels 1, 2, and 3 are enabled, audio downlink channels 4 and 5 are disabled, and the command channel is enabled:

- Num_min_write_access = 4, because three audio downlinks and the command channels are enabled.
- The first writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 1 data.
- The second writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 2 data.
- The third writing to the MCPDM_DN_DATA register should correspond to the audio downlink channel 3 data.
- The fourth writing to the MCPDM_DN_DATA register should correspond to the command information data.

NOTE: When the command channel is enabled and no command data must be sent to the external audio companion chip, 0x0000 must be written to the 16 lower bits of the MCPDM_DN_DATA register as command data.

The audio downlink and command channels cannot be enabled or disabled on the fly during downlink signaling. The downlink path must first be forced to reset by setting the MCPDM_CTRL[12] SW_DN_RST bit to 1 before enabling or disabling any channels.

Because the audio downlink channel data are 24 bits wide and the MCPDM_DN_DATA register is 32 bits wide, the MCPDM_CTRL[8] PDMOUTFORMAT bit indicates the justification of the 24-bit audio downlink channel data in the MCPDM_DN_DATA register:

- When the MCPDM_CTRL[8] PDMOUTFORMAT is cleared to 0, the 24-bit-wide signed audio downlink channel data are left-justified with eight 0 padding bits for the lower bits (24 bits data Left Justified + 8 bits pad).
- When MCPDM_CTRL[8] PDMOUT FORMAT is set to 1, the 24-bit-wide signed audio downlink channel data are right-justified and sign-extended (8 bits Pad + 24 bits data Right Justified). For both cases (right or left-justified), 24 bits data transfer starts with MSB First format.

NOTE: The MCPDM_CTRL[8] PDMOUTFORMAT bit does not affect the command information format. When the command information data are written to the MCPDM_DN_DATA register, only the 16 lower bits are significant.

The setting of the MCPDM_CTRL[8] PDMOUTPUTFORMAT bit also affects the audio uplink channel data format.

23.6.4.8.2.1.3 Offset Cancellation

Because audio downlink channels 1 and 2 are related to the analog headset downlink path within the external audio companion chip, an offset cancellation feature is available for these channels to eliminate the offset of the analog headset downlink path.

When the offset cancellation feature is enabled, an offset value is subtracted from the audio data before being sent to the pulse-density modulator. The offset values are read from registers within the external audio companion chip and configured in the MCPDM_DN_OFFSET[5:1] DN_OFST_RX1 bit field for the audio downlink channel 1, and in the MCPDM_DN_OFFSET[13:9] DN_OFST_RX2 bit field for the audio downlink channel 2.

The offset cancellation feature is enabled or disabled by configuring the MCPDM_DN_OFFSET[0] DN_OFST_RX1_EN bit for the audio downlink channel 1, and the MCPDM_DN_OFFSET[8] DN_OFST_RX2_EN bit for the audio downlink channel 2 (00: Disabled; 10: Enabled).

23.6.4.8.2.1.4 Pulse-Density Modulators

Each 24-bit-wide data related to an audio downlink channel is processed by a pulse-density modulator. The purpose of this modulator is to upsample the incoming audio data and then perform a 1-bit pulse-density modulation to generate a 1-bit data flow at a rate of 3.528 Mbps (for a sampling frequency of 88.2 kHz) or 3.84 Mbps (for a sampling frequency of 96 kHz). The 1-bit pulse-density modulation allows using a 1-bit analog-to-digital converter (ADC) implemented in the external audio companion chip to convert the audio digital data to an audio analog signal.

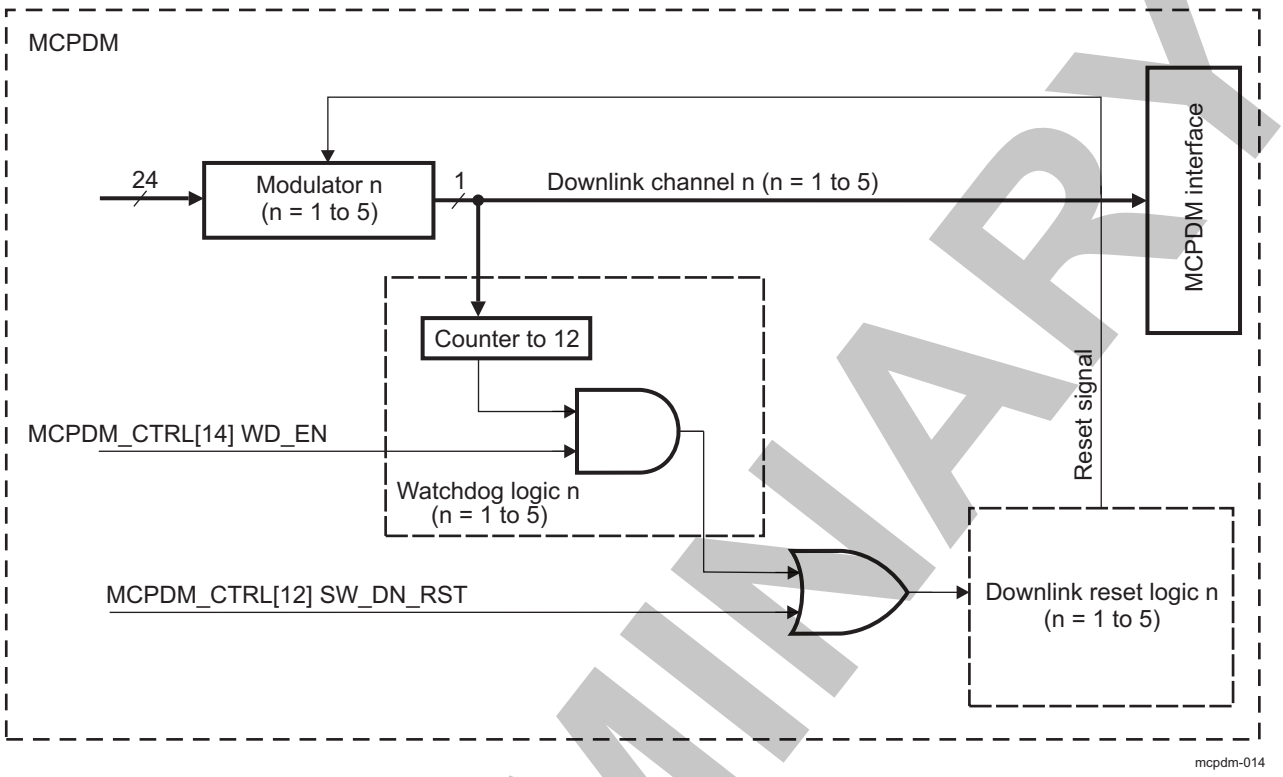
23.6.4.8.2.1.4.1 Pulse-Density Modulators Watchdog Logic

If the 1-bit data flow coming out of the pulse-density modulator has 12 or more consecutive 1s or 0s, the pulse-density modulator had entered into an unstable or saturated condition. An unstable or saturated condition leads to unpredictable behavior of the pulse-density modulator, thereby producing random noise. To prevent this unstable or saturated condition from occurring, a watchdog logic is used to monitor the 1-bit output of the pulse-density modulator for 12 consecutive 1s or 12 consecutive 0s. If entry to an unstable condition is detected, the watchdog logic asserts the reset of the MCPDM downlink paths for one clock pulse to put the MCPDM hardware logic, related to the downlink mechanism, to initial state.

The watchdog logic is disabled by default. To enable it, the MCPDM_CTRL[14] WD_EN bit must be set to 0x1. If the watchdog logic is disabled, only the assertion of the downlink path reset MCPDM_CTRL[12] SW_DN_RST bit is allowed to reset the MCPDM hardware logic, which is related to the downlink mechanism. If the watchdog logic is enabled, the downlink mechanism logic is reset when the downlink path reset or the watchdog reset is asserted.

Figure 23-155 shows the MCPDM watchdog logic mechanism.

Figure 23-155. MCPDM Watchdog Logic



23.6.4.8.2.1.5 Downlink Data Sent to the External Audio Companion Chip

The MCPDM interface transmits the audio downlink channel data and command data to the external audio companion chip at a clock rate of 17.64 MHz (for a sampling frequency of 88.2 kHz) or 19.2 MHz (for a sampling frequency of 96 kHz).

The command data are sent on the frame-sync signal (ABEMCPDM_FRAME) when the command channel is enabled. When the command channel is disabled or the command data is 0x0000, no command data is sent on the frame-sync signal.

NOTE: For more information about protocols and data formats in normal mode, see Section 23.6.2.4.1, *Protocols and Data Formats in Normal Mode*.

For more information about protocols and data formats in command mode, see Section 23.6.2.4.2, *Protocols and Data Formats in Command Mode*.

23.6.4.9 Error Reporting

During normal operation, when interrupt and DMA requests are properly served, no FIFO-uplink-full and no FIFO-downlink-empty events should occur.

Nevertheless, if one of these events occurs, the corresponding path must be forced to reset by software before being reconfigured. For more information about events servicing, see Section 23.6.5.1.2, *MCPDM Events Servicing*.

Moreover, a FIFO-uplink-empty or FIFO-downlink-full event occurs only when all the channels of the corresponding path have been disabled during normal operation.

NOTE: Channels must not be enabled or disabled during normal operation.

Channels can be enabled or disabled when the corresponding path is forced to reset. For more information about MCPDM software reset, see Section 23.6.4.3, *MCPDM Software Reset*.

23.6.5 MCPDM Programming Guide

23.6.5.1 MCPDM Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

23.6.5.1.1 Global Initialization

23.6.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules in the device when the MCPDM module is to be used for the first time after a device reset. Initialization of surrounding modules is based on the environment and integration of the MCPDM. For more information, see Section 23.6.2, *MCPDM Environment*, and Section 23.6.3, *MCPDM Integration*.

Table 23-465 describes the global initialization of surrounding modules.

Table 23-465. Global Initialization of Surrounding Modules

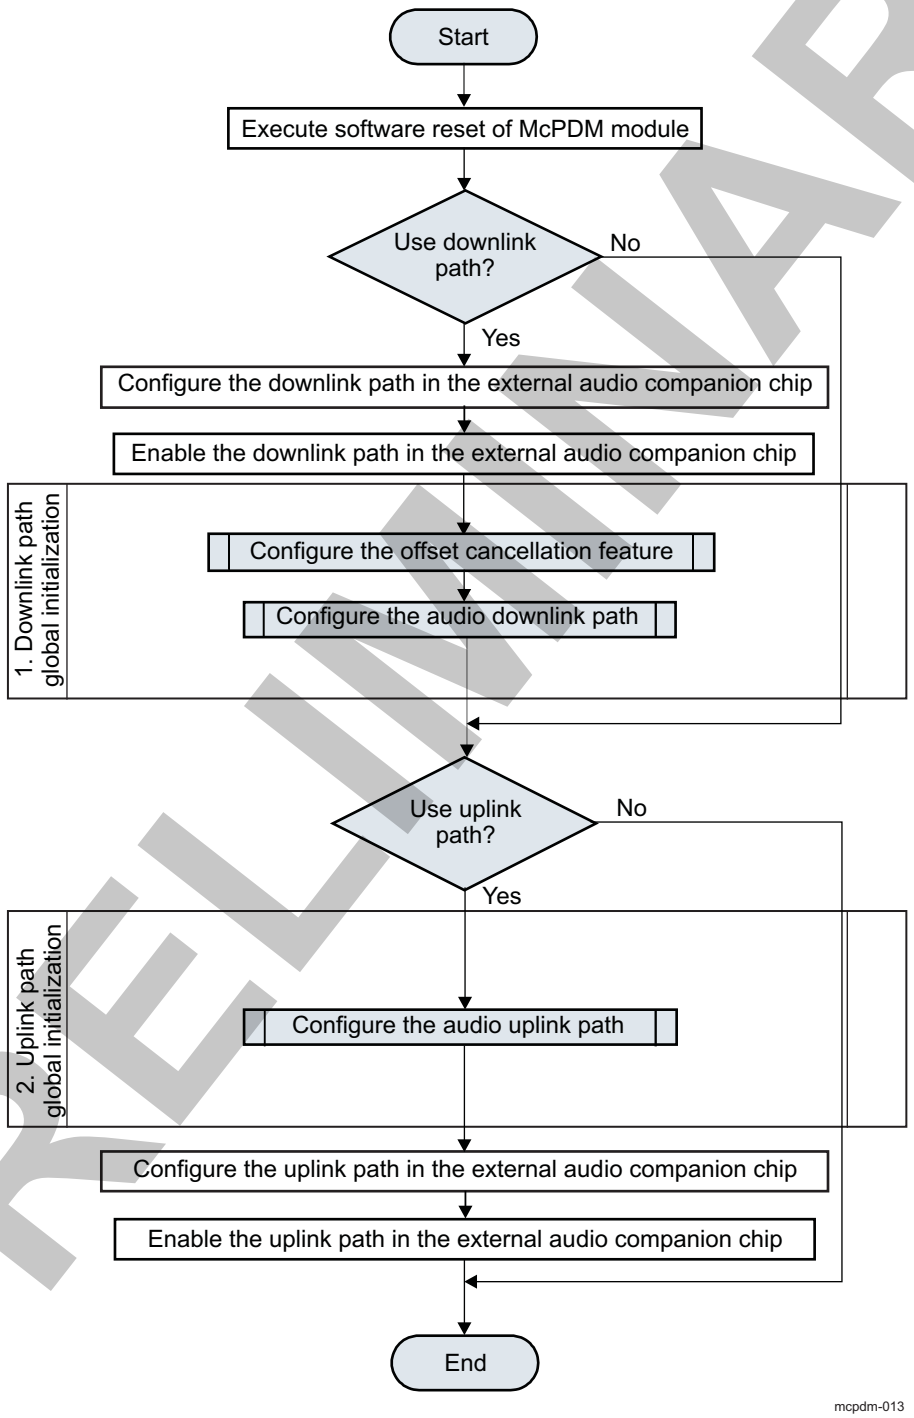
Surrounding Modules	Comments
PRCM module	The MCPDM interface clock must be enabled and the functional clock must not be gated.
Control module	The MCPDM-specific pad muxing must be configured in the device control module.
(Optional) Cortex-A15 MPU INTC (or DSP INTC)	The Cortex-A15 MPU (or DSP) INTC must be configured to enable the interrupt request generation to the Cortex-A15 MPU (or DSP) subsystem when interrupt requests are generated by the MCPDM module.
(Optional) sDMA (or eDMA or aDMA)	The sDMA (or eDMA or aDMA) controller must be configured to account for the DMA requests generated by the MCPDM module in the case of autonomous data transfers from/to memory.
(Optional) Interconnect	For more information about the interconnect configuration, see Chapter 14, *Interconnect*.
External audio chip	Initialize the external audio chip based on specific needs.
I^2C controller	For more information about I^2C initialization, see Section 23.1, *Multimaster High-Speed I^2C Controller*.

23.6.5.1.1.2 MCPDM Global Initialization

23.6.5.1.1.2.1 Main Sequence—MCPDM Global Initialization

This procedure initializes the MCPDM after a power-on reset (POR) or software reset. Figure 23-156 shows a flow chart for the global initialization of the MCPDM module.

Figure 23-156. MCPDM Global Initialization Flow Chart



The MCPDM software reset is executed by setting the MCPDM_SYSCONFIG[0] SOFTRESET bit to 0x1. To detect the reset done event, user software must check this bit until it is cleared to 0x0 by the hardware.

Configuration of the offset cancellation feature is optional. The use of that feature depends on the characteristics of the external audio chip attached to the MCPDM interface. If the external chip adds some DC offset on its output, then the offset cancellation feature of the MCPDM must be used.

Table 23-466 describes the steps of the downlink path global initialization.

Table 23-466. MCPDM Downlink Path Global Initialization

Procedure	Step	Access Type	Register/Bit Field/Programming Model	Value
Configure the offset cancellation feature. Only downlink path 1 and downlink path 2 can use the offset cancellation feature.	1. Read the offset value for audio downlink path 1 from the external audio companion chip through the I^2C interface.	R	Offset register 1 in the external audio companion chip	OFFSET1
	2. Configure the offset of audio downlink path 1.	W	MCPDM_DN_OFFSET[5:1] DN_OFST_RX1	OFFSET1
	3. Enable the offset cancellation feature for audio downlink path 1.	W	MCPDM_DN_OFFSET[0] DN_OFST_RX1_EN	0x1
	4. Read the offset value for audio downlink path 2 from the external audio companion chip through the I^2C interface.	R	Offset register 2 in the external audio companion chip	OFFSET2
	5. Configure the offset of audio downlink path 2.	W	MCPDM_DN_OFFSET[13:9] DN_OFST_RX2	OFFSET2
	6. Enable the offset cancellation feature for audio downlink path 2.	W	MCPDM_DN_OFFSET[8] DN_OFST_RX2_EN	0x1
Configure the audio downlink path.	1. Enable the interrupt request generation for the downlink path.	W	a. MCPDM_IRQENABLE_SET[3] DN_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[2] DN_IRQ_ALMST_EMPTY_MASK c. MCPDM_IRQENABLE_SET[1] DN_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[0] DN_IRQ_MASK	When downlink DMA request not used: 0xF When downlink DMA request used: 0xE
	2. Configure the FIFO downlink threshold.	W	MCPDM_FIFO_CTRL_DN[3:0] DN_TRESH	FIFO downlink threshold
	3. Enable the DMA request generation for the downlink path (optional: only if DMA request generation for the downlink path is required).	W	MCPDM_DMAENABLE_SET[0] DMA_DN_ENABLE	0x1
	4. Enable the downlink channels.	W	MCPDM_CTRL	See Table 23-462.

Table 23-467 describes the steps of the uplink path global initialization.

Table 23-467. MCPDM Uplink Path Global Initialization

Step	Access Type	Register/Bit Field/Programming Model	Value
1. Enable the interrupt request generation for the uplink path.	W	a. MCPDM_IRQENABLE_SET[11] UP_IRQ_FULL_MASK b. MCPDM_IRQENABLE_SET[10] UP_IRQ_ALMST_FULL_MASK c. MCPDM_IRQENABLE_SET[9] UP_IRQ_EMPTY_MASK d. MCPDM_IRQENABLE_SET[8] UP_IRQ_MASK	When uplink DMA request not used: 0xF When uplink DMA request used: 0xE
2. Configure the FIFO uplink threshold.	W	MCPDM_FIFO_CTRL_UP[3:0] UP_TRESH	FIFO uplink threshold
3. Enable the DMA request generation for the uplink path (optional: only if DMA request generation for the uplink path is required).	W	MCPDM_DMAENABLE_SET[1] DMA_UP_ENABLE	0x1
4. Configure the FIFO uplink sampling frequency.	W	MCPDM_CTRL[13] DIV_SEL	0x-

Table 23-467. MCPDM Uplink Path Global Initialization (continued)

Step	Access Type	Register/Bit Field/Programming Model	Value
5. Enable the uplink channels.	W	MCPDM_CTRL	See Table 23-462.

23.6.5.1.2 MCPDM Events Servicing

23.6.5.1.2.1 Downlink Path Event Servicing

Table 23-468 to Table 23-471 describe the downlink path event servicing.

When the four downlink interrupts are enabled and then the downlink channel(s) is enabled, the FIFO-downlink-write request (MCPDM_IRQSTATUS = 0x1) is generated instead of the FIFO-downlink-empty request (MCPDM_IRQSTATUS = 0x2). The first audio data to be sent is written from the interrupt handler. The MCPDM module can work in two ways:

- Enable the desired downlink channels, and then write in the downlink FIFO the audio data that is going to be sent.
- Write the audio data in the downlink FIFO, and then enable the desired downlink channels to send this audio data.

Either way, the FIFO-downlink-write request is generated.

Table 23-468. FIFO-Downlink-Full Event Servicing

23.7 Digital Microphone Module

This section describes the digital microphone (DMIC) module.

23.7.1 DMIC Overview

The DMIC module consists of an audio module dedicated to a mobile telephone terminal. The DMIC allows the support of up to six digital microphones. It provides an interface between the audio backend (ABE) module and microphones connected through the 6-wire DMIC serial interface.

The DMIC supports six paths. Because each path is composed of two digital microphone channels, the DMIC can be used with three stereo or six mono microphones. Each path is enabled or disabled independently.

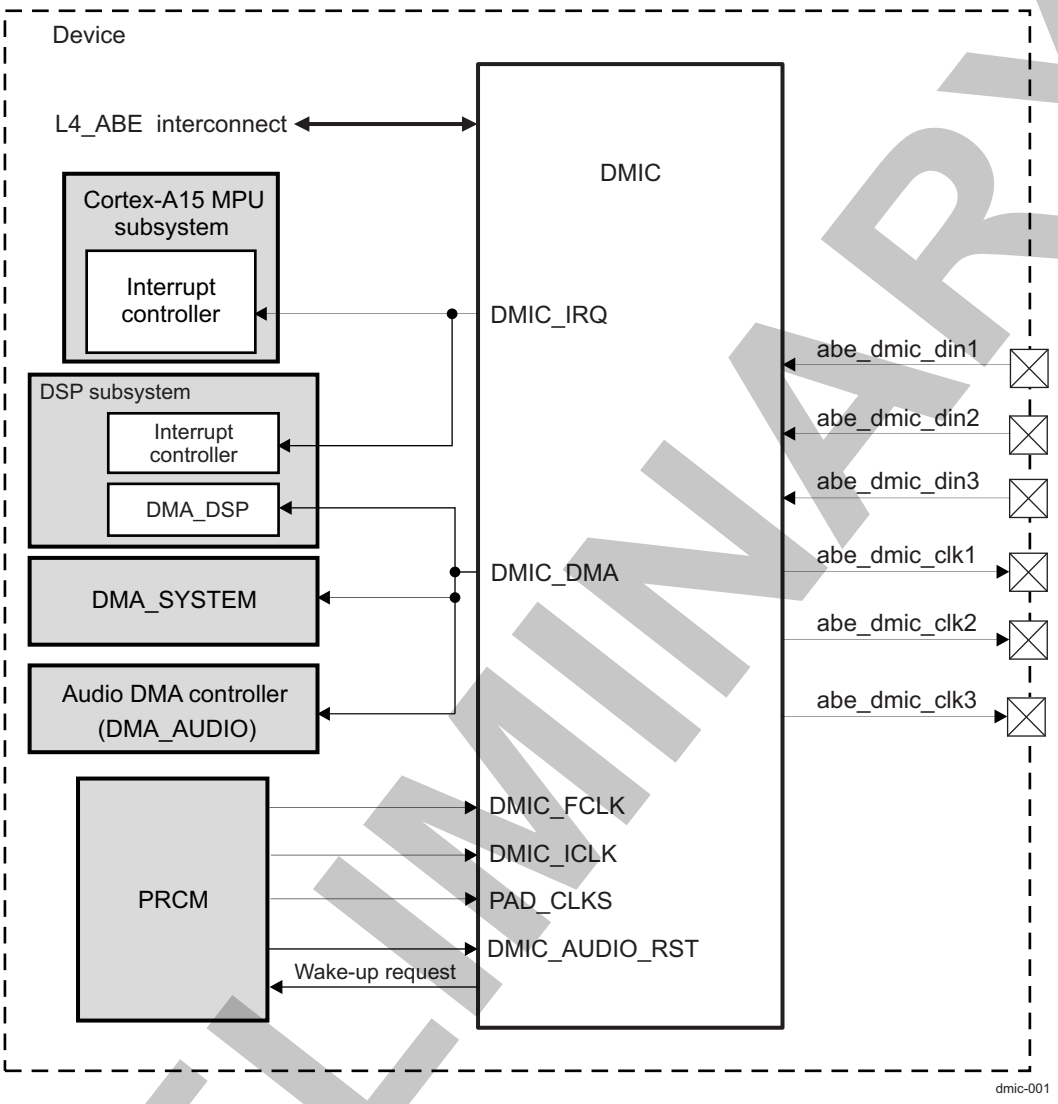
The DMIC generates a pulse-density modulated (PDM) stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC (oversampling clock).

Each microphone is directly connected to a filter decimator to extract the audio samples at the desired accuracy and sample rate. Data are stored in the first in first out (FIFO), which is controlled by interrupt request (IRQ) and direct memory access (DMA) request.

The DMIC pads are supplied with 1.8 V. These pads assure the transition to the host supply.

Figure 23-157 shows the DMIC in the device.

Figure 23-157. DMIC



The main features of the DMIC are:

- Six external pin connections (three data lines and three clock lines)
- Using the three clock lines, the DMIC delivers three clock signals (same frequency, individually gateable) for all digital microphones.
- Using the three data lines, the DMIC receives audio data from external microphones.
- Supports stereo (up to three) and mono (up to six) digital microphones
- Each line can support two microphones working in clock phase opposition.
- Selectable functional clock source
- Programmable output clock frequency (32 × FS, 50 × FS, 64 × FS, or 80 × FS, where FS = 48 kHz)
- Programmable data sampling sensibility (rising or falling edge)
- One RX FIFO (16 words of 144 bits)
- Supports IDLE request/acknowledge power, reset, and clock management (PRCM) module protocol
- Interconnect sample format: 32 bits (only 24 are significant)
- One IRQ to the microprocessor unit (Cortex™-A15 microprocessor unit [MPU]) and digital signal processor (DSP) subsystems
- One DMA request capability on programmable FIFO threshold

23.7.2 DMIC Environment

This section describes the DMIC application fields from an environment point of view (that is, external connections). It presents the DMIC connectivity options, lists possible interfaces, and details the protocol and data format used in each case.

23.7.2.1 DMIC Interface With External MIC

23.7.2.1.1 DMIC Interface Overview

The DMIC interface is a 6-wire interface. The DMIC can support up to three external stereo and six mono digital microphones. A DMIC is an external module that can deliver data. A clock is sent from the host to the microphone.

Figure 23-158 and Figure 23-159 show two cases of use of the DMIC, but all configurations are possible with stereo and mono digital microphones. The output of the DMIC is in 32-bit format.

Figure 23-158 shows the DMIC used with three stereo DMICs.

Figure 23-158. DMIC With Three Stereo DMICs

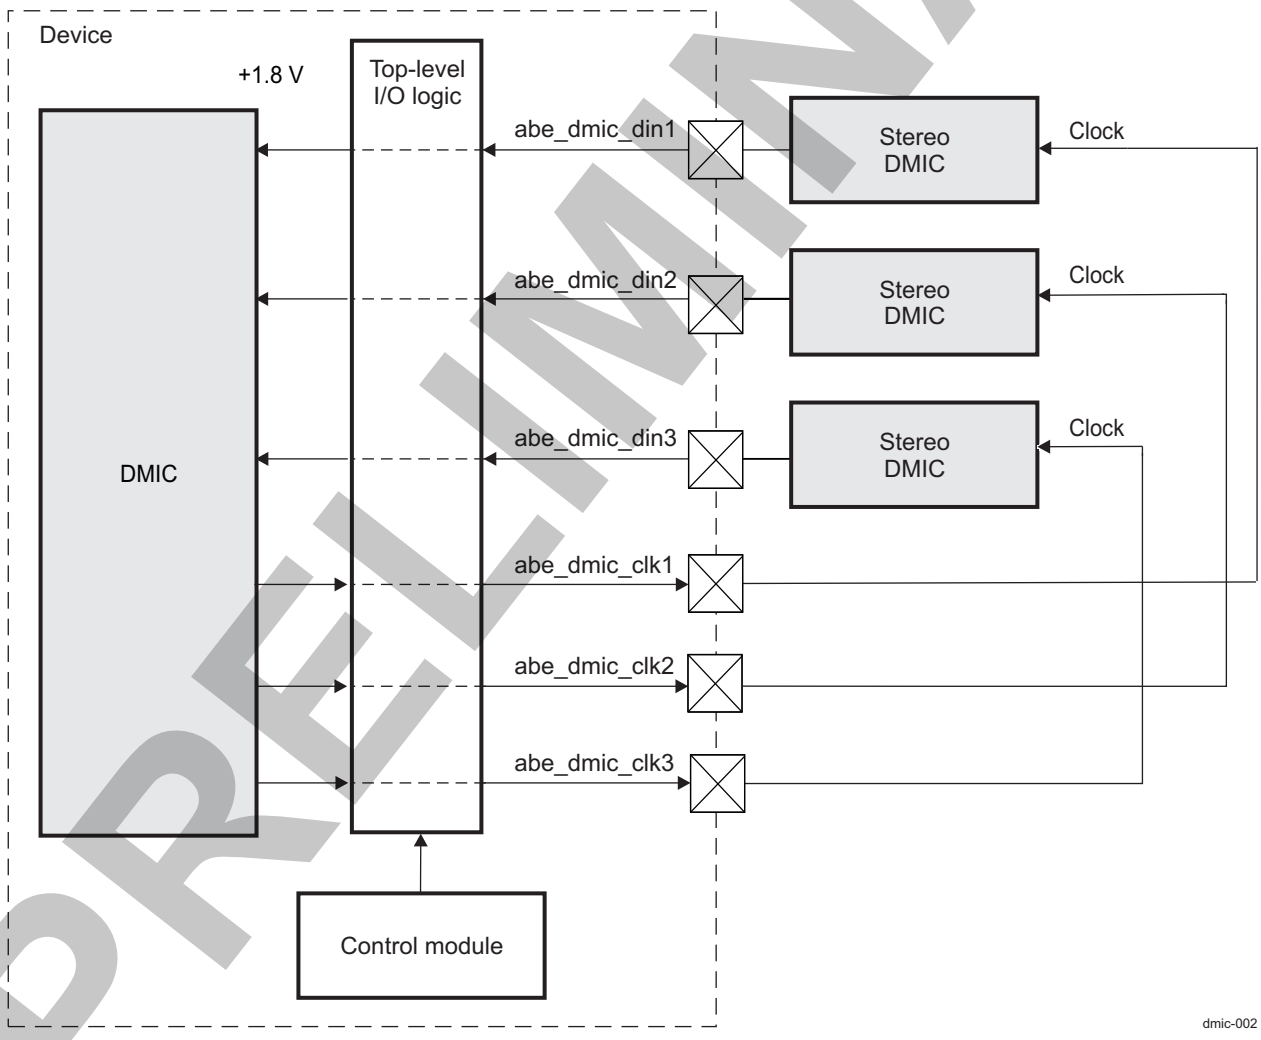


Figure 23-159 shows the DMIC used with six mono DMICs.

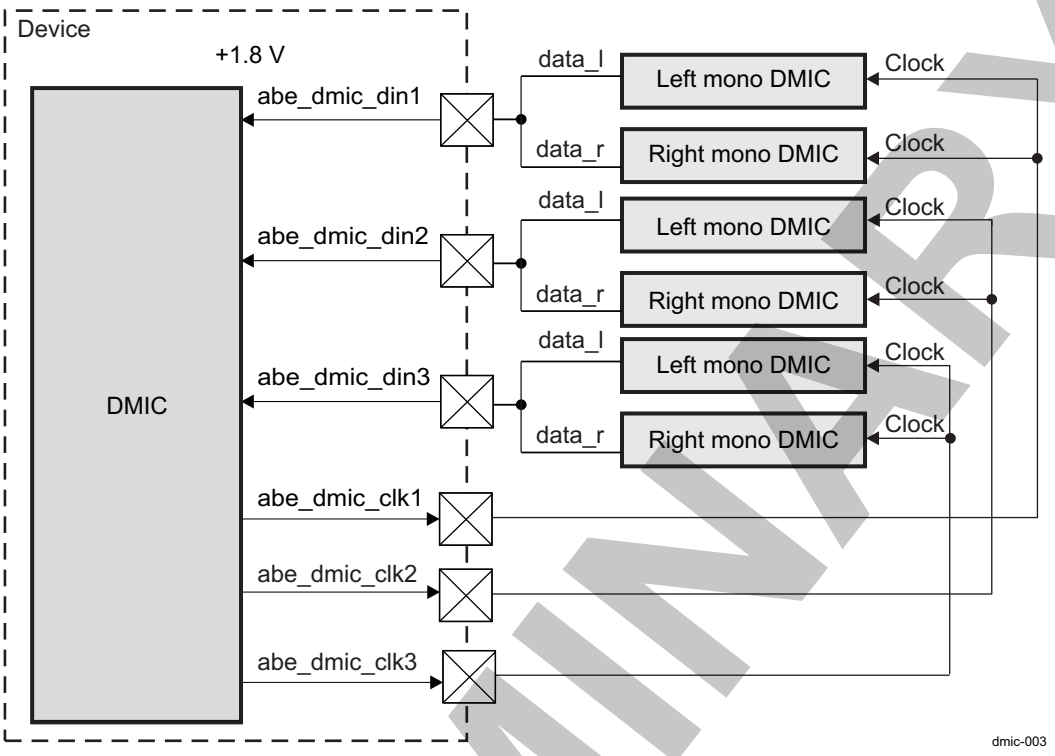
Figure 23-159. DMIC With Six Mono DMICs



23.7.2.1.2 DMIC Signals

Table 23-510 describes the signals in the DMIC.

Table 23-510. Input/Output

Signal Name	I/O[1]	Description	Reset Value[2]
abe_dmic_clk1	O	Digital (stereo) microphone clock output 1	Hi-Z
abe_dmic_clk2	O	Digital (stereo) microphone clock output 2	Hi-Z
abe_dmic_clk3	O	Digital (stereo) microphone clock output 3	Hi-Z
abe_dmic_din1	I	Digital (stereo) microphone data input 1	Hi-Z
abe_dmic_din2	I	Digital (stereo) microphone data input 2	Hi-Z
abe_dmic_din3	I	Digital (stereo) microphone data input 3	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High impedance

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

All DMIC external connections have pullup or pulldown resistors, selected and configured in the control module registers.

23.7.2.1.3 Serial Data Format

The DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock. Then, the filter decimator extracts the 24-bit audio samples.

23.7.2.1.3.1 DMIC Clock Generation and Synchronization

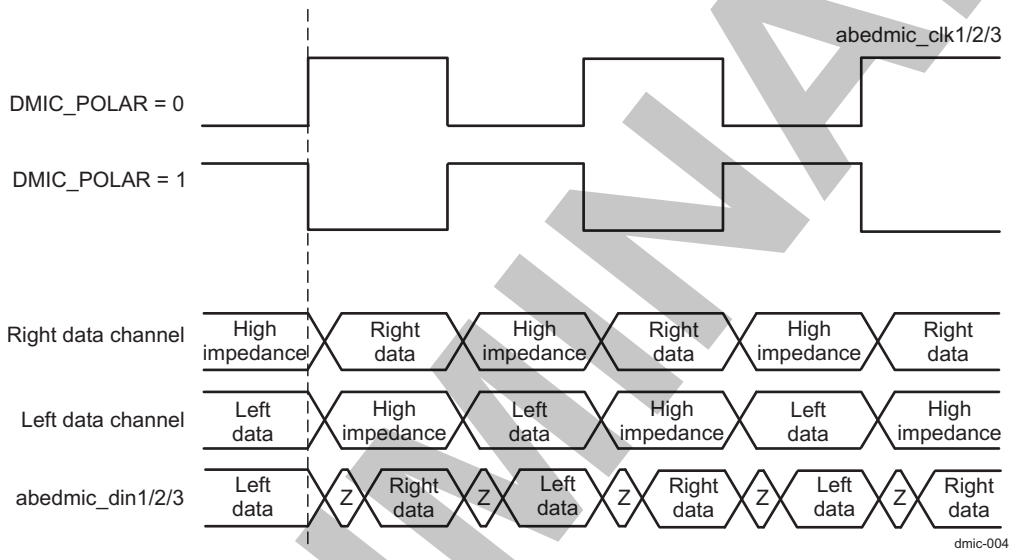
When the DMIC_POLAR bit is set to 0, the microphone left data is generated on the abe_dmic_clk low level. When DMIC_POLAR is set to 1, the microphone left data is generated on the abe_dmic_clk high level. There are three DMIC_POLARx bits (where x = 1, 2, or 3) corresponding to the three stereo paths:

- DMIC_CTRL[4] for path 1
- DMIC_CTRL[5] for path 2
- DMIC_CTRL[6] for path 3

The DMIC_POLARx bits are set depending on the configuration of the external digital microphone.

Figure 23-160 is a diagram of the DMIC interface with a DMIC.

Figure 23-160. DMIC Interface Diagram With External DMICs



23.7.2.2 DMIC Functional Path

The DMIC path processes, decimates, and filters the data from the DMIC interface, and stores the processed data in the FIFO. The FIFO is controlled by IRQ and DMA requests and is fed outside of the DMIC.

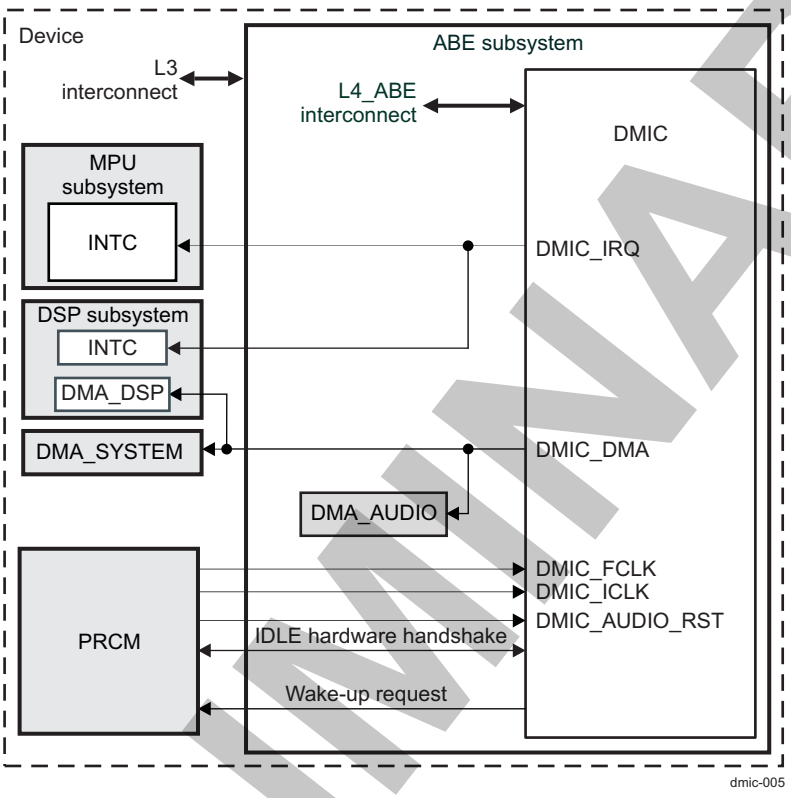
For more information about microphone data processing, see Section 23.7.4.7, *Audio Data Processing*.

23.7.3 DMIC Integration

This section describes the integration of the DMIC in the device, and includes information about clocks, resets, and hardware requests.

Figure 23-161 shows the DMIC integration.

Figure 23-161. DMIC Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Chapter 3, *Power, Reset, and Clock Management*.

The DMIC integration includes:

- One functional clock
- One interface clock
- One IRQ
- One DMA_SYSTEM/DMA_AUDIO/DMA_DSP request
- IDLE hardware handshake
- Wake-up request

Table 23-511 through Table 23-513 summarize the integration of the module in the device.

Table 23-511. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DMIC	PD_AUDIO	Yes	L4_ABE

Table 23-512. Clocks and Resets

Table 23-513. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
DMIC	DMIC_IRQ	DSP_IRQ_83	DSP	DMIC interrupt to the DSP subsystem
	DMIC_IRQ	MPU_IRQ_114	Cortex™-A15 MPU	DMIC interrupt to the Cortex-A15 MPU subsystem
DMA Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
DMIC	DMIC_DMA	DMA_SYSTEM_DREQ_66	DMA_SYSTEM	DMA request to the system DMA (DMA_SYSTEM)
	DMIC_DMA	DMA_AUDIO_DREQ_1	DMA_AUDIO	DMA request to the audio DMA (aDMA)
	DMIC_DMA	DMA_DSP_DREQ_44	DMA_DSP	DMA request to the DSP DMA (eDMA)

NOTE:

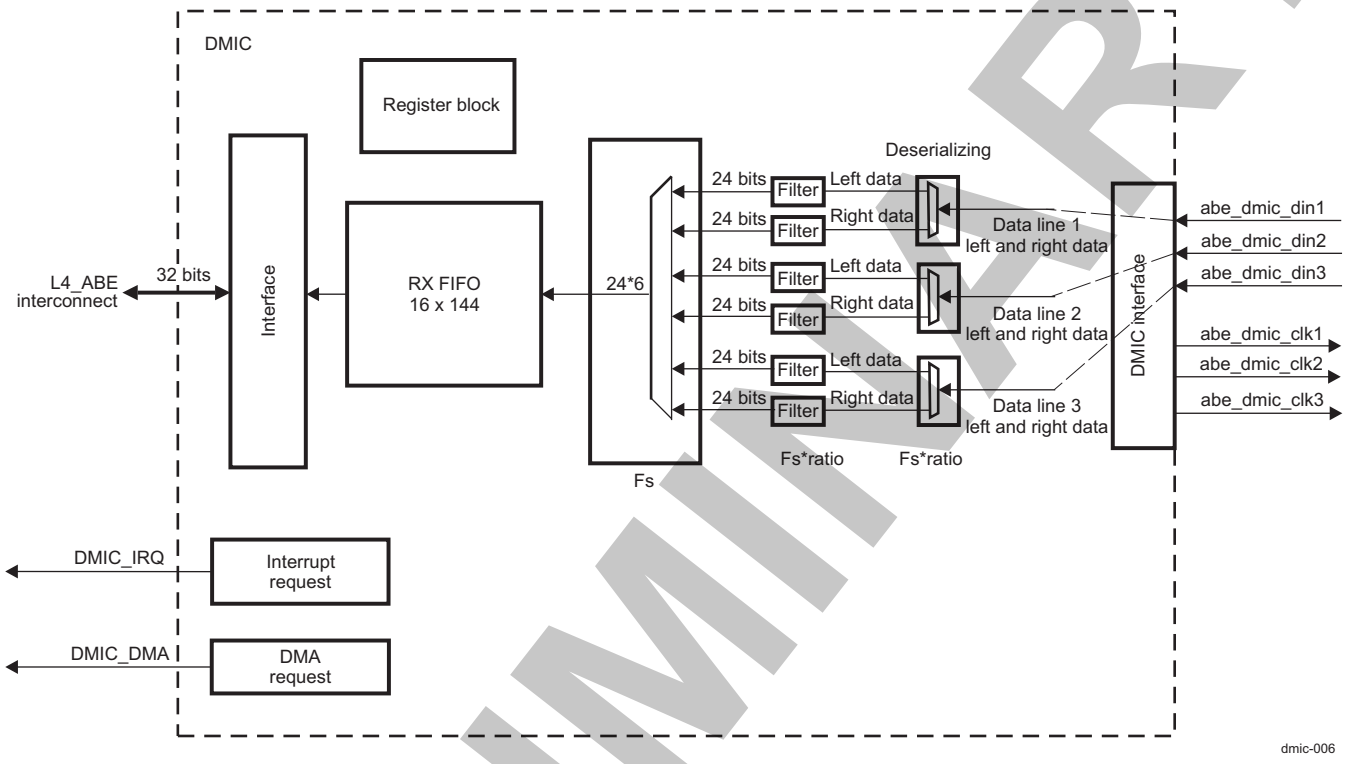
- For a description of the interrupt source, see Section 23.7.4.5, *Interrupt Requests*.
- For a description of the DMA source, see Section 23.7.4.6, *DMA Requests*.
- For information about PRCM clock gating and management and PRCM reset sources and distribution, see Chapter 3, *Power, Reset, and Clock Management*.

23.7.4 DMIC Functional Description

23.7.4.1 Block Diagram

Figure 23-162 is the DMIC block diagram.

Figure 23-162. DMIC Block Diagram

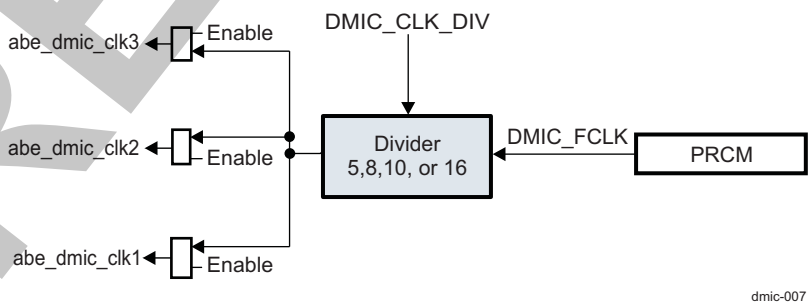


23.7.4.2 DMIC Clock Configuration

The DMIC operates from one interface clock to interface with the L4_ABE interconnect and one selectable (among three) functional clock. These clocks are provided by the PRCM module. For the interface clock, request and acknowledge are set up between the PRCM module and the DMIC.

Figure 23-163 shows the DMIC clock selection.

Figure 23-163. DMIC Clock Selection



DMIC_FCLK is the source clock signal. Several source clocks are available and are selected according to the configuration of the DMIC_CTRL[9:7] DMIC_CLK_DIV bit field. For more information about DMIC_FCLK selection, see Figure 23-163. abe_dmic_clkx are the output clocks generated in the DMIC and are fed to the external microphones. They are also the internal clocks of the external microphones. The performance in terms of signal-to-noise ratio (SNR) depends on these clocks. Users must take care

about the value of abe_dmic_clkx (the analog-to-digital converter [ADC] clock) when selecting the source clock (DMIC_FCLK). FS is the output sample rate from DMIC. For example, when DMIC_FCLK = 19.2 MHz and DMIC_CTRL[9:7] DMIC_CLK_DIV = 000, the Ratio is 25, DMIC is providing a 96-KHz sampling rate to the Audio Engine Subsystem or DMA_SYSTEM. Table 23-514 describes the abe_dmic_clkx generation.

Table 23-514. abe_dmic_clkx Generation

DMIC_FCLK	DMIC_ CLK_DIV	Ratio DMIC_FCLK/ abe_dmic_clk	abe_dmic_clk = ADC Clock	FS	Ratio = abe_dmic_clk/FS = 96 kHz
19.2/17.64 MHz	000	8	2.4/2.205 MHz	96/88.2 kHz	25
	001	5	3.84/3.528 MHz	96/88.2 kHz	40
19.2 MHz	110	5	3.84 MHz	192 kHz	20
24 MHz	010	10	2.4 MHz	96 kHz	25
24.576 MHz	011	8	3.072 MHz	96 kHz	32
	100	16	1.536 MHz	96 kHz	16
12 MHz	101	5	2.4 MHz	96 kHz	25

The maximum clock on the interface is 3.84 MHz, with a source clock of 19.2 MHz.

23.7.4.3 DMIC Software Reset

Table 23-515 lists the different types of software reset available at the module level.

Table 23-515. Reset Description

Type	Name	Source	Description
Software	DMIC_SYSCONFIG[1] SOFTRESET	–	Module software reset
Software	DMIC_CTRL[10] SW_DMIC_RST	–	Reset-enabled DMIC paths

The software path reset is gated by:

- DMIC_CTRL[0] DMIC_UP1_EN for path 1
- DMIC_CTRL[1] DMIC_UP2_EN for path 2
- DMIC_CTRL[2] DMIC_UP3_EN for path 3
- DMIC_CTRL[10] SW_DMIC_RST

When the DMIC_CTRL[10] SW_DMIC_RST bit is set to 1, the corresponding enabled DMIC paths are reset. Resets are cleared by writing 0.

NOTE: A software reset is required to change the configuration of enabled paths; for example, to disable path 3, a software reset of path 3 is mandatory for the change to be considered.

A module software reset can be performed by setting the DMIC_SYSCONFIG[1] SOFTRESET bit. This action starts a soft reset sequence.

The software reset status of the module can be checked by reading the DMIC_SYSCONFIG[0] SOFTRESET bit (0: reset is done; 1: reset is ongoing).

23.7.4.4 DMIC Power Management

Table 23-516 describes the power-management features available for the DMIC.

Table 23-516. Local Power-Management Features

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	DMIC_SYSCONFIG[3:2] SIDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	DMIC_IRQWAKEEN[0] IRQ_WAKEUP_EN DMIC_DMAWAKEEN[0] DMA_WAKEUP_EN	This register holds one active-high enable bit per event source that can generate a wake-up signal.

23.7.4.5 DMIC Interrupt Requests

Table 23-517 lists the event flags, and their mask, that can cause module interrupts.

Table 23-517. Interrupt Events

Nonmaskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
DMIC_IRQSTATUS_RAW[3] DMIC_IRQ_EMPTY	DMIC_IRQSTATUS[3] DMIC_IRQ_EMPTY	DMIC_IRQENABLE_CLR[3] DMIC_IRQ_EMPTY_MASK	DMIC_IRQENABLE_SET[3] DMIC_IRQ_EMPTY_MASK	FIFO empty event. This event occurs when the FIFO is already empty and a new word is read from the FIFO by software.
DMIC_IRQSTATUS_RAW[2] DMIC_IRQ_ALST_FULL	DMIC_IRQSTATUS[2] DMIC_IRQ_ALST_FULL	DMIC_IRQENABLE_CLR[2] DMIC_IRQ_ALST_FULL_MASK	DMIC_IRQENABLE_SET[2] DMIC_IRQ_ALST_FULL_MASK	FIFO almost-full event. This event occurs when the FIFO contains (FIFO size – 1) words and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[1] DMIC_IRQ_FULL	DMIC_IRQSTATUS[1] DMIC_IRQ_FULL	DMIC_IRQENABLE_CLR[1] DMIC_IRQ_FULL_MASK	DMIC_IRQENABLE_SET[1] DMIC_IRQ_FULL_MASK	FIFO full event. This event occurs when the FIFO is already full and a new word is written to the FIFO.
DMIC_IRQSTATUS_RAW[0] DMIC_IRQ	DMIC_IRQSTATUS[0] DMIC_IRQ	DMIC_IRQENABLE_CLR[0] DMIC_IRQ_MASK	DMIC_IRQENABLE_SET[0] DMIC_IRQ_MASK	FIFO read request event. This event occurs when the number of words stored in the FIFO is equal to or greater than the FIFO threshold.

(1) The DMIC_IRQSTATUS_RAW register is used primarily for debug purposes.

The interrupt line is asserted (active high) when one of the following signals appears:

- DMIC_IRQ_EMPTY
- DMIC_IRQ_ALST_FULL
- DMIC_IRQ_FULL
- DMIC_IRQ

Read the DMIC_IRQSTATUS register to determine which event occurred.

CAUTION

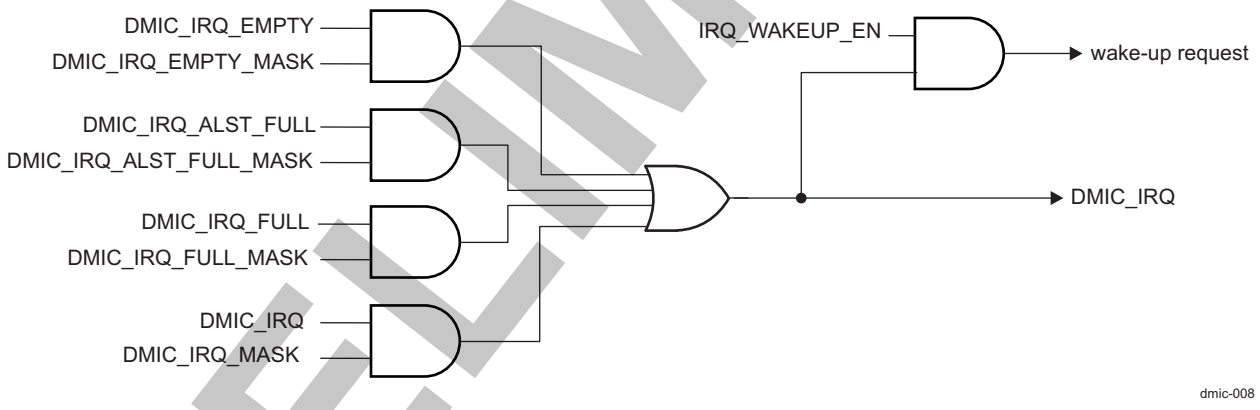
Interrupt lines must be cleared by software. Write 1 in the DMIC_IRQSTATUS register to clear the corresponding event.

An event can generate an IRQ when the corresponding mask bit in the DMIC_IRQENABLE_SET register is set to 1. Events are register bits that belong to the DMIC_IRQSTATUS and DMIC_IRQSTATUS_RAW registers (the same register accessed by two interconnect addresses). In the case of the DMIC_IRQSTATUS_RAW register, status event is set even if it is not enabled (used primarily for debug purposes). The DMIC_IRQSTATUS register is set by writing 1 to the DMIC_IRQSTATUS_RAW register.

Each internal interrupt signal can be masked by enabling the corresponding mask in the DMIC_IRQENABLE_SET register or disabling it in the DMIC_IRQENABLE_CLR register. This mechanism is defined in Section 23.7.6, *DMIC Register Manual*.

Figure 23-164 shows the interrupt tree with the event generated and the mask that enables or disables the event. All events are summarized to give the single interrupt generation.

Figure 23-164. Interrupt Tree



23.7.4.6 DMIC DMA Requests

The DMIC can generate one DMA request to the DMA_SYSTEM, DMA_AUDIO, and DMA_DSP controllers (see Table 23-518).

Table 23-518. DMIC DMA Request

Name	Description	Enable DMA Bit	Disable DMA Bit
DMIC_DMA_ENABLE	Data ready in FIFO (threshold is reached)	DMIC_DMAENABLE_SET[0] DMA_ENABLE	DMIC_DMAENABLE_CLR[0] DMA_ENABLE

The DMA lines can be enabled or disabled depending on the value of the bits in the DMIC_DMAENABLE_SET and DMIC_DMAENABLE_CLR registers, respectively.

A DMA request is sent when data is ready in the FIFO. This request is used only to notify the host that data are ready in the FIFO.

23.7.4.7 Audio Data Processing

The DMIC supports six audio paths and can be used with three stereo or six mono microphones. Each path is independent and is enabled or disabled by using the following bits:

- DMIC_CTRL[0] DMIC_UP1_EN
- DMIC_CTRL[1] DMIC_UP2_EN
- DMIC_CTRL[2] DMIC_UP3_EN

23.7.4.7.1 Filtering

The external DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC inside the device. The aim of the DMIC audio path is to process data from the DMIC interface, decimate and filter the data, and store the processed data in the FIFO.

The format of the DMIC data is 24 bits (the transfer format is 32 bits long). The following bits allow switching the polarity of the interface:

- DMIC_CTRL[4] DMIC_POLAR1
- DMIC_CTRL[5] DMIC_POLAR2
- DMIC_CTRL[6] DMIC_POLAR3

For more information, see Section 23.7.2.1.3.1, *DMIC Clock Generation and Synchronization*.

Processed data from the DMIC interface are stored in the FIFO. The FIFO is controlled by the IRQ and DMA request and externally fed by the DMIC using the following interconnect format.

The three uplink paths are identical. Each uplink path is composed of a left and a right channel. The DMIC interface delivers six parallel data of 1 bit (3 × 2 paths of stereo data that can be used at six mono paths). Each bit goes to a filter. The aim of the filter is to limit the noise and perform decimation by factor D. Factor D depends on the DMIC_CLK_DIV register bits, as described in the ratio defined in Table 23-514. The filters are sinc filter order 4. They are chosen with regard to the nature of the analog converter.

The format of the filter output is 24 bits.

23.7.4.8 FIFO Management

The DMIC implements an internal FIFO controlled by IRQ and DMA request. The host must read words in the FIFO. The interrupt line is used not only to inform the host that data are ready in the FIFO, but also to warn the host about events that can occur, such as FIFO full, almost full, or empty. A DMA request is used only to inform the host that data are ready in the FIFO.

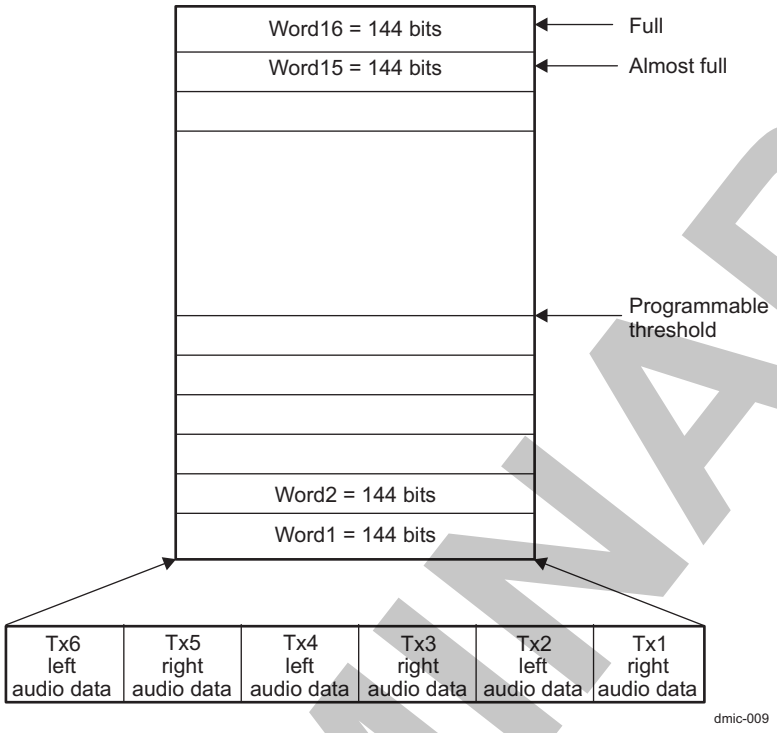
23.7.4.8.1 FIFO General Description

The DMIC communicates with the host through L4_ABE interconnect access. DMIC audio data coming from external microphones are stored in the FIFO. The DMIC FIFO allows the exchange of information between the DMIC and the host. Each audio data is 24 bits long. The DMIC FIFO contains 16 words. Each word is the combination of six audio data (24 × 6 = 144 bits) coming from the interface. The FIFO is controlled by interrupt lines and DMA requests. For more information about IRQs and DMA controls, see Section 23.7.4.5, *DMIC Interrupt Requests*, and Section 23.7.4.6, *DMIC DMA Requests*.

FIFO write access is done in the functional clock domain, and read access is done in the interface clock domain.

Figure 23-165 is an overview of the DMIC FIFO.

Figure 23-165. DMIC FIFO



23.7.4.8.2 FIFO Operations

Audio data are filled in the FIFO from DMIC internal filters. The host must read words in the FIFO. The number of reads depends on the application that is configured by the following bits:

- DMIC_CTRL[0] DMIC_UP1_EN
- DMIC_CTRL[2] DMIC_UP3_EN
- DMIC_CTRL[1] DMIC_UP2_EN
- DMIC_FIFO_CTRL[3:0] DMIC_TRESH (FIFO threshold)

If only uplink path 2 and path 3 are enabled, for example, the Tx1 and Tx2 words are left and right data for path 2, and Tx3 and Tx4 are left and right data for path 3.

When the FIFO threshold is reached, and depending on conditions, an event is sent to the DMA handler. The host must read the exact number of words in the FIFO.

Two accesses are required to read a complete stereo audio path.

The number of read accesses from the host is determined by the following equation:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × (DMIC_TRESH)

The FIFO threshold is programmed through the DMIC_FIFO_CTRL[3:0] DMIC_TRESH bit field.

NOTE: If DMIC_TRESH = 1, the host is expected to perform 1 × (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 read access every 96 kHz (2 × FS).

If DMIC_TRESH = 2, the host is expected to perform (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 4 read access every 48 kHz (FS).

If DMIC_TRESH = 12, the host is expected to perform (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 12 read access every 8 kHz (FS/6).

23.7.4.8.3 FIFO Output Range Definition

The DMIC_CTRL[3] DMICOUTFORMAT bit allows determining the format of the output of the DMIC uplink module.

When DMICOUTFORMAT = 0, the data going from the FIFO are left-shifted by 8 bits. When DMICOUTFORMAT = 1, the data are signed-extended on 32 bits.

The DMIC uplink modules process audio data based on twos complement format.

NOTE: When DMICOUTFORMAT = 0, the maximum positive swing analog voltage corresponds to a final DMIC output of 0x7FFF FF00. The maximum negative swing analog voltage corresponds to a final DMIC output of 0x8000 0000.

When DMICOUTFORMAT = 1, the sign is extended: The maximum positive swing analog voltage corresponds to a final DMIC output of 0x007F FFFF. The maximum negative swing analog voltage corresponds to a final DMIC output of 0xFF80 0000.

Reading the value of the corresponding audio data in the FIFO requires access to the DMIC_DATA_REG register. The first access gives the value of Tx1 right data, the second gives the value of Tx2 left data, up to Tx6 (the left audio data of the last audio path). If the path is disabled, 0x0 is read. All data are duplicated (for debug purposes) in their corresponding left or right data registers. Table 23-519 describes the audio data path registers.

Table 23-519. Audio Data Path Registers

Stereo Audio Path	Mono Audio Path	Data Register
Right path 1	Mono path 1	DMIC_FIFO_DMIC1R_DATA[23:0]
Left path 1	Mono path 2	DMIC_FIFO_DMIC1L_DATA[23:0]
Right path 2	Mono path 3	DMIC_FIFO_DMIC2R_DATA[23:0]
Left path 2	Mono path 4	DMIC_FIFO_DMIC2L_DATA[23:0]
Right path 3	Mono path 5	DMIC_FIFO_DMIC3R_DATA[23:0]
Left path 3	Mono path 6	DMIC_FIFO_DMIC3L_DATA[23:0]

The output of the DMIC path for interconnect access is in 32-bit format.

23.7.5 DMIC Programming Guide

23.7.5.1 DMIC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

23.7.5.1.1 Global Initialization

23.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMIC is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMIC. For more information, see Section 23.7.3, *DMIC Integration*, and Section 23.7.2, *DMIC Environment*.

Table 23-520 describes the global initialization of surrounding modules.

Table 23-520. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. See Chapter 18, *Control Module*.
(optional) Cortex-A15 MPU interrupt controller (INTC) (or DSP INTC)	INTC configuration must be done to enable the interrupts from the DMIC. See Chapter 17, *Interrupt Controllers*.
(optional) DMA_SYSTEM (or DMA_DSP or DMA_AUDIO)	DMA configuration must be done to enable the DMIC DMA channel requests.
(optional) Interconnect	For more information about the interconnect configuration, see Chapter 14, *Interconnect*.

NOTE: The INTC and DMA configurations are necessary if the interrupt and DMA-based communication modes are used.

23.7.5.1.2 DMIC Global Initialization

23.7.5.1.2.1 Main Sequence – DMIC Global Initialization

The procedure in Table 23-521 initializes the DMIC after a power-on reset (POR).

Table 23-521. DMIC Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute a software reset.	DMIC_SYSCONFIG[0] SOFTRESET	0x1
Wait for the software reset completion by polling.	DMIC_SYSCONFIG[0] SOFTRESET	==0x0
Configure the local power management.	DMIC_SYSCONFIG[3:2] SIDLEMODE	0x-
Select the DMIC FIFO threshold.	DMIC_FIFO_CTRL[3:0] DMIC_TRESH	0x-
Select the DMIC output clock frequency.	DMIC_CTRL[9:7] DMIC_CLK_DIV	0x-
Select the DMIC FIFO data output format.	DMIC_CTRL[3] DMICOUTFORMAT	0x-
Select the level (high or low) of the clock signal abe_dmic_clki when the left data is to be generated (extracted) from the external microphone i (where i = 1 to 3).	DMIC_CTRL[j] DMIC_POLARi (where j = 4 to 6, and i = 1 to 3)	0x-
Enable audio path i (where i = 1 to 3).	DMIC_CTRL[k] DMIC_POLARi (where k = 0 to 2, and i = 1 to 3)	0x1

23.7.5.1.2 Operational Mode Configuration

23.7.5.1.2.1 DMIC Polling Mode

Figure 23-166 shows the polling mode. Table 23-522 summarizes the register calls for the polling mode. For the number of read accesses used while reading the received audio data, see Section 23.7.4.8, *FIFO Management*.

Figure 23-166. Polling Mode

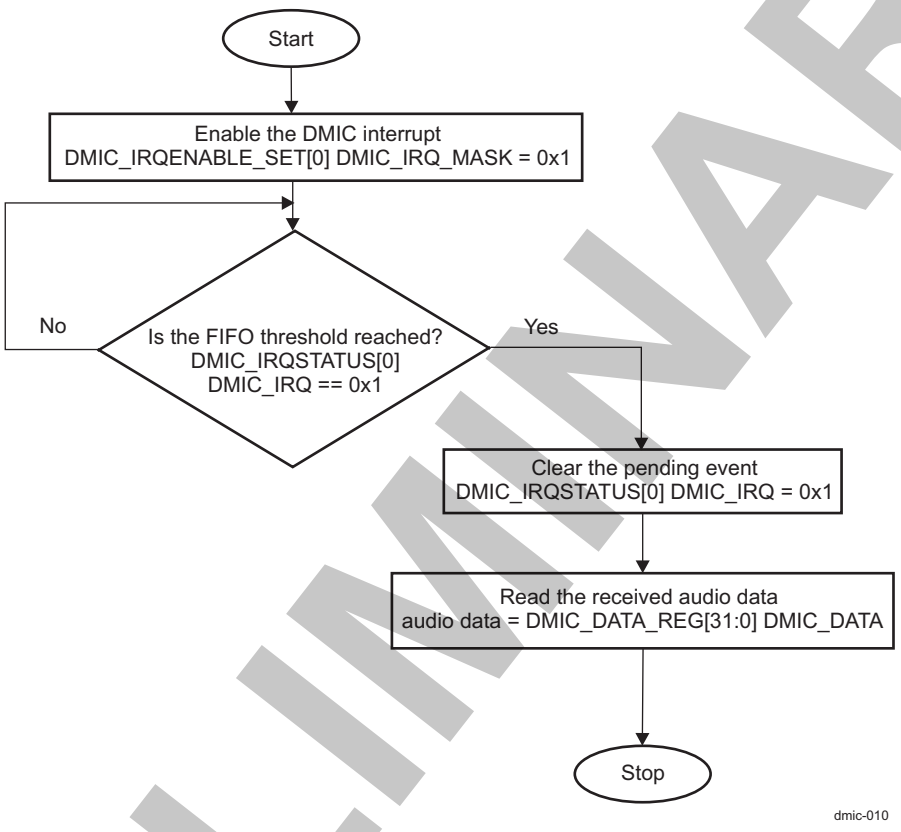


Table 23-522. Register Call Summary for Polling Mode

Register Name	Register Name	Register Name
DMIC_IRQENABLE_SET	DMIC_IRQSTATUS	DMIC_DATA_REG

23.7.5.1.2.2 DMIC Interrupt Mode

Table 23-523 lists the procedure to initialize interrupt mode.

Table 23-523. Interrupt Mode

Step	Register/Bit Field/Programming Model	Value
Enable the DMIC interrupts.	DMIC_IRQENABLE_SET[3:0]	0xF

23.7.5.1.2.3 DMIC DMA Mode

Table 23-524 lists the procedure to initialize DMA mode.

Table 23-524. DMA Mode

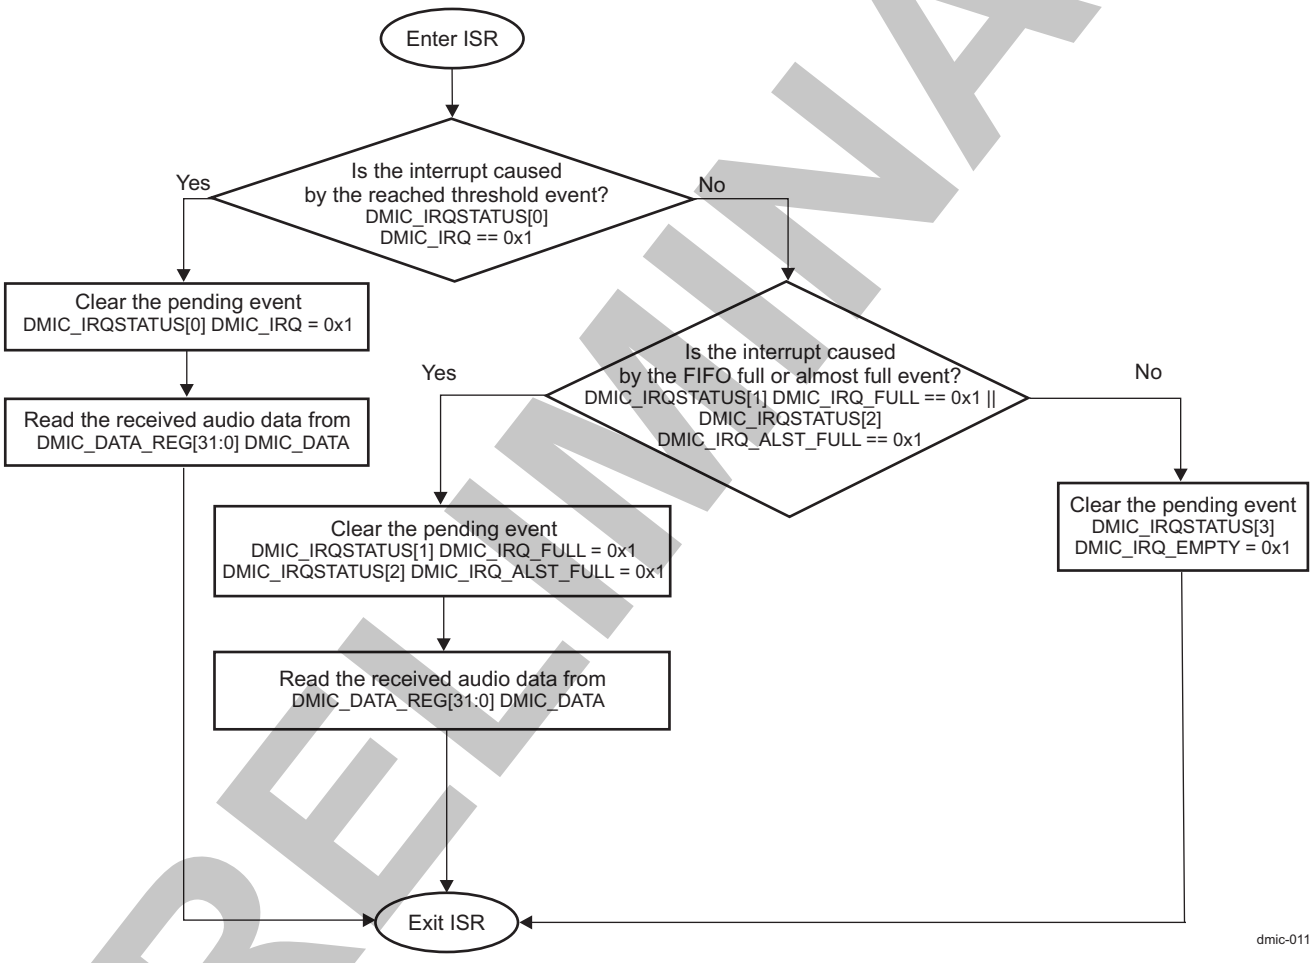
Step	Register/Bit Field/Programming Model	Value
Enable the DMIC DMA interrupt event.	DMIC_DMAENABLE_SET[0] DMA_ENABLE	0x1

23.7.5.1.3 DMIC Events Servicing

23.7.5.1.3.1 DMIC Interrupt Servicing

This section describes the interrupt event servicing of the module. Figure 23-167 shows the interrupt handler.

Figure 23-167. Interrupt Handler



When the interrupt is caused by the reached threshold event, for the number of read accesses used while reading the received audio data, see Section 23.7.4.8, *FIFO Management*.

When the interrupt is caused by a FIFO full or almost-full event, software must read all the available data in the FIFO. If a FIFO full event occurred, the number of read accesses must be the maximum:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × 15

If a FIFO almost-full event occurred, the number of read accesses must be:

Num_rd_access = (DMIC_UP1_EN + DMIC_UP2_EN + DMIC_UP3_EN) × 2 × 14

Table 23-525 summarizes the register call for the interrupt handler.

Table 23-525. Register Call Summary for the Interrupt Handler

23.8 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (MCASP).

23.8.1 MCASP Overview

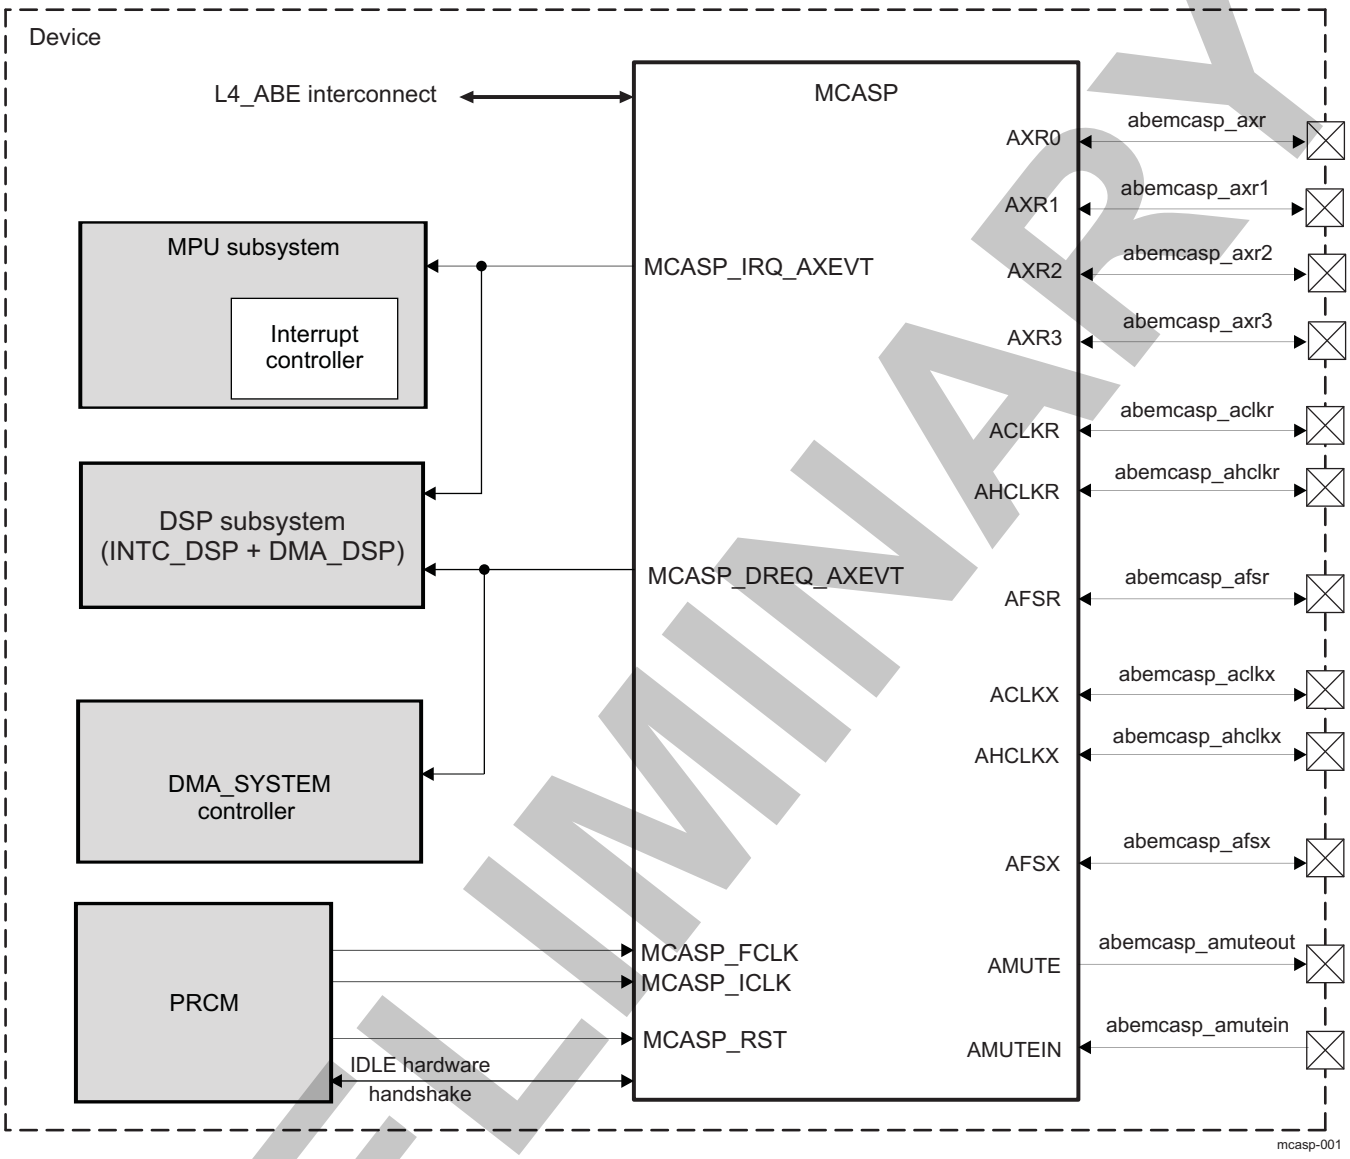
This section introduces the multichannel audio serial port (MCASP) module and describes its main functions and connections in the device.

The MCASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The MCASP module can operate in both transmit and receive modes. The MCASP is useful for time- division multiplexed (TDM) stream, Inter-IC Sound (I2S) protocols reception and transmission as well as for an intercomponent digital audio interface transmission (DIT). The MCASP has the flexibility to gluelessly connect to a Sony / Philips digital interface (S/PDIF) transmit physical layer component.

Although intercomponent digital audio interface reception (DIR) mode (i.e. S/PDIF stream receiving) is NOT natively supported by the MCASP module, a specific TDM mode implementation for the MCASP receivers allows an easy connection to external DIR components (for example, S/PDIF to I2S format converters).

Figure 23-168 shows the MCASP module in the device.

Figure 23-168. MCASP Module



The MCASP module includes the following main features:

- Support of the idle request/acknowledge protocol
- Four serializers - each serializer having associated one transmit (Tx) and one receive (Rx) channel, which allows support of :
  - 4 data channels, each configurable to either transmit or receive at a time
- A single 32-bit buffer per serializer for transmit and receive operations
- One transmit direct memory access (DMA) request linked with each of the 4 serializers
- One transmit interrupt request linked with each of the 4 serializers

NOTE: Because a serializer receive and transmit channels data is shared on the same MCASP data pin, user can choose to have either Tx or Rx function from a serializer, NOT both at the same time.

23.8.2 MCASP Environment

This section describes the MCASP application fields from an environment point of view (external connections), along with the MCASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case.

23.8.2.1 MCASP Signals

Table 23-566 describes the MCASP module pins, their corresponding signal names at device level and specifies their links to functions.

Table 23-566. MCASP I/O Signals

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
AXR0	abemcasp_axr	I/O	Audio transmit / receive data - channel 0	HiZ
AXR1	abemcasp_axr1	I/O	Audio transmit / receive data - channel 1	HiZ
AXR2	abemcasp_axr2	I/O	Audio transmit / receive data - channel 2	HiZ
AXR3	abemcasp_axr3	I/O	Audio transmit / receive data - channel 3	HiZ
ACLKX	abemcasp_aclkx	I/O	Transmit bit clock	HiZ
AHCLKX	abemcasp_ahclkx	I/O	Transmit high-frequency master clock	HiZ
AFSX	abemcasp_afsx	I/O	Transmit frame synchronization	HiZ
ACLKR	abemcasp_aclkr	I/O	Receive bit clock	HiZ
AHCLKR	abemcasp_ahclkr	I/O	Receive high-frequency master clock	HiZ
AFSR	abemcasp_afsr	I/O	Receive frame synchronization	HiZ
AMUTE	abemcasp_amuteout	O	Mute out to external	HiZ
AMUTEIN	abemcasp_amutein	I	Mute in from external	HiZ

(1) I = Input; O = Output; I/O = Bidirectional

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the Section 18.4.8, *Pad Functional Multiplexing and Configuration* and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in *Chapter 18, Control Module*.

Figure 23-168, *MCASP Module*, also illustrates module pin signals mapping to MCASP signals visible at device pad level.

All MCASP pins on the device can be individually programmed as general-purpose input/output (GPIO) if they are not used for MCASP serial port functions.

The MCASP includes the following pins:

- Serializer 0 :
  - AXR0 : serial data transmission / reception pin 0. The corresponding MCASP signal at device level is named "abemcasp_axr".
- Serializer 1 :
  - AXR1 : serial data transmission / reception pin 1. The corresponding MCASP signal at device level is named "abemcasp_axr1".
- Serializer 2 :
  - AXR2 : serial data transmission / reception pin 2. The corresponding MCASP signal at device level is named "abemcasp_axr2".
- Serializer 3 :
  - AXR3 : serial data transmission / reception pin 3. The corresponding MCASP signal at device level is named "abemcasp_axr3".
- Transmit clock generator (one for all serializers) :

  - ACLKX : MCASP transmit bit clock. The corresponding MCASP signal at device level is named "abemcasp_aclkx".
  - AHCLKX: MCASP transmit high-frequency master clock. The corresponding MCASP signal at device level is named "abemcasp_ahclkx".
- Transmit frame-sync generator (one for all serializers) :
  - AFSX: MCASP transmit frame sync. The corresponding MCASP signal at device level is named "abemcasp_afsx".
- Receive clock generator (one for all serializers):
  - ACLKR : MCASP receive bit clock. The corresponding MCASP signal at device level is named "abemcasp_aclkr".
  - AHCLKR: MCASP receive high-frequency master clock. The corresponding MCASP signal at device level is named "abemcasp_ahclkr".
- Receive frame-sync generator (one for all serializers):
  - AFSR: MCASP receive frame sync. The corresponding MCASP signal at device level is named "abemcasp_afsr".
- Mute in/out:
  - AMUTEIN: MCASP mute input (from external device). The corresponding MCASP signal at device level is named "abemcasp_amutein".
  - AMUTE: MCASP mute output. The corresponding MCASP signal at device level is named "abemcasp_amuteout".

NOTE: A serializer AXRn data pin (where n=0 to 3 in the device) is shared between the transmit and receive logic of this serializer. The direction of data is determined in the MCASP_PDIR and the function (Tx or Rx) is selected in the corresponding serializer control register MCASP_XRSRCTLn.

23.8.2.2 Protocols and Data Formats

23.8.2.2.1 Protocols Supported

The MCASP transmit section supports several industry formats, such as :

- various TDM streams from 2 to 32 slots
- a variety of I2S and similar bit-stream formats
- S/PDIF industry format supported in DIT-transfer mode of the module

The MCASP receive section supports several industry formats, such as :

- various TDM streams from 2 to 32 slots
- a variety of I2S and similar bit-stream formats
- A 384-slot TDM stream designed for easy interface to external DIR-chip component, transmitting DIR-frames to MCASP using the I2S protocol (one time slot for each DIR-subframe)

Programmable clock and frame-synchronization generator modules are individually available for the transmit and receive section, respectively. This allows the MCASP to receive and transmit at different rates. For example, the sample rate of MCASP received data can be 44.1 kHz but the output data can be sampled out at 96 kHz.

The MCASP transmit and receive sections can be independently programmed to support the following options on the basic serial protocol:

- Programmable clock and frame-sync polarity (rising or falling edge):
  - for the ACLKX, AHCLKX, and AFSX signals in the MCASP transmitting part
  - for the ACLKR, AHCLKR, and AFSR signals in the MCASP receiving part
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot

length

- First-bit data delay: 0-, 1-, 2-bit clocks
- Left- / right- alignment of word inside slot
- Bit order: Most-significant bit (MSB) first or least-significant bit (LSB) first reception / transmission
- Bit mask/pad/rotate function
- Automatically aligns data in Q31- or integer format
- Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

NOTE: In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all the 4 serial data pins - AXR0 - AXR3 operating as 192 kHz stereo channels.

The DIT-transfer mode includes the following additional for a MCASP transmitter features:

- Transmit-only mode: 384 time slots (subframe) per frame
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Separate valid bit (V) for subframes A and B

NOTE: The MCASP does NOT natively support DIR-mode reception (i.e. receiving in the S/PDIF format). To allow this, the MCASP can use a DIR-input to I2S-output converter implemented by an external device (i.e. external DIR component). To facilitate reception in this case, the TDM mode of MCASP receivers logic is extended to support a non-standard 384-slot TDM stream.

NOTE: An external transceiver must be connected to the MCASP port in the device to translate the electrical signals delivered by the MCASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

23.8.2.2.2 Definition of Terms

The serial bitstream transmitted or received by a MCASP serializer is a long sequence of 1s and 0s on an audio transmit / receive pins: AXR0 through AXR3 (signals named "abemcasp_axr, abemcasp_axr1, abemcasp_axr2 and abemcasp_axr3" at device level). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 23-169 shows two of the three basic components: the clock signal (ACLKX / ACLKR) and the data signals AXRn, where n=0 to 3. Figure 23-169 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter and receiver uses the signals ACLKX and ACLKR as serial clock, respectively. Optionally, a receiver can use ACLKX as the serial clock when a transmitter and receiver (not from the same serializer) of the MCASP are configured to operate synchronously.

- Bit:

  A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A '1' is represented by a logic high on AXRn (n=0 to 3) pins for the entire duration of the bit. A 0 is represented by a logic low on an AXRn pin for the entire duration of the bit.
- Word:

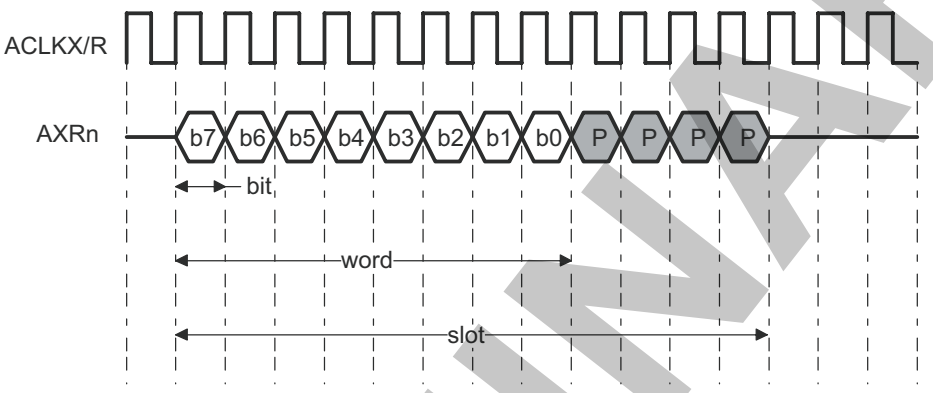
  A word is a group of bits that make up the data being transferred between the MCASP and the external device. Figure 23-169 shows an 8-bit word.
- Slot:

  A slot consists of the bits that make up the word and can consist of additional bits used to pad the

word to a convenient number of bits for the interface between the MCASP and the external device. In Figure 23-169, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the MCASP on an AXRn pin (n=0 to 3) with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word, i.e. left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size. Figure 23-170 shows these options.

Figure 23-169. Definition of Bit, Word, and Slot



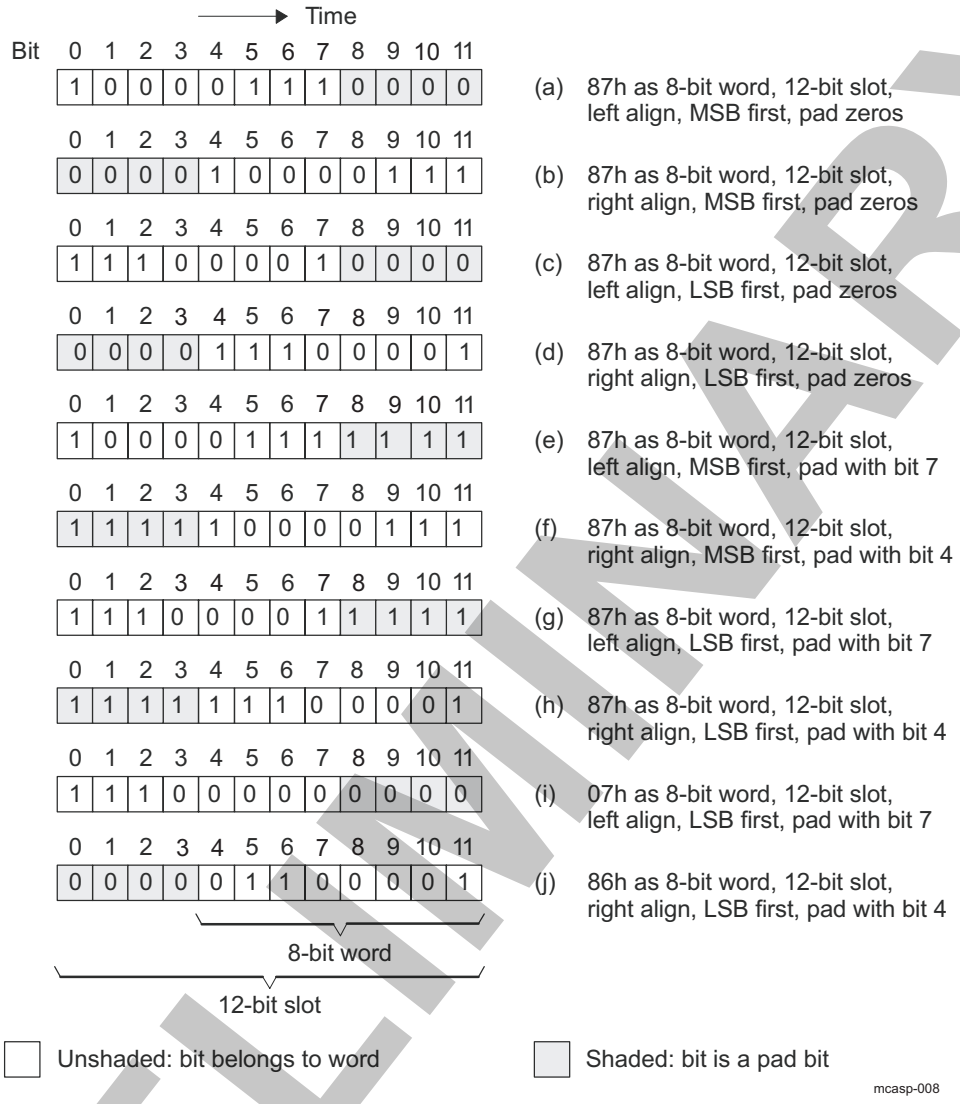
(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left-aligned.

mcasp-010

Figure 23-170. Bit Order and Word Alignment Within a Slot Examples



- Frame

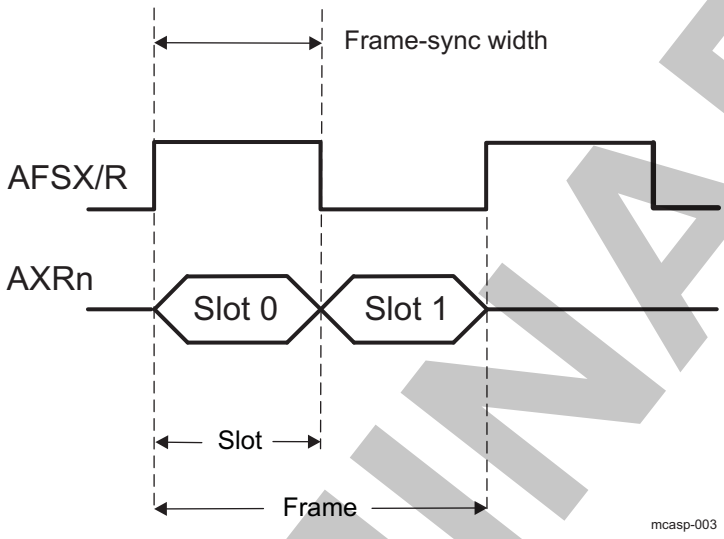
  The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this chapter. A frame contains one or multiple slots, as determined by the desired protocol. Figure 23-171 shows an example frame of data and the frame definitions. In operation, the transmitter uses abemcasp_afsx, and the receiver - abemcasp_afsr signal. Figure 23-171 does NOT specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, each transmitter / receiver uses AFSX / AFSR as a frame synchronization signal, respectively. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the MCASP are configured to operate synchronously. This example shows two slots in a frame (I2S format) and a frame-sync (FS) duration of a slot length.

  This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (TDM-mode and DIT-mode supported formats), see Section 23.8.2.2.3, *TDM Format* and Section 23.8.2.2.5, *S/PDIF-Coding Format*.

NOTE: All of the 4 MCASP serializers share the same, device pad accessible, clock and frame signals, as follows:

- AHCLKX, ACLKX and AFSX for the transmitting section
- AHCLKR, ACLKR and AFSR for the receiving section

Figure 23-171. Definition of Frame and Frame-Sync Width



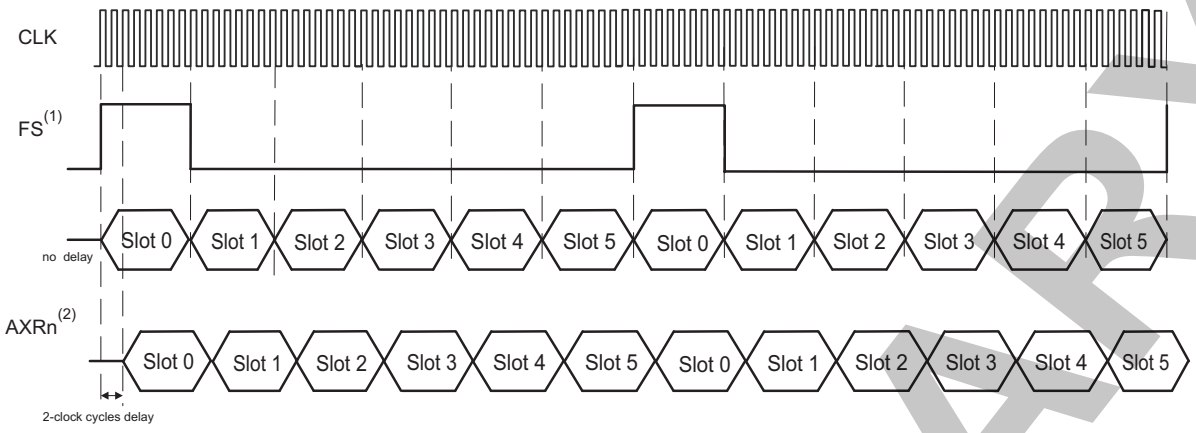
The following terms are used throughout this chapter:

- DIT: Digital audio interface transmit. The MCASP supports transmitting in S/PDIF format on each AXRn (n=0 to 3) data pin.
- DIR: Digital audio interface receive. The MCASP does NOT natively support receiving in S/PDIF format on AXRn (n=0 to 3) data pins and requires an external DIR-to-TDM or DIR-to-I2S converter chip for a DIR-frame reception.
- Slot or time slot: For DIT / DIR format, a MCASP time slot corresponds to a DIT / DIR subframe.

23.8.2.2.3 TDM Format

The TDM format is used to transfer data between the MPU (or DSP) and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices. An example for a 6-slot (channel) TDM transmission on one MCASP data pin - AXRn is illustrated on Figure 23-172.

Figure 23-172. TDM Format - 6 channel example



(1) - Frame sync duration of 1 slot - length is shown. A single bit - duration of FS is also supported

(2) - Slot 0 of AXRn stream shown offsetted with 0- and 2-cycle delay from the frame sync respectively

mcasp-035

The TDM format uses three signals In a basic synchronous serial interface : data (AXRn), clock (CLK) and frame sync (FS). The data signal present on AXRn pin is fully synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (see also Section 23.8.2.2.2), the latter being also refered to as the "time-slots" or "channels" in TDM terminology. A frame consists of multiple time-slots. Each TDM frame is marked by the frame sync signal (AFSX or AFSR). The TDM transfer is continuous and periodic, with no delays between slots.

Within a certain frame, the last bit of slot N is followed immediately on the next serial clock with the first bit of the next slot N+1. On the boundary between two adjacent TDM-frames, the last bit of the last slot from the frame M, is followed immediately on the next clock cycle with the first bit of the first slot from the next frame M+1. For MCASP, there is an option to offset the first bit of the first slot with a 0-,1- or 2-cycle delay from the frame sync signal.

The frame sync - AFSX/AFSR only marks the beginning of slot 0 and start of a new frame. Since it does NOT determine the boundaries of a slot, **there is a requirement for a connected transmitter and receiver to agree on the number of transfered bits per slot.**

In a typical audio system involving MCASP module, a single TDM data frame is transfered during each sample period Ts of a data converter. The user has following choices to implement multiple channels :

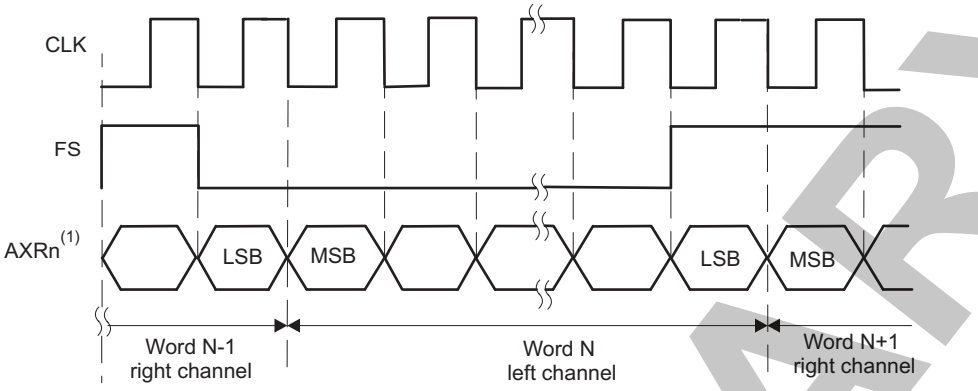
- Use more data slots (on a price of higher speed serial clock) per frame transmitted / received on just one of the available MCASP data pins (AXR0 - AXR3).
- Use less number of slots per TDM frame (requires a slower serial clock), making them available on several of the MCASP pins (AXR0 - AXR3).

23.8.2.2.4 I2S Format

The TDM transfer mode of the MCASP supports the I2S format when frame is configured to have 2 slots. I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format equals size of a slot. The frame signal is also referred to as "word select" in the I2S format.

The I2S protocol is illustrated on Figure 23-173.

Figure 23-173. I2S Format Overview



(1) - The example shows I2S data MSB-first transmission with 1-clock cycle delay between FS and data MSB

mcasp-036

23.8.2.2.5 S/PDIF Coding Format

The MCASP transmitter supports the S/PDIF format with 1.2- and 1.8-V biphase-mark encoded output. The S/PDIF format is supported by the DIT- transfer mode of the MCASP. This section briefly discusses the S/PDIF coding format.

NOTE: The DIR- reception of S/PDIF format frames is NOT natively supported from the device MCASP. For this purpose, an external DIR-to-TDM transfer mode adapter can be used between the remote device S/PDIF transmitter output and the MCASP TDM-only compatible receiver input.

23.8.2.2.5.1 Biphase-Mark Code

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). For each serializer transmitter n (where n=0 to 3), the clock, frame, and data are embedded in only one signal - the data signal AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 23-174 and Table 23-567 show how data is encoded to the BMC format.

As shown in Figure 23-174, the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 23.8.2.2.5.3, *Frame Format*, for details on how this clock rate is derived based on the S/PDIF format).

Figure 23-174. Biphase-Mark Code

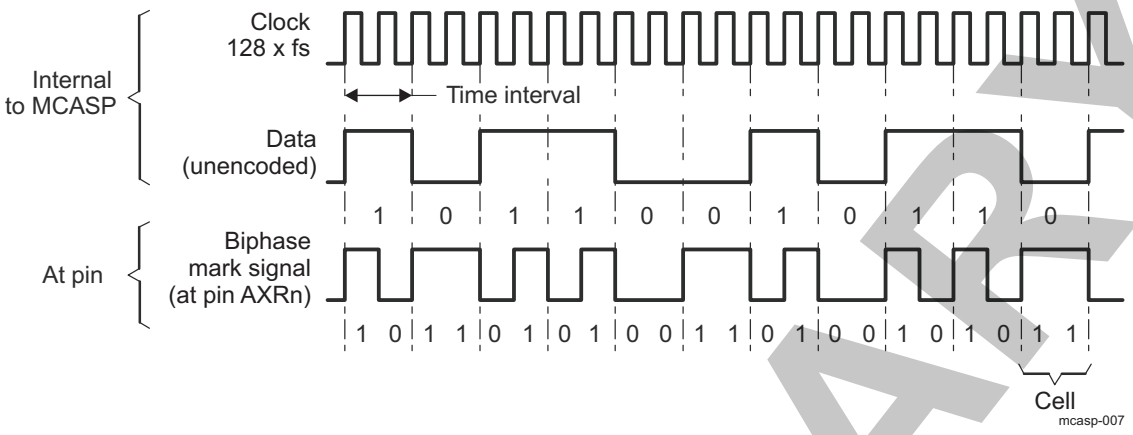


Table 23-567. Biphase-Mark Encoder

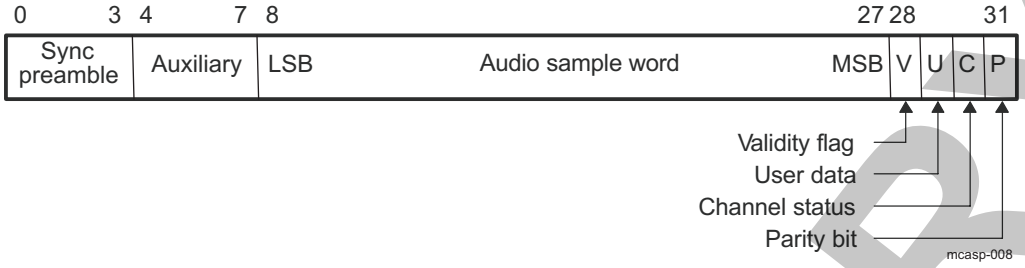
Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at Pin AXRn
0	0	11
0	1	00
1	0	10
1	1	01

23.8.2.2.5.2 S/PDIF Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. Figure 23-175 shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 23-568.
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in Table 23-568, the preambles (time intervals 0–3) are also defined with even parity.

Figure 23-175. S/PDIF Subframe Format



As listed in Table 23-568, the MCASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the MCASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

Table 23-568. Preamble Codes

Preamble Code[1]	Previous Logical State	Logical States on pin AXRn[2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

(1) Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

(2) The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

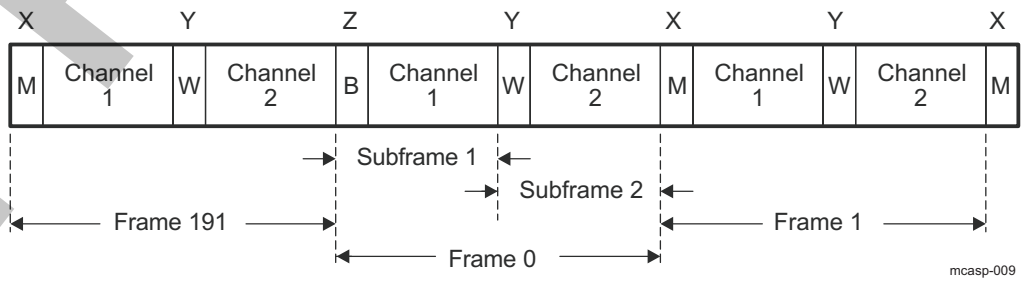
23.8.2.2.5.3 Frame Format

An S/PDIF frame is composed of two subframes (see Figure 23-176). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells per subframe × 2 clocks per cell × 2 subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHZ.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B- channels, both set to '0'). The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 23-176. S/PDIF Frame Format



23.8.3 MCASP Integration

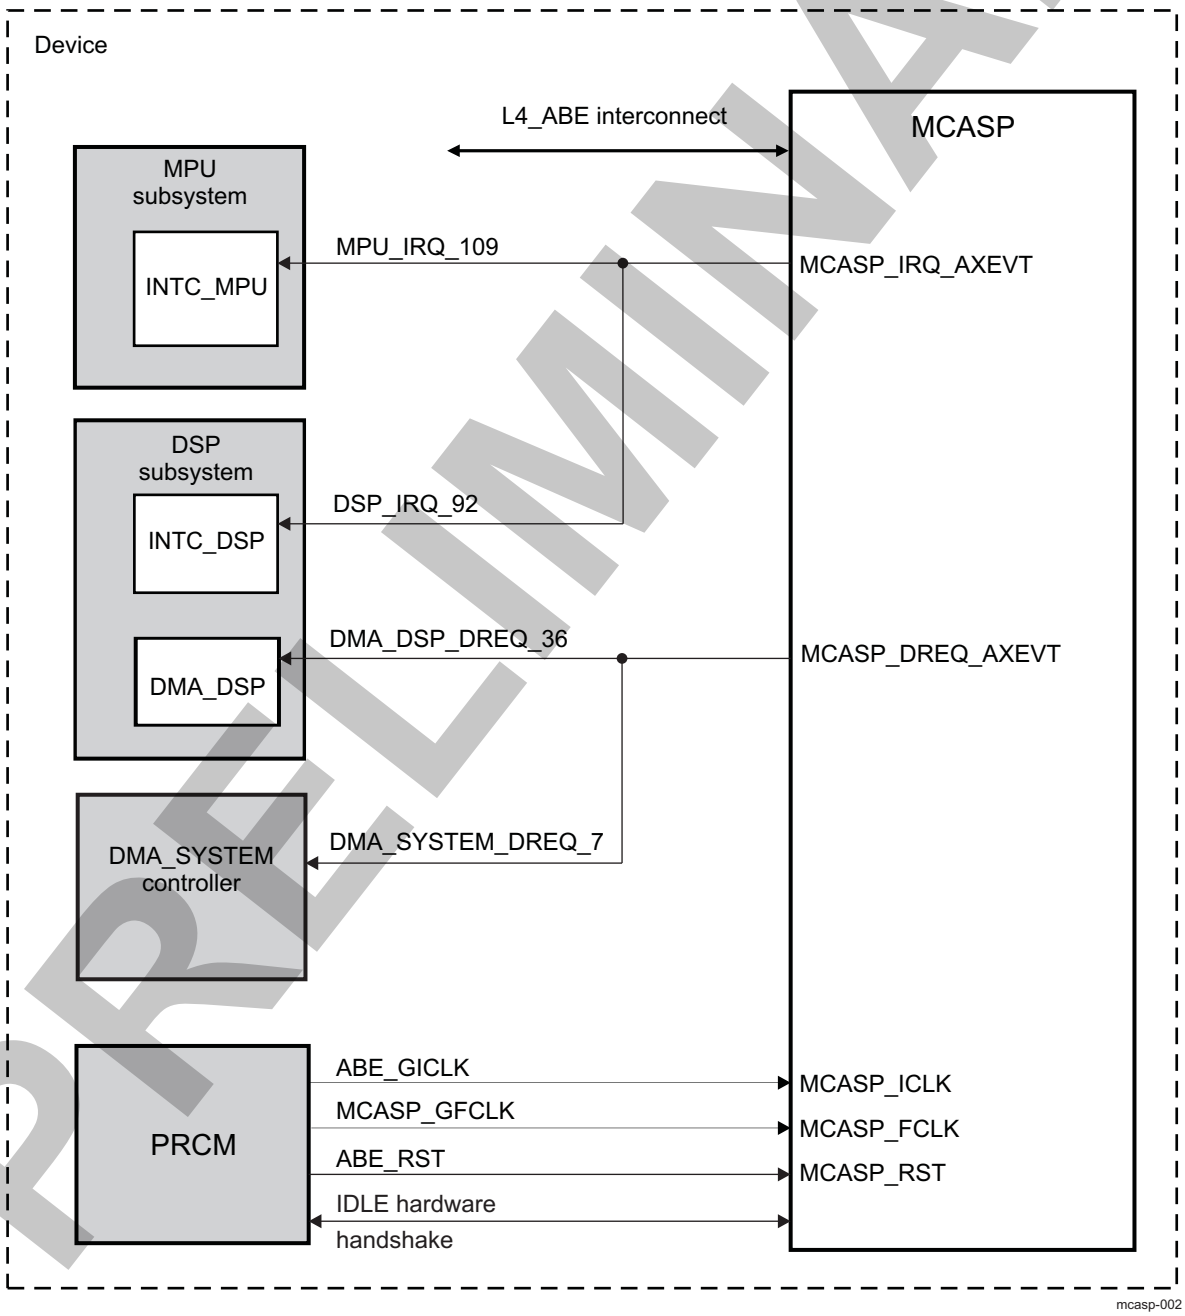
This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The MCASP includes the following features:

- IDLE hardware handshake
- One DMA request for all transmitters
- One interrupt request (IRQ) for all transmitters
- NO interrupt (IRQ) and DMA requests are implemented for the MCASP receivers at device level.

Figure 23-177 shows MCASP integration.

Figure 23-177. MCASP Integration



NOTE: For more information about the IDLE hardware handshake, see Section 3.1.1.1.2, *Module Level Clock Management* of Chapter 3, *Power, Reset, and Clock Management*.

Table 23-569 through Table 23-571 summarize the integration of the module in the device.

Table 23-569. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
MCASP	PD_ABE	NO	L4_ABE

Table 23-570. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
MCASP	MCASP_ICLK	ABE_GICLK	PRCM	MCASP interface clock
	MCASP_FCLK	MCASP_GFCLK	PRCM	MCASP functional clock
Resets				
MCASP	MCASP_RST	ABE_RST	PRCM	AUDIO power domain reset

Table 23-571. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
MCASP	MCASP_IRQ_AXEVT	DSP_IRQ_92	INTC_DSP	MCASP transmit interrupt to the DSP interrupt controller
		MPU_IRQ_109	INTC_MPU	MCASP transmit interrupt to the MPU interrupt controller
DMA Requests				
MCASP	MCASP_DREQ_AXEVT	DMA_SYSTEM_DREQ_7	DMA_SYSTEM	MCASP data transmit DMA request line to the system DMA (DMA_SYSTEM)
		DMA_DSP_DREQ_36	DMA_DSP	MCASP data transmit DMA request line to the DSP DMA (DMA_DSP)

NOTE:

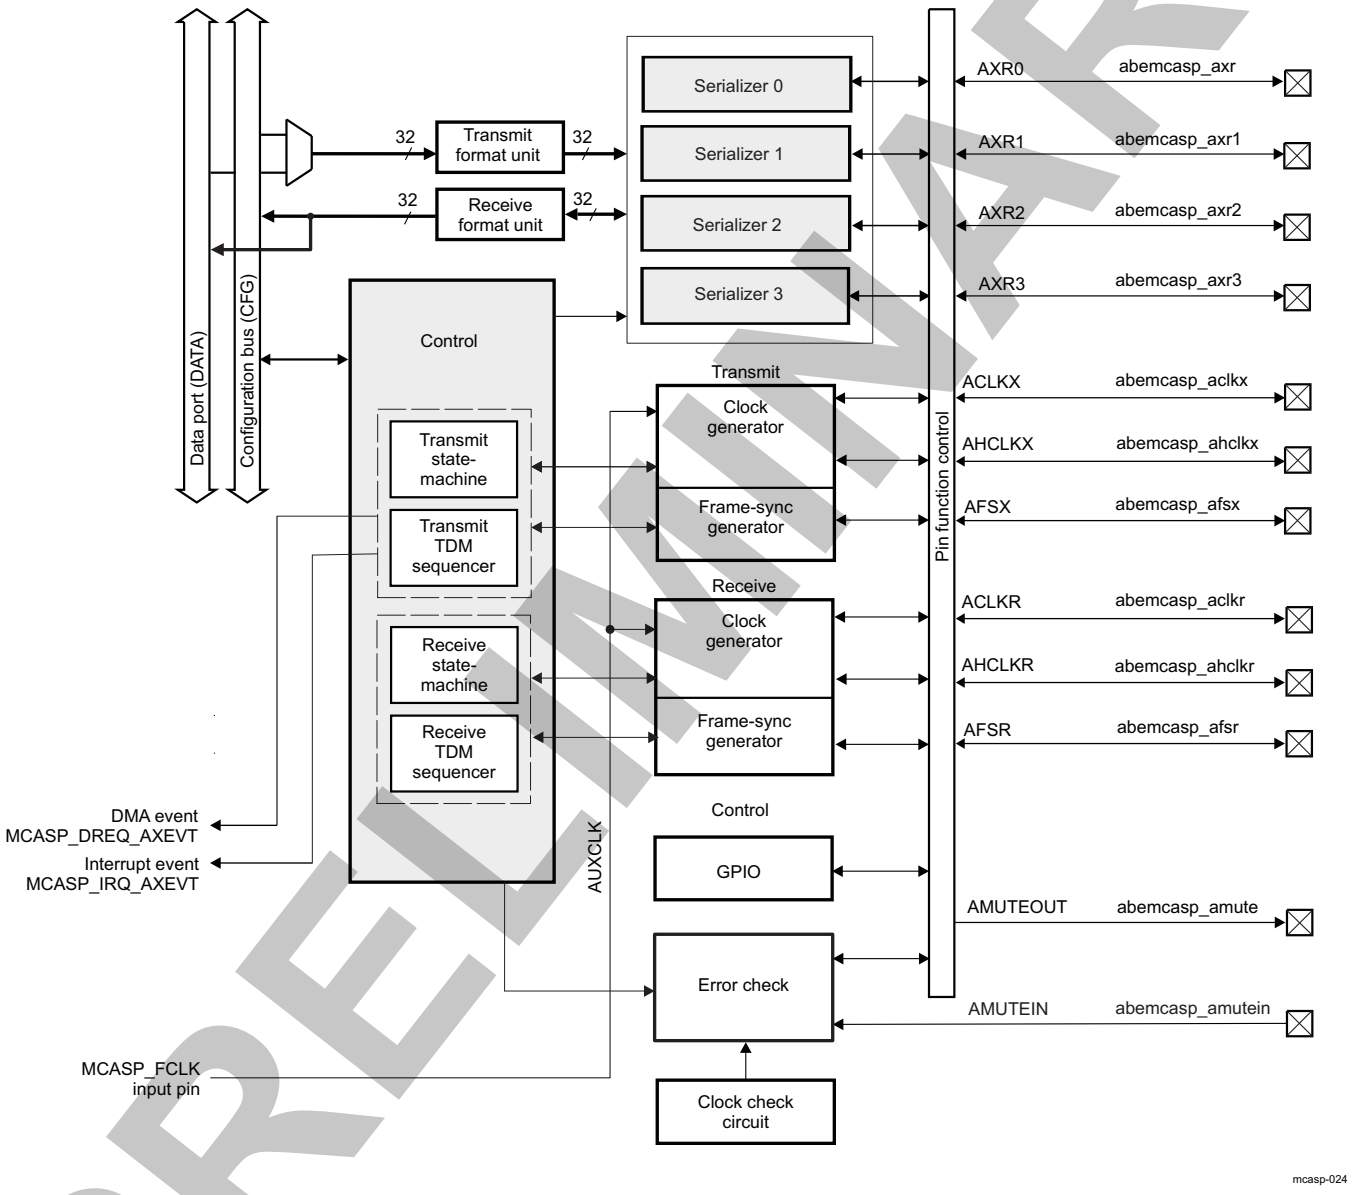
- For the description of the interrupt source, see Section 23.8.4.11, *Interrupt Requests*.
- For the description of the DMA source, see Section 23.8.4.12, *DMA Requests*.

23.8.4 MCASP Functional Description

23.8.4.1 Block Diagram

Figure 23-178 shows the major blocks of the MCASP. The MCASP has a total of 4 serializers sharing a clock and frame-sync generator, format unit, and error-checking logic independently for the receive and transmit part.

Figure 23-178. MCASP Block Diagram



NOTE: The AUXCLK clock is sourced directly from the MCASP_FCLK functional clock input which is tied to the PRCM.MCASP_GFCLK clock. For more information, see Section 3.6, *Clock Management Functional Description* of Chapter 3, *Power, Reset and Clock Management*.

23.8.4.2 MCASP Clock and Frame-Sync Configurations

There are three scenarios to provide clock source signals for the Tx part and four scenarios for the Rx part of the MCASP serializers. The first three scenarios are identical between the Tx and Rx part of the MCASP. They feature an asynchronous operation between receiver and transmitter channels using independent Tx / Rx bit rate clock sources (either internal or external).

In the first scenario, the transmit - XCLK and receive - RCLK serial clocks (clock at the bit rate) are generated internally by passing through a couple of clock dividers off the internal functional clock source (AUXCLK). In this case, the bit rate clock is generated internally and is driven out on the pin ACLKX for the Tx part (signal named - "abemcasp_aclkx at device level)" and pin ACLKR for the Rx part (signal named - abemcasp_aclkr at device level), respectively. An internally generated high-frequency clock can be optionally driven out onto the AHCLKX pin for the Tx part (signal named - "abemcasp_ahclkx" at device level) and AHCLKR pin for the Rx part (signal named - "abemcasp_ahclkr" at device level) to serve as a reference clock for other components in the system.

In the second scenario, an external for the device clock, is passed on the ACLKX (for the TX part) and ACLKR (for the RX part) pins which are configured as inputs. In this case the Rx- / Tx- high-speed clock logic is bypassed for the XCLK / RCLK generation.

In the third (mixed) scenario, an externally driven (master) high-frequency clock is applied on the AHCLKX (for the TX part) / AHCLKR (for the RX part) pins, which are configured as inputs. In this case the AHCLKX / AHCLKR clock frequency can be divided down via programming the ACLKX / ACLKR associated dividers to produce the necessary bit rate clock. The high-speed clock divider can NOT be used.

In the fourth clock generation scenario the bit rate clock for MCASP receivers - RCLK is derived from the bit rate clock of the MCASP transmitters - XCLK for a synchronous operation between transmitters and receivers. Hence, the whole receiver clock generator logic is bypassed.

A typical role of the MCASP frame sync signal is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

For an asynchronous operation, the AFSX (Tx part) and AFSR (Rx part) frame synchronization signals can be sourced internally or delivered externally independently for the Tx and Rx channels. During synchronous operation the receive frame sync - AFSR signal is derived from the transmit frame sync - AFSX signal. A synchronous and asynchronous mode applies to bit rate clock and frame sync signals at the same time.

23.8.4.2.1 Transmit Clock

The transmit high-speed and transmit clock configuration is controlled by the following registers:

- MCASP_ACLKXCTL
- MCASP_AHCLKXCTL

In case, the transmit bit clock, ACLKX, is generated internally, the MCASP_ACLKXCTL[5] CLKXM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKXCTL[4:0] CLKXDIV bit field) from the source signal.

If the transmit high-frequency master clock, AHCLKX, is also sourced internally (that is first scenario described in Section 23.8.4.2, the MCASP_AHCLKXCTL[15] HCLKXM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKXCTL[11:0] HCLKXDIV bit field) from the MCASP internal clock source AUXCLK.

Internally, the MCASP always shifts transmit data at the rising edge of the internal transmit clock - XCLK, (see Figure 23-179). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If MCASP_ACLKXCTL[7] CLKXP = 0, the CLKXP mux directly passes ACLKX signal to XCLK. As a result, the MCASP shifts transmit data at the rising edge of ACLKX. If MCASP_ACLKXCTL[7] CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the MCASP shifts transmit data at the falling edge of ACLKX.

It can be seen in Figure 23-179 that XCLK is propagated to the Rx clock logic, to allow an internally synchronous operation between MCASP transmitters and receivers. This is used for example in the MCASP loopback mode.

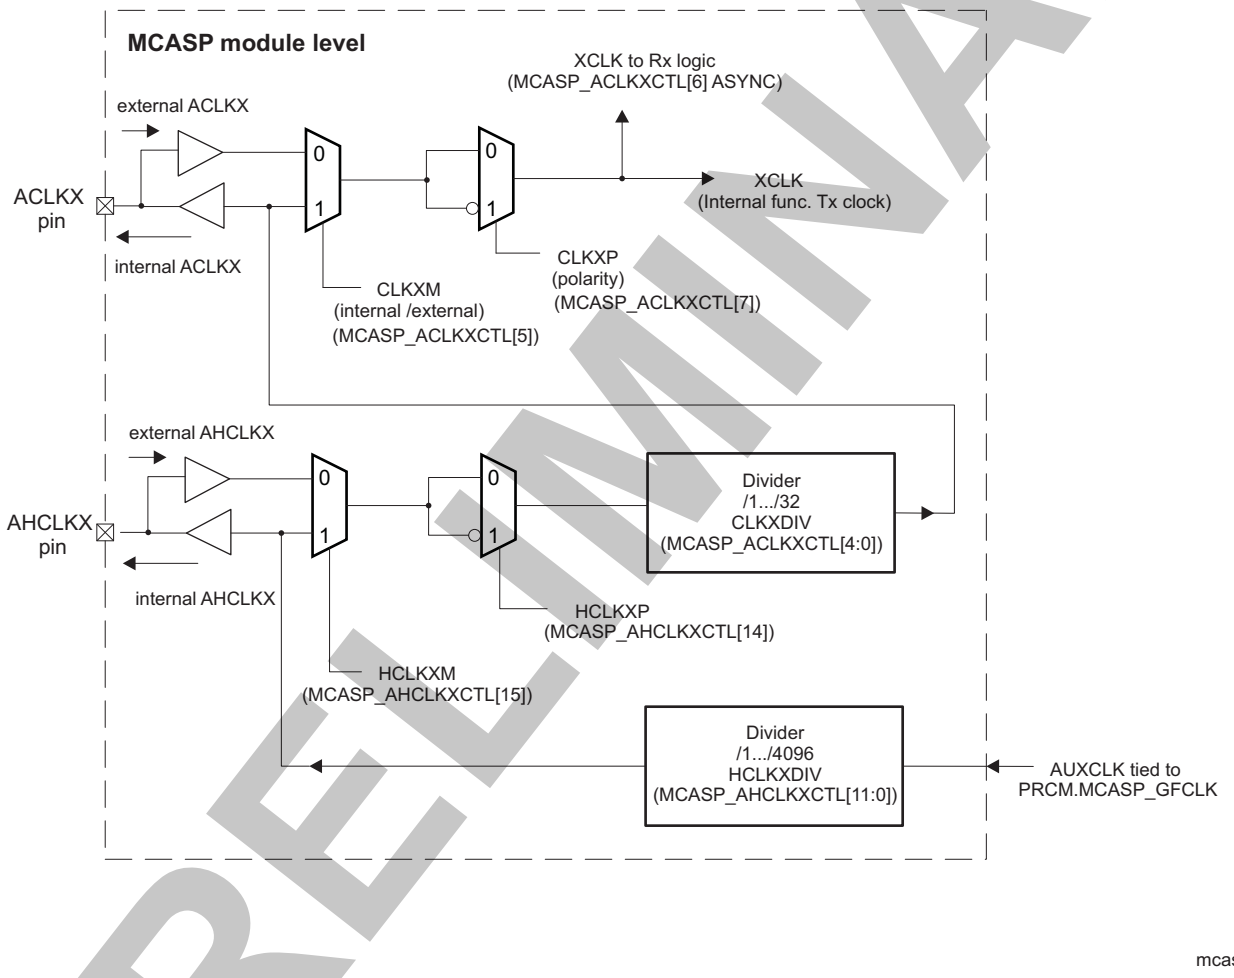
NOTE: The polarity of ACLKX can be controlled in MCASP_ACLKXCTL[7] CLKXP, regardless of ACLKX signal being internally or externally sourced.

In addition, there is an option to invert polarity of the AHCLKX master high speed clock via writing the MCASP_AHCLKXCTL[14] HCLKXP bit.

NOTE: In a similar way, the polarity of AHCLKX clock can be controlled in MCASP_AHCLKXCTL[14] HCLKXP, regardless of the AHCLKX signal being internally or externally sourced.

Figure 23-179 is the block diagram of the transmit clock generator.

Figure 23-179. Transmit Clock Generator Block Diagram



mcasp-022

23.8.4.2.2 Receive Clock

The MCASP receive clock generator is built on a very similar to the transmit clock generator (but independent) circuit.

The receive clock configuration is controlled by the following registers:

- MCASP_ACLKRCTL
- MCASP_AHCLKRCTL

In case, the receive bit clock, ACLKR, is generated internally (but asynchronously to XCLK), the MCASP_ACLKRCTL[5] CLKRM bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the MCASP_ACLKRCTL[4:0] CLKRDIV bit field) from the source signal.

If the receive high-frequency master clock, AHCLKR, is also sourced internally (that is first scenario described in Section 23.8.4.2, the MCASP_AHCLKRCTL[15] HCLKRM bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the MCASP_AHCLKRCTL[11:0] HCLKRDIV bit field) from the MCASP internal clock source AUXCLK.

The receive high-frequency master clock - AHCLKR may be (but is not required to be) output on the AHCLKR pin where it is available to other devices in the system. Regardless if AHCLKR is either internally generated or externally sourced, polarity of the high-frequency clock may be programmed via bit MCASP_AHCLKRCTL [14] HCLKRP to be either rising or falling edge.

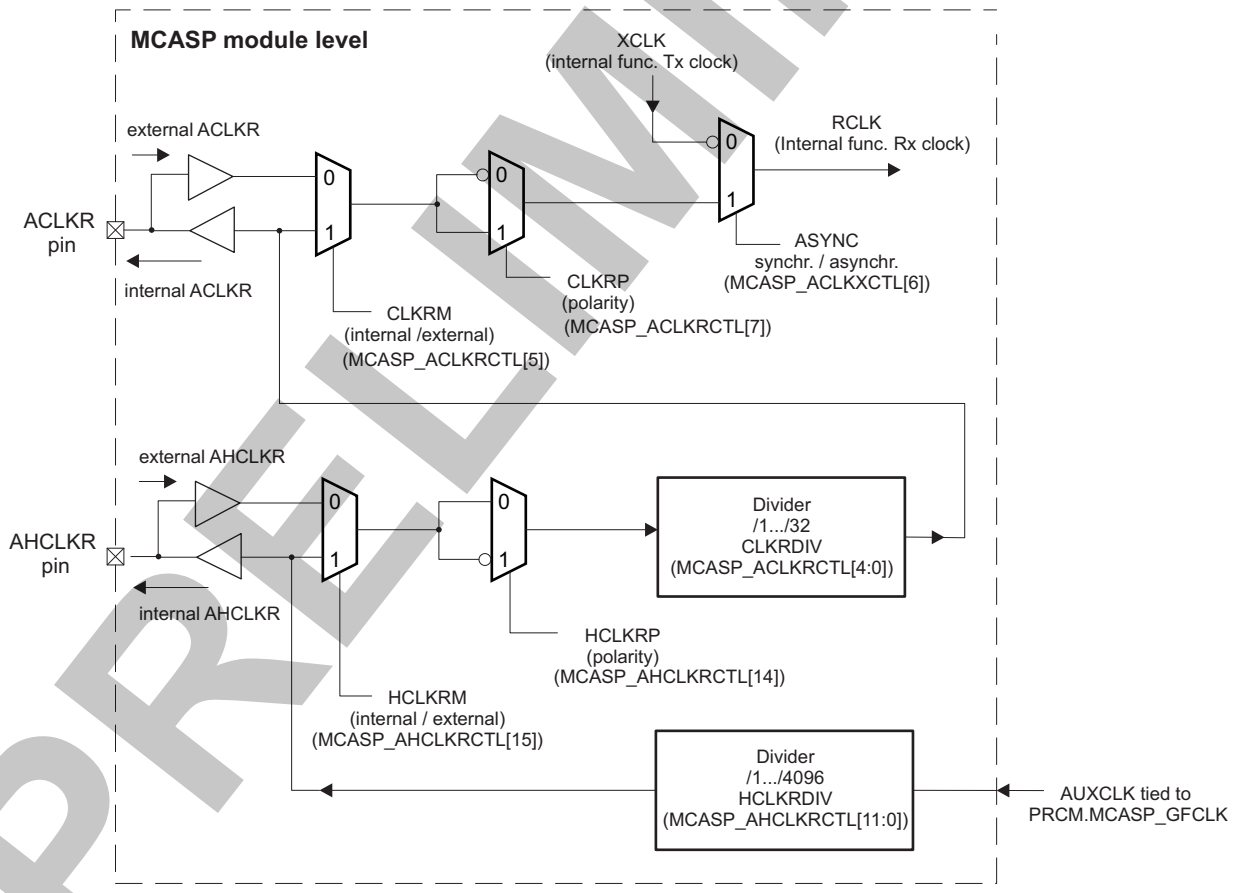
NOTE: The polarity of ACLKR can be controlled in MCASP_ACLKRCTL[7] CLKRP, regardless of ACLKR signal being internally or externally sourced.

In a similar way, the polarity of AHCLKR clock can be controlled in MCASP_AHCLKRCTL[14] HCLKRP, regardless of the AHCLKR signal being internally or externally sourced.

There is an option for the MCASP receiver to be configured to operate synchronously to the ACLKX and AFSX signals. The XCLK output of the Tx Clock generator (see Figure 23-179and Figure 23-180) becomes source of the receive clock (RCLK output), when the MCASP_ACLKXCTL[6] ASYNC bit in the transmit clock control register is set to '0b0'. For more information, refer to Section 23.8.4.2.4.

Figure 23-179 is the block diagram of the receive clock generator.

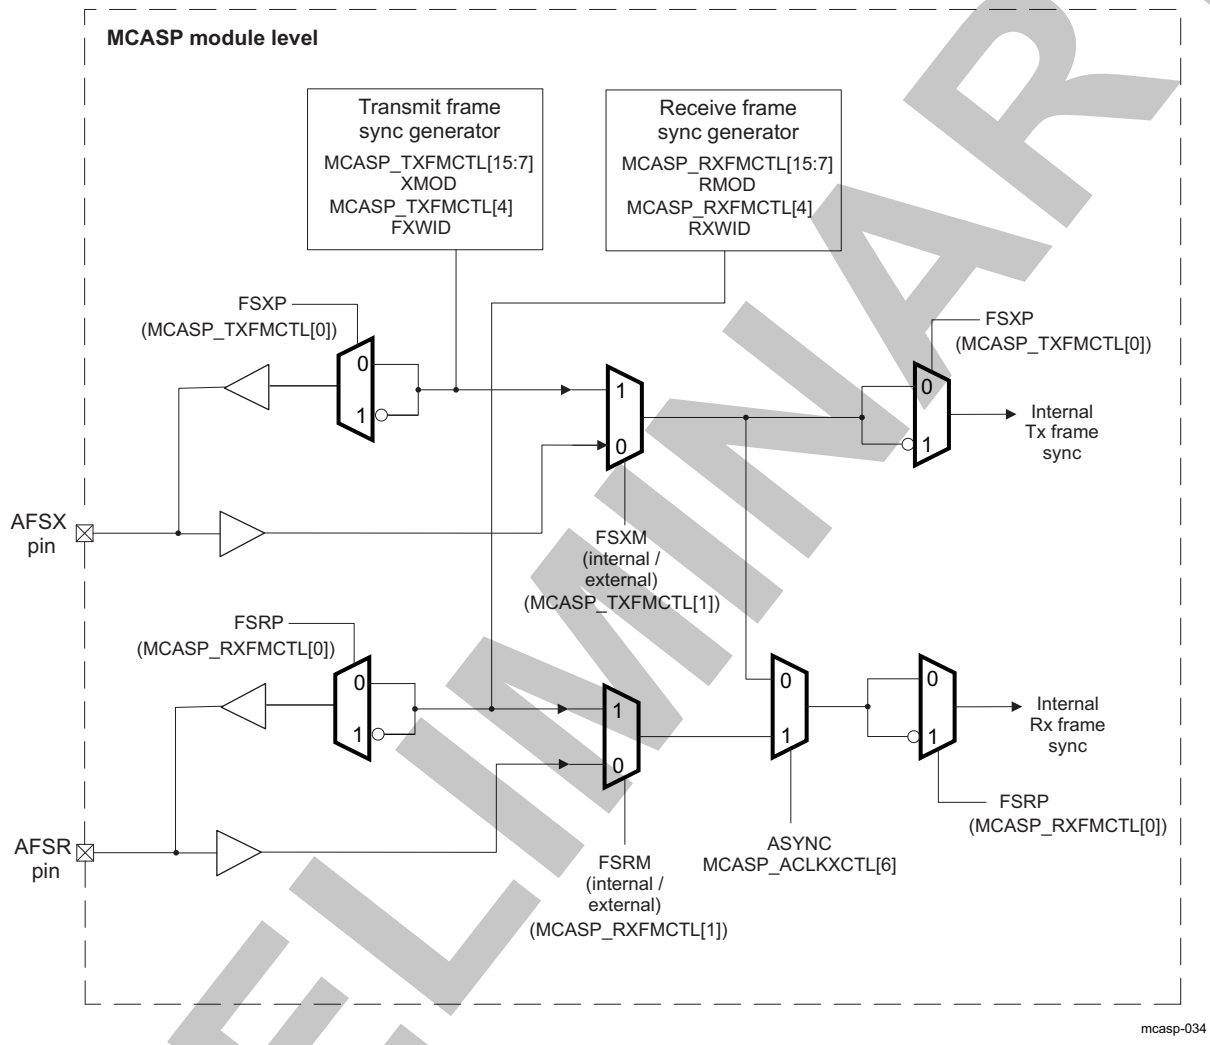
Figure 23-180. Receive Clock Generator Block Diagram



23.8.4.2.3 Frame-Sync Generator

The MCASP frame sync generator logic is illustrated in Figure 23-181. The transmit frame-sync pin is AFSX (signal named "abemcasp_afsx" at device level), and the receive frame-sync pin is AFSR (signal named "abemcasp_afsr" at device level) .

Figure 23-181. Frame Sync Generator Block Diagram



For the transmit logic, following frame-sync generator configurations can be selected :

- Internally / externally generated frame-sync via configuring bit MCASP_TXFMCTL[1] FSXM
- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_TXFMCTL[0] FSXP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_TXFMCTL[4] FXWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_TXFMCTL[15:7] XMOD, as follows:
  - For DIT mode (384 slots) - MCASP_TXFMCTL[15:7] XMOD = 0x180
  - For I2S mode (2 TDM slots) - MCASP_TXFMCTL[15:7] XMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_TXFMCTL[15:7] XMOD set in range 0x3 - 0x20
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_TXFMT[17:16] XDATDLY

For the receive logic, following frame-sync generator configurations can be selected :

- Internally / externally generated frame-sync via configuring bit MCASP_RXFMCTL[1] FSRM

- Frame-sync polarity: Rising edge or falling edge via configuring bit MCASP_RXFMCTL[0] FSRP
- Frame-sync width: "single bit" or "single word" via configuring bit MCASP_RXFMCTL[4] FRWID
- Frame sync mode - the appropriate frame sync generation pattern for the selected transfer mode is defined in the bitfield MCASP_RXFMCTL[15:7] RMOD, as follows:
  - For I2S mode (2 TDM slots) - MCASP_RXFMCTL[15:7] RMOD = 0x2
  - For TDM mode (from 3 to 32 TDM slots) - MCASP_RXFMCTL[15:7] RMOD set in range 0x3 - 0x20
  - For the special 384-slot TDM mode - MCASP_RXFMCTL[15:7] RMOD=0x180
- Bit delay: 0, 1, or 2 cycles before the first data bit. This delay is defined in MCASP_RXFMT[17:16] RDATDLY
- Selecting the source (AFSX or AFSR) of receiver internal frame synchronization. This is done in the same bit - MCASP_ACLKXCTL[6] ASYNC, used to define the receiver internal clock source. For more details, refer to Section 23.8.4.2.4.

Regardless of the AFSX / AFSR being internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSXP/FSRP = 1, the frame sync polarity is falling edge.

NOTE: Certain restrictions apply to the receive and transmit logic settings, when MCASP_ACLKXCTL[6] ASYNC is set to 0b0. They are described in Section 23.8.4.2.4.

23.8.4.2.4 Synchronous and Asynchronous Transmit and Receive Operations

Synchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC is written to 0b0, the transmit and receive sections operate synchronously to the transmit section clock and transmit frame sync signals.

Though Rx section may have a different data format , it has to be configured to have the same slot size than the transmit section one. As shown on the Figure 23-180, with the ASYNC bit set to 0b0, the RCLK becomes an inverted version of the transmit clock generator XCLK output.

When MCASP_ACLKXCTL[6] ASYNC = 0b0, both Rx and Tx sections use the same clock and frame sync signals. For this reason, they must be aligned on the following settings:

- MCASP_TXDITCTL[0] DITEN = 0 (that is, transmission in TDM mode is enabled)
- The total number of bits per frame must be the same (that is, RSSZ * RMOD product value must equal XSSZ * XMOD product value)
- The settings in MCASP_ACLKRCTL are NOT considered
- FSXM must match FSRM
- FXWID must match FRWID

For all other settings, the transmit and receive sections may be programmed independently.

Asynchronous Transmit and Receive Operations -

When MCASP_ACLKXCTL[6] ASYNC = 0b1, Tx and Rx operate independently from each other with separate clock and frame sync signals.

NOTE: Synchronous transmit and receive operations are allowed only in the MCASP TDM (I2S) mode (i.e. when MCASP_TXDITCTL[0] DITEN=0b0).

23.8.4.3 Serializers

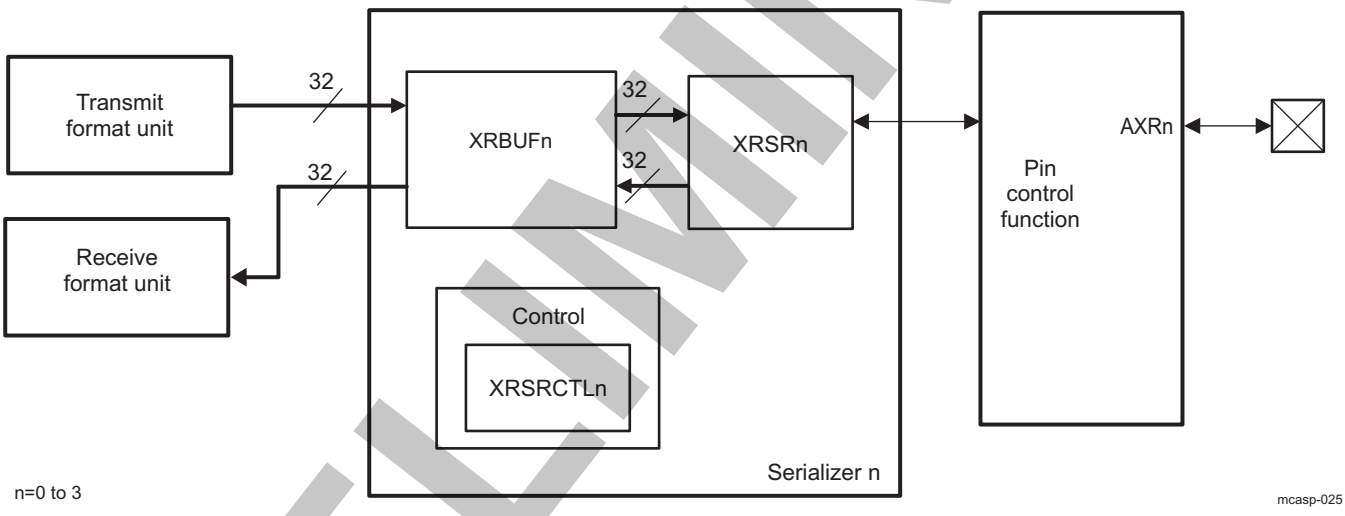
The four MCASP serializers shift serial data in (Rx) and out (Tx) of the MCASP. A given serializer n (where n=0 to 3) consists of a shift register (XRSRn) with a single-entry data buffer XRBUFn used either for transmitting (write accessible in register MCASP_TXBUFn) or for receiving (read accessible in register MCASP_RXBUFn) data. In addition, each serializer has a dedicated control register (MCASP_XRSRCTLn) and a serial bidirectional data pin - AXRn. The register MCASP_XRSRCTLn allows n-th serializer to be configured as a transmitter, receiver, or as inactive. There are transmit and receive data formatting units to support data alignment options of the MCASP which are shared between all Tx and Rx serializers, respectively.

A given serializer XRSRn shifter configured as a receiver in MCASP_XRSRCTLn, shifts in data through MCASP corresponding device level bidirectional data pad- (abemcasp_axr through abemcasp_axr3). A given serializer XRSRn shifter configured as a transmitter in MCASP_XRSRCTLn, shifts out data on MCASP corresponding device level bidirectional data pad -(abemcasp_axr through abemcasp_axr3).

The serializer is clocked from the transmit section clock (ACLKX signal) if configured to transmit or clocked from the receive section clock (ACLKR signal) if configured to receive. A serializer configured to transmit and receive operates in lockstep, which means that for MCASP there are at most a couple of zones, one for transmit and one for receive.

Figure 23-182 is the serializer block diagram.

Figure 23-182. Individual Serializer and Connections Within MCASP



Transmission on the n-th serializer (where n=0 to 3 for the device) is performed as follows: the microprocessor unit (MPU) services the MCASP by writing data into the register MCASP_TXBUFn, which is an alias of the serializer data buffer - XRBUFn for transmit function. The data automatically passes through the transmit format unit before reaching the XRBUFn register in the serializer. The data is then copied from the XRBUFn to XRSRn and shifted out from AXRn synchronously to the serial clock.

Reception from the n-th serializer (where n=0 to 3 for the device) is performed as follows: the data is shifted into the MCASP XRSRn serializer register through the AXRn pin, bit by bit. Once the entire slot becomes available within the XRSRn shift register, the data is copied into the serializer data buffer - XRBUFn ,and can be accessed in the MCASP_RXBUFn register, which is an alias of the serializer data buffer - XRBUFn for receive function. When MPU reads data from this register, the MCASP passes the data through the receive format unit, hence it returns formatted data to the MPU.

Serializer controls:

A serializer n is configured as inactive via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x0.

For a transmitting serializer, the MCASP_XRSRCTLn[3:2] DISMOD bitfield, defines the AXRn pin output state, during inactive slots (HIGH, LOW or Hi-Z).

Transmit function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x1.

Receive function for the n-th serializer is selected via setting bitfield MCASP_XRSRCTLn[1:0] SRMOD to 0x2.

In the DIT-transmission mode (that is S/PDIF format data transmission) : in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). For more information, see Section 23.8.2.2.5

23.8.4.4 Format Units

The MCASP has one transmit data formatting unit and one receive data formatting unit, shared between the device 4 MCASP serializers. These units automatically remap the data bits within the transmitted or received words between a natural format for the MPU (such as a Q31 representation) and the required format for the external serial device (for example I2S format). During the remapping process, the format unit can also mask off certain bits.

Since all transmitters share the same data formatting unit, the MCASP only supports one transmit format at a time. For example, the MCASP does NOT transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the MCASP only supports one data format at a time, and this format applies to all receiving serializers.

NOTE: The MCASP can transmit in one format while receiving in a completely different format.

The bit mask and pad stage of each of Tx and Rx format units includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits. The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the MCASP_RXFMT / MCASP_TXFMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation. The bit order - reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit order reversal is not enabled, then the MCASP will naturally transmit and receive in an LSB first order. Finally, note that the RDATDLY / XDATDLY bits in the MCASP_RXFMT / MCASP_TXFMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, RDATDLY / XDATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay. The combination of all the options in MCASP_RXFMT / MCASP_TXFMT means that the MCASP supports a wide variety of data formats, both on the serial data lines, and in the internal CPU (MPU or DSP) data representation.

23.8.4.4.1 Transmit Format Unit

The MCASP transmit formatting unit consists of three stages :

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB-first or LSB-first)

Figure 23-183 shows the transmit formatting unit.

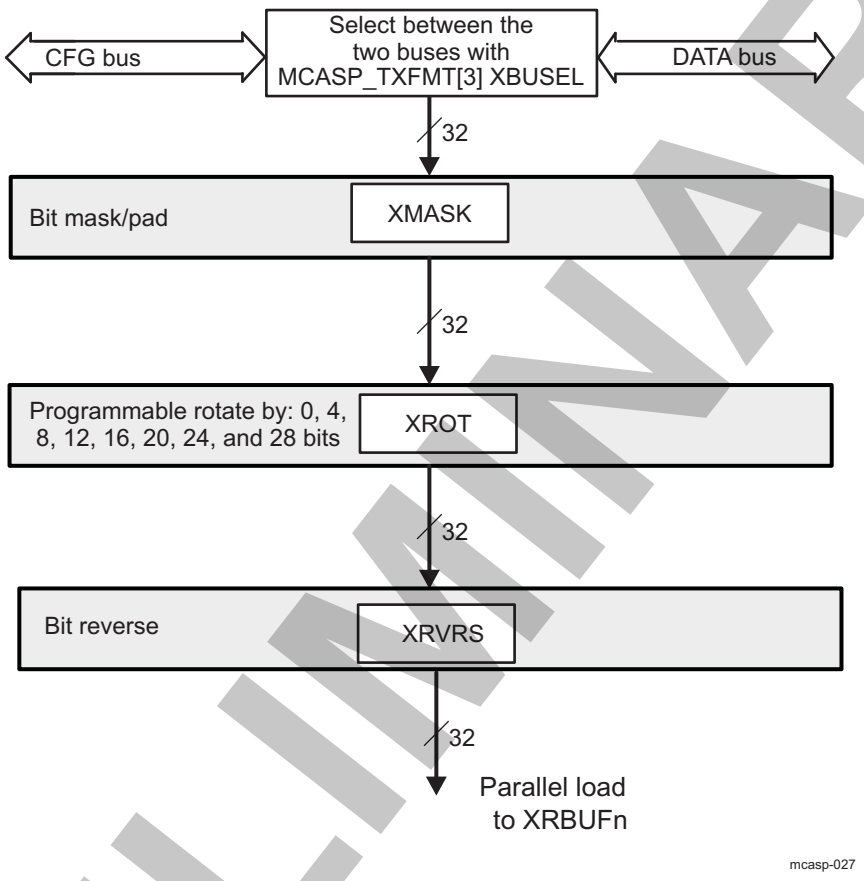
The MCASP transmitter supports serial formats of :

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size <= Slot size
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the bitstream format register - MCASP_TXFMT:

- XRVRS: bit reverse (1) or no bit reverse (0)
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- XSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

Figure 23-183. Transmit Format Unit



As shown in Figure 23-183, the data to the transmit format unit can come from the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_TXFMT[3] XBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 23.8.4.10.1.3, *Transfers Through the DATA Port*, and Section 23.8.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

In the transmit format unit (TFU), the input data bits are first masked-off with the MCASP_TXMASK[31:0] XMASK contents. The masked data is then right-rotated to MCASP_TXFMT[2:0] XROT positions, to produce the output word for a TDM- or DIT- transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

23.8.4.4.1.1 TDM Mode Transmission Data Alignment Settings

The TDM-mode transmission settings are relevant for I2S-protocol and protocols using more than 2 TDM-slots.

XSSZ should always be programmed to match the slot size of the serial stream. **Note that, TDM word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the XROT field.**

The Table 23-572 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

The Table 23-572 assumes that all slot size (SLOT in Table 23-572) and word size (WORD in Table 23-572) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit, and the data is aligned in the same representation as it is written to the transmitter by the MPU or DSP (typically Q31 or integer).

Table 23-572. MCASP TFU TDM Mode Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_TXFMT bits	
			XROT[1]	XRVRS
MSB first[2]	Left aligned	Q31 fraction	0	1
MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
LSB first	Left aligned	Q31 fraction	32 - WORD	0
LSB first	Right aligned	Q31 fraction	32 - SLOT	0
MSB first[2]	Left aligned	Integer	WORD	1
MSB first	Right aligned	Integer	SLOT	1
LSB first	Left aligned	Integer	0	0
LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To transmit in I2S format, select MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

23.8.4.4.1.2 DIT Mode Transmission Data Alignment Settings

In case of a DIT-mode (S/PDIF protocol) transmission, while left-aligned Q31 data should be right-rotated to a multiple by 4 positions, no right-rotation is required for a right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The MCASP_TXFMT[17:16] XDATDLY bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- MCASP_TXFMT[2:0] XROT =
  - 0x2 (rotate right by 8 bits) - for a 24-bit output audio data
  - 0x3 (rotate right by 12 bits) - for a 20-bit output audio data
  - 0x4 (rotate right by 16 bits) - for a 16-bit output audio data
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0xFFFFFF00 – 0xFFFF0000
- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- MCASP_TXFMT[2:0] XROT = 0x0 (rotate right by 0 bits regardless of the audio word length)
- MCASP_TXFMT[15] XRVRS = 0x0 – Bit reversal is not enabled; the MCASP naturally transmits and receives in a LSB-first order.
- MCASP_TXMASK[32] XMASK = 0x00FFFFFF – 0x0000FFFF

- MCASP_TXFMT[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in Table 23-573 should be applied to MCASP in cases of DIT-transmitting a Q31 data as a 24-bit, 20-bit and 16-bit left- or right- aligned audio word, respectively. Note that the listed settings let the MCASP TFU preserve the most significant bits and cut only the LSBs of the original Q31 MPU data:

Table 23-573. MCASP TFU DIT-Mode Example Settings

Output Audio Word Alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFFF000	0x3
LEFT	24	8	0xFFFFFF00	0x2
RIGHT	16	0	0x0000FFFF	0x0
RIGHT	20	0	0x000FFFFF	0x0
RIGHT	24	0	0x00FFFFFF	0x0

Assuming that a Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by MPU on the MCASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of same word, preserving the MSBs, according to the Table 23-573, the user must set XMASK=0xFFFFF000, and to select a right-rotation to 12 positions (XROT=0x3).

- After applying 0-s (XPAD=0) as masking-off bits at the first TFU stage, word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right is performed in TFU, the 20-bit output word obtained is : 0x000FA5AF.Thus the word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT-transmission.

Assuming that a right-aligned Q31 data word - 0x yyyyE4B4 is generated by MPU on the MCASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word, preserving the MSBs, according to the table MCASP TFU Example Settings, user is supposed to set XMASK=0x0000FFFF, and to select right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage – 0x0000E4B4.

The above examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

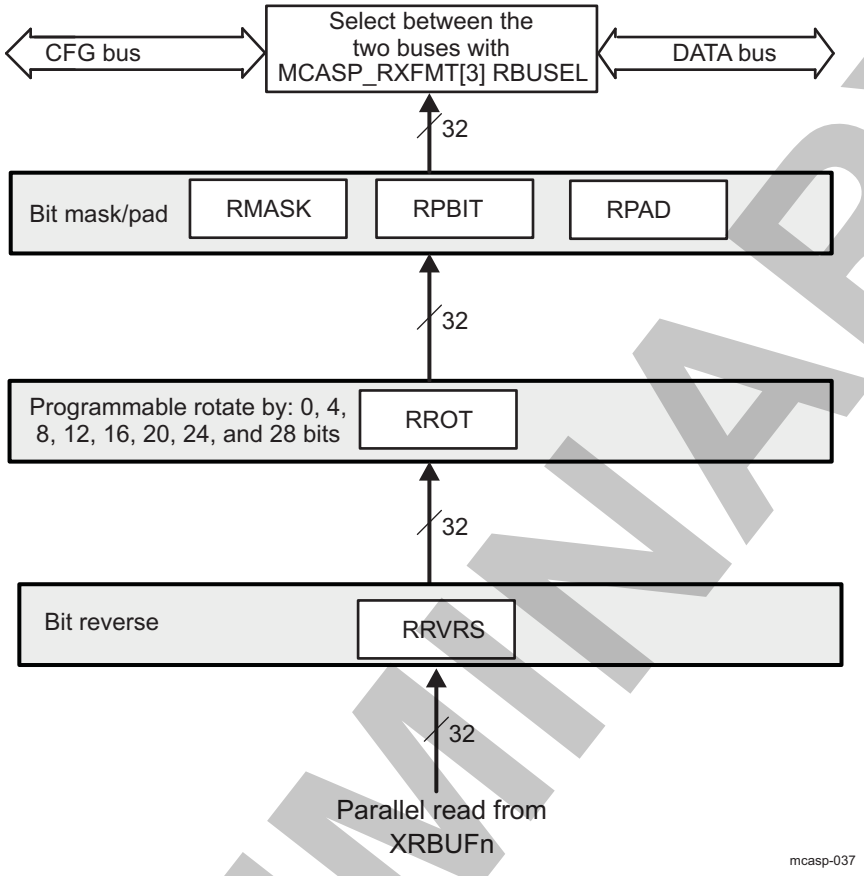
23.8.4.4.2 Receive Format Unit

The MCASP receive formatting unit consists of three stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 23-184 shows the receive format unit (RFU).

Figure 23-184. Receive Format Unit



The MCASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits
- Word size <= Slot size
- Alignment when more bits are available per slot than bits per word within the slot, then:
  - Left aligned = word shifted first, remaining bits are pad
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB
  - LSB: least-significant bit of word is shifted out last, last bit is MSB

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register - MCASP_RXFMT:

- RRVRS: bit reverse (1) or no bit reverse (0)
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits

As shown on Figure 23-184, the data processed in the RFU can be output to CPUs (device MPU / DSP) through the configuration port (CFG) or the data port (DATA). The selection is made through the MCASP_RXFMT[3] RBUSEL bit. According to port type selected, data transfer has different behaviour. For more details, refer to the Section 23.8.4.10.1.3, *Transfers Through the DATA Port*, and Section 23.8.4.10.1.4, *Transfers Through the Configuration (CFG) Bus*.

23.8.4.4.2.1 TDM Mode Reception Data Alignment Settings

RSSZ should always be programmed to match the slot size of the serial stream. **Note that the word size is not directly programmed into the MCASP, but rather is used to determine the rotation needed in the RROT field.**

Table 23-574shows the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

Table 23-574. MCASP RFU Settings

Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	MCASP_RXFMT bits	
			RROT[1]	RRVRS
MSB first[2]	Left aligned	Q31 fraction	SLOT	1
MSB first	Right aligned	Q31 fraction	WORD	1
LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
LSB first	Right aligned	Q31 fraction	0	0
MSB first[2]	Left aligned	Integer	SLOT - WORD	1
MSB first	Right aligned	Integer	0	1
LSB first	Left aligned	Integer	32 - SLOT	0
LSB first	Right aligned	Integer	32 - WORD	0

(1) WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

(2) To receive in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

The Table 23-574 assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask / pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1. The receive bit mask / pad unit operates on data as the final step of the receive format unit (see Figure 23-184), and the data is aligned in the same representation as it is read from the receiver by the DSP (typically Q31 or integer).

23.8.4.5 State-Machines

The receive and transmit sections have independent state machines.

Each state-machine controls the interactions between the various units in the MCASP Rx and Tx sections, respectively. In addition, each state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the RX / TX state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register (MCASP_TXFMT) and it reports the MCASP status and error conditions in the transmitter status register (MCASP_TXSTAT).

Similarly, the receive state-machine is controlled by the receive bitstream format register (MCASP_RXFMT) and it reports the MCASP status and error conditions in the receiver status register (MCASP_RXSTAT).

23.8.4.6 TDM Sequencers

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of MCASP_RXTDM / MCASP_TXTDM and determines if the MCASP should receive/transmit in that time slot.

There are two possibilities for a slot: The MCASP either performs Rx / Tx operations during the time slot (transmit / receive bit is active), or the MCASP skips Rx / Tx operations during the time slot (transmit/receive bit is inactive). In the latter case, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot.

In addition, during time of inactive slots, the serializers programmed as transmitters place their data output pins - AXRn in a predetermined state - logic low, high, or high impedance (tri-stated) as programmed in each serializer control register MCASP_XRSRCTLn[3:2] DISMOD. Refer also to section Section 23.8.4.9.1.1, *TDM Time Slots Generation and Processing*, for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

In case of a DIT-transmission (S/PDIF transfers): the time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to a MCASP_TXBUFn (where n=0 to 3) register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the MCASP_TXTDM register and reports the current transmit slot to the MCASP_TXTDMSLOT[8:0] XSLOTCNT bit field.

23.8.4.7 MCASP Software Reset

The MCASP can be put into reset through the global transmit and receive control register (MCASP_GBLCTL). A valid serial clock must be supplied to the MCASP to assert the software reset bits in the MCASP_GBLCTL register.

23.8.4.8 MCASP Power Management

Table 23-575 describes power-management features available to the MCASP.

Table 23-575. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	MCASP_SYSCONFIG[1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

CAUTION

No wakeup schema is supported for the MCASP. To ensure a correct behavior after enabling MCASP at device PRCM level, the user software is strongly recommended to choose **No Idle** mode, setting MCASP_SYSCONFIG[1:0] IDLE_MODE to 0x1. Before disabling MCASP at device PRCM level, user software is strongly recommended to choose a **Smart-Idle** mode, setting MCASP_SYSCONFIG[1:0] IDLE_MODE to 0x2.

23.8.4.9 Transfer Modes

23.8.4.9.1 Time-Division Multiplexed (TDM) Transfer Mode

The MCASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 23.8.2.2.3.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock
- AFSX - transmit frame sync (or commonly called left/right clock)
- One or more serial data pins, AXRn (where n=0 to 3 in the device), whose serializers are configured to transmit

For more details on MCASP transmitting serializers clock and frame sync options, refer to the section Section 23.8.4.2.1, *Transmit Clock*, and Section 23.8.4.2.3, *Frame-Sync Generator* .

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)

- One or more serial data pins, AXRn (where n= 0 to 3 for the device) , whose serializers are configured to receive

For more details on MCASP receiving serializers clock and frame sync options, refer to the Section 23.8.4.2.2, *Receive Clock*, and Section 23.8.4.2.3, *Frame-Sync Generator* .

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are highlighted in bold :

- MCASP_PFUNC : The clock, frame, data pins must be configured for MCASP function.
- MCASP_PDIR: The clock, frame, data pins must be configured to the direction desired.
- MCASP_PDOUT, MCASP_PDIN, MCASP_PDSET, MCASP_PDCLR : Not applicable. Leave at default.
- MCASP_GBLCTL : Follow the initialization sequence is described in the Section 23.8.5.2, *Operational Modes Configuration*.
- MCASP_AMUTE: Program all fields according to mute control desired.
- MCASP_LBCTL: If loopback mode is desired, configure this register according to Section 23.8.4.14, otherwise leave this register at default.
- MCASP_TXDITCTL: DITEN must be left at default 0 to select TDM mode (transmitters only).
- MCASP_RXMASK / MCASP_TXMASK: Mask desired bits according to Section 23.8.4.4, *Format Units*.
- MCASP_RXFMT / MCASP_TXFMT: Program all fields according to data format desired. See the Section 23.8.4.4, *Format Units*.
- MCASP_RXFMCTL / MCASP_TXFMCTL : Set RMOD / XMOD bits to (0x2 - 0x20) for Rx / Tx (2- 32 slots) TDM mode. In addition, set RMOD to 0x180 if 384-slot TDM stream has to be received by MCASP. Configure other fields as desired.
- MCASP_ACLKRCTL / MCASP_ACLKXCTL : Program all fields according to bit clock desired. For more inforamtion , refer to Section 23.8.4.2.
- MCASP_AHCLKRCTL / MCASP_AHCLKXCTL: Program all fields according to high-frequency clock desired. For more details, refer to Section 23.8.4.2.
- MCASP_RXTDM / MCASP_TXTDM : Program all fields according to the time slot characteristics desired.
- MCASP_EVTCTLX : Program all fields according to transmit interrupts desired.
- MCASP_RXCLKCHK / MCASP_TXCLKCHK: Program all fields according to clock checking desired.
- MCASP_XRSRCTLn : Program all fields according to serializer operation desired.

NOTE: The MCASP_DITCSRAi, MCASP_DITCSRBi, MCASP_DITUDRAi, MCASP_DITUDRBi (i=0 to 5) settings are NOT applicable in TDM transfer modes. They have to be kept at their default values.

23.8.4.9.1.1 TDM Time Slots Generation and Processing

TDM mode on the MCASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the MCASP may be configured to participate or to be inactive by configuring MCASP_TXTDM and/or MCASP_RXTDM registers.

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either MCASP_TXTDM or MCASP_RXTDM to determine if the MCASP transmits / receives in that time slot.

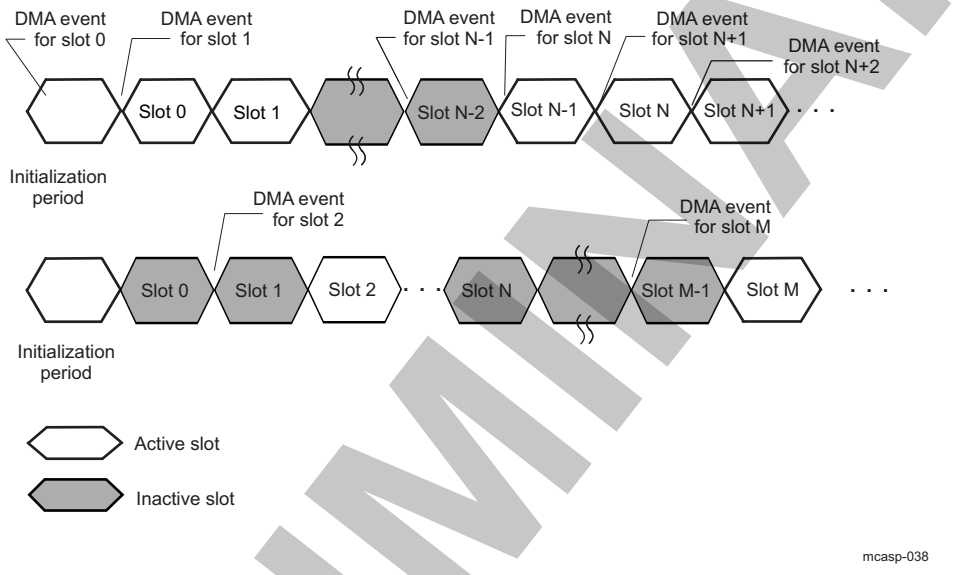
NOTE: If a MCASP_TXTDM / MCASP_RXTDM bit defines an active slot (number of slot matches the bit position), the MCASP functions normally during that time slot; otherwise, the MCASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. MCASP (transmit only) data pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bitfield MCASP_XRSRCTLn[3:2] DISMOD.

Figure 23-185 shows when the transmit DMA event - AXEVT is generated. See Section 23.8.4.10.1, *Data Ready Status and Event / Interrupt Generation* for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless of the previous time slot (slot N - 1) being active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUFn to XRSRn generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 23-185. Transmit DMA Event (AXEVT) Generation in TDM Time Slots



23.8.4.9.1.2 Special 384-Slot TDM Mode for Connection to External DIR

The MCASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF receiver ICs whose natural block (block corresponds to MCASP frame) size is 384 samples. The receive TDM time slot register (MCASP_RXTDM) should be programmed to all 1s during reception of a DIR block. **Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).** To receive data in DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock
- AFSR - receive frame sync (or commonly called left/right clock)
- In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK
- One or more serial data pins, AXRn, whose serializers have been configured to receive (n=0 to 3)
- For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in MCASP_RXFMCTL to 384 (0x180) to receive 384 time slots

23.8.4.9.2 DIT Transfer Mode

The DIT transfer mode of the MCASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. **The DIT mode applies only to a serializer configured as transmitter, NOT receiver.** For a description of the S/PDIF format, see Section 23.8.2.2.5, *S/PDIF Coding Format*.

23.8.4.9.2.1 Transmit DIT Encoding

When the MCASP operates in DIT mode, the data transmitted is output as a biphase-mark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the MCASP. The MCASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

NOTE: The transmit TDM time slot register (MCASP_TXTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- AHCLKX – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin (AXRn) of a serializer n configured to transmit.

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

23.8.4.9.2.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register (MCASP_TXFMCTL):
  - Internally generated transmit frame sync, FSXM = 1
  - Rising-edge frame sync, FSXP = 0
  - Bit-width frame sync, FXWID = 0
  - 384-slot TDM, XMOD = 1 1000 0000b
- In the transmit clock control register (MCASP_ACLKXCTL), ASYNC = 1
- In the transmit bitstream format register (MCASP_TXFMT), XSSZ = 1111 (32-bit slot size)

All combinations of abemcasp_ahclkx and abemcasp_aclkx are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- MCASP_PFUNC: The data pin - AXRn (n=0 to 3) must be configured for MCASP function. If abemcasp_ahclkx is used, it must also be configured for MCASP function. Other pins can be configured to function as GPIOs, if desired.
- MCASP_PDIR: The data pin must be configured as output. If internal clock source AUXCLK is used as the reference clock, it may be output as the abemcasp_ahclkx device level signal by configuring AHCLKX pin as an output.
- MCASP_GBLCTL: Global initialization
- MCASP_AMUTE: Program all fields according to the mute control desired.
- MCASP_TXDITCTL: The **DITEN** bit must be set to 0b1 to enable DIT mode. Configure other bits as desired.
- **MCASP_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP_TXFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. The **XROT** bit is configured, as described in the Section 23.8.4.4.1.2 .
- **MCASP_TXFMCTL**: Configure the bits according to former discussions.
- **MCASP_ACLKXCTL**: **ASYNC** = 1. Program the CLKXDIV bits to obtain the bit clock rate desired. CLKXM = 1.
- **MCASP_AHCLKXCTL**: Program the HCLKXDIV bits to obtain the high-frequency bit clock rate desired.
- **MCASP_TXTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- MCASP_EVTCTLX: Program all fields according to the interrupts desired.
- MCASP_TXCLKCHK: Program all fields according to the clock checking desired.

- MCASP_XRSRCTLn: Set **SRMOD** = 1 (transmitter) for the DIT pins.
- **MCASP_DITCSRAi** and **MCASP_DITCSRBi**: Program the channel status bits as desired.
- **MCASP_DITUDRAi** and **MCASP_DITUDRBi**: Program the user data bits as desired.

NOTE: In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to 2 serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for TDM (I2S) mode, due to the need to generate Biphase Mark Encoded Data - see Section 23.8.2.2.5.1).

23.8.4.9.2.3 DIT Channel Status and User Data Register Files

The channel status registers (MCASP_DITCSRAi and MCASP_DITCSRBi) and user data registers (MCASP_DITUDRAi and MCASP_DITUDRBi) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the MPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 23.8.2.2.5.2, *S/PDIF Subframe Format*. The channel status information (C) and user data (U) are defined in the following DIT control registers:

- MCASP_DITCSRA0 to MCASP_DITCSRA5: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- MCASP_DITCSRB0 to MCASP_DITCSRB5: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- MCASP_DITUDRA0 to MCASP_DITUDRA5: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- MCASP_DITUDRB0 to MCASP_DITUDRB5: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in Figure 23-176. There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in Table 23-576.

Table 23-576. Channel Status and User Data for Each DIT Block

23.8.4.10 Data Transmission and Reception

The MPU services the MCASP by writing data to the MCASP_TXBUFn registers for transmit operations, and by reading data from the MCASP_RXBUFn registers for receive operations. The MCASP sets status flags and notifies the MPU whenever data is ready to be serviced. The Section 23.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, discusses data-ready status in details.

The MCASP transmit / receive XRBUFn buffer can be accessed through one of the two peripheral ports of the device:

- DATA port: This port is dedicated to DMA_SYSTEM and DMA_DSP initiated data transfers on the device for MCASP transmit (Tx) purposes.
- Configuration bus (CFG): The configuration bus- CFG port is used for peripheral configuration control and receive / transmit data transfers initiated by the CPU (MPU Cortex-A15 or DSP) in the device.

Section 23.8.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 23.8.4.10.1.4, *Transfers Through the Configuration Bus (CFG),* discuss how to perform transfers through the data port (DATA) and the configuration port (CFG), respectively.

The MPU and DMA usages are discussed in Section 23.8.4.10.1.5, *Using the MPU for MCASP Servicing*, and Section 23.8.4.10.1.6, *Using the DMA for MCASP Servicing*, respectively.

MCASP DATA port allows DMAs (both DMA_DSP and DMA_SYSTEM) to access the MCASP transmit buffer more efficiently on the L3_MAIN-interconnect, using burst transfers. The physical addresses to access these registers are listed in Table 23-690.

23.8.4.10.1 Data Ready Status and Event/Interrupt Generation

23.8.4.10.1.1 Transmit Data Ready

The transmit data ready flag - XDATA in the MCASP_TXSTAT register reflects the data ready status of XRBUFn buffers (where n=0 to 3 for the device) for all of the active slot transmitting serializers. The XDATA flag is set whenever data is transferred from a transmitting serializer buffer - XRBUFn (where n=0 to 3) to its corresponding XRSRn shift register. Thus, the XDATA bit indicates the global event that some of the serializers data buffer - XRBUFn is emptied and ready to accept new data from the host (MPU/ DSP or DMAs). The transmit data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn[4] XRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Tx buffer must be serviced (written). When MCASP_TXBUFn is written to by the host, the MCASP_XRSRCTLn[4] XRDY is deasserted to 0b0. As XDATA global flag is an OR-event of all active serializers XRDY flags, it indicates to software the moment, when write service operation has to be initiated by the MCASP host (XDATA=0b1). The XRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_TXBUFn register has to be currently written. Once all requested MCASP_TXBUFn are written, the serializers control XRDY flags are cleared to 0b0. As a consequence, XDATA flag is deasserted to 0b0, to indicate to SW that write operation is completed for all serializers.

The global XDATA flag can be cleared when the MCASP_TXSTAT[5] XDATA bit is written to 0b1, or once MCASP_TXBUFn registers of all the serializers, that have previously raised their XRDY flags, are written with corresponding active slot data by the host.

Whenever XDATA is set, the DMA AXEVT event is automatically generated (if enabled in the MCASP_TXEVTCTL register) to notify the DMA of the MCASP_TXBUFn empty status. An interrupt - MCASP_IRQ_AXEVT can be also generated if the XDATA interrupt is enabled in the MCASP_EVTCTLX register (for details, see Section 23.8.4.11.1, *Transmit Data Ready Interrupt*).

For DMA requests, the MCASP does not require that MCASP_TXSTAT be read between DMA events. This means that, even if MCASP_TXSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

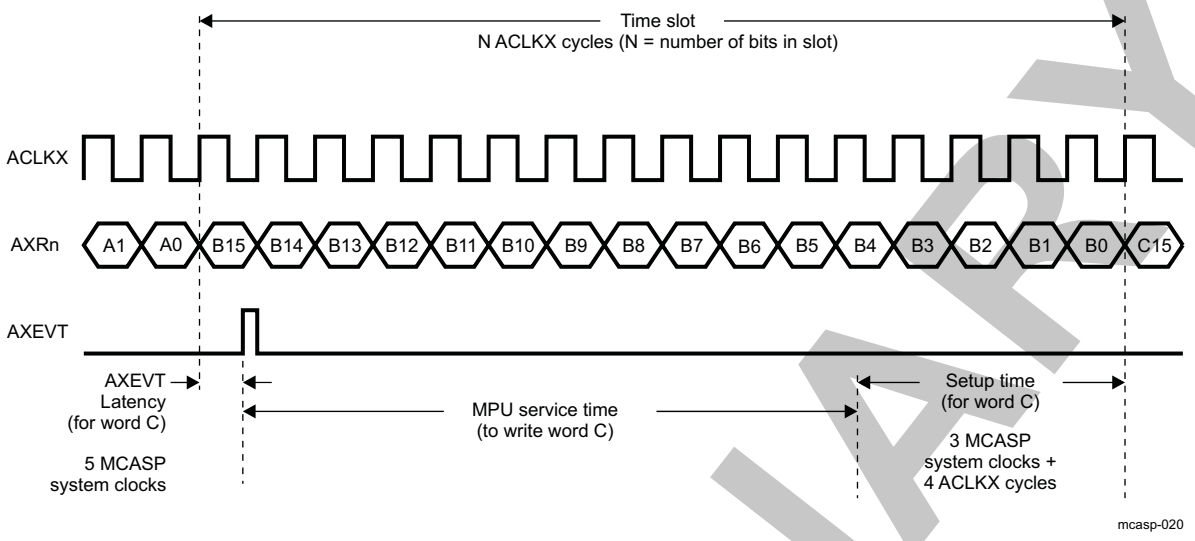
Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 23-186 shows the timing details of when AXEVT is generated at the MCASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the MCASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five MCASP system clocks (AXEVT latency) before AXEVT is active at the MCASP boundary. Upon AXEVT, the DSP / MPU can begin servicing the MCASP by writing word C into the MCASP_TXBUFn (service time). The MPU must write word C into the MCASP_TXBUFn within the setup time required by the MCASP (setup time).

The maximum service time (see Figure 23-186) can be calculated as:

Service Time = Time Slot – AXEVT Latency –Setup Time

Figure 23-186. MPU Service Time Upon Transmit DMA Event (AXEVT)



23.8.4.10.1.2 Receive Data Ready

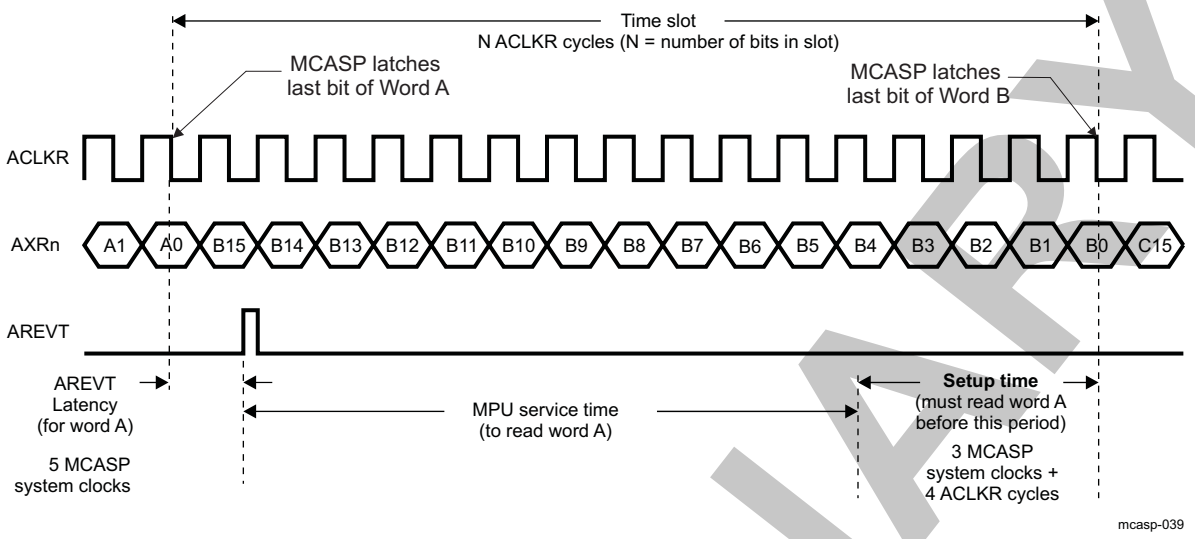
Similarly, the receive data ready flag - RDATA in the MCASP_RXSTAT register reflects the data ready status of XRBUFn buffers (where n=0 to 3 for the device) for all of the **active slot receiving serializers**. The RDATA flag is set whenever data is transferred from a receiving serializer shift register XRSRn to its corresponding XRBUFn data buffer. Thus, the RDATA bit indicates the global event that some of the receivers data buffer - RXBUFn already contains received data (i.e. a buffer is full) and is ready to transfer it to the host (MPU / DSP). The receive data ready event is individually indicated per serializer in its corresponding control register MCASP_XRSRCTLn [5] RRDY status bit. When this bit is set to 0b1, it notifies to host that this serializer Rx buffer must be serviced (read). When MCASP_RXBUFn is read from the host, the MCASP_XRSRCTLn [5] RRDY is deasserted to 0b0. As RDATA global flag is an OR-event of all active serializers RRDY flags, it indicates to software the moment, when read service operation has to be initiated by the MCASP host (RDATA=0b1). The RRDY flags have to be sequentially scanned by user software to determine which serializer MCASP_RXBUFn register has to be currently read. Once all requested MCASP_RXBUFn are read, the serializers control RRDY flags are cleared to 0b0. As a consequence, RDATA flag is deasserted to 0b0, to indicate to SW that read operation is completed for all serializers.

The global RDATA flag can be cleared when the MCASP_RXSTAT[5] RDATA bit is written to 0b1, or once MCASP_RXBUFn registers of all the serializers, that have previously raised their RRDY flags, are read by the host.

Figure 23-187 shows the timing details of when AREVT event is generated at the MCASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the MCASP sets the RDATA flag and generates an AREVT event. However, it takes up to five MCASP system clocks (AREVT Latency) before AREVT is active at the MCASP boundary. Upon AREVT, the DSP / MPU can begin servicing the MCASP by reading Word A from the MCASP_RXBUFn (service time). The DSP / MPU must read Word A from the MCASP_RXBUFn register no later than the setup time required by the MCASP (Setup Time).

The maximum service time (see Figure 23-187) can be calculated as:
Service Time = Time Slot - AREVT Latency - Setup Time

Figure 23-187. MPU Service Time Upon Receive Event (AREVT)



23.8.4.10.1.3 Transfers Through the Data Port (DATA)

CAUTION

To perform internal transfers through the DATA port, clear the XBUSEL / RBUSEL bit to 0b0 in the MCASP_TXFMT / MCASP_RXFMT register, respectively. Failure to do so may result in software malfunction.

In a typical MCASP transfer scenario, the DMA_SYSTEM or DMA_DSP write accesses the XRBUFn transmit buffer (where n= 0 to 3) through the MCASP data port (DATA) on L3_MAIN. MPU and DSP hosts can access both XRBUFn transmit and receive data buffers on their corresponding DATA port address for MPU / DSP private access or via DATA port corresponding address on L3_MAIN. To perform transfers through the DATA port, simply have the DMA_SYSTEM / DMA_DSP write the MCASP Tx buffer through L3_MAIN DATA port location. The MPU / DSP write or read access corresponding Tx / Rx buffer through L3_MAIN or MPU / DSP private access DATA port location, as specified in the Table 23-690.

NOTE: DMA_SYSTEM and DMA_DSP can be used to serve only **transmit (Tx) channel data transfers** through DATA port on L3_MAIN. This is because MCASP AREVT event is NOT linked to DMA_SYSTEM / DMA_DSP in the device.

For accesses through the DATA port, the DMAs / MPU or DSP service all the serializers through accessing only a single address. In addition, as can be seen in Table 23-690, **the same physical DATA port address is used regardless of a read or write access is performed** by device MPU / DSP. The MCASP automatically cycles through the **active slot** transmitting / receiving serializers, internally generating the appropriate offsets.

NOTE: DATA port allows the DMAs / MPU or DSP to automatically access only the data buffers. There is no way for DMAs / MPU or DSP to access the MCASP configuration registers addressing their corresponding MCASP DATA port.

For transmit operations through the DATA port, **the host must always write to the same transmit buffer DATA port address** (which is same than the receive buffer DATA port adress) to service all of the active slot transmitting serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the DMAs (DMA_SYSTEM or DMA_DSP) / MPU or DSP destination address to match the **DATA port location of XRBUFn buffer**.

In addition, the DMAs / MPU or DSP must write the buffers of all transmitting serializers in incremental (although not necessarily consecutive) order. For example, if only serializers 1 and 3 are set up as active transmitters, the DMAs / MPU or DSP should write to the same transmit buffer DATA port address twice - first data for serializer 1 and second data for serializer 3 upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

NOTE: For write transfers through MCASP DATA port it is preferable to use DMA_SYSTEM / DMA_DSP on L3_MAIN. This is because DMAs initiated traffic gets better advantage of the burst transfers supported by DATA port.

For receive operations through the DATA port, **the MPU or DSP must always read from the same receive buffer DATA port address** (which is same than the transmit buffer DATA port adress) to service all of the active slot receiving serializers. Regardless of MCASP serializer 0 being configured inactive or active, the user software must always configure the MPU or DSP source address to match the **DATA port location of XRBUFn buffer**.

In addition, reads from the receive buffer for all active slot receiving serializers through the Rx DATA port return data in incremental (although not necessarily consecutive) order. For example, if serializers 0, 1 and 3 are set up as active receivers, the MPU or DSP should read from the same receive buffer DATA port address three times to obtain data for serializers 0,1 and 3 in this exact order, upon each receive data ready event.

NOTE: To service a serializer for a transmit or receive operation through the MCASP DATA port, the initiator always writes (preferably DMA_SYSTEM and DMA_DSP) and reads (MPU and DSP only) from the same address (refer to Table 23-690), respectively.

See Section 23.8.6.2.3, *MCASP_DATA Register Summary*, for more details about XRBUFn buffer physical address corresponding to the MCASP DATA port on:

- L3_MAIN.
- DSP private access bus.
- MPU private access bus.

NOTE: When transmitting through the DATA port, the DMAs / MPU or DSP must write data (at the same address) to each serializer configured as **active** (active slot selected in MCASP_TXTDM) and **transmit** (Tx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do so results in a buffer underrun condition (see Section 23.8.4.15.1, *Buffer Underrun Error - Transmitter*). Similarly, when MPU / DSP receives, data must be read from each serializer configured as **active** (active slot selected in MCASP_RXTDM) and **receive** (Rx enabled in MCASP_XRSRCTLn) within each time slot. Failure to do results in a buffer overrun condition (see Section 23.8.4.15.2 , *Buffer Overrun Error - Receiver*).

23.8.4.10.1.4 Transfers Through the Configuration Bus (CFG)

CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL / RBUSEL bit to 1 in the MCASP_TXFMT / MCASP_RXFMT registers, respectively. Failure to do so may result in software malfunction.

In this method, the DMAs / MPU or DSP accesses the XRBUFn transmit or receive buffer (only DSP and MPU) through corresponding configuration bus (CFG) address.

The exact XRBUFn transmit / receive buffer physical address for any particular serializer is determined by adding the transmit / receive buffer alias register offset for that particular serializer to the base address of MCASP CFG port actual for L3_MAIN accesses or device MPU / DSP private accesses. The XRBUF buffer of the n-th serializer (n=0 to 3) configured as a transmitter is aliased - MCASP_TXBUFn in the CFG port address space. For example, the XRBUF2 transmit buffer is mapped as the MCASP_TXBUF2 register. Similarly, the XRBUF buffer of the n-th serializer (n=0 to 3) configured as a receiver is aliased - MCASP_RXBUFn in the CFG port address space. For example , the XRBUF3 receive buffer is mapped as the MCASP_RXBUF3 register.

Accessing the XRBUF through the DATA port (see Section 23.8.4.10.1.3) is different than CFG port accesses because the DATA port access demands the same physical address, regardless of transfer direction or current channel index , while accessing through the peripheral configuration port - CFG, the DMA, MPU or DSP must provide the exact MCASP_TXBUFn or MCASP_RXBUFn (MPU and DSP only) address upon accessing n-th serializer TX or RX buffer, respectively. For more details about MCASP_TXBUFn and MCASP_RXBUFn (where n=0 to 3) addresses corresponding to MCASP CFG port, see Section 23.8.6.2.1, *MCASP_CFG Register Summary*.

23.8.4.10.1.5 Using the MPU or DSP for MCASP Servicing

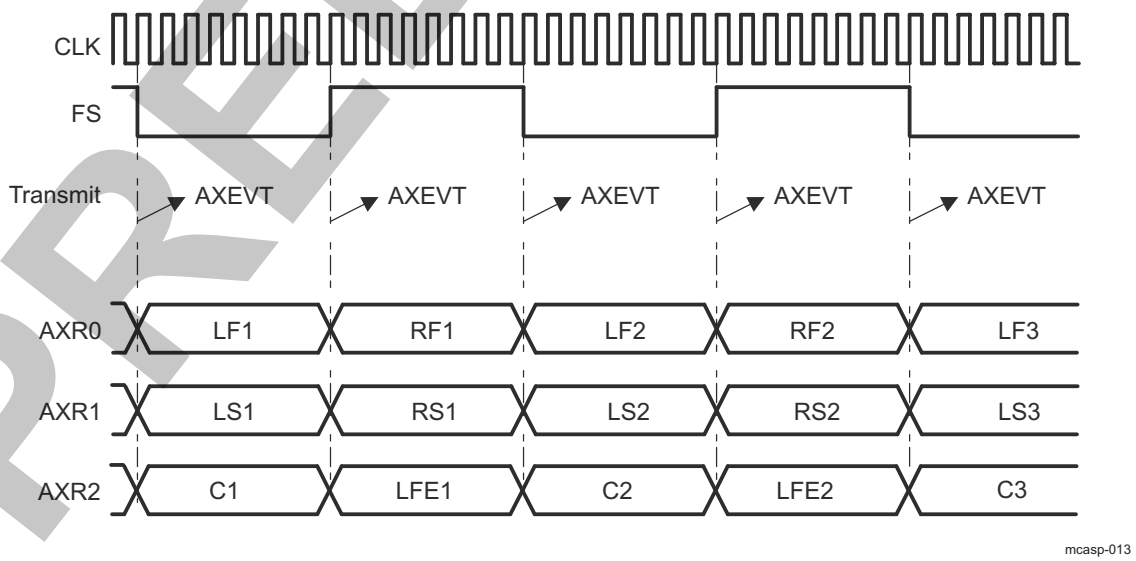
The MPU or DSP can be used to service the MCASP transmit channels through interrupts (upon MCASP_IRQ_AXEVT interrupt). Another way to service the transmit and receive channels, a polling of the XDATA bit in the MCASP_TXSTAT register and RDATA bit in the MCASP_RXSTAT register can be performed by device CPUs, respectively. As discussed in Section 23.8.4.10.1.3, *Transfers Through the Data Port (DATA)*, and Section 23.8.4.10.1.4, *Transfers Through the Configuration Bus (CFG)* , the MPU and DSP can access MCASP XRBUF serializer buffer through their corresponding DATA and CFG port locations.

To use the MPU or DSP to service the MCASP transmitter through interrupts, the XSTAT bit must be enabled in the MCASP_EVTCTLX register, to generate the MCASP_IRQ_AXEVT interrupt to the MPU / DSP subsystem interrupt controllers upon data ready.

23.8.4.10.1.6 Using the DMA for MCASP Servicing

The typical scenario is to use the DMA_SYSTEM / DMA_DSP to service the MCASP transmit logic through the DATA port, although the DMA can also service the MCASP transmit logic through the configuration bus (CFG). DMA_SYSTEM and DMA_DSP can NOT be used to service MCASP receive logic, and the device CPUs (device MPU / DSP) must directly read back MCASP_RXSTAT[5] RDATA flag and MCASP_XRSRCTLn[5] RRDY, to appropriately service the AREVT events.

Figure 23-188. DMA Transmit Event in an Audio Example – One Event



The DMA event - AXEVT (MCASP_DREQ_AXEVT output), which is triggered upon each XDATA transition from 0 to 1, is used to service the MCASP XRBUFn transmit buffers.

Figure 23-188 is an example of an audio system with six audio channels (LF, RF, LS, RS, C and LFE) transmitted through the MCASP signals - AXR0 (device signal - abemcasp_axr), AXR1 (device signal - abemcasp_axr1) and AXR2 (device signal - abemcasp_axr2). It shows the points at which event AXEVT is triggered.

In Figure 23-188, a Tx DMA event AXEVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Transmit DMA events are generated automatically upon transmit data ready, **provided that DMA TX requests generation is enabled in the MCASP_TXEVTCTL register.**

23.8.4.11 Events and Interrupt Requests

Table 23-577 lists all the event flags. Only the transmit events are capable to generate MCASP module interrupts in the device. Source of each of these TX / RX events can be a TX / RX channel from MCASP serializer 0 through serializer 3.

Table 23-577. TX Events[1]

Event Mask	Event Flag	Map to	Description
MCASP_EVTCTLX[0] XUNDRN	MCASP_TXSTAT[0] XUNDRN	MCASP_IRQ_AXEVT	Transmit buffer underrun
MCASP_EVTCTLX[1] XSYNCERR	MCASP_TXSTAT[1] XSYNCERR	MCASP_IRQ_AXEVT	Unexpected transmit frame sync
MCASP_EVTCTLX[2] XCKFAIL	MCASP_TXSTAT[2] XCKFAIL	MCASP_IRQ_AXEVT	Transmit clock failure
MCASP_EVTCTLX[3] XDMAERR	MCASP_TXSTAT[7] XDMAERR	MCASP_IRQ_AXEVT	DATA port transmit error
MCASP_EVTCTLX[4] XLAST	MCASP_TXSTAT[4] XLAST	MCASP_IRQ_AXEVT	Transmit last slot interrupt
MCASP_EVTCTLX[5] XDATA	MCASP_TXSTAT[5] XDATA	MCASP_IRQ_AXEVT	Transmit data-ready interrupt
MCASP_EVTCTLX[7] XSTAFRM	MCASP_TXSTAT[6] XSTAFRM	MCASP_IRQ_AXEVT	Transmit start of frame interrupt
n.a.	MCASP_TXSTAT[8] XERR	n.a.	OR-event of all Tx-error events: (XDMAERR | XCKFAIL | XUNDRN | XSYNCERR). It is cleared ONLY when all error flags are cleared
n.a.	MCASP_TXSTAT[3] XTDMSLOT	n.a.	Qualifies the current TDM slot as an odd or an even slot.

(1) Global events for all transmitting serializers n (where n=0 to 3 in the device).

Table 23-578. RX Events[1]

Event Flag[2]	Description
MCASP_RXSTAT[0] ROVRN	Receive buffer overrun
MCASP_RXSTAT[1] RSYNCERR	Unexpected receive frame sync
MCASP_RXSTAT[2] RCKFAIL	Receive clock failure
MCASP_RXSTAT[7] RDMAERR	DATA port receive error
MCASP_RXSTAT[4] RLAST	Receive last slot
MCASP_RXSTAT[5] RDATA	Receive data-ready
MCASP_RXSTAT[6] RSTAFRM	Receive start of frame
MCASP_RXSTAT[8] RERR	OR-event of all Rx-error events: (RDMAERR | RCKFAIL | ROVRN | RSYNCERR). RERR event is cleared once all error flags are cleared.
MCASP_RXSTAT[3] RTDMSLOT	Qualifies the current TDM slot as an odd or an even slot.

(1) Global events for all receiving serializers n (where n=0 to 3 in the device).
(2) The MCASP receive logic events are not mapped to a MPU / DSP INTC interrupt line.

Software has to read the MCASP_TXSTAT / MCASP_RXSTAT register to determine which event occurs at a global level for MCASP Tx / Rx logic. In addition user software has to scan the XRDY / RRDY read-only flags in the MCASP_XRSRCTLn (where n= 0 to 3 in the device) registers to determine which active serializer is the actual source of the event.

A Tx interrupt line (MCASP_IRQ_AXEVT) is asserted (active high) when one of the MCASP_TXSTAT notified events occurs, provided that it is enabled in its corresponding MCASP_EVTCTLX bit. See also Section 23.8.4.11.4, *Multiple Interrupts* and the Section 23.8.4.10.1, *Data Ready Status and Event / Interrupt Generation*.

NOTE: At device level, there is no interrupt line to MPU_INTC and INTC_DSP associated with the MCASP AREVT event.

23.8.4.11.1 Transmit Data Ready Event and Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the MCASP_TXSTAT register and XDATA is enabled in MCASP_EVTCTLX. The Section 23.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the MCASP_TXSTAT register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior than the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

23.8.4.11.2 Receive Data Ready Event

The Section 23.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when RDATA flag is set in the MCASP_RXSTAT register.

A receiver start of frame (RSTAFRM) event is triggered by the recognition of a receiver frame sync.

A receiver last slot (RLAST) event is a qualified version of the data ready (RDATA) event. It has the same behavior as the data ready event, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

23.8.4.11.3 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register (MCASP_TXSTAT) :

- Transmit underrun (XUNDRN)
- Unexpected transmit frame sync (XSYNCERR)
- Transmit clock failure (XCKFAIL)
- Transmit DATA port error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register (MCASP_EVTCTLX). If the enable bit is set, an interrupt is requested when the interrupt flag is set in MCASP_TXSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

In the receive status register (MCASP_RXSTAT) :

- Receiver overrun (ROVRN)
- Unexpected receive frame sync (RSYNCERR)
- Receive clock failure (RCKFAIL)
- Receive DATA port error (RDMAERR)

Because the MCASP receive error flags do NOT source interrupts in the device, these flags have to be explicitly polled by the CPUs (MPU / DSP) in the MCASP_RXSTAT register.

23.8.4.11.4 Multiple Interrupts

This only applies to Tx interrupts and not to Tx DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in MCASP_TXSTAT is set and the interrupt is enabled in MCASP_EVTCTLX.
- **Outstanding Interrupt Request:**An interrupt request has been issued on one of the MCASP transmit interrupt port, but that request has not yet been serviced.
- **Serviced:** The CPUs write to MCASP_TXSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in MCASP_TXSTAT and the interrupt enabled in MCASP_EVTCTLX generates a request on the MCASP transmit interrupt port - AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the MCASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the MCASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to MCASP_TXSTAT. If any interrupt requests are active after the write, a new request is generated on the MCASP transmit interrupt port.

One outstanding interrupt request is allowed on Tx interrupt port.

23.8.4.12 DMA Requests

The MCASP can generate one DMA request to the DMA_SYSTEM and DMA_DSP controllers to transmit data (MCASP_DREQ_AXEVT). A DMA request to transmit data is generated if the XDATDMA bit in the MCASP_TXEVTCTL register is cleared.

NOTE: The MCASP receive logic AREVT event does NOT have associated DMA request line to the device DMA_SYSTEM and DMA_DSP.

23.8.4.13 Audio Mute (AMUTE) Function

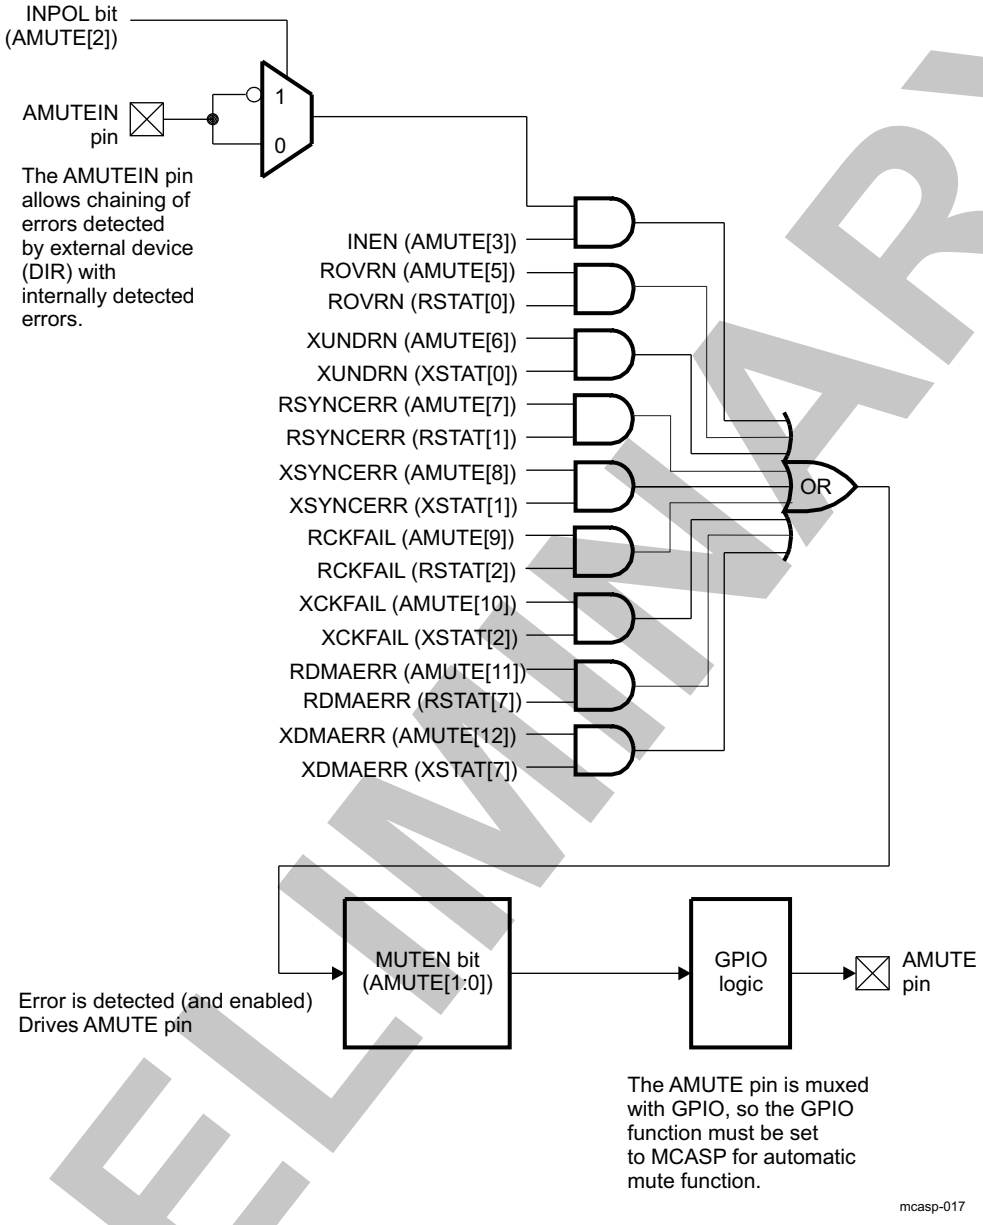
The MCASP includes an automatic audio mute function (see Figure 23-189) that asserts, in hardware, the AMUTE pin (signal named "abemcasp_amuteout" at device level) to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (MCASP_AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the MCASP input pin AMUTEIN (signal named "abemcasp_amutein" at device level). Typically, the AMUTEIN input is shared with a device interrupt pin.

The device level abemcasp_amutein input signal (MCASP pin AMUTEIN) allows the on-chip logic to consider a mute input from other devices in the system so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in the MCASP_AMUTE register, and it must be explicitly enabled.

In addition to the external abemcasp_amutein input, the device abemcasp_amuteout output signal (MCASP pin AMUTE) may be asserted when one of the error interrupt flags is set and its mute function is enabled in the MCASP_AMUTE register.

When one or more errors are detected and enabled, the abemcasp_amuteout signal is driven to an active state that is selected by MUTEN in the MCASP_AMUTE register. The active polarity of the MCASP AMUTE output is programmable by the MUTEN bit (the inactive polarity is the opposite of the active polarity). The AMUTE pin output remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the MCASP AMUTEIN input is inactive.

Figure 23-189. Audio Mute (AMUTE) Block Diagram

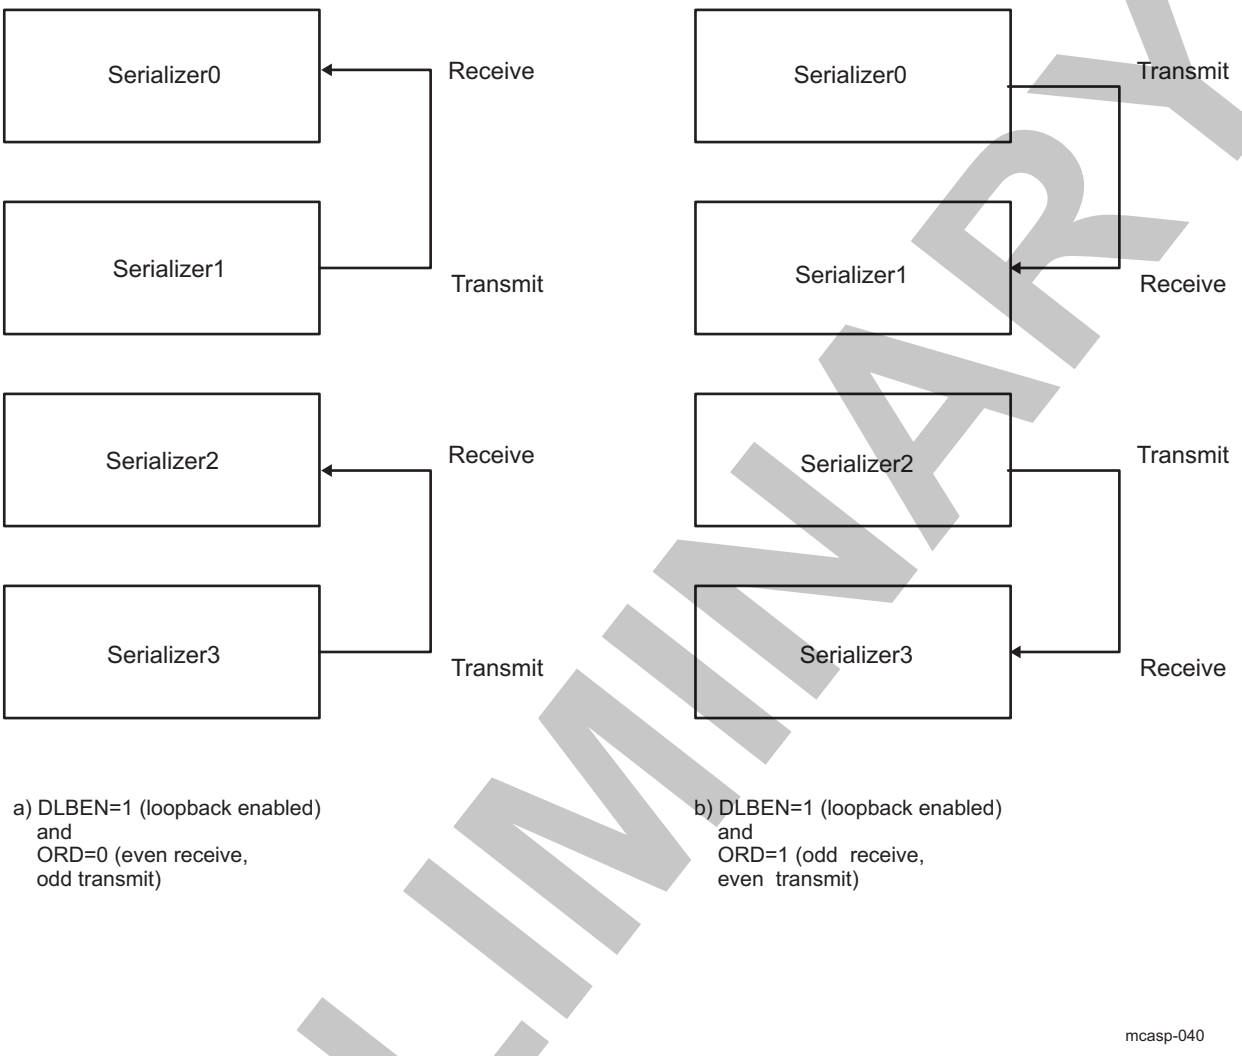


23.8.4.14 Loopback Modes

The MCASP features a digital loopback mode (DLB) that allows loopback test transfers in TDM mode between MCASP transmitters and receivers within the same device. In loopback mode, the output of a transmit serializer is connected internally to the input of a receive serializer. Therefore, a receiver data can be checked against a transmitter data to ensure that the MCASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 0x180).

Figure 23-190shows the basic logical connection of the serializers in loopback mode.

Figure 23-190. MCASP Serializers Operation in Loopback Mode



Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register - MCASP_LBCTL as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, the odd serializers must be configured as transmitters and even serializers as receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, the even serializers must be configured as transmitters and odd serializers as receivers.

User can choose in software (bit IOLBEN of the MCASP_LBCTL) between a MCASP module internal loopback and a device I/O level loopback.

When a **MCASP internal loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b0), it is NOT necessary to configure MCASP_PFUNC and MCASP_PDIR registers for MCASP pin settings. Nevertheless, data can be optionally made externally visible at the I/O pin of the transmit serializer, if the pin is configured as a MCASP output pin by setting the corresponding MCASP_PFUNC bit to 0 (i.e. to function as MCASP, not GPIO) and MCASP_PDIR bit to 1 (output).

When a **device I/O level loopback** is selected (MCASP_LBCTL[4] IOLBEN=0b1), the MCASP_PFUNC and MCASP_PDIR registers must be configured with the appropriate settings for AXR0 through AXR3 pins, according to ORD bit configuration.

In case of device I/O loopback, the connectivity is externally applied between device pads (i.e. reaching device I/O buffers) corresponding to :

- abemcasp_axr

- abemcasp_axr1 - abemcasp_axr3

Hence, the corresponding padconfiguration registers must be appropriately configured in the device Control Module - CTRL_MODULE_CORE_PAD. For more details, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in *Chapter 18, Control Module*.

When In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the MCASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bitfield of the MCASP_LBCTL register to 0x1 and the ASYNC bit of the MCASP_ACLKXCTL register to 0b0.

23.8.4.14.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format :

- The bit - MCASP_LBCTL[0] DLBEN must be set to 0b1 to enable a loopback mode. It must be kept at 0b0 during normal MCASP operation.
- The MCASP_LBCTL[4] IOLBEN bit must be set to select between internal (MCASP local) loopback mode or device I/O level loopback mode.
- The MCASP_LBCTL[3:2] MODE bitfield must be set to 0x1 for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The MCASP_LBCTL[1] ORD must be programmed appropriately to select odd or even serializers to be transmitters or receivers.
- The corresponding serializers must be configured accordingly.
- The bit - MCASP_ACLKXCTL[6] ASYNC must be cleared to 0b0 to ensure synchronous transmit and receive operations.
- The bitfields - MCASP_RXFMCTL[15:7] RMOD and MCASP_TXFMCTL[15:7] XMOD must be set within range (0x2- 0x20) to indicate TDM mode.

NOTE: Loopback mode does not apply to DIT mode, because MCASP receivers do NOT natively support DIR - reception.

23.8.4.15 Error Reporting

The MCASP includes error-checking capability for the serial protocol and data underrun. In addition, the MCASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX / AHCLKR clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected or the AMUTEIN input pin is asserted, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt can be generated if desired, based on one or more error sources.

23.8.4.15.1 Buffer Underrun Error -Transmitter

A buffer underrun occurs when a serializer (n=0 to 3) is instructed by the transmit state-machine to transfer data from XRBUFn buffer to XRSRn shift register, but the corresponding (MCASP_TXBUFn) register has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The MCASP_TXSTAT[0] XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

A pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the MCASP and restart with the proper initialization.

23.8.4.15.2 Buffer Overrun Error-Receiver

A buffer overrun occurs when a serializer (n=0 to 3) is instructed to transfer data from XRSRn shift register to XRBUFn receiver buffer, but the corresponding MCASP_RXBUFn register has not yet been read since the last time the transfer occured. When this occurs, the receiver state machine sets the overrun flag - ROVRN. However, the individual serializer writes over the data in the XRBUFn buffer register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The MCASP_RXSTAT[0] ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the host catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the host - DSP / MPU explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

23.8.4.15.3 DATA Port Error - Transmitter

A transmit DATA port error, as indicated by the XDMAERR flag in the MCASP_TXSTAT register, occurs when the DMA,MPU or DSP writes more words to the DATA port of the MCASP than it should.

The MCASP_TXSTAT[7] XDMAERR=0b1 indicates that the DMA , MPU or DSP wrote too many words to the MCASP DATA port for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in MCASP_TXSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the DMA, MPU or DSP. The MCASP transmitter and the DMA must be reinitialized to resynchronize them.

23.8.4.15.4 DATA Port Error - Receiver

A receive DATA port error, as indicated by the RDMAERR flag in the MCASP_RXSTAT register, occurs when the MPU or DSP reads more words from the DATA port of the MCASP than it should.

The MCASP_RXSTAT[7] RDMAERR indicates that the MPU or DSP read too many words from the MCASP DATA port for a given receive AREVT event. Reading too few words results in a receiver overrun error setting ROVRN in MCASP_RXSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the MCASP and the MPU / DSP.

23.8.4.15.5 Unexpected Frame Sync Error

An unexpected frame sync occurs when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.

An unexpected frame sync occurs also if the frame sync does NOT occur exactly during the correct bit clock (not a cycle earlier or later) and before slot 0.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. **Early:** An early unexpected frame sync occurs when the MCASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
1. **Late:** A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error event flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

23.8.4.15.6 Clock Failure Detection

23.8.4.15.6.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (MCASP_TXCLKCHK).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (MCASP_TXSTAT).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
   (a) The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (MCASP_EVTCTLX)
   (b) The mute option (XCKFAIL) in the mute control register (MCASP_AMUTE)

To start the receive clock failure check procedure:

1. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (MCASP_RXCLKCHK).
2. Clear receive clock failure flag (RCKFAIL) in the receive status register (MCASP_RXSTAT).
3. Wait until first measurement is taken (> 32 AHCLKR clock periods).
4. Verify no clock failure is detected.
5. Repeat steps 2–4 until clock is running and is no longer issuing clock failure errors.
6. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
   (a) mute option (RCKFAIL) in the mute control register (MCASP_AMUTE)

23.8.4.15.6.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see Figure 23-191) works off the internal MCASP system clock and the external high-frequency serial clock (abemcasp_ahclkx). It continually counts the number of system clocks for every 32 high-rate serial clock (abemcasp_ahclkx) periods, and stores the count in XCNT of the transmit clock check control register (MCASP_TXCLKCHK) every 32 high-rate serial clock cycles.

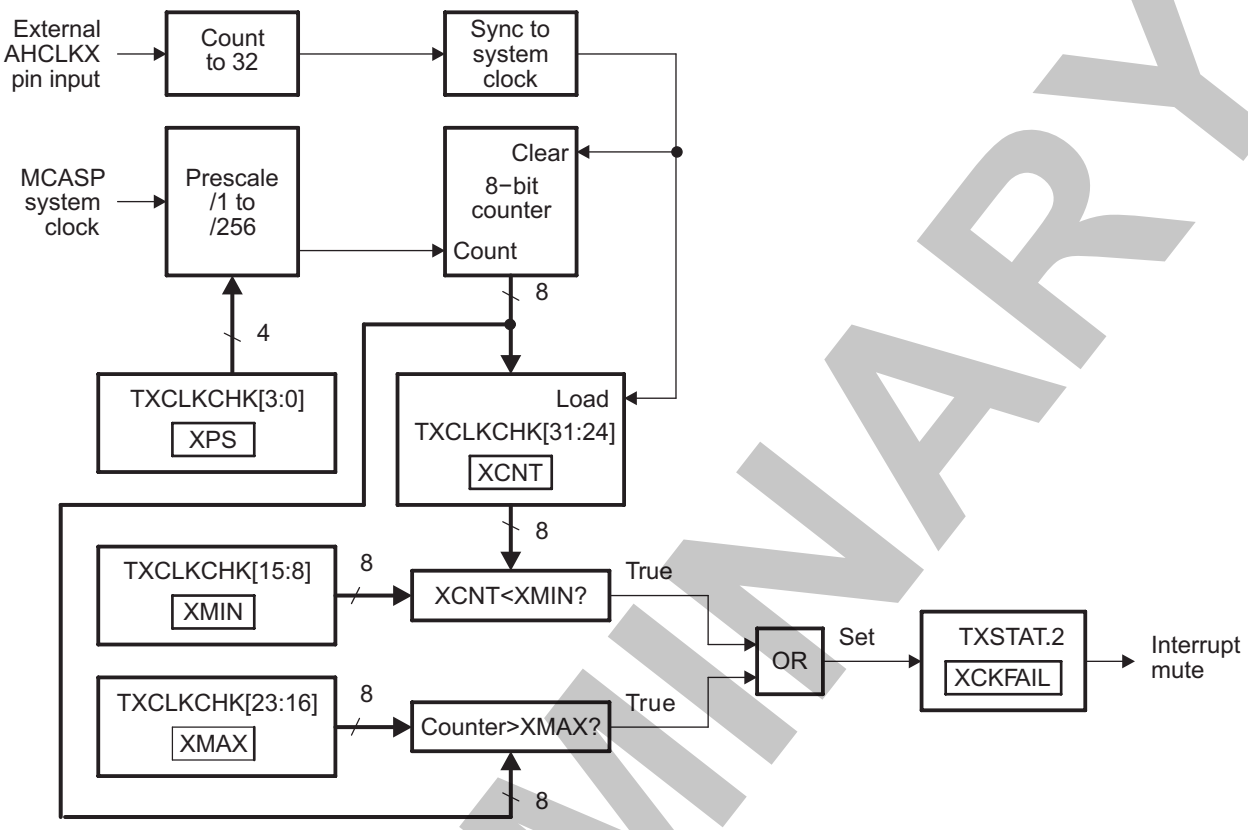
The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in MCASP_TXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running system clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in MCASP_TXSTAT is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in MCASP_EVTCTLX is set.

Figure 23-191. Transmit Clock Failure Detection Circuit Block Diagram



23.8.4.15.6.3 Receive Clock Failure Check and Recovery

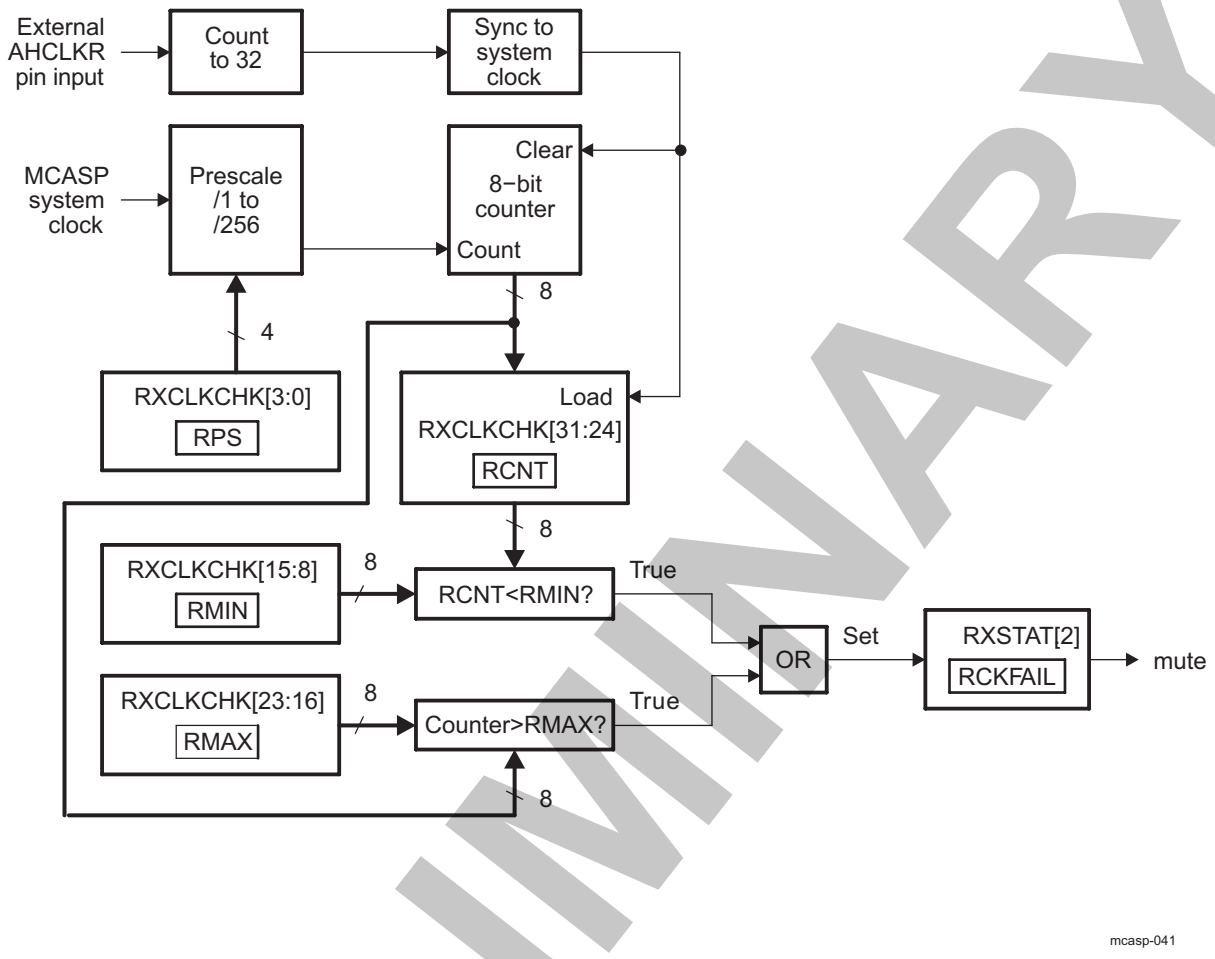
The receive clock failure check circuit (see Figure 23-192) works off both the internal MCASP system clock and the external high-frequency serial clock (AHCLKR) coming from the device abemcasp_ahclkr input. It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (MCASP_RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an event (RCKFAIL in MCASP_RXSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR signal is internally generated or externally sourced.

Figure 23-192. Receive Clock Failure Detection Circuit Block Diagram



23.8.5 MCASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the MCASP module.

23.8.5.1 Global Initialization

23.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the MCASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MCASP (for more information, see Section 23.8.3, *MCASP Integration*, and Section 23.8.2, *MCASP Environment*).

Table 23-579, describes the global initialization of surrounding modules.

Table 23-579. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*).
(Optional) INTC_MPU or INTC_DSP	Interrupt controllers (INTC_MPU and INTC_DSP) configuration must be done to enable the interrupts from the MCASP. (For more details on MPU interrupt controller requests, see Section 17.3.2, *Interrupt Requests to INTC_MPU* in Chapter 17, *Interrupt Controllers*. For more information on the DSP interrupt controller requests, see Section 5.3.2.6, *DSP INTC*, in Chapter 5, *DSP Subsystem*).
(Optional) DMA_SYSTEM or DMA_DSP	DMA configuration must be done to enable the MCASP DMA data channel requests. For more information on DMA_SYSTEM and DMA_DSP configuration, see Section 16.5, *DMA_SYSTEM Basic Programming Model,* in Chapter 16, *System DMA* and Section 5.2, *DSP Subsystem Integration*, in Chapter 5, *DSP Subsystem* .
(Optional) L4_ABE and L3_MAIN Interconnects	For more information about the interconnect configuration, see Section 14.2.1, *L3_MAIN Interconnect Overview* in Chapter 14, *Interconnect*.

NOTE: The INTC_MPU / INTC_DSP and the DMA_SYSTEM / DMA_DSP configurations are required when the interrupt and DMA-based communication modes are used.

23.8.5.1.2 MCASP Global Initialization

23.8.5.1.2.1 Main Sequence – MCASP Global Initialization for DIT-Transmission

The procedure in Table 23-580 initializes the MCASP serializers (0-3) transmitters to operate in DIT-mode (S/PDIF-transmission protocol) after a power-on reset (POR).

CAUTION

Before performing MCASP global initialization, If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 23-580. MCASP Transmitters Global Initialization for DIT-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP components.	MCASP_GBLCTL[12:8]	0x00

Table 23-580. MCASP Transmitters Global Initialization for DIT-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	MCASP_SYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 23.8.5.1.2.1.1.	
5. Configure the transmit frame sync generator.	See Section 23.8.5.1.2.1.2.	
6. Configure the transmit clock generator.	See Section 23.8.5.1.2.1.3.	
7. Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMS	0xFFFF FFFF
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. (1)	MCASP_XRSRCTLn [1:0] SRMOD, where n=0 to 3	0x1
9. Configure the MCASP pins functionality.	See Section 23.8.5.1.2.1.4.	
10. Configure the MCASP mute input / output conditions.	See Table 23-585.	
11. Enable the MCASP DIT - transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1 (2)
12. Configure DIT-specific subframe fields.	See Table 23-586.	
13. Release from reset state the divider that outputs the AHCLKX clock. (3)	MCASP_GBLCTL[9] XHCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
15. Release from reset state the divider that outputs the ACLKX clock. (3)	MCASP_GBLCTL[8] XCLKRST	0x1
16. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(1) For an unused serializer n (where n=0 to 3), write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.
(2) This globally configures all active transmitters to operate in DIT-mode.
(3) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKXCTL and MCASP_ACLKXCT registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

23.8.5.1.2.1.1 Subsequence – Transmit Format Unit Configuration for DIT-Transmission

The procedure in Table 23-581 configures the transmit frame format unit of the MCASP module for a DIT-transmission.

NOTE:

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

Table 23-581. Transmit Format Unit Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	MCASP_TXFMT[7:4] XSSZ	0xF
IF: the MPU, DSP or DMA data to transmit is left-aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	MCASP_TXMASK[31:0] XMASK	0x- (1)
Rotate data right by a multiple-of-4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (1)
ELSE		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	MCASP_TXMASK[31:0] XMASK	0x- (1)
Rotate data right by 0-bit positions.	MCASP_TXFMT[2:0] XROT	0x0

(1) Refer to Section 23.8.4.4.1, *Transmit Fromat Unit* and Section 23.8.4.4.1.2, *DIT-Mode Transmission Data Alignment Settings.*

Table 23-581. Transmit Format Unit Configuration for DIT-Transmission (continued)

Step	Register/Bit Field/Programming Model	Value
ENDIF		
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

23.8.5.1.2.1.2 Subsequence – Transmit Frame Synchronization Generator Configuration for DIT-Transmission

The procedure in Table 23-582 configures the transmit frame synchronization generator of the MCASP module.

NOTE: The frame synchronization signal is always rising-edge active and always has a single-bit width.

Table 23-582. Transmit Frame-Synchronization Generator Configuration for DIT-Transmission

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	MCASP_TXFMCTL[15:7] XMOD	0x180
Select internally-generated transmit frame sync.	MCASP_TXFMCTL[1] FSXM	0x1

23.8.5.1.2.1.3 Subsequence – Transmit Clock Generator Configuration for DIT-Transmission

NOTE: By default, the ACLKX and AHCLKX clocks are generated only from the MCASP internal clock source.

The procedure in Table 23-583 configures the transmit clock generator of the MCASP module.

Table 23-583. Transmit Clock Generator Configuration in DIT-Mode

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– AHCLKX.	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Set he divisor for the internally generated transmission clock– ACLKX.	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See Section 23.8.4.15.6.1, *Clock Failure Check Startup*.	

23.8.5.1.2.1.4 Subsequence—MCASP Pins Functional Configuration

The procedure in Table 23-584 configures the MCASP pins for MCASP functionality.

Table 23-584. MCASP Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the MCASP pins as outputs: AFSX (device level: abemcasp_afsx) AHCLKX (device level: abemcasp_ahclkx) ACLKX (device level: abemcasp_aclkx) AMUTE (device level: abemcasp_amuteout) Desired i-th MCASP data pin AXRi (i=0 to 3) (device level: abemcasp_axr - abemcasp_axr3) is configured as an output for DIT-transmission.	MCASP_PDIR[28] AFSX; MCASP_PDIR[27] AHCLKX; MCASP_PDIR[26] ACLKX; MCASP_PDIR[25] AMUTE; MCASP_PDIR [i] AXRi , where i=0 to 3	0x1 0x1 0x1 0x1 0x1

23.8.5.1.2.1.5 Subsequence – MCASP Mute Input/Output Trigger Condition Settings

The procedure in Table 23-585 configures the behavior of the mute associated I/Os and different trigger conditions for the MCASP mute output functionality.

Table 23-585. MCASP Mute Input/Output Trigger Condition Settings

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on transmit DATA port error.	MCASP_AMUTE[12] XDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit clock failure.	MCASP_AMUTE[10] XCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error.	MCASP_AMUTE[8] XSYNCERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit underrun error.	MCASP_AMUTE[6] XUNDRN	0x1
Optional: Enable sensitivity of the abemcasp_amuteout output to abemcasp_amutein error source.	MCASP_AMUTE[3] INEN	0x1
Optional: Select the abemcasp_amutein input polarity.	MCASP_AMUTE[2] INPOL	0x1
Optional: Configure the behavior of the abemcasp_amuteout output.	MCASP_AMUTE[1:0] MUTEN	0x1

23.8.5.1.2.1.6 Subsequence – DIT-specific Subframe Fields Configuration

The procedure in Table 23-586 configures the DIT-specific subframe fields as part of the S/PDIF format data.

Table 23-586. DIT-Specific Subframe Fields Configuration

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5 MCASP_DITUDRBi[31:0] DITUDRBi, where i= 0 to 5	0x- 0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0] , where i = 0 to 5 MCASP_DITCSRBi[31:0] , where i = 0 to 5	0x- 0x-

23.8.5.1.2.2 Main Sequence – MCASP Global Initialization for TDM-Reception

The procedure in Table 23-587 initializes a MCASP serializer n (where n=0 to 3) receiver(s) to operate in TDM-mode (the only mode supported by MCASP receivers) after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols reception.

CAUTION

Before performing MCASP global initialization, If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the MCASP_GBLCTL register.

NOTE: The MCASP receivers support only TDM-frames (including 384-TDM frames) reception. DIT-frames reception (i.e. S/PDIF stream) can be implemented indirectly via an external DIR-chip converter with DIT-input and TDM (I2S)-compatible output connected to device MCASP receiver input (TDM-only compatible).

Table 23-587. MCASP Receivers Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP receive components.	MCASP_GBLCTL[4:0]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[4:0]	=0x00
3. Configure the local power management.	MCASP_SYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the receive format unit.	See Section 23.8.5.1.2.2.1.	
5. Configure the receive frame sync generator.	See Section 23.8.5.1.2.2.2.	
6. Configure the receive clock generator.	See Section 23.8.5.1.2.2.3.	
7. Program all bits -RTDMSk (where k=0 to 31) according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_RXTDM [k] RTDMSk , where k=0 to 31	0x-
8. Configure the desired n-th serializer (n=0 to 3) for receive mode operation. (1)	MCASP_XRSRCTLn [1:0] SRMOD , where n = 0 to 3	0x2
9. Configure the MCASP pins functionality.	See Section 23.8.5.1.2.2.4.	
10. Configure the MCASP mute input/output conditions.	See Table 23-592.	
11. Optional : Configure a MCASP Rx channel for a loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 23.8.4.14.1, *Loopback Mode Configurations*.	0x-(2)
12. Release from reset state the divider that outputs the AHCLKR clock.(3) See also (4).	MCASP_GBLCTL[1] RHCLKRST	0x1
13. Poll the bit to ensure that it is successfully latched in the register. See also (4).	MCASP_GBLCTL[1] RHCLKRST	=0x1
14. Release from reset state the divider that outputs the ACLKR clock. (3) See also (5).	MCASP_GBLCTL[0] RCLKRST	0x1
15. Poll the bit to ensure that it is successfully latched in the register. See also (5).	MCASP_GBLCTL[0] RCLKRST	=0x1

(1) For an unused serializer n (where n=0 to 3), write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

(2) In this case the receiver clock and frame sync are derived from the MCASP transmitter logic, so MCASP_ACLKXCTL[6] ASYNC must be set to 0b0. Neither MCASP internal receiver clock and frame sync generators, nor external clock and frame sync source are used.

(3) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKRCTL and MCASP_ACLKRCTL registers are ignored; hence, the reception clock does not stop during the reset state of the dividers.

(4) This step is necessary even if external high-frequency serial clocks are used.

(5) This step can be skipped if external serial clocks are used and they are running.

23.8.5.1.2.2.1 Subsequence – Receive Format Unit Configuration in TDM Mode

The procedure in Table 23-588 configures the receive frame format unit of the MCASP module for TDM slots reception.

Table 23-588. Receive Format Unit Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_RXFMT[7:4] RSSZ	0x-(1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_RXMASK[31:0] RMASK	0x-(2)
Select a padding value for masked-out bits.	MCASP_RXFMT[14:13] RPAD	0x-

(1) Refer to Section 23.8.4.4.2, *Receive Format Unit*, regarding options for received TDM-slot sizes.

(2) For more details on Rx masking value, refer to Section 23.8.4.4.2.1, *TDM - Mode Reception Data Alignment Settings*

Table 23-588. Receive Format Unit Configuration for TDM-Reception (continued)

Step	Register/Bit Field/Programming Model	Value
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_RXBUFn which value to be used as a pad value in case MCASP_RXFMT[14:13] RPAD=0x2.	MCASP_RXFMT[12:8] RPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_RXFMT[2:0] RROT	0x- (3)
Received stream bit order (LSB- or MSB-first). **Must be set to 0x1 for an I2S stream reception (MSB-first).**	MCASP_RXFMT[15] RRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. **Must be set to 0x1 for an I2S stream reception.**	MCASP_RXFMT[17:16] RDATDLY	0x-
Select to read data from active serializers receive buffers using peripheral (CFG) or DATA port	MCASP_RXFMT[3] RBUSEL	0x-

(3) For more details on rotation and received TDM stream bit order, refer to Section 23.8.4.4.2.1, *TDM - Mode Reception Data Alignment Settings* and Table 23-574, *MCASP RFU Settings*.

23.8.5.1.2.2.2 Subsequence – Receive Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 23-589 configures the transmit frame synchronization generator of the MCASP module.

NOTE: The same bit - MCASP_ACLKXCTL[6] ASYNC which is used to determine if MCASP receivers and transmitters work synchronously on the same clock, is also used to define if receiver frame sync is derived from the transmit frame sync generator, or generated independently in the receiver (either inernally or externally sourced). Hence, the settings in below table Table 23-589 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0.

Table 23-589. Receive Frame-Synchronization Generator Configuration for TDM-Reception

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame. Must be set to 0x2 , in case of an I2S-reception. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_RXFMCTL[15:7] RMOD	0x- (1)
Choose the receive frame sync width -single bit / single word. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_RXFMCTL[4] FRWID	0x-
Select start of received frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_RXFMCTL[0] FSRP	0x-
IFreceive frame sync - FS is internally generated	Software test condition	
Select internally- generated receive frame sync. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b1
If MCASP receiver is required to output internally generated frame, AFSR pin (device level: abemcasp_afsr) must be set as an output **in step 9 of the sequence documented in the** Table 23-587. This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSR pin outputting a frame to an external device.	MCASP_PDIR[31] AFSR	0b1
ELSE		

(1) Must be set to 0x180 in case of 384-TDM slot frame reception from a DIR component I2S-output. For more details on TDM-frame settings, refer to Section 23.8.4.9.1 .

Table 23-589. Receive Frame-Synchronization Generator Configuration for TDM-Reception (continued)

Step	Register/Bit Field/Programming Model	Value
Select externally- generated receive frame sync. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_RXFMCTL[1] FSRM	0b0
Setup the AFSR pin as input (device level: abemcasp_afsr)	MCASP_PDIR[31] AFSR	0b0
ENDIF		
To generate MCASP receive frame sync in receiver logic , select an asynchronous frame sync.	MCASP_ACLKXCTL[6] ASYNC	0b1

23.8.5.1.2.2.3 Subsequence – Receive Clock Generator Configuration

The procedure in Table 23-590 configures the receive clock generator of the MCASP module.

NOTE: The settings in below table Table 23-590 have no effect, if MCASP_ACLKXCTL[6] ASYNC = 0 (i.e. receive clock is sourced from the inverted version of the transmit clock). For example, such is the case when MCASP loopback mode is used.

Table 23-590. Receive Clock Generator Configuration

Step	Register/Bit Field/Programming Model	Value
To use the MCASP receive clock generator or an external clock, select an asynchronous receiver clock schema (ASYNC=1). Otherwise an inverted version of transmit clock XCLK is used (receiver synchronized with transmitter).	MCASP_ACLKXCTL[6] ASYNC	0b1
IFreceive clock - RCLK is internally generated	Software test condition	
IF high-speed receive clock - AHCLKR is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKRCTL[15] HCLKRM	0b1
Select the internal high-speed clock source polarity : non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKR in range (1 - 4096).	MCASP_AHCLKRCTL[11:0] HCLKRDIV	0x-
Optional : If MCASP receiver is required to output internally generated high-frequency clock, AHCLKR pin (device level: abemcasp_ahclkr) must be set as an output **in step 9 of the sequence documented in the** Table 23-587. This must NOT be done in current step because the clock control register - MCASP_AHCLKRCTL must be appropriately configured prior to AHCLKR pin outputting a high-speed clock to an external device.	MCASP_PDIR[30] AHCLKR	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKRDIV divider can not be used).	MCASP_AHCLKRCTL[15] HCLKRM	0b0
Select the external high-speed receive clock polarity : non-inverted or inverted.	MCASP_AHCLKRCTL[14] HCLKRP	0x-
Setup an input directon for the AHCLKR pin (device level abemcasp_ahclkr)	MCASP_PDIR[30] AHCLKR	0b0
ENDIF		
Select an internally-generated receive clock.	MCASP_ACLKRCTL[5] CLKRM	0b1
Receiver samples on rising / falling edge. **Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.**	MCASP_ACLKRCTL[7] CLKRP	0x-

Table 23-590. Receive Clock Generator Configuration (continued)

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated receive clock– ACLKR in range (1 - 32).	MCASP_ACLKRCTL[4:0] CLKRDIV	0x-
Optional: If MCASP receiver is required to output internally generated clock, ACLKR pin (device level: abemcasp_aclkr) must be set as an output **in step 9 of the sequence documented in the** Table 23-587. This must NOT be done in current step because the clock control register - MCASP_ACLKRCTL must be appropriately configured prior to ACLKR pin outputting a receive clock to an external device.	MCASP_PDIR[29] ACLKR	0b1
ELSE		
Select an externally-generated receive clock. Note that in this case the AHCLKR signal path and the CLKRDIV divider are NOT used.	MCASP_ACLKRCTL[5] CLKRM	0b0
Receiver samples on rising / falling edge. **Select Rx sampling on the rising edge if transmitter shifts out on falling edge, and vice versa.**	MCASP_ACLKRCTL[7] CLKRP	0x-
Setup an input directon for the ACLKR pin (device level abemcasp_aclkr)	MCASP_PDIR[29] ACLKR	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 23.8.4.15.6.1, *Clock Failure Check Startup*.	

23.8.5.1.2.2.4 Subsequence—MCASP Receiver Pins Functional Configuration

The procedure in Table 23-591 configures the MCASP pins for MCASP functionality.

Table 23-591. MCASP Receiver Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the MCASP pins direction : AFSR (device level: abemcasp_afsr) AHCLKR (device level: abemcasp_ahclkr) ACLKR(device level: abemcasp_aclkr) Desired i-th MCASP data pin AXRi (i=0 to 3) (device level: abemcasp_axr - abemcasp_axr3) is configured as an input for receiving.	MCASP_PDIR[31] AFSR; MCASP_PDIR[30] AHCLKR; MCASP_PDIR[29] ACLKR; MCASP_PDIR[i] AXRi;	0x-(1) 0x-(2) 0x- (2) 0x0

(1) See Table 23-589.

(2) For more details on MCASP clock configurations , refer to Table 23-590.

23.8.5.1.2.2.5 Subsequence – MCASP Receive Mute Input/Output Trigger Condition Settings

The procedure in Table 23-592 configures the behavior of the mute associated I/Os and different receive trigger conditions for the MCASP mute output functionality.

Table 23-592. MCASP Receive Mute Input/Output Trigger Condition Settings

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on receive DATA port error.	MCASP_AMUTE[11] RDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on receive clock failure.	MCASP_AMUTE[9] RCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on receive frame synchronization error.	MCASP_AMUTE[7] RSYNCERR	0x1

Table 23-592. MCASP Receive Mute Input/Output Trigger Condition Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on receive overrun error.	MCASP_AMUTE[5] ROVRN	0x1
Optional: Enable sensitivity of the abemcasp_amuteout output to abemcasp_amutein error source.	MCASP_AMUTE[3] INEN	0x1
Optional: Select the abemcasp_amutein input polarity.	MCASP_AMUTE[2] INPOL	0x1
Optional: Configure the behavior of the abemcasp_amuteout output.	MCASP_AMUTE[1:0] MUTEN	0x1

23.8.5.1.2.3 Main Sequence – MCASP Global Initialization for TDM -Transmission

The procedure in Table 23-593 initializes a MCASP serializer n (where n=0 to 3) transmitter(s) to operate in TDM-mode after a power-on reset (POR). This is used for I2S (2-slot TDM) and other TDM-based audio protocols transmission.

CAUTION

Before performing MCASP global initialization, If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the MCASP_GBLCTL register.

Table 23-593. MCASP Transmitters Global Initialization for TDM-Mode Operation

Step	Register/Bit Field/Programming Model	Value
1. Apply software reset to different MCASP transmit components.	MCASP_GBLCTL[12:8]	0x00
2. Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
3. Configure the local power management.	MCASP_SYSCONFIG[1:0] IDLE_MODE	0x1
4. Configure the transmit format unit.	See Section 23.8.5.1.2.3.1.	
5. Configure the transmit frame sync generator.	See Section 23.8.5.1.2.3.2.	
6. Configure the transmit clock generator.	See Section 23.8.5.1.2.3.3.	
7. Program all bits - XTDMSk , where k=0 to 31, according to the time slot characteristics desired (positions of active versus inactive slots within a frame).	MCASP_TXTDM [k] XTDMSk, where k=0 to 31(1)	0x-
8. Configure the desired n-th serializer (n=0 to 3) for transmit mode operation. (2)	MCASP_XRSRCTLn[1:0] SRMOD;	0x1
9. Setup all active transmitters to operate in TDM mode.	MCASP_TXDITCTL[0] DITEN	0x0(3)
10. Configure the MCASP pins functionality.	See Section 23.8.5.1.2.3.4.	
11. Configure the MCASP mute input/output conditions.	See Table 23-598.	
12. Optional : Configure a MCASP Tx channel for loopback operation (TDM mode only) in MCASP_LBCTL [31:0].	See Section 23.8.4.14.1, *Loopback Mode Configurations*.	0x-

(1) Appropriately program in bitfield MCASP_XRSRCTLn [3:2] DISMOD, the desired level (high-impedance state, 0, or 1) at AXRn (n=0 to 3) output, during time of inactive slots. Note, that this setting soes NOT apply when all slots are programmed to be active within a frame (in particular DIT-mode).

(2) For an unused serializer n (where n=0 to 3), write MCASP_XRSRCTLn [1:0] SRMOD=0x0 to disable it.

(3) All active transmit channels operate either in TDM mode or in DIT mode depending on DITEN value. There is no option to choose Tx Mode between DIT and TDM separately per serializer transmitter.

Table 23-593. MCASP Transmitters Global Initialization for TDM-Mode Operation (continued)

Step	Register/Bit Field/Programming Model	Value
13. Release from reset state the divider that outputs the AHCLKR clock. See (4)	MCASP_GBLCTL[9] XHCLKRST	0x1
14. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[9] XHCLKRST	=0x1
15. Release from reset state the divider that outputs the ACLKR clock. See (4)	MCASP_GBLCTL[8] XCLKRST	0x1
16. Poll the bit to ensure that it is successfully latched in the register.	MCASP_GBLCTL[8] XCLKRST	=0x1

(4) During reset state the local MCASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the MCASP_AHCLKX and MCASP_ ACLKX registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

23.8.5.1.2.3.1 Subsequence – Transmit Format Unit Configuration in TDM Mode

The procedure in Table 23-594 configures the transmit frame format unit of the MCASP module for TDM slots transmission.

Table 23-594. Transmit Format Unit Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Configure the desired TDM-slot size	MCASP_TXFMT[7:4] XSSZ	0x- (1)
Set data mask out value (0x0000 0000 - 0xFFFF FFFF).	MCASP_TXMASK[31:0] XMASK	0x- (2)
Select a padding value for masked-out bits.	MCASP_TXFMT[14:13] XPAD	0x-
Specify position (0x0-0x1F) of the bit in corresponding register MCASP_TXBUFn which value to be used as a pad value in case MCASP_TXFMT[14:13] XPAD=0x2.	MCASP_TXFMT[12:8] XPBIT	0x-
Rotate data right by a multiple of 4- bit positions.	MCASP_TXFMT[2:0] XROT	0x- (3)
transmitted stream bit order (LSB- or MSB-first). **Must be set to 0x1 for an I2S stream transmission (MSB-first).**	MCASP_TXFMT[15] XRVRS	0x- (3)
Specify a delay between frame sync and first bit of data in number of bits. **Must be set to 0x1 for an I2S stream transmission.**	MCASP_TXFMT[17:16] XDATDLY	0x-
Select to write data to active serializers transmit buffers using peripheral (CFG) or DATA port	MCASP_TXFMT[3] XBUSEL	0x-

(1) Refer to Section 23.8.4.4.1, *Transmit Format Unit* , regarding options for transmitted TDM-slot sizes.
(2) For more details on Tx masking value, refer to Section 23.8.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings*
(3) For more details on rotation and transmitd TDM stream bit order, refer to Section 23.8.4.4.1.1, *TDM - Mode Transmission Data Alignment Settings* and Table 23-572, *MCASP TFU TDM Mode Settings*.

23.8.5.1.2.3.2 Subsequence – Transmit Frame Synchronization Generator Configuration in TDM Mode

The procedure in Table 23-595 configures the transmit frame synchronization generator of the MCASP module.

Table 23-595. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission

Step	Register/Bit Field/Programming Model	Value
Select number of TDM slots per frame (2 - 32). Must be set to 0x2 , in case of an I2S-transmission. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_TXFMCTL[15:7] XMOD	0x-
Choose the transmit frame sync width -single bit / single word. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_TXFMCTL[4] FXWID	0x-

Table 23-595. Transmit Frame-Synchronization Generator Configuration for TDM-Transmission (continued)

Step	Register/Bit Field/Programming Model	Value
Select start of transmit frame sync polarity - rising / falling edge. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_TXFMCTL[0] FSXP	0x-
IFtransmit frame sync - FS is internally generated	Software test condition	
Select internally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b1
If MCASP transmitter is required to output internally generated frame, AFSX pin (device level: abemcasp_afsx) must be set as an output **in step 10 of the sequence documented in the** Table 23-593. This must NOT be done in current step because the frame control register - MCASP_TXFMCTL must be appropriately configured prior to AFSX pin outputting a frame sync to an external device.	MCASP_PDIR[28] AFSX	0b1
ELSE		
Select externally- generated transmit frame sync. For more details on frame-sync generator, refer to Section 23.8.4.2.3.	MCASP_TXFMCTL[1] FSXM	0b0
Setup the AFSX pin as input (device level: abemcasp_afsx)	MCASP_PDIR[28] AFSX	0b0

23.8.5.1.2.3.3 Subsequence – Transmit Clock Generator Configuration for TDM Cases

The procedure in Table 23-596 configures the transmit clock generator of the MCASP module.

Table 23-596. Transmit Clock Generator Configuration for TDM Cases

Step	Register/Bit Field/Programming Model	Value
IFtransmit clock - XCLK is internally generated	Software test condition	
IF high-speed transmit clock - AHCLKX is internally generated based on AUXCLK	Software test condition	
Select an internally-generated high-frequency clock.	MCASP_AHCLKXCTL[15] HCLKXM	0b1
Select the high-frequency clock source polarity : non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Set the divisor for the internally generated high-frequency clock – AHCLKX in range (1 - 4096).	MCASP_AHCLKXCTL[11:0] HCLKXDIV	0x-
Optional : If MCASP transmitter is required to output internally generated high-frequency clock, AHCLKX pin (device level: abemcasp_ahclkx) must be set as an output **in step 10 of the sequence documented in the** Table 23-593. This must NOT be done in current step because the clock control register - MCASP_AHCLKXCTL must be appropriately configured prior to AHCLKX pin outputting a high-speed clock to an external device.	MCASP_PDIR[27] AHCLKX	0b1
ELSE		
Select an externally-generated high frequency clock (HCLKXDIV divider can not be used).	MCASP_AHCLKXCTL[15] HCLKXM	0b0
Select the high-speed transmit clock source polarity : non-inverted or inverted.	MCASP_AHCLKXCTL[14] HCLKXP	0x-
Setup an input directon for the AHCLKX pin (device level abemcasp_ahclkx)	MCASP_PDIR[27] AHCLKX	0b0
ENDIF		

Table 23-596. Transmit Clock Generator Configuration for TDM Cases (continued)

Step	Register/Bit Field/Programming Model	Value
Select an internally-generated transmit clock.	MCASP_ACLKXCTL[5] CLKXM	0b1
Transmitter samples on rising / falling edge. **Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.**	MCASP_ACLKXCTL[7] CLKXP	0x-
Set the divisor for the internally generated transmit clock– ACLKX in range (1 - 32).	MCASP_ACLKXCTL[4:0] CLKXDIV	0x-
Optional: If MCASP transmitter is required to output internally generated clock, ACLKX pin (device level: abemcasp_aclkx) must be set as an output **in step 10 of the sequence documented in the** Table 23-593. This must NOT be done in current step because the clock control register - MCASP_ACLKXCTL must be appropriately configured prior to ACLKX pin outputting a transmit clock to an external device.	MCASP_PDIR[26] ACLKX	0b1
ELSE		
Select an externally-generated transmit clock. Note that in this case the AHCLKX signal path and the CLKXDIV divider are NOT used.	MCASP_ACLKXCTL[5] CLKXM	0b0
Transmitter samples on rising / falling edge. **Select Tx shifting out data on the rising edge if receiver samples on falling edge, and vice versa.**	MCASP_ACLKXCTL[7] CLKXP	0x-
Setup an input directon for the ACLKX pin (device level abemcasp_aclkr)	MCASP_PDIR[26] ACLKX	0b0
ENDIF		
Configure the transmit clock failure detect logic.	See Section 23.8.4.15.6.1, *Clock Failure Check Startup*.	

23.8.5.1.2.3.4 Subsequence—MCASP Transmit Pins Functional Configuration

The procedure in Table 23-597 configures the MCASP pins for MCASP functionality.

Table 23-597. MCASP Transmit Pins Functional Configuration

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have MCASP functionality.	MCASP_PFUNC[31:0]	0x0
Configure the MCASP pins direction : AFSX (device level: abemcasp_afsr) AHCLKX (device level: abemcasp_ahclkr) ACLKX (device level: abemcasp_aclkr) Desired i-th MCASP data pin AXRi (i=0 to 3) (device level: abemcasp_axr - abemcasp_axr3) is configured as an ouput for transmission.	MCASP_PDIR[28] AFSR; MCASP_PDIR[27] AHCLKR; MCASP_PDIR[26] ACLKR; MCASP_PDIR[i] AXRi, where i =0 to 3	0x-(1) 0x-(2) 0x- (2) 0x1

(1) See Table 23-595.

(2) For more details on MCASP clock configurations , refer to Table 23-590.

23.8.5.1.2.3.5 Subsequence – MCASP Transmit Mute Input / Output Trigger Condition Settings

The procedure in Table 23-598 configures the behavior of the mute associated I/Os and different transmit trigger conditions for the MCASP mute output functionality.

Table 23-598. MCASP Transmit Mute Input / Output Trigger Condition Settings

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on transmit DATA port error.	MCASP_AMUTE[12] XDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit clock failure.	MCASP_AMUTE[10] XCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error.	MCASP_AMUTE[8] XSYNCERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit underrun error.	MCASP_AMUTE[6] XUNDRN	0x1
Optional: Enable sensitivity of the abemcasp_amuteout output to abemcasp_amutein error source.	MCASP_AMUTE[3] INEN	0x1
Optional: Select the abemcasp_amutein input polarity.	MCASP_AMUTE[2] INPOL	0x1
Optional: Configure the behavior of the abemcasp_amuteout output.	MCASP_AMUTE[1:0] MUTEN	0x1

23.8.5.2 Operational Modes Configuration

23.8.5.2.1 MCASP Transmission Modes

23.8.5.2.1.1 Main Sequence – MCASP DIT- / TDM- Polling Transmission Method

Figure 23-193 shows the MCASP DIT- / TDM- polling method.

NOTE:

- The MCASP polling transmission model considers the MPU/DSP as the source of audio data for the MCASP transmission buffer.
- The transmit DMA request is disabled and the XDMAERR event is not analyzed.

Figure 23-193. MCASP DIT- / TDM- Transmission Polling Method

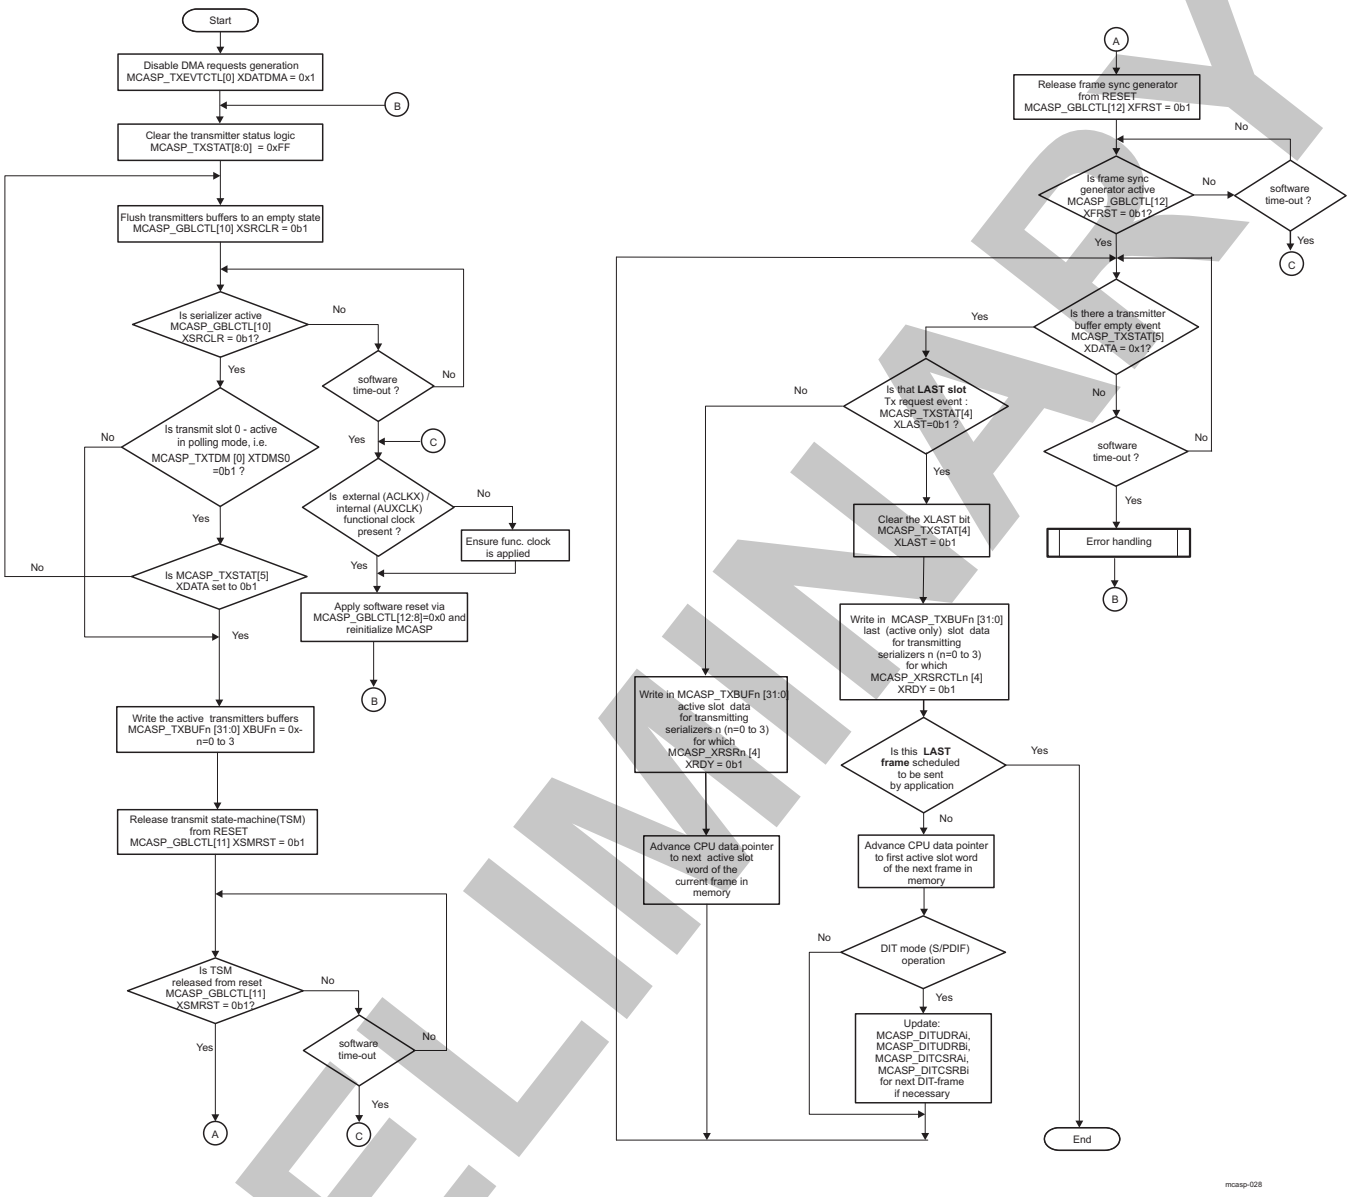


Table 23-599 summarizes the register call for the transmission DIT- / TDM- polling mode.

Table 23-599. Register Call Summary for Main Sequence – MCASP DIT- / TDM- Transmission Polling Method

Register Name
MCASP_TXEVTCTL
MCASP_TXSTAT
MCASP_GBLCTL
MCASP_TXTDM
MCASP_TXBUFn (n=0 to 3)
MCASP_XRSRCTLn (n=0 to 3)
MCASP_DITUDRAi (i=0 to 5)
MCASP_DITUDRBi (i=0 to 5)
MCASP_DITCSRAi (i=0 to 5)

Table 23-599. Register Call Summary for Main Sequence – MCASP DIT- / TDM- Transmission Polling Method (continued)

Register Name
MCASP_DITCSRBi (i=0 to 5)

Table 23-600 summarizes the subprocess call for the DIT- / TDM- transmission polling mode.

Table 23-600. Subprocess Call Summary for Main Sequence – MCASP DIT- / TDM- Transmission Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 23-197

23.8.5.2.1.2 Main Sequence – MCASP DIT- / TDM - Interrupt Transmission Method

Figure 23-194 shows the initial setup for interrupt-based transmission.

Figure 23-194. Subsequence – DIT- / TDM- Transmission Startup Procedure

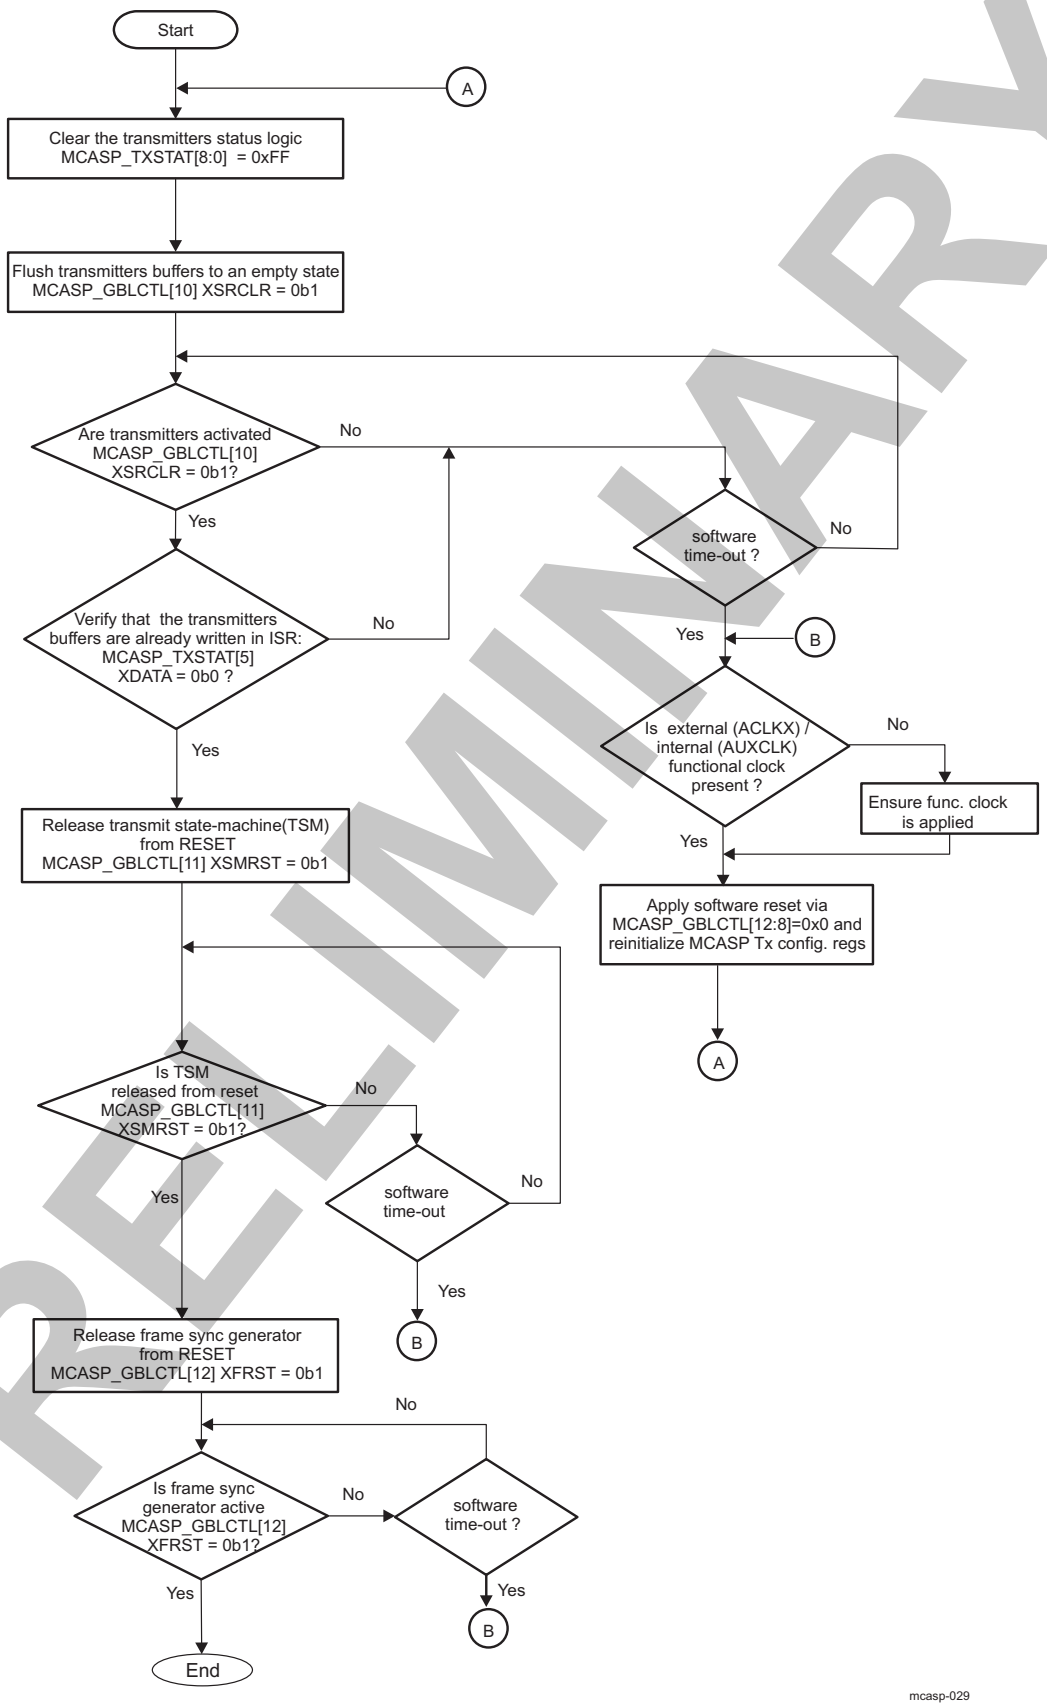

Table 23-601 shows the configuration of the MCASP using an interrupt method for DIT- / TDM-transmission.

Table 23-601. MCASP DIT- / TDM- Interrupt Transmission Model

Step	Register/Bit Field/Programming Model	Value
Disable Tx DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x1
Enable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt (useful for DIT user data/ channel status next S/PDIF frame info update.)	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
IFwrite transfer is through the MCASP DATA port (MCASP_TXFMT[3] XBUSEL is set to 0b0).	Software test condition (setting is done in step4 of the *MCASP Transmitters Global Initialization* - see Table 23-581)	
Enable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x1
ELSE		
Disable the DATA port error based interrupt.	MCASP_EVTCTLX[3] XDMAERR	0x0
ENDIF		
DIT / TDM - Transmission Startup Procedure	See Figure 23-194.	

Table 23-602 summarizes the register call to initialize the MCASP to transmit using interrupt events.

Table 23-602. Register Call Summary for Subsequence – MCASP DIT- / TDM- Transmission Startup Procedure

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXSTAT

23.8.5.2.1.3 Main Sequence –MCASP DIT- / TDM - Mode DMA Transmission Method

Table 23-603 shows the configuration of the MCASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. Table 23-602 shows the initial setup for DMA - based transmission.

NOTE: Because of the DATA port burst access capability with the DMA method, it is strongly recommended that DMA transfers are initiated through the MCASP DATA port.

Table 23-603. MCASP DMA Transmission Model with Interrupt Events Servicing

Step	Register/Bit Field/Programming Model	Value
Recommended: Select DATA port to access the transmit buffers.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the Tx DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x0
Enable the Tx DMA error event, because of MCASP DATA port usage.	MCASP_EVTCTLX[3] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt, as DMA is used to service this request.	MCASP_EVTCTLX[5] XDATA	0x0

Table 23-603. MCASP DMA Transmission Model with Interrupt Events Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
DMA startup transmission procedure. **This procedure is identical than the one shown in** Figure 23-194. The only difference is that DMA automatically services all the AXEVT events raised by the MCASP, and no CPU data processing intervention is required. The CPU is involved only in error handling shown in Figure 23-196.	See Figure 23-194.	

23.8.5.2.2 MCASP Reception Modes

23.8.5.2.2.1 Main Sequence – MCASP Polling Reception Method

Figure 23-195 shows the MCASP polling reception method.

NOTE: The MCASP polling reception model considers the MPU/DSP as the accessor of audio data from the MCASP receive buffers.

Figure 23-195. MCASP Polling Reception Method

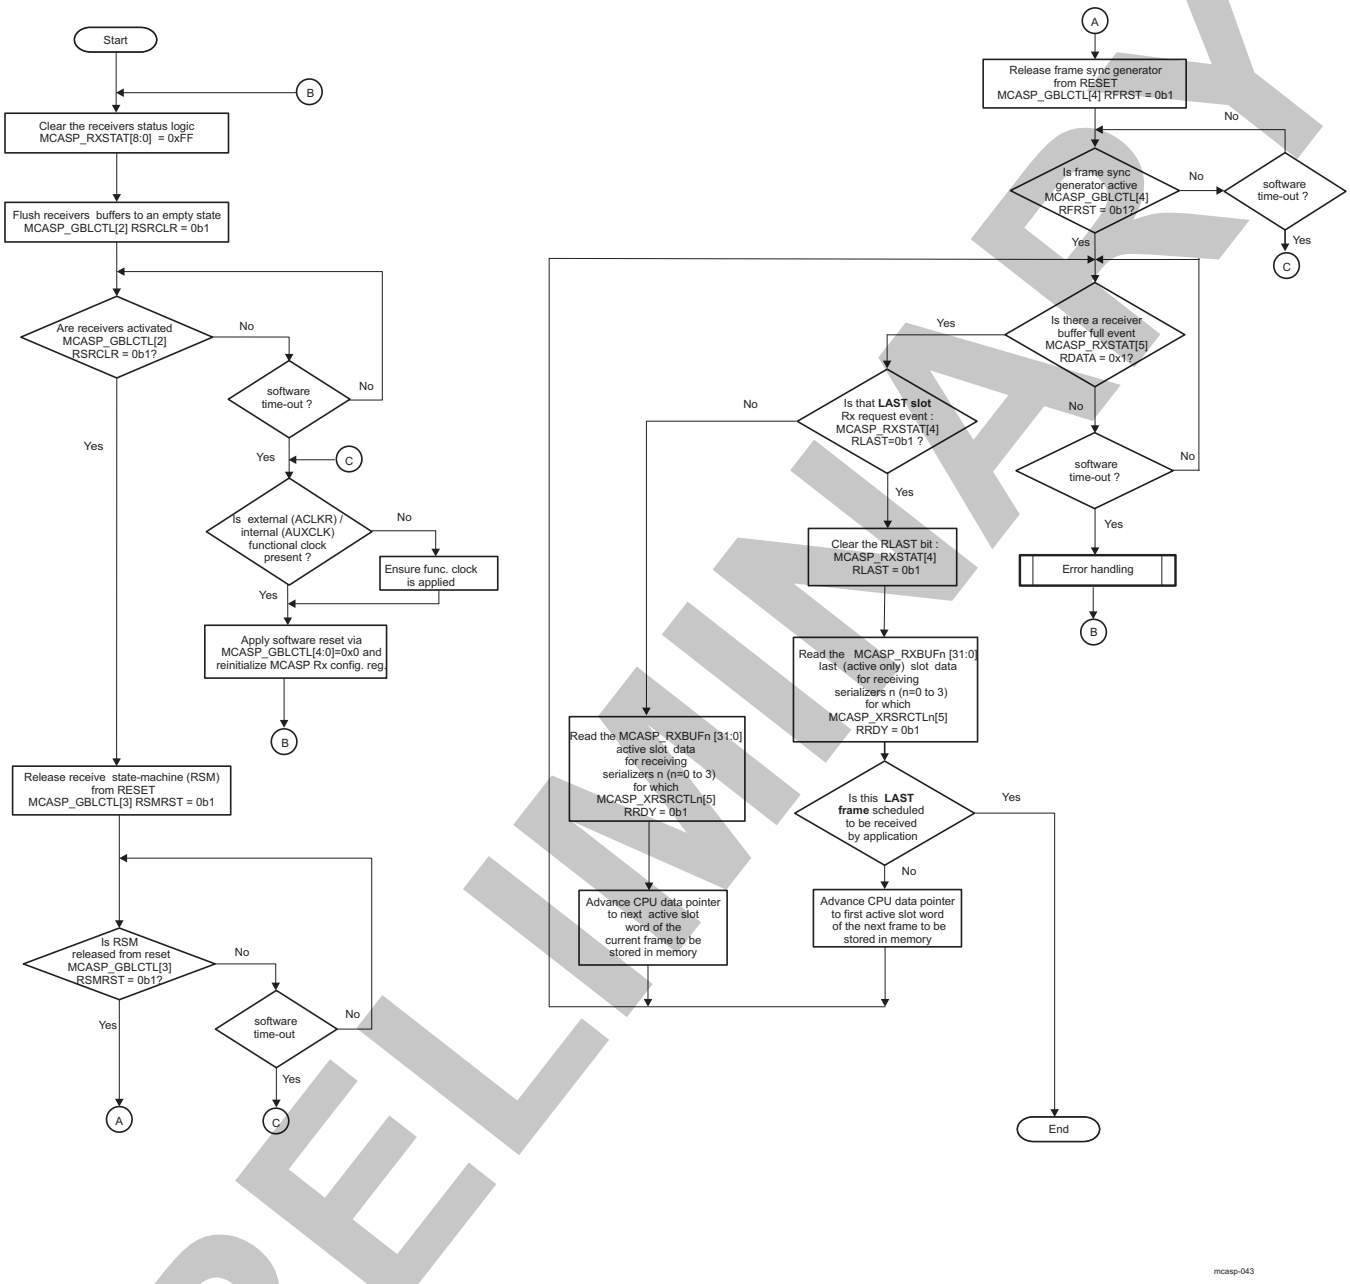

Table 23-604 summarizes the register call for the reception polling mode.

Table 23-604. Register Call Summary for Main Sequence – MCASP Reception Polling Method

Register Name
MCASP_RXSTAT
MCASP_GBLCTL
MCASP_RXBUFn (n=0 to 3)
MCASP_XRSRCTLn (n=0 to 3)

Table 23-605 summarizes the subprocess call for the polling mode.

Table 23-605. Subprocess Call Summary for Main Sequence – MCASP Reception Polling Method

Subprocess Name	Cross-Reference
Error handling	Figure 23-198

23.8.5.2.3 MCASP Event Servicing

23.8.5.2.3.1 MCASP DIT- / TDM- Transmit Interrupt Events Servicing

Figure 23-196 shows the flow of DIT- / TDM- mode transmit interrupt events servicing for the MCASP module.

Figure 23-196. MCASP Transmit Interrupt Events Servicing

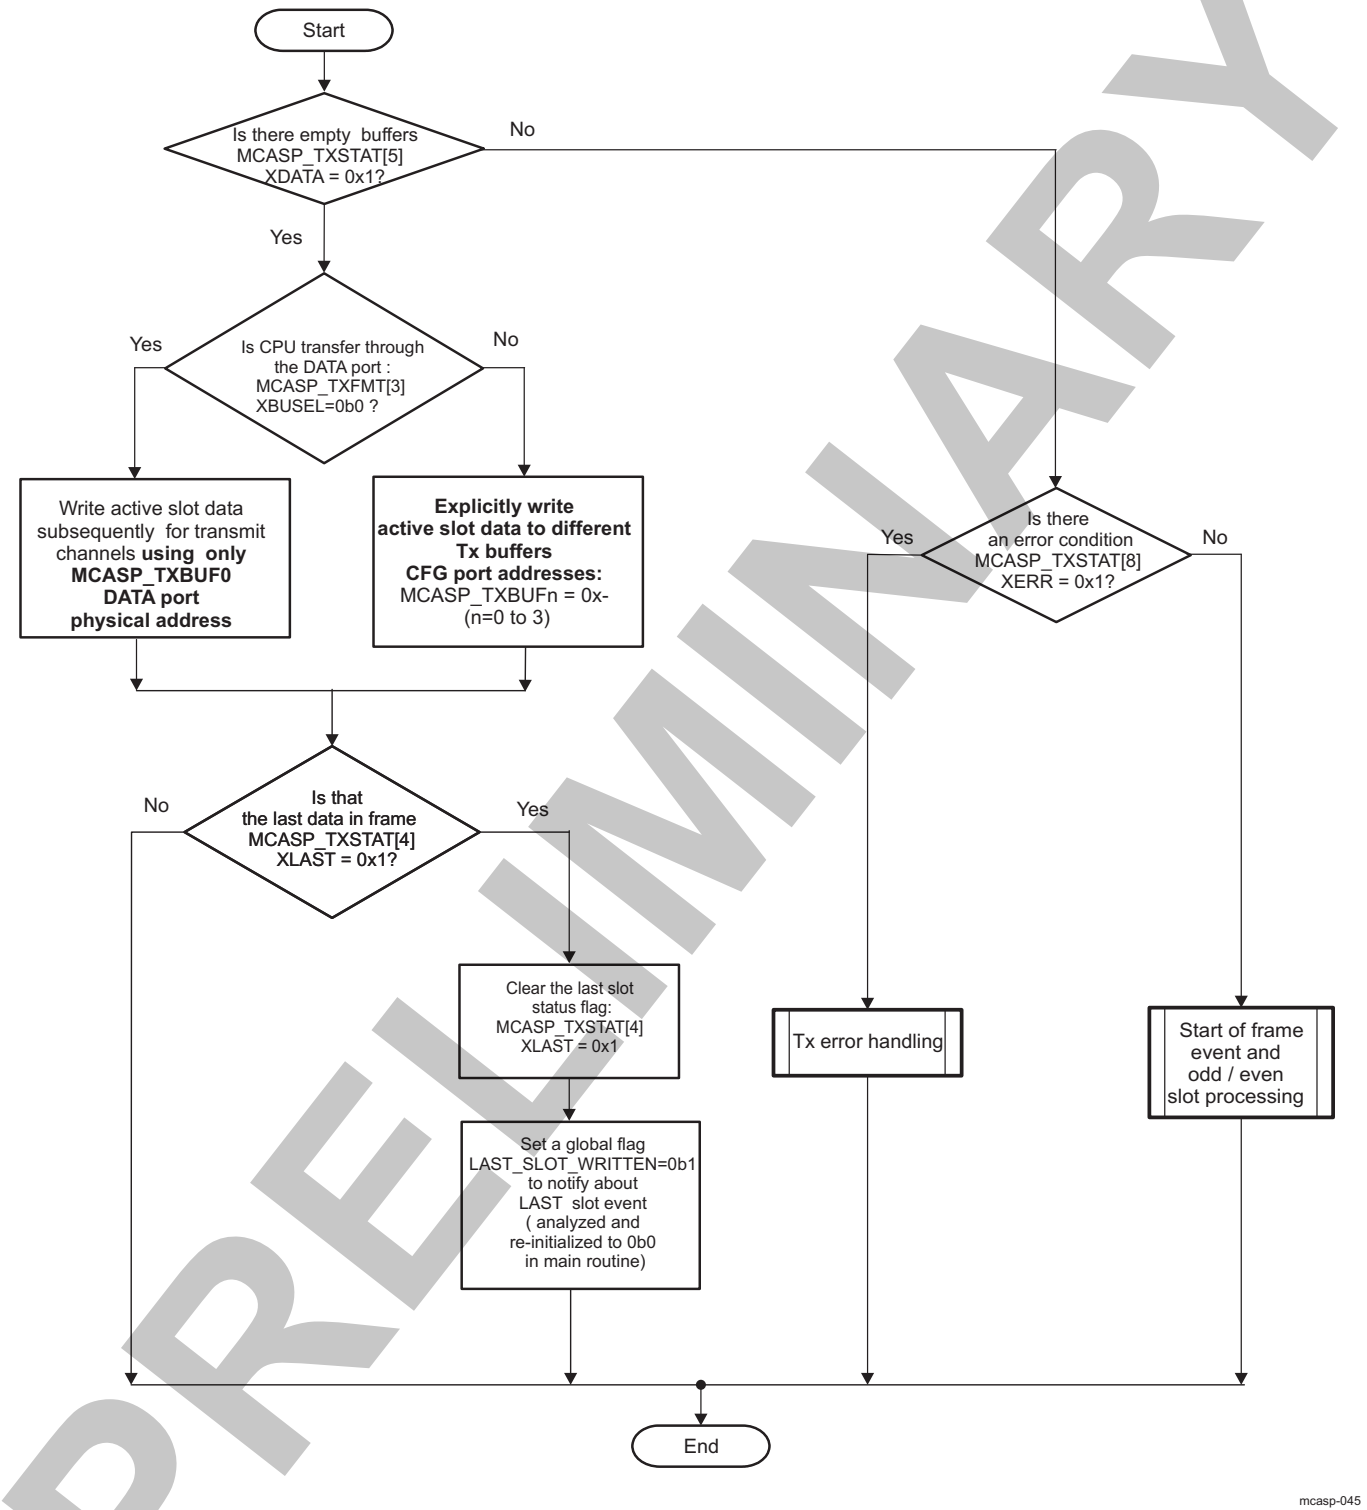

Table 23-606 lists the register call summary for the transmit interrupt events servicing.

Table 23-606. Register Call Summary for MCASP Transmit Interrupt Events Servicing

Register Name	Register Name	Register Name
MCASP_TXSTAT	MCASP_TXBUFn	MCASP_TXFMT

Table 23-607 lists the subprocess call summary for transmit interrupt events servicing.

23.8.5.2.3.2 Subsequence – MCASP DIT- / TDM -Modes Transmit Error Handling

Figure 23-197 shows the transmit error handling schema for the MCASP, which can be implemented as part of the Tx interrupt service routine or as part of the Tx polling sequence.

Figure 23-197. MCASP Transmit Error Handling

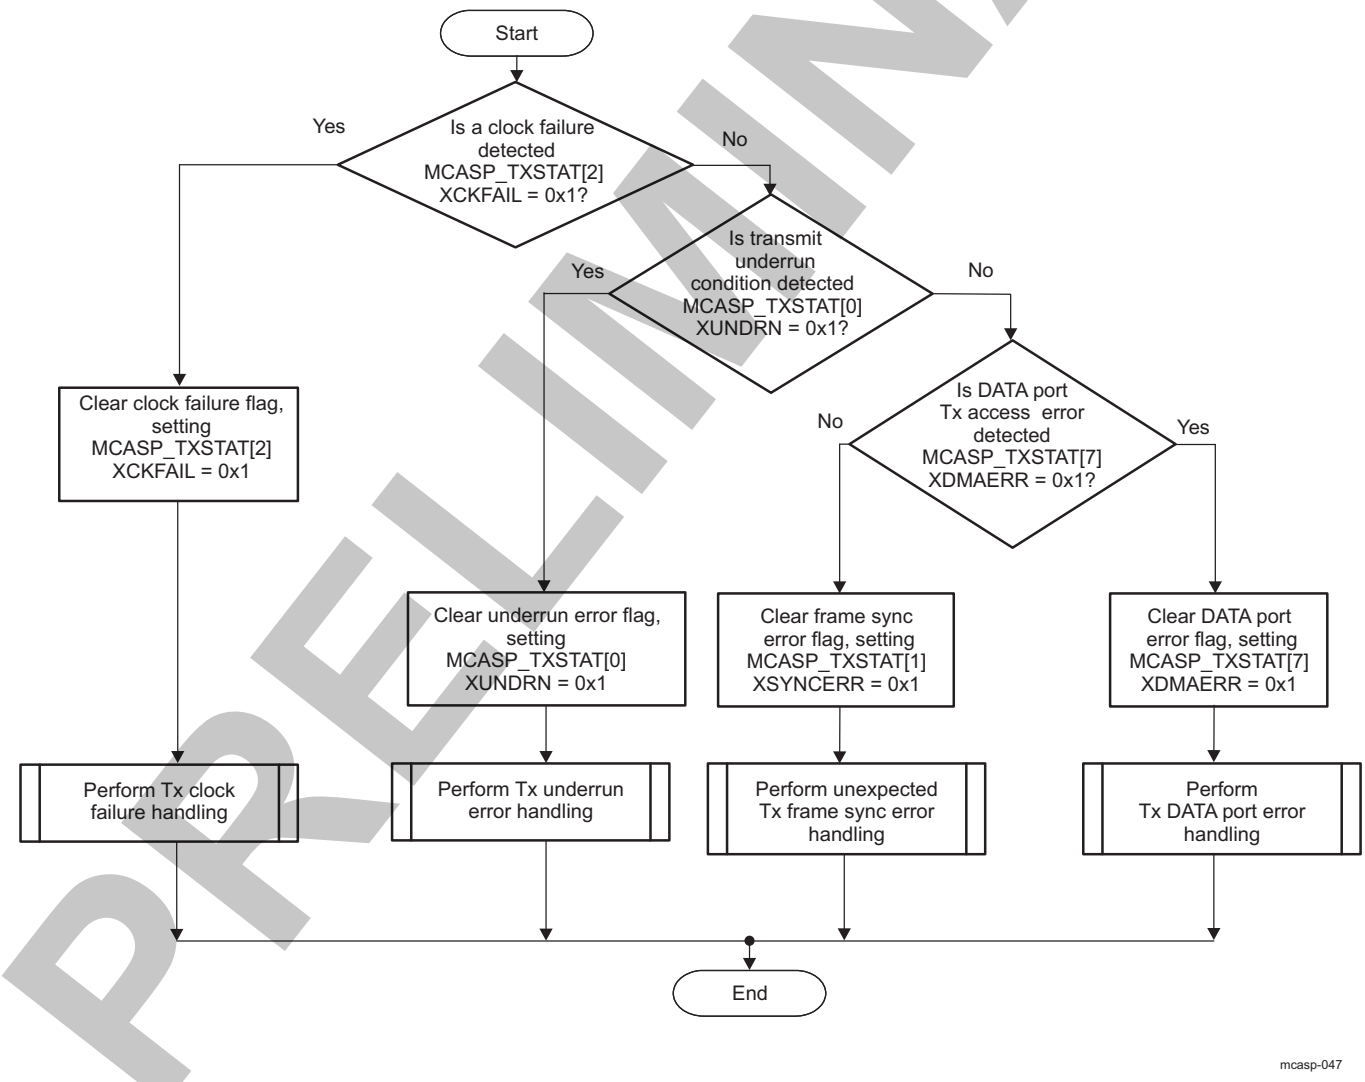

Table 23-608 lists the register call summary for the MCASP transmit error handling.

Table 23-608. Register Call Summary for MCASP Transmit Error Handling

Register Name
MCASP_TXSTAT

NOTE:

- For more information about transmit clock failure handling, see Section 23.8.4.15.6.2, *Transmit Clock Failure Check and Recovery*.
- For more information about transmit buffer underrun handling, see Section 23.8.4.15.1, *Buffer Underrun Error -Transmitter*.
- For more information about DATA port Tx error handling, see Section 23.8.4.15.3, *DATA Port Error - Transmitter*.
- For more information about unexpected Tx frame sync error handling , see Section 23.8.4.15.5, *Unexpected Frame Sync Error*.

23.8.5.2.3.3 Subsequence – MCASP Receive Error Handling

Figure 23-198 shows the receive error handling schema for the MCASP, which can ONLY be implemented as part of the Rx polling sequence.

Figure 23-198. MCASP Receive Error Handling

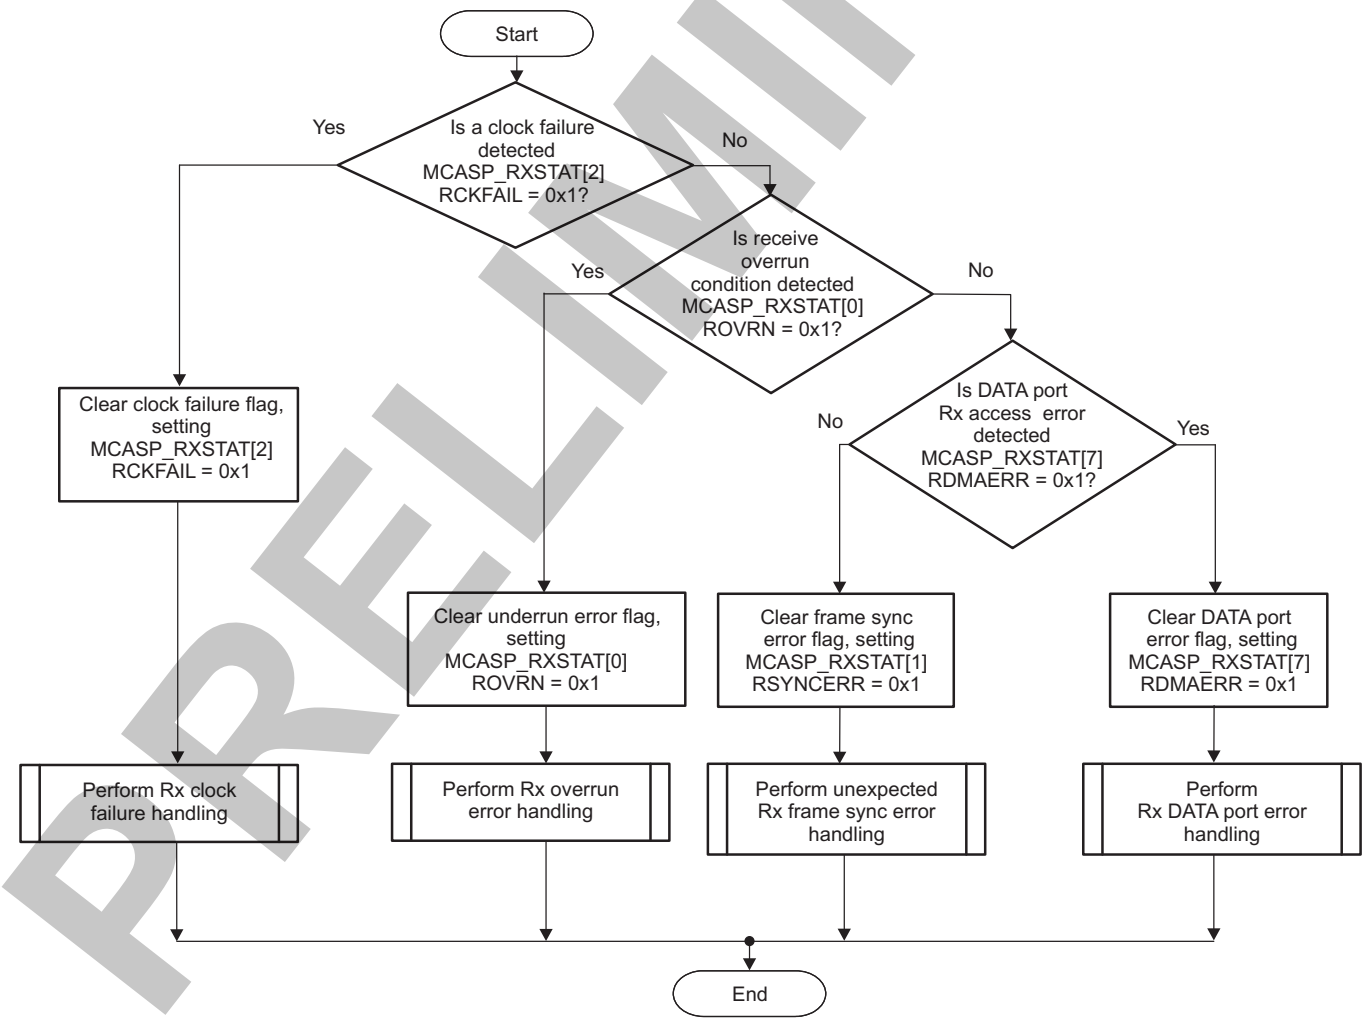

Table 23-609 lists the register call summary for the MCASP receive error handling.

Table 23-609. Register Call Summary for MCASP Receive Error Handling

Register Name
MCASP_RXSTAT

NOTE:

- For more information about receive clock failure handling, see Section 23.8.4.15.6.3, *Receive Clock Failure Check and Recovery*.
- For more information about receive buffer overrun handling, see Section 23.8.4.15.2, *Buffer Overrun Error - Receiver* .
- For more information about DATA port Rx error handling, see Section 23.8.4.15.4, *DATA Port Error - Receiver* .
- For more information about unexpected Rx frame sync error handling , see Section 23.8.4.15.5, *Unexpected Frame Sync Error*.

23.8.6 MCASP Register Manual

23.8.6.1 MCASP Instance Summary

Section 23.8.5.1.1 summarizes the MCASP instances.

Table 23-610. MCASP Instance Summary

Module Name	Base Address L3_MAIN Interconnect	Base Address Cortex-A15 Private Access	Base Address DSP Private Access	Size
MCASP_CFG	0x4902 8000	0x4012 8000	0x01D2 8000	4 KiB
MCASP_DATA	0x4902 A000	0x4012 A000	0x01D2 A000	4 KiB

NOTE: Private access is an access that does not use the L3_MAIN / L4 interconnects.

23.8.6.2 MCASP Registers

23.8.6.2.1 MCASP_CFG Register Summary

Table 23-611 summarizes the MCASP_CFG register mapping.

(1) i = 0 to 5
(2) n = 0 to 3
(3) j = 0 to 11
(4) k = 0 to 11
(5) l = 0 to 11

NOTE: The address locations listed in Table 23-611, *MCASP_CFG Register Mapping Summary*, are relevant for accessing:

- all MCASP configuration registers
- MCASP_TXBUFn registers, (n=0 to 3)
- MCASP_RXBUFn registers, (n=0 to 3)

through the MCASP peripheral configuration (CFG) port.

The MCASP_TXFMT[3] XBUSEL bit must be set to 0b1, to allow CFG port write accesses to the MCASP XRBUFn buffer. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b1, to allow CFG port read accesses to the MCASP XRBUFn buffer.

23.8.6.2.2 MCASP_CFG Register Description

Table 23-612 through Table 23-686 describe the individual MCASP_CFG register bits.

NOTE: For all of the below described regsiters, **the indexes n and N, when applying to serializers (NOT slots), vary in the range from 0 to 3**. The MCASP AXR0 - AXR3 I/Os match the device boundary level - abemcasp_axr - abemcasp_axr3 signals, respectively.

Description	Specifies the function of the pins as either a MCASP pin or a GPIO pin		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AFSR	AHCLKR	ACLKR	AFSX	AHCLKX	ACLKX	AMUTE	RESERVED																					AXR3	AXR2	AXR1	AXR0

Bits	Field Name	Description	Type	Reset
31	AFSR	Determines if AFSR pin (device level abemcasp_afsr signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
30	AHCLKR	Determines if AHCLKR pin (device level abemcasp_ahclkr signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
29	ACLKR	Determines if ACLKR pin (device level abemcasp_aclkr signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
28	AFSX	Determines if AFSX pin (device level abemcasp_afsx signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
27	AHCLKX	Determines if AHCLKX pin (device level abemcasp_ahclkx signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
26	ACLKX	Determines if ACLKX pin (device level abemcasp_aclkx signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0

Bits	Field Name	Description	Type	Reset
25	AMUTE	Determines if AMUTE pin (device level abemcasp_amuteout signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
24:4	RESERVED	Reserved	RW	0x000
3	AXR3	Determines if AXR3 pin (device level abemcasp_axr3 signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
2	AXR2	Determines if AXR2 pin (device level abemcasp_axr2 signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
1	AXR1	Determines if AXR1 pin (device level abemcasp_axr1 signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0
0	AXR0	Determines if AXR0 pin (device level abemcasp_axr signal) functions as MCASP or GPIO. 0x0: Pin functions as MCASP pin 0x1: Pin functions as GIO pin	RW	0

Table 23-620. MCASP_PDOUT

Address Offset	0x0000 0018		
Physical Address	0x4902 8018 0x4012 8018 0x01D2 8018	**Instance**	MCASP_CFG_MAIN_L3 MCASP_CFG_CORTEX-A15 MCASP_CFG_DSP

Description

Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by MCASP_PDOUT is not affected by writing to MCASP_PDIR and MCASP_PFUNC. However, the data value in MCASP_PDOUT is driven out onto the MCASP pin only if the corresponding bit in MCASP_PFUNC is set to 1 (GPIO function) and the corresponding bit in MCASP_PDIR is set to 1 (output).

When reading data, it returns the corresponding bit value in MCASP_PDOUT[n]; it does not return the input from the I/O pin.

When writing data, writes to the corresponding MCASP_PDOUT[n] bit.

PDOUT has these aliases or alternate addresses:

- MCASP_PDSET - when written to at this address, writing a 1 to a bit in MCASP_PDSET sets the corresponding bit in MCASP_PDOUT to 1; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged.
- MCASP_PDCLR - when written to at this address, writing a 1 to a bit in MCASP_PDCLR clears the corresponding bit in MCASP_PDOUT to 0; writing a 0 has no effect and keeps the bits in MCASP_PDOUT unchanged

There is only one set of data-out bits, MCASP_PDOUT[31:0]. The other registers, MCASP_PDSET and MCASP_PDCLR, are just different addresses for the same control bits, with different behaviors during writes.

Type RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AFSR	AHCLKR	ACLKR	AFSX	AHCLKX	ACLKX	AMUTE	RESERVED																					AXR3	AXR2	AXR1	AXR0

Bits	Field Name	Description	Type	Reset
31	AFSR	Determines drive on AFSR output pin when the corresponding MCASP_PFUNC[31] and MCASP_PDIR[31] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
30	AHCLKR	Determines drive on AHCLKR output pin when the corresponding MCASP_PFUNC[30] and MCASP_PDIR[30] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
29	ACLKR	Determines drive on ACLKR output pin when the corresponding MCASP_PFUNC[29] and MCASP_PDIR[29] bits are set to 1 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
28	AFSX	Determines drive on AFSX output pin when the corresponding MCASP_PFUNC[28] and MCASP_PDIR[28] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
27	AHCLKX	Determines drive on AHCLKX output pin when the corresponding MCASP_PFUNC[27] and MCASP_PDIR[27] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
26	ACLKX	Determines drive on ACLKX output pin when the corresponding MCASP_PFUNC[26] and MCASP_PDIR[26] bits are set to 1 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Bits	Field Name	Description	Type	Reset
25	AMUTE	Determines drive on AMUTE output pin when the corresponding MCASP_PFUNC[25] and MCASP_PDIR[25] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
24:4	RESERVED	Reserved	RW	0x000
3	AXR3	Determines drive on AXR3 output pin when the corresponding MCASP_PFUNC[3] and MCASP_PDIR[3] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
2	AXR2	Determines drive on AXR2 output pin when the corresponding MCASP_PFUNC[2] and MCASP_PDIR[2] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
1	AXR1	Determines drive on AXR1 output pin when the corresponding MCASP_PFUNC[1] and MCASP_PDIR[1] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0
0	AXR0	Determines drive on AXR0 output pin when the corresponding MCASP_PFUNC[0] and MCASP_PDIR[0] bits are set to 1. 0x0: The pin drives low. 0x1: The pin drives high.	RW	0

Table 23-628. MCASP_GBLCTL

Address Offset	0x0000 0044		
Physical Address	0x4902 8044 0x4012 8044 0x01D2 8044	**Instance**	MCASP_CFG_MAIN_L3 MCASP_CFG_CORTEX-A15 MCASP_CFG_DSP
Description	Global transmit control register - provides initialization of the transmit and receive sections. The bit fields in MCASP_GBLCTL are synchronized and latched by the transmitter and receiver corresponding clocks - abemcasp_aclkx clock (bits [12:8]) and abemcasp_aclkr (bits [4:0]), respectively. Before programming MCASP_GBLCTL, ensure that the serial clocks are running. If the corresponding external serial clocks - abemcasp_clkx and abemcasp_aclkr, are not yet running, select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL and ACLKRCTL before programming the MCASP_GBLCTL. Also, after programming any bits in MCASP_GBLCTL, do not proceed until reading back from MCASP_GBLCTL and verifying that the bits in MCASP_GBLCTL are latched.

12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0

Bits	Field Name	Description	Type	Reset
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. AXR[n] pin state : If MCASP_PFUNC[n] = 0 and MCASP_PDIR[n] = 1, the corresponding serializer [n] drives the AXR[n] pin to the state specified for inactive time slot. 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from XBUF[n] to XRSR[n]. The transmit state-machine sets the underrun flag (XUNDRN) in MCASP_XSTAT, if XBUF[n] have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in MCASP_XSTAT is set to indicate XBUF is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:5	RESERVED	Reserved	RW	0x0
4	RFRST	Receive frame sync generator reset enable bit. 0x0: Receive frame sync generator is reset. 0x1: Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
3	RSMRST	Receive state machine reset enable bit. 0x0: Receive state machine is held in reset. 0x1: Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.	RW	0
2	RSRCLR	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0x0: Receive serializers are cleared. 0x1: Receive serializers are active.	RW	0
1	RHCLKRST	Receive high-frequency clock divider reset enable bit. 0x0: Receive high-frequency clock divider is held in reset. 0x1: Receive high-frequency clock divider is running.	RW	0
0	RCLKRST	Receive clock divider reset enable bit. 0x0: Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: Receive clock divider is running.	RW	0

RESERVED																			XDMAERR	RDMAERR	XCKFAIL	RCKFAIL	XSYNCERR	RSYNCERR	XUNDRN	ROVRN	INSTAT	INEN	INPOL	MUTEN

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XDMAERR	Drives AMUTE active enable bit on transmit DMA error (XDMAERR). 0x0: Drive is disabled. Detection of transmit DMA error is ignored by abemcasp_amuteout. 0x1: Drive is enabled (active). Upon detection of transmit DMA error, abemcasp_amuteout is active and is driven according to MUTEN bits.	RW	0
11	RDMAERR	If receive DMA error (RDMAERR), drive AMUTE active enable bit. 0x0: Drive is disabled. Detection of receive DMA error is ignored by AMUTE. 0x1: Drive is enabled (active). Upon detection of receive DMA error, AMUTE is active and is driven according to MUTEN bit.	RW	0
10	XCKFAIL	XMT bad clock. Drives AMUTE active enable bit on transmit clock failure (XCKFAIL). 0x0: Drive is disabled. Detection of transmit clock failure is ignored by abemcasp_amuteout. 0x1: Drive is enabled (active). Upon detection of transmit clock failure, abemcasp_amuteout is active and is driven according to MUTEN bits.	RW	0
9	RCKFAIL	If receive clock failure (RCKFAIL), drive AMUTE active enable bit. 0x0: Drive is disabled. Detection of receive clock failure is ignored by AMUTE. 0x1: Drive is enabled (active). Upon detection of receive clock failure, AMUTE is active and is driven according to MUTEN bit.	RW	0

Bits	Field Name	Description	Type	Reset
8	XSYNCERR	XMT unexpected FS. Drives AMUTE active enable bit on unexpected transmit frame-sync error (XSYNCERR). 0x0: Drive is disabled. Detection of unexpected transmit frame-sync error is ignored by abemcasp_amuteout. 0x1: Drive is enabled (active). Upon detection of unexpected transmit frame-sync error, abemcasp_amuteout is active and is driven according to MUTEN bit.	RW	0
7	RSYNCERR	If unexpected receive frame sync error (RSYNCERR), drive AMUTE active enable bit. 0x0: Drive is disabled. Detection of unexpected receive frame sync error is ignored by AMUTE. 0x1: Drive is enabled (active). Upon detection of unexpected receive frame sync error, AMUTE is active and is driven according to MUTEN bit.	RW	0
6	XUNDRN	XMT underrun occurs. Drives AMUTE active enable bit on ransmit underrun error (XUNDRN). 0x0: Drive is disabled. Detection of transmit underrun error is ignored by abemcasp_amuteout. 0x1: Drive is enabled (active). Upon detection of transmit underrun error, abemcasp_amuteout is active and is driven according to MUTEN bit.	RW	0
5	ROVRN	If receiver overrun error (ROVRN), drive AMUTE active enable bit. 0x0: Drive is disabled. Detection of receiver overrun error is ignored by AMUTE. 0x1: Drive is enabled (active). Upon detection of receiver overrun error, AMUTE is active and is driven according to MUTEN bit.	RW	0
4	INSTAT	Status of mute in pin, determines drive on AXR[n] pin, when the MCASP_PFUNC[n] and MCASP_PDIR[n] bits are set to 1. Read 0x0: Inactive Read 0x1: Active. Audio mute in error is detected.	R	0
3	INEN	Drive the device level abemcasp_amuteout signal active when abemcasp_amutein error is active. 0x0: Drive is disabled. abemcasp_amutein is ignored by abemcasp_amuteout. 0x1: Drive is enabled (active). INSTAT = 1 drives abemcasp_amuteout active.	RW	0
2	INPOL	Audio mute in - AMUTEIN pin (device level abemcasp_amutein signal) polarity select bit 0x0: Polarity is active high. A high on abemcasp_amutein sets INSTAT to 1. 0x1: Polarity is active low. A low on abemcasp_amutein sets INSTAT to 1.	RW	0
1:0	MUTEN	AMUTE pin (device level abemcasp_amuteout signal) enable bit field (unless overridden by GPIO registers) 0x0: Disabled, pin goes to 3-state condition. 0x1: Pin is driven high if error is detected. 0x2: Pin is driven low if error is detected.	RW	0x0

Table 23-648. MCASP_RXSTAT

Address Offset	0x0000 0080		
Physical Address	0x4902 8080 0x4012 8080 0x01D2 8080	**Instance**	MCASP_CFG_MAIN_L3 MCASP_CFG_CORTEX-A15 MCASP_CFG_DSP
Description	The receiver status register (MCASP_RXSTAT) provides the receiver status and receive TDM time slot number.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								RERR	RDMAERR	RSTAFRM	RDATA	RLAST	RTDMSLOT	RCKFAIL	RSYNCERR	ROVRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x00 0000
8	RERR	RERR bit always returns a logic-OR of: ROVRN | RSYNCERR | RCKFAIL | RDMAERR Allows a single bit to be checked to determine if a receiver error has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	RDMAERR	Receive DMA error flag. RDMAERR is set when the CPU reads more serializers through the DMA port in a given time slot than were programmed as receivers. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive DMA error did not occur. 0x1: Receive DMA error did occur.	RW	0
6	RSTAFRM	Receive start of frame flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new receive frame sync (AFSR) is detected. 0x1: A new receive frame sync (AFSR) is detected.	RW	0
5	RDATA	Receive data ready flag. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: No new data in RBUF. 0x1: Data is transferred from XRSR to RBUF and ready to be serviced by the CPUs.	RW	0
4	RLAST	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. RDATA is also set.	RW	0
3	RTDMSLOT	Returns the LSB of RSLOT. Allows a single read of MCASP_RXSTAT to determine whether the current TDM time slot is even or odd. 0x0: Current TDM time slot is odd. 0x1: Current TDM time slot is even.	RW	0
2	RCKFAIL	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receive clock failure did not occur. 0x1: Receive clock failure did occur.	RW	0
1	RSYNCERR	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Unexpected receive frame sync did not occur. 0x1: Unexpected receive frame sync did occur.	RW	0
0	ROVRN	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0x0: Receiver overrun did not occur. 0x1: Receiver overrun did occur.	RW	0

Table 23-652. MCASP_RXCLKCHK

Address Offset	0x0000 0088		
Physical Address	0x4902 8088 0x4012 8088 0x01D2 8088	**Instance**	MCASP_CFG_MAIN_L3 MCASP_CFG_CORTEX-A15 MCASP_CFG_DSP
Description	The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit.		
Type	RW		

31 30 29 28 27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6 5 4 3 2 1 0
RCNT	RMAX	RMIN	RESERVED RPS

Bits	Field Name	Description	Type	Reset
31:24	RCNT	0x0 - 0xFF: Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.	R	0x00
23:16	RMAX	0x00-0xFF: Receive clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in MCASP_RXSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	RMIN	0x00 - 0xFF: Receive clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
7:4	RESERVED		RW	0x0
3:0	RPS	Receive clock check prescaler value. 0x0: MCASP system clock divided by 1 0x1: MCASP system clock divided by 2 0x2: MCASP system clock divided by 4 0x3: MCASP system clock divided by 8 0x4: MCASP system clock divided by 16 0x5: MCASP system clock divided by 32 0x6: MCASP system clock divided by 64 0x7: MCASP system clock divided by 128 0x8: MCASP system clock divided by 256 0x9 - 0xF: Reserved	RW	0x0

Table 23-668. MCASP_TXSTAT

Address Offset	0x0000 00C0		
Physical Address	0x4902 80C0 0x4012 80C0 0x01D2 80C0	**Instance**	MCASP_CFG_MAIN_L3 MCASP_CFG_CORTEX-A15 MCASP_CFG_DSP
Description	Transmitter status register - If the MCASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the MCASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN | XSYNCERR | XCKFAIL | XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the DATA port of the MCASP in a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect. 0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect 0x0: XBUF[n] is written and is full 0x1: Data is copied from XBUF[n] to XRSR[n]. XBUF[n] is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0

Bits	Field Name	Description	Type	Reset
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF[n] to XRSR[n], but XBUF[n] has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in MCASP_EVTCTLX are set. This bit is cleared by writing a 1 to iit. Writing a 0 has no effect. 0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

Description	Transmit clock check control register - configures the transmit clock failure detection circuit.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
XCNT								XMAX								XMIN								RESERVED				XPS			

Bits	Field Name	Description	Type	Reset
31:24	XCNT	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (abemcasp_ahclkx) signals, and stores the count in XCNT until the next measurement is taken	R	0x00
23:16	XMAX	0x0 to 0xFF: Transmit clock maximum boundary. This 8-bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (abemcasp_ahclkx) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
15:8	XMIN	0x0 to 0xFF: Transmit clock minimum boundary. This 8-bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (abemcasp_ahclkx) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.	RW	0x00
7:4	RESERVED	Reserved	RW	0x0
3:0	XPS	Transmit clock check prescaler value 0x0: MCASP system clock divided by 1 0x1: MCASP system clock divided by 2 0x2: MCASP system clock divided by 4 0x3: MCASP system clock divided by 8 0x4: MCASP system clock divided by 16 0x5: MCASP system clock divided by 32 0x6: MCASP system clock divided by 64 0x7: MCASP system clock divided by 128 0x8: MCASP system clock divided by 256 0x9 to 0xF: Reserved	RW	0x0

Description	Serializer n control register, (where n=0 to 3 in the device).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																										RRDY	XRDY	DISMOD		SRMOD	

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved	RW	0x0000000
5	RRDY	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSRn to RBUFn. Read 0x0: Receive buffer (MCASP_RXBUFn) is empty. Read 0x1: Receive buffer (MCASP_RXBUFn) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.	R	0

Bits	Field Name	Description	Type	Reset
4	XRDY	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). Read 0x0: The transmit buffer (MCASP_TXBUFn) contains data. Read 0x1: The transmit buffer (MCASP_TXBUFn) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.	R	0
3:2	DISMOD	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a MCASP pin (PFUNC = 0). 0x0: Drive on pin is 3-state. 0x1: Reserved 0x2: Drive on pin is logic low. 0x3: Drive on pin is logic high.	RW	0x0
1:0	SRMOD	Serializer mode bit 0x0:The serializer is inactive 0x1:The serializer is operating in transmit mode. 0x2: The serializer is operating in receive mode. 0x3: Reserved	RW	0x0

23.8.6.2.3 MCASP_DATA Register Summary

Table 23-690 summarizes the MCASP_DATA register mapping.

Table 23-690. MCASP_DATA Register Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	MCASP_DATA Physical Address L3_MAIN Interconnect	MCASP_DATA Physical Address Cortex-A15 Private Access	MCASP_DATA Physical Address DSP Private Access
MCASP_RXBUF	RW	32	0x0000 0000[1]	0x4902 A000	0x4012 A000	0x01D2 A000

(1) 0x000 is just an example DATA port offset value. Actually, whatever the offset value is added to 0x_2 A000 base address, it is ignored (don't care) when MPU / DSP perfomrs accesses to XRBUFn RX/TX buffers through the MCASP DATA port.

NOTE: For MCASP XRBUF buffer accesses through the MCASP DATA port, the destination physical address is always the same regardless of current channel index or transfer direction. The MCASP_TXFMT[3] XBUSEL bit must be set to 0b0, to allow write transfers through the DATA port. The MCASP_RXFMT[3] RBUSEL bit must be set to 0b0, to allow read transfers through the DATA port.

NOTE: The MCASP DATA port is exclusively assigned for DMAs / MPU and DSP accesses to the MCASP channels transmit and receive buffer (MPU / DSP only) registers. All other MCASP module registers must be accessed through the MCASP CFG (peripheral) port.

23.8.6.2.4 MCASP_DATA Register Description

Table 23-691. MCASP_RXBUF

Address Offset	0x0000 0000		
Physical Address	0x4902 A000 0x4012 A000 0x01D2 A000	**Instance**	MCASP_DATA_MAIN_L3 MCASP_DATA_CORTEX-A15 MCASP_DATA_DSP
Description	Through the DATA port , the Host can service all serializers through a single address and the MCASP automatically cycles through the appropriate serializers. For transmit operations through the DATA port, the Host should write to the same DATA port address to service all of the active transmit serializers upon each transmit data ready event. Similarly, for receive operations through the DATA port, the Host should read from the same RBUF DATA port address to service all of the active receive serializers upon each receive data ready event. To enable accesses from the Host to the McASP XRBUF registers through the DATA port, one must clear the XBUSEL/RBUSEL bits to 0 in the respective MCASP_TXFMT /MCASP_RXFMT registers in the MCASP_CFG Memory Map.		
Type	RW

23.9 MIPI-HSI

This section describes the MIPI high-speed synchronous serial interface (HSI).

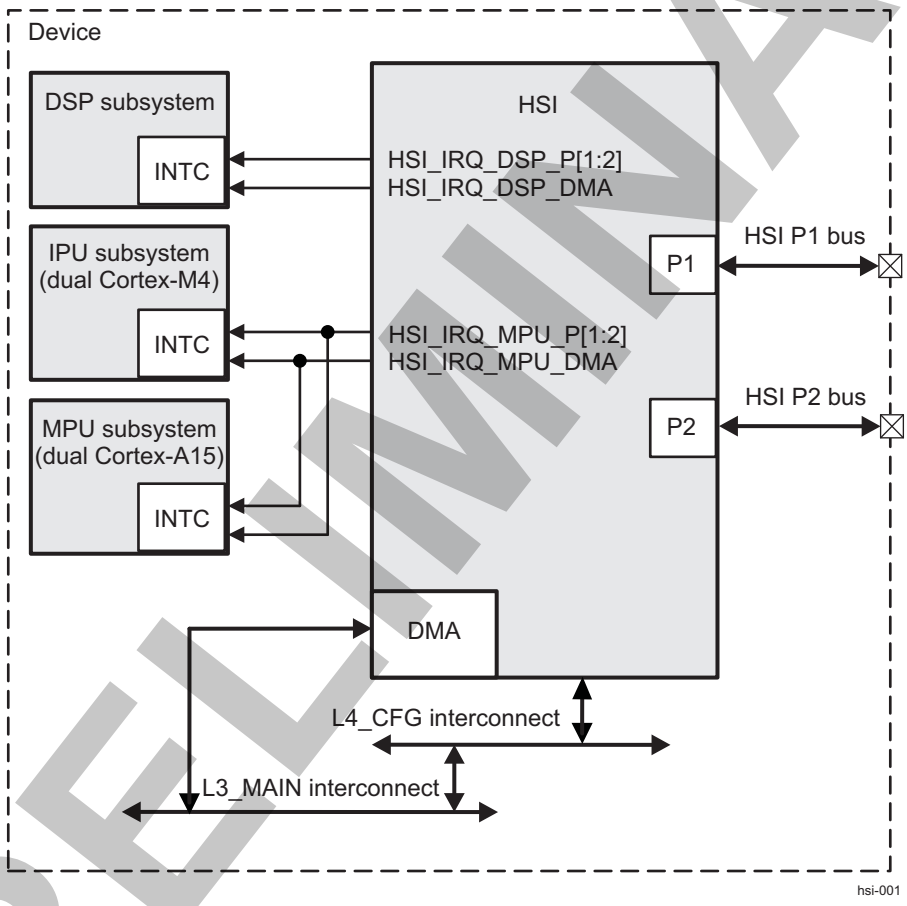
23.9.1 HSI Overview

The MIPI HSI module is a multichannel and full-duplex serial communications interface, composed of two transmitters (HST) in charge of the transmitted information and two receivers (HSR) in charge of the received information, sharing a 16-channel DMA.

The HSI peripheral is typically used to enable the device to exchange information with an external cellular modem.

Figure 23-199 is an overview of the HSI module.

Figure 23-199. HSI Overview



HSI supports the following features:

- Full duplex
- No static clock matching
- Interface speed up to 192 Mbps on transmitter and up to 225 Mbps on receiver
- Transmission speed and operation mode dynamically configurable
- Logical channels:
  - Up to 16 logical channels on receiver
  - Up to 16 logical channels on transmitter
- One 32-request DMA engine:
  - 16 transmit + 16 receive requests from HSI port
  - 16 logical DMA channels

- Interrupt requests:
  - Three to each processor subsystem (two from HSI port, one from DMA)

23.9.2 HSI Environment

This section describes the HSI application fields from an environment point of view (external connections).

23.9.2.1 HSI Signals

Table 23-693 describes the HSI module I/O signals.

Table 23-693. HSI I/O Signals

Pin Name	I/O[1]	Description	Reset Value[2]
hsi1_cawake	I	HSI port 1 wake-up signal from an external serial transmitter	Hi-Z
hsi1_cadata	I	HSI port 1 receiver data from an external transmitter	Hi-Z
hsi1_caflag	I	HSI port 1 receiver flag from an external transmitter	Hi-Z
hsi1_acready	O	HSI port 1 synchronization signal to an external transmitter	0
hsi1_acwake	O	HSI port 1 wake-up signal to an external serial receiver	0
hsi1_acdata	O	HSI port 1 transmission data (level transmission signaling) to an external receiver	1
hsi1_acflag	O	HSI port 1 transmission flag (bit transition signaling) to an external receiver	1
hsi1_caready	I	HSI port 1 synchronization signal from an external receiver	Hi-Z
hsi2_cawake	I	HSI port 2 wake-up signal from an external serial transmitter	Hi-Z
hsi2_cadata	I	HSI port 2 receiver data from an external transmitter	Hi-Z
hsi2_caflag	I	HSI port 2 receiver flag from an external transmitter	Hi-Z
hsi2_acready	O	HSI port 2 synchronization signal to an external transmitter	0
hsi2_acwake	O	HSI port 2 wake-up signal to an external serial receiver	0
hsi2_acdata	O	HSI port 2 transmission data (level transmission signaling) to an external receiver	1
hsi2_acflag	O	HSI port 2 transmission flag (bit transition signaling) to an external receiver	1
hsi2_caready	I	HSI port 2 synchronization signal from an external receiver	Hi-Z

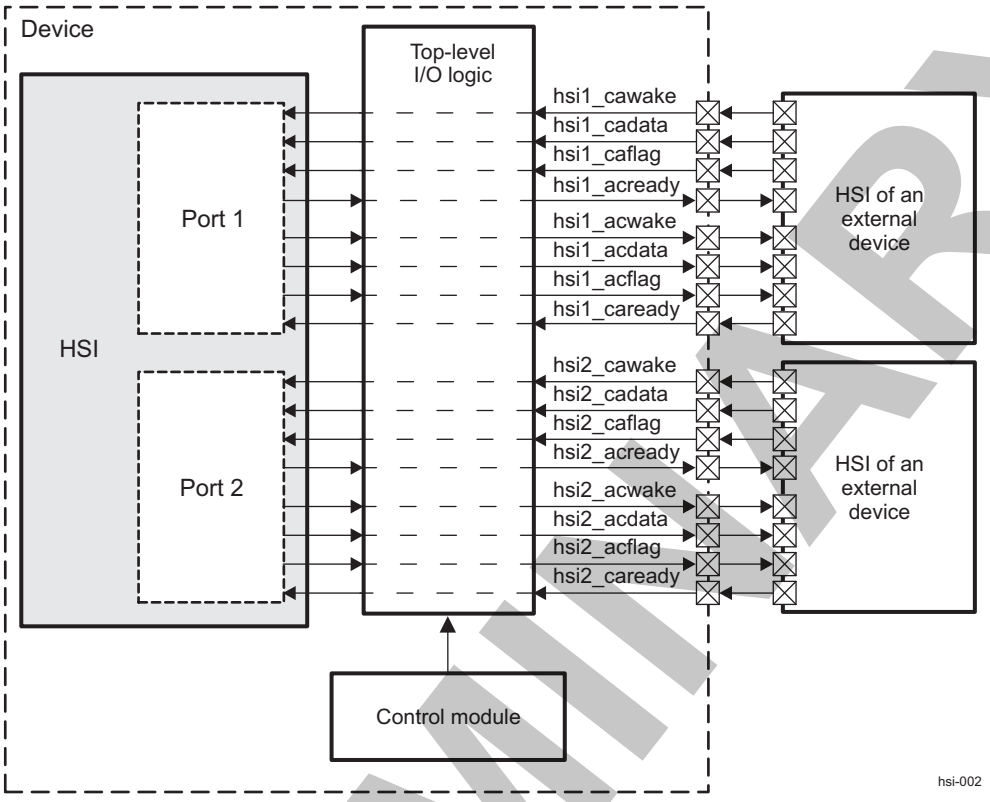
(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High impedance

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

23.9.2.2 HSI Typical Application

Figure 23-200 shows the HSI typical application.

Figure 23-200. HSI Typical Application

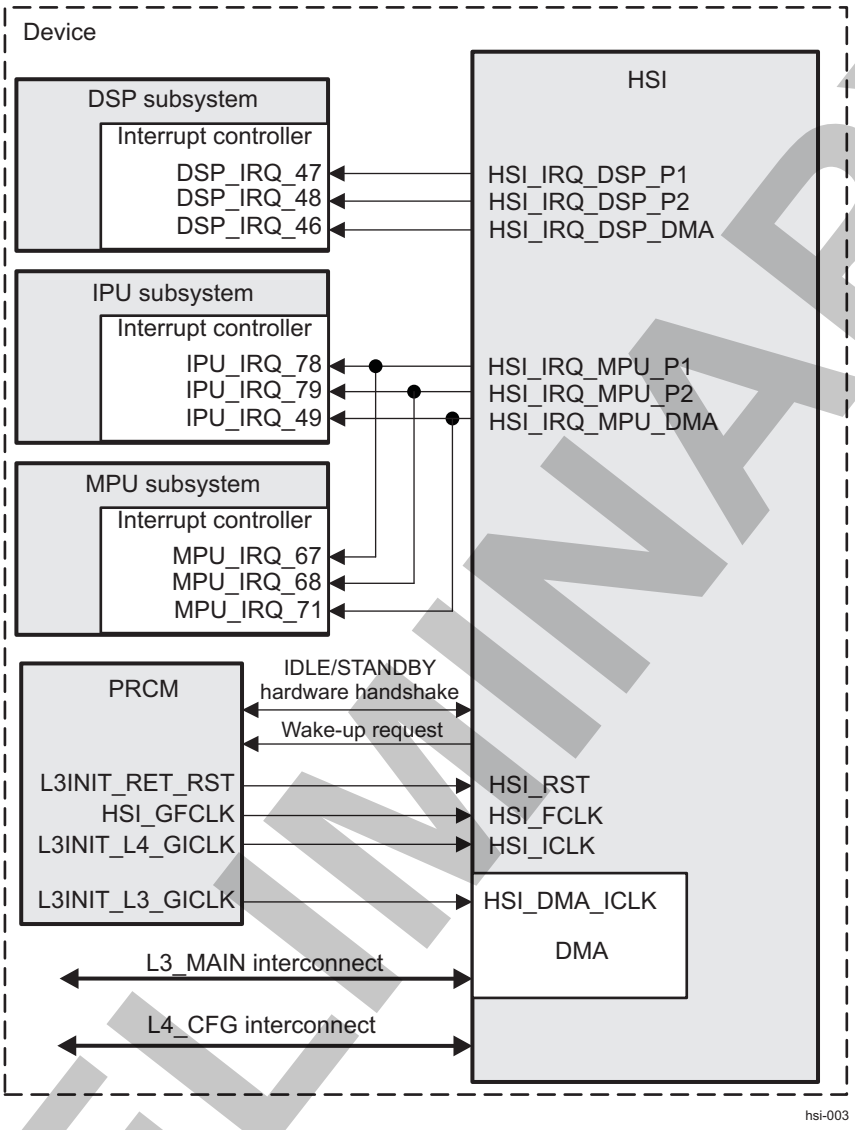


23.9.3 HSI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-201 shows the HSI module integration.

Figure 23-201. HSI Integration



NOTE: For more information about the IDLE/STANDBY hardware handshake and the wake-up request, see Chapter 3, *Power, Reset, and Clock Management*.

Interrupt lines HSI_IRQ_MPU_P[1:2] and HSI_IRQ_MPU_DMA are shared between the INTC_MPU and INTC_IPU. It is strongly recommended to unmask each interrupt source in only one INTC at a time.

Table 23-694 through Table 23-696 summarize the integration of the module in the device.

Table 23-694. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
HSI	PD_L3INIT	NA	L3_MAIN L4_CFG

	HSI_IRQ_DSP_P2	DSP_IRQ_48	DSP	HSI DSP request – Port 2
	HSI_IRQ_MPU_DMA[(1)]	MPU_IRQ_71	MPU (dual Cortex-A15)	HSI DMA engine MPU request
	HSI_IRQ_MPU_P1[(1)]	MPU_IRQ_67	MPU	HSI MPU request – Port 1
	HSI_IRQ_MPU_P2[(1)]	MPU_IRQ_68	MPU	HSI MPU request – Port 2
No DMA Requests				

(1) Interrupts shared between the INTC_MPU and INTC_IPU

NOTE: For a description of interrupt sources, see Section 23.9.4.5, *Interrupt Requests*.

23.9.4 HSI Functional Description

NOTE: In the functional description section, the following common internal signal names are used for the corresponding external HSI signals (for simplification):

- WAKE: hsi1_cawake, hsi1_acwake, hsi2_cawake, and hsi2_acwake
- DATA: hsi1_cadata, hsi1_acdata, hsi2_cadata, and hsi2_acdata
- FLAG: hsi1_caflag, hsi1_acflag, hsi2_caflag, and hsi2_acflag
- READY: hsi1_acready, hsi1_caready, hsi2_acready, and hsi2_caready

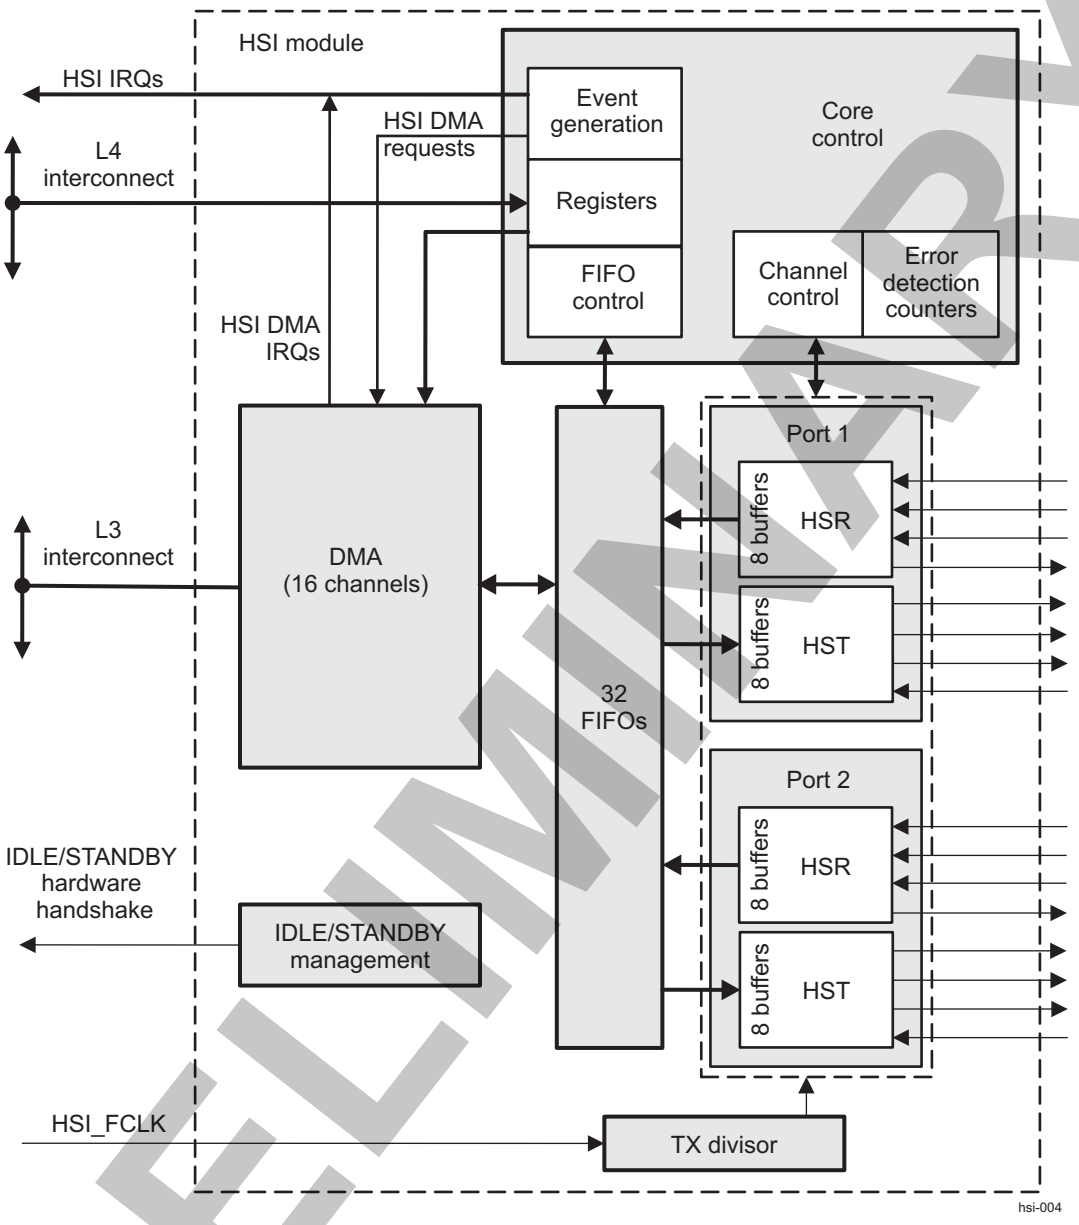
23.9.4.1 Block Diagram

The HSI controller is a subsystem built around two full-duplex multichannel synchronous serial interfaces. It contains a 16-bidirectional-logical-channel DMA in charge of handling data transfers between HSI modules and the L3_MAIN interconnect. Interrupt access to data is also available.

NOTE: Transmit data cannot be read back, and received data cannot be written in DMA and IRQ-based transfers.

Figure 23-202 shows most HSI module features.

Figure 23-202. HSI Controller Architecture Overview



NOTE: A bypass path in the DMA allows a processor (MPU or DSP) to retrieve or provide data received or to be transmitted on an interrupt triggered access, when the DMA is not enabled.

23.9.4.2 Clock Configuration

The HSI module has four fully asynchronous clock domains:

- Interface clock domain
- Functional clock domain
- Receive clock domain on port 1
- Receive clock domain on port 2

23.9.4.2.1 Interface Clock Domain

The following clocks are part of the interface clock domain:

- HSI_DMA_ICLK runs the interface master port (L3_MAIN). This clock is used for DMA master access to the L3_MAIN interconnect and also serves as the DMA functional clock.
- HSI_ICLK runs the interface slave port (L4). This clock is used to configure the module and to transmit and receive data through register access in an interrupt-based manner.

23.9.4.2.2 Functional Clock Domain

The functional clock (HSI_FCLK) runs the transmitter/receiver logic.

23.9.4.2.2.1 Transmit Clock

The transmit clock is obtained from the functional clock and is used to generate transmitter DATA and FLAG lines, according to the standard. Namely, the DATA line must always reflect the transmitted bit value, whereas the FLAG line must provide a transition (0 to 1, or 1 to 0) when the current DATA value is the same as the previous one.

The transmit data rate is programmable through the HST_DIVISOR_Pp[7:0] TX_RATE_DIV_VAL bit field.

Transmit clock = HSI_FCLK / (TX_RATE_DIV_VAL + 1).

23.9.4.2.2.2 Receive Error Detection Counters Clocks

The functional clock is also used to obtain clocks for receive error counters, which are independently divided versions of the functional clock. Division is set by software through the HSR_DIVISOR_Pp[7:0] RX_RATE_DIV_VAL bit field, which sets the bit rate clock for the frame time-out counter. This clock is further divided to generate an edge per frame to be sent to the frame burst counter.

23.9.4.2.3 Receive Clock Domain (Port 1 and Port 2)

The RX clock is retrieved from the DATA and FLAG signals available on the serial interface. A self-clocked source synchronous receiver implementation is done as follows: simple XOR of the DATA and FLAG signals recovers a signal displaying a transition on every bit time. From this signal, two clocks are generated with the appropriate phase, which can recover bit values, by sampling the DATA line, where the transmitted bit is always available.

23.9.4.3 Software Reset

The HSI module can be reset by software through the HSI_SYSCONFIG[1] SOFTRESET bit. Setting this bit to 1 enables an active global software reset that is functionally equivalent to a hardware reset. The HSI_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is set to 1. Software must ensure that the software reset completes before performing HSI operations.

The DMA engine can be independently reset by software through the DMA_GRST[0] SWRESET bit. Setting this bit to 1 resets the DMA registers and logic. This bit is automatically cleared when the DMA reset completes.

23.9.4.4 Power Management

Table 23-697 describes power-management features available for the HSI module.

NOTE: For descriptions of IdleMode and StandbyMode features, see Chapter 3, *Power, Reset, and Clock Management*.

Table 23-697. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	HSI_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the HSI_ICLK clock upon the interface activity.
	DMA_GCR[3] AUTOGATING	This bit allows a local power optimization inside the module by gating the HSI_DMA_ICLK clock upon the interface activity.
Slave idle modes	HSI_SYSCONFIG[4:3] SIDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Master standby modes	HSI_SYSCONFIG[13:12] MIDLEMODE	Force-standby, no-standby, smart-standby, and smart-standby wake-up modes are available.

23.9.4.4.1 HSI Module Power-Management Modes

23.9.4.4.1.1 Standby

When asserted, this signal informs the PRCM module that HSI is quiet and does not generate any traffic on the interconnect.

The HSI module supports four STANDBY handshake modes, selected through the HSI_SYSCONFIG[13:12] MIDLEMODE bit field:

- Force-standby (0x0): Selecting this mode asserts the standby signal unconditionally of the HSI activity. Software must ensure that HSI is disabled and does not generate any activity before activating this mode.
- No-standby (0x1): Standby signal is never asserted.
- Smart-standby (0x2): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion).
- Smart-standby wakeup (0x3): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion). It can also generate a wake-up request.

23.9.4.4.1.2 Idle

The PRCM module asserts an IDLE request signal when it requires the HSI slave port to be idled. Any access to this port after the IDLE request signal has been asserted generates an error.

The HSI module supports four IDLE handshake modes, selected through the HSI_SYSCONFIG[4:3] SIDLEMODE bit field:

- Force-idle (0x0): An IDLE request is acknowledged unconditionally.
- No-idle (0x1): An IDLE request is never acknowledged.
- Smart-idle (0x2): Acknowledgment to an IDLE request is given based on the internal HSI module activity.
- Smart-idle wakeup (0x3): Acknowledgment to an IDLE request is given based on the internal HSI module activity. Additionally, when in this mode, the HSI module is allowed to generate a wake-up request.

23.9.4.4.1.3 Auto-Idle

The HSI module provides an auto-idle option for the interface clock domain. Auto-idle mode is enabled by setting the HSI_SYSCONFIG[0] AUTOIDLE and/or DMA_GCR[3] AUTOGATING bits to 1. When this mode is enabled and there is no activity on the interconnect interface, the interface clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interface clock is restarted without any latency penalty.

23.9.4.4.1.4 DMA Engine Switch Off Mode

The DMA interface clock (HSI_DMA_ICLK) can be switched off by setting the DMA_GCR[0] SWITCH_OFF bit to 1. DMA clock activity is then cut off. Software must ensure that ongoing transitions are complete before cutting off clocks. Once the DMA is switched off, access to reset this bit is possible only through the configuration port.

23.9.4.5 Interrupt Requests

Table 23-698 lists the event flags, and their mask, that can cause module interrupts.

Table 23-698. Events

Event Flag	Event Mask	Map to	Description
HSI_Pp_M_IRQrU_STATUS[27] HSR_WAKE_RISE; [26] HSR_WAKE_FALL	HSI_Pp_M_IRQrU_ENABLE[27] HSR_WAKE_RISE; [26] HSR_WAKE_FALL	HSI_IRQ_MPU_P1 HSI_IRQ_MPU_P2	Wake detected on any channel 8–15.

23.9.4.5.1 Interrupts

By default, there are 4 interrupt output lines per HSI port (Mpuirq_0, Mpuirq_1, Dspirq_0, and Dspirq_1), and 2 in case of DMA interrupt (MPU, DSP). The following registers are related to these interrupt outputs:

- Status registers:
  - HSI_Pp_M_IRQrU_STATUS / HSI_Pp_M_IRQr_STATUS for Mpuirq_r (where r = 0 or 1)
  - HSI_Pp_D_IRQrU_STATUS / HSI_Pp_D_IRQr_STATUS for Dspirq_r (where r = 0 or 1)
  - HSI_DMA_M_IRQSTATUS for DMA interrupt to MPU
  - HSI_DMA_D_IRQSTATUS for DMA interrupt to DSP
- Enable registers:
  - HSI_Pp_M_IRQrU_ENABLE / HSI_Pp_M_IRQr_ENABLE for Mpuirq_r (where r = 0 or 1)
  - HSI_Pp_D_IRQrU_ENABLE / HSI_Pp_D_IRQr_ENABLE for Dspirq_r (where r = 0 or 1)
  - HSI_DMA_M_IRQENABLE for DMA interrupt to MPU
  - HSI_DMA_D_IRQENABLE for DMA interrupt to DSP

However, Mpuirq_0 and Mpuirq_1 are further combined (logical OR) into one common interrupt output per port (HSI_P1_MPU_IRQ for port 1, and HSI_P2_MPU_IRQ for port 2). The same goes for Dspirq_0 and Dspirq_1 (HSI_P1_DSP_IRQ for port 1, and HSI_P2_DSP_IRQ for port 2).

This means that it is enough to enable one of the FIFO/WAKE/BREAK/ERROR interrupt events per port (for example, in HSI_Pp_M_IRQ0(U)_ENABLE) for the corresponding interrupt request to be raised. Enabling both HSI_Pp_M_IRQ0(U)_ENABLE and HSI_Pp_M_IRQ1(U)_ENABLE would only mean extra checks and clears (in the corresponding IRQ status register). The same is also valid for the DSP-related IRQ enable/status registers.

The HSI module outputs six interrupt signals (for more information, see Section 23.9.3, *MIPI HSI Integration*). All the interrupts are active-high level-sensitive. Each interrupt line is activated by a set of individual sources. All interrupt sources can individually be enabled and disabled.

For each interrupt, 2 status bits and 2 mask bits are provided, allowing independent masking for the different processors (that is, 1 status bit and 1 mask bit for the MPU [Cortex-A15 or Cortex-M4] interrupts, and 1 status bit and 1 mask bit for the DSP interrupts).

Interrupts in the HSI module are intended to:

- Signal any error condition in reception
- Support the WAKE condition detection

- Support the BREAK condition detection
- Warn of DMA transfer status or problems
- Signal to processors when to read received data and to write data to transmit

Because DMA has only 16 channels, 16 RX FIFO and 16 TX FIFO are managed by a mix of DMA-driven and interrupt-driven read/write policies.

23.9.4.5.1.1 HSI Interrupt Generation

Five types of interrupt events can be generated by each HSI port:

- Transmit FIFO not full: Occurs when TX FIFO is not full, so data can be written for transmission
- Received data available: Occurs when one data frame has been received and is available on the RX FIFO for reading
- Overrun: Occurs when data overrun is detected on HSI port *p* channel *i*
- Error: Any error defined by the MIPI HSI protocol activates this source of interrupt if this source is enabled.
- Break condition detected: Occurs upon reception of a continuous string of 0s that exceed those possible in any FRAME mode frame (data + header). Because FRAME mode always put a 1 before any frame, the maximum number of 0s occurring during normal transmission is clearly 32 plus the base 2 logarithm of channels used. Hardware works out this number based on register information on channels and receive mode and issues an interrupt if this source is enabled.

All the events are cleared by software, upon setting the corresponding register bit to 1. Setting the bit to 0 has no effect.

23.9.4.5.1.2 DMA Interrupt Generation

Three types of interrupt events can be generated by each DMA channel:

- End of Block: Enabled through the DMA_CSR_CCIR_i[5] BLOCK_IE bit, it occurs when the last element of the transfer has been written into destination. The DMA_CEN_i[15:0] SIZE bit field defines the number of elements in a block.
- Half Block: Enabled through the DMA_CSR_CCIR_i[2] HALF_IE bit, it occurs when a half of the elements have been written into destination.
- Time-out error: Enabled through the DMA_CSR_CCIR_i[0] TOU_IE bit, it occurs when destination slave answers by an error code.

All interrupt events are generated on the same logical channel dedicated interrupt line. When an interrupt is issued by a logical channel, its DMA_CSR_CCIR_i status register is set to record the interrupt cause, if the interrupt event bit is enabled in the relevant DMA_CSR_CCIR_i register. The processor interrupt service routine can read this channel status register to identify the sources of the interrupt. The status bits are automatically cleared after they are read by the processor, unless it is an emulation read.

There are two classes of DMA interrupt events:

- Error events: Errors during the transfer
- Status events: DMA transfer status, such as end of block or half-block

The DMA manages the two classes differently.

For an enabled error event, the following sequence occurs:

1. The appropriate bit in the DMA_CSR_CCIR_i register is set.
2. An interrupt is generated.
3. The ports are released.
4. The currently active logical channel is disabled and must be reprogrammed.
5. Other channels are not affected, and a new channel can get over, according to programmed priorities.

For an enabled status event, the following sequence occurs:

1. The appropriate bit in the DMA_CSR_CCIR_i register is set.

2. An interrupt is generated.
3. A new interrupt cannot be generated until the status register is read and thereby cleared.

All the events are cleared by software, upon setting the corresponding interrupt status register (HSI_DMA_M_IRQSTATUS or HSI_DMA_D_IRQSTATUS) to 1. Setting the interrupt status register to 0 has no effect.

23.9.4.6 DMA Module

23.9.4.6.1 DMA Overview

The DMA module transfers data between the HSI interfaces and the device on-chip memories. The DMA module supports 16 logical channels and is a dual-port initiator (peripheral port/memory port) with one slave port for configuration. The memory port provides an interface to the memory space and the peripheral port provides an interface to the HSI interfaces. In the HSI controller, the L4_CFG port accesses can be routed directly to the HSI interfaces. This is done by setting the DMA in bypass mode to route the DMA slave port to the DMA peripheral port.

DMA features:

- One target port, for configuration
- 16 logical channels: *n* for transmission and *16-n* for reception
- One initiator port, for transfer to/from memory
- One port to/from LCH memory (this memory holds some registers)
- 32-bit data handling only
- Constant addressing mode on peripheral port/FIFO
- Post-increment addressing mode with burst support on memory port
- Software enabling
- Hardware activation of data transfer on peripheral port
- Logical channels interleaving with only few-cycles-latency
- Fixed allocation of memory and peripheral port to a logical channel
- LCH first-come-first-served + fixed priority arbitration
- Low-power operation (hardware control for clock domains activity)
- Software reset

23.9.4.6.2 DMA Memories

DMA channel register memory is managed by the DMA. Only the DMA interfaces this memory. A processor must program the DMA registers included in this memory.

The DMA has access to 16 dual-port FIFO 8 × 32 bits for reception and 16 dual-port FIFO 8 × 32 bits for transmission. They are provided in the form of two separate memories.

23.9.4.6.3 DMA Basic Operation Outline

DMA write and read operations are helped by tags, to manage possibly disorderly answers. Posted or nonposted operations are possible. In any case, the interconnect always manages them as nonposted. This is consistent with DMA operations that need to know (for example, if main memory write was successful). If not, the error response from L3_MAIN interconnect slave produces a DMA error and the corresponding interrupt. DMA addressing of FIFO memories is always on a constant address, corresponding to 1 of the 16 HST_BUFFER_Pp_CHN_i (or HSR_BUFFER_Pp_CHN_i) registers.

These registers are associated with the 16 FIFOs, and the naming reflects only the reset value of the association FIFO, HSI logical channel. Therefore, at reset, the FIFO addressed on the HSR_BUFFER_P2_CHN_4 register is associated with the fourth logical channel of the second port. Nevertheless, software can change this mapping and associate the same FIFO (for example, to the seventh channel of the first port). This mapping is performed by software through the HST_MAPPINGf[4:1] CH_NUMBER or HSR_MAPPINGf[4:1] CH_NUMBER bit fields.

23.9.4.6.4 DMA Configuration

Before performing a DMA transfer, the following DMA registers must be configured:

- DMA_CCR_CSDP_i: Sets source and destination parameters and channel control
  - DMA_CCR_CSDP_i[15:14] DST_BURST_EN: Destination burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
  - DMA_CCR_CSDP_i[12:9] DST: Transfer destination (0x8: transfer to memory port; 0x9: transfer to peripheral port)
  - DMA_CCR_CSDP_i[8:7] SRC_BURST_EN: Source burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
  - DMA_CCR_CSDP_i[5:2] SRC: Transfer source (0x8: transfer from memory port; 0x9: transfer from peripheral port)
  - DMA_CCR_CSDP_i[31:30] DST_ADD_MODE: Destination addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
  - DMA_CCR_CSDP_i[29:28] SRC_ADD_MODE: Source addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
- DMA_CSR_CCIR_i: Enables DMA sources of interrupt events
- DMA_CSSA_i[31:0] ADDR: Stores 32 bits of the source address
- DMA_CDSA_i[31:0] ADDR: Stores 32 bits of the destination address
- DMA_CEN_i[31:0] SIZE: Defines the number of elements in a block. The maximum number of elements is 65535.

To start a DMA transfer, the DMA channel to be used must be enabled by setting the DMA_CCR_CSDP_i[23] ENABLE bit to 1. Once the DMA transfer is finished, the DMA_CCR_CSDP_i[23] ENABLE bit is automatically reset by hardware.

The DMA_CDAC_CSAC_i[15:0] ADDRESS_CSAC (or DMA_CDAC_CSAC_i[31:15] ADDRESS_CDAC) bit field can be used to monitor the progress of a DMA transfer on the channel source (or destination). It is a snapshot of the source (or destination) address generated by the channel counter. It is incremented on each access made on channels.

23.9.4.7 HSR Module

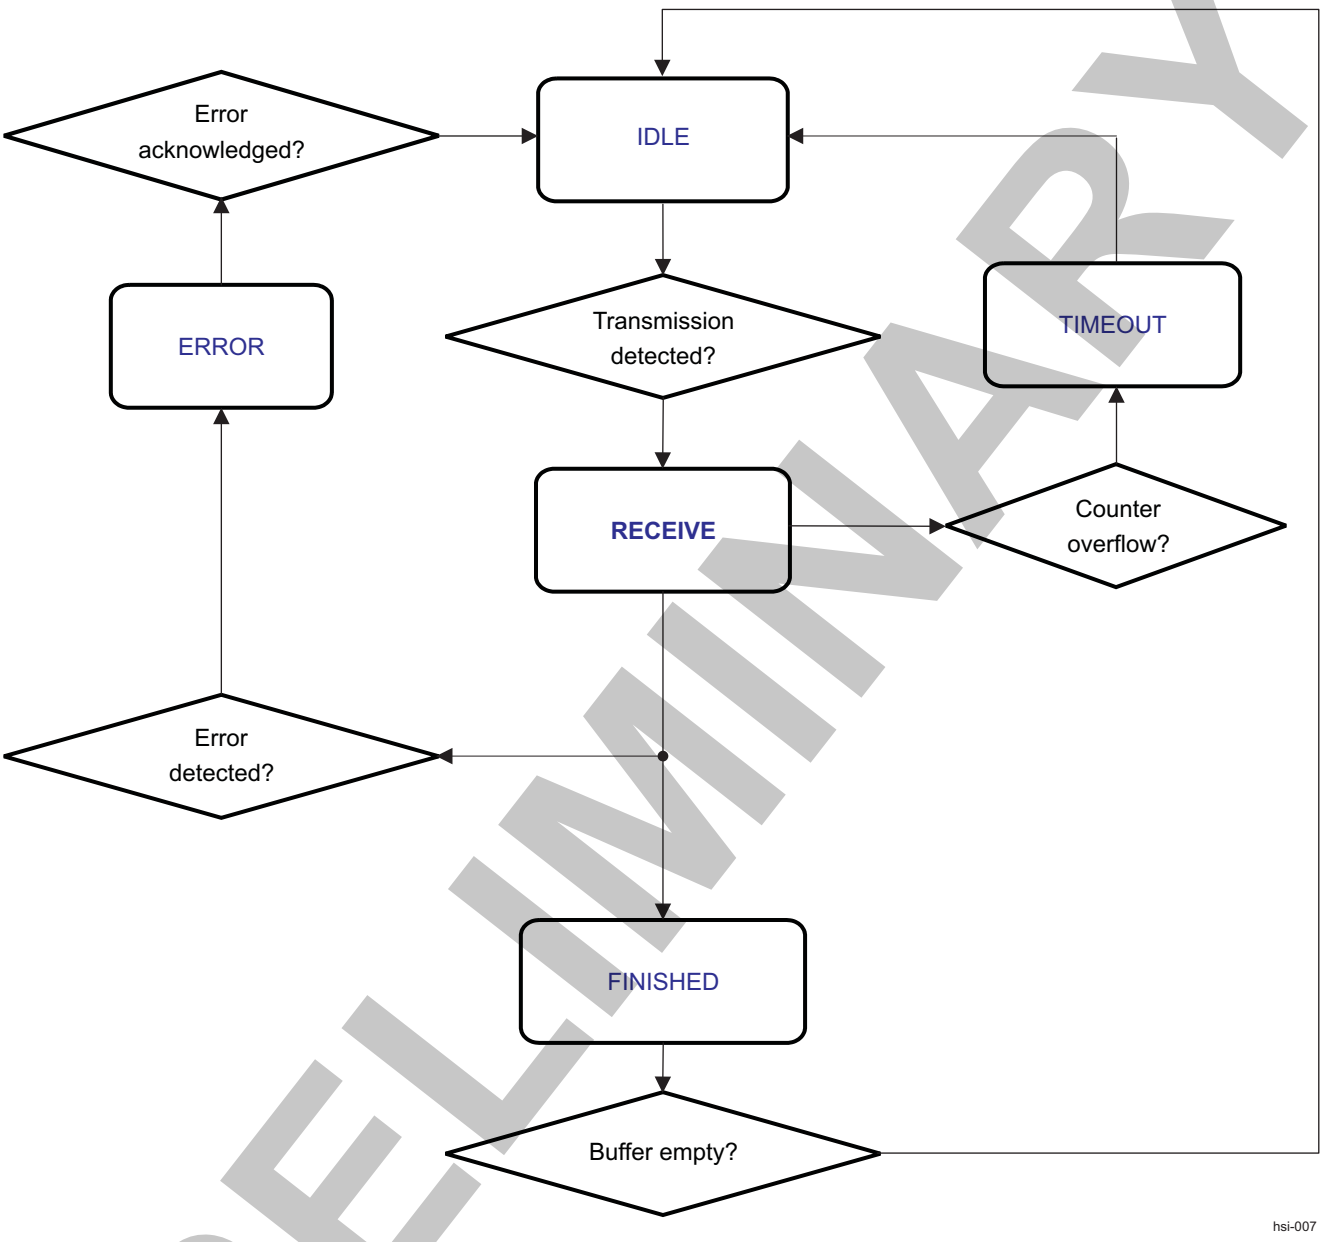
The HSR module is the receiver part of the HSI module. It features 16 channels.

23.9.4.7.1 Receive Data

The value on the DATA line is always the transmitted bit, when sampled by the clock recovered. The double level of buffering allows the data to be safely transferred to the FIFO, while a new frame is stored. Data headers do not belong in FIFO and must be decoded to load data on the correct FIFO (there is one logical FIFO per logical channel).

Figure 23-203 shows the receive state-machine implemented in the HSI module.

Figure 23-203. Receive FSM



23.9.4.7.2 Transmission Detection

Reception starts upon two alternate conditions:

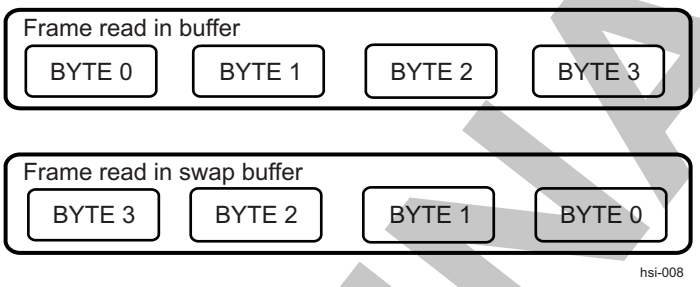
- The remote transmitter raises the WAKE line (in this case, it does not actually transmit until the local receiver raises the READY line).
- An activity (in the form of transitions) appears on the FLAG/DATA lines, in case the remote transmitter does not implement the WAKE signal. The receiver must then save and store the received data, at least one frame long, before preventing further transmission by setting READY to 0.

23.9.4.7.3 Receive Buffers

For each logical channel, the HSR_BUFFER_Pp_CHN_i[31:0] DATA bit field holds one frame. The appropriate bit in the HSR_BUFSTATE_Pp register is set to 1 by hardware when the corresponding HSR_BUFFER_Pp_CHN_i register holds one frame. Reading the HSR_BUFFER_Pp_CHN_i[31:0] DATA bit field automatically resets the appropriate bit in HSR_BUFSTATE_Pp. This lets the receiver put another data frame in HSR_BUFFER_Pp_CHN_i, setting again HSR_BUFSTATE_Pp.

Some applications need reversed byte ordering of frames. This is supported by the HSR_SWAPBUFFER_Pp_CHN_i register (see Figure 23-204). By reading this register instead of the corresponding HSR_BUFFER_Pp_CHN_i register on the same channel, byte ordering of the 4 bytes in a frame is reversed.

Figure 23-204. HSR_SWAPBUFFER_Pp_CHN_i Register



Reading the MSB of the HSR_SWAPBUFFER_Pp_CHN_i register sets the corresponding bit of HSR_BUFSTATE_Pp to empty.

NOTE: Read access to the register with 0x3 and 0xF byte-enable removes the receive FIFO-related item. If only 16-bit accesses are used, the upper 2 bytes must be read first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

23.9.4.7.4 Receive Operations

Logically, the receiver amounts to the receiver shift register, double-buffering and the FSM. The current state of the FSM can be observed and controlled through the HSR_RXSTATE_Pp[2:0] RXSTATEVAL bit field. For the receive FSM, a functional description is shown in Figure 23-203.

The receiver FSM is in IDLE state when no transmission is detected, or the HSR_MODE_Pp[1:0] MODE_VAL bit field = FRAME and no synchronization bit is detected. Otherwise, it stores the first received bit and transitions to RECEIVING state, where it stops until a full frame is received.

Depending on the selected flow control, the READY line may have to go to 0 after the first bit is received.

Upon receiving a full frame, the FSM transitions to FINISHED state. Otherwise, the FSM transitions to TIMEOUT state as soon as a time-out value (if enabled and programmed in the HSR_COUNTERS_Pp[19:0] FT bit field) is reached. Then it moves to IDLE state.

After entering RECEIVED state, the FSM stays there until the received frame is correctly stored and there is room for another frame. At this point, READY is raised and the FSM goes to IDLE state. In pipelined flow, flow control by READY is not operating at each byte, and in real time flow it is never operating. In both cases, the FSM transitions immediately to IDLE, to receive more data. Illegal transitions or flags raised by error counters (see Section 23.9.4.11, *Error Reporting*), move the FSM to ERROR state, and then to HALT, to wait until the error is acknowledged by software, warned by an interrupt. Except for pipelined control flow, the READY output is always 1 in IDLE state and 0 anywhere else. In pipelined mode, the READY signal stays to 1, and is cleared by a condition on buffer full. The FSM state can be controlled by software by writing in the HSR_RXSTATE_Pp[2:0] RXSTATEVAL bit field. This can be useful to recover from an error condition.

23.9.4.7.5 Receive Exceptions

23.9.4.7.5.1 Break

Remote transmitter can force synchronization by a long enough string of 0s (equal to the number of header + data bits in the frame + 1). In frame mode, this sends an interrupt.

23.9.4.7.5.2 Overrun

An overrun condition is possible during real-time flow, if received data occur when the FSM is in FINISHED state. Whenever this happens, the HSR_OVERRUN_Pp[15:0] OVERRUN_VAL bit field is set for the corresponding logical channel, which in turn generates an interrupt.

An overrun exception is a legacy condition required in previous SSI hardware, where reception without the READY signal had to be supported. In HSI the READY signal always exists, but it cannot be used during real-time flow and the last 8 bits of a frame during pipelined flow. During real-time data flow, overrun can occur at any time. The main goal of using real-time flow is flushing FIFOs after an error. In that case, an overrun interrupt does not seem worth to be raised. Data does not have to be discarded. The real-time data are discarded if the receiver cannot follow the transmission rate, otherwise, the real-time data is kept in FIFO.

23.9.4.7.5.3 Errors

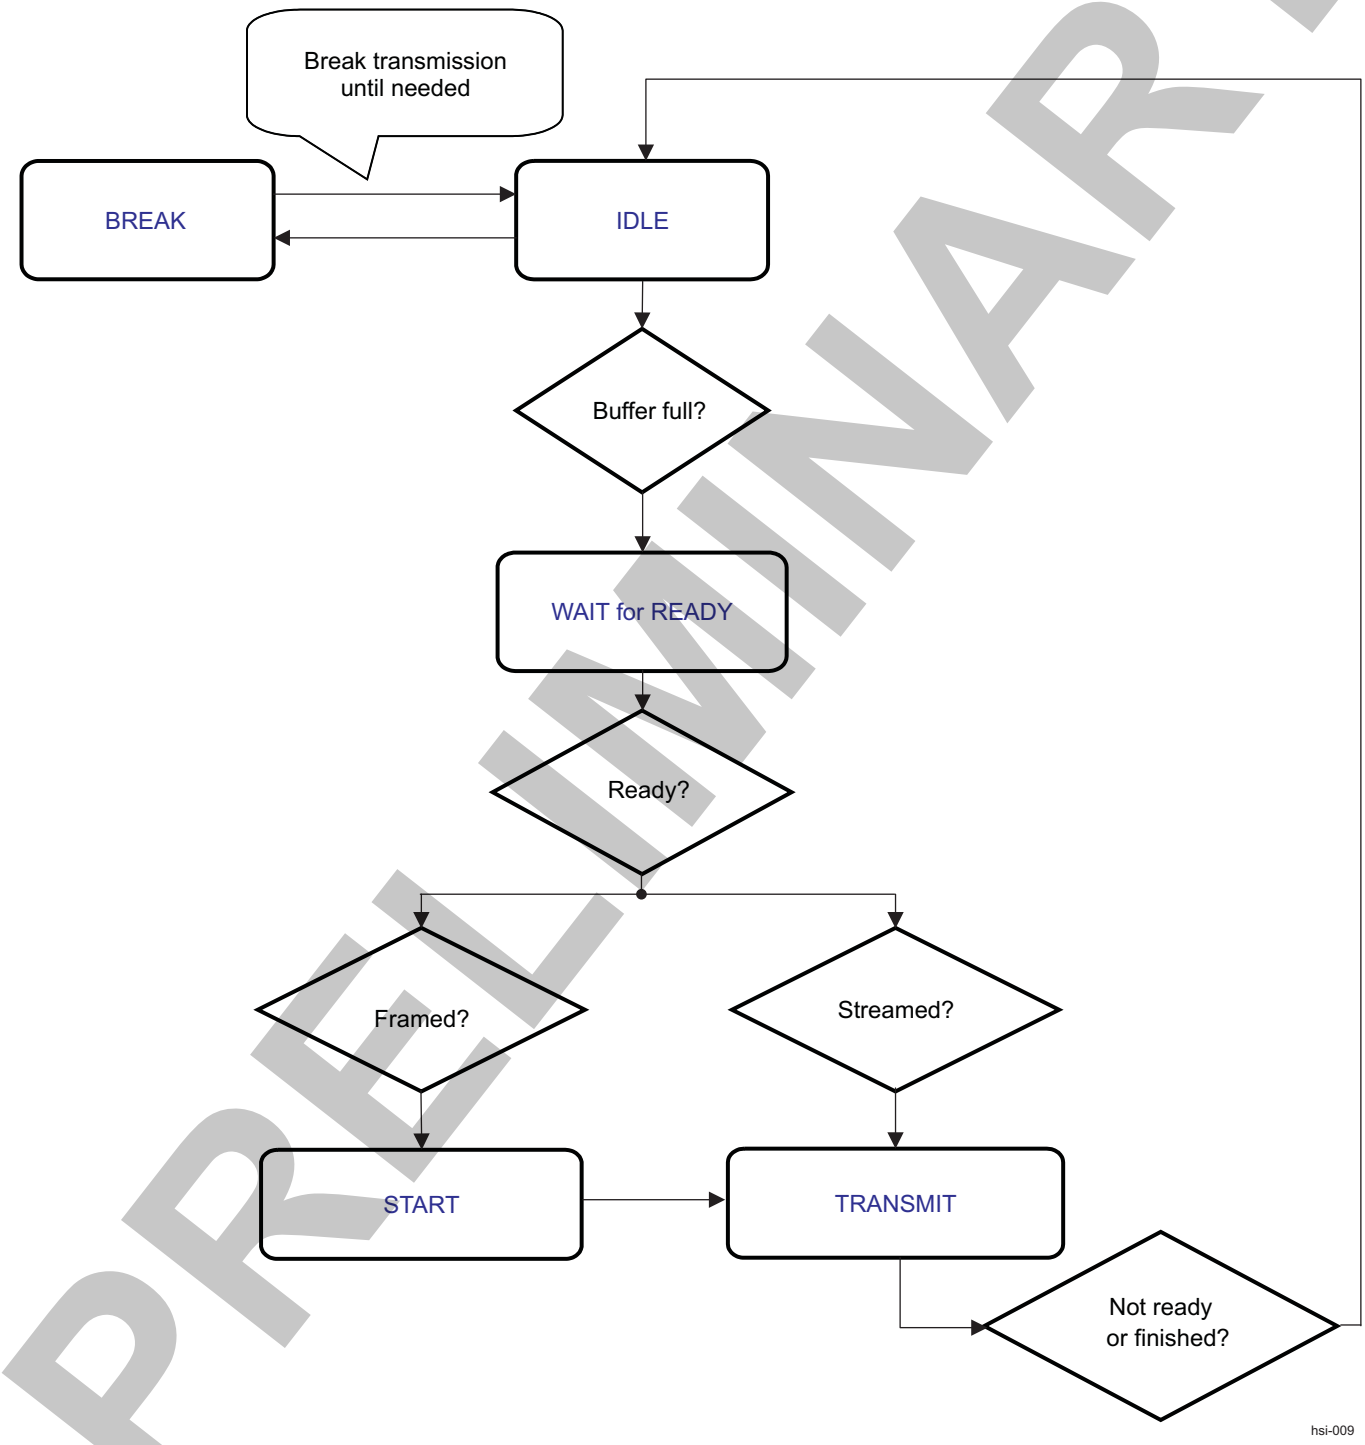
Several sources of errors are possible. In any of them, the receiver FSM stays in ERROR state until the error interrupt is acknowledged by writing the HSR_ERRORACK_Pp registers. Sources of errors include receive FRAME TIMEOUT, other receive errors flagged by error counters, and any other abnormal condition, as explained in Section 23.9.4.11, *Error Reporting*.

23.9.4.8 HST Block

The HST block is the transmitter part of the HSI module. It features 16 channels.

Figure 23-205 shows the receive state-machine implemented in the HSI module.

Figure 23-205. Transmit FSM



23.9.4.8.1 Configuration

Configuration of the component is expressed in terms of operation mode, number of logical channels, bit rate divisor, and arbitration mode.

23.9.4.8.1.1 Mode Register

The HST_MODE_Pp register cannot be changed without stopping the link.

There is one HST_MODE_Pp[3:2] FLOW_VAL bit field for each active transmit channel and another HSR_MODE_Pp[3:2] FLOW_VAL bit field for each active receive channel. The local transmitter (communicating with the remote receiver) uses the HST_MODE_Pp[3:2] FLOW_VAL bit field for interpretation of the received READY line, for example to signal errors.

The HST_MODE_Pp register has the following bit fields:

- WAKE_CTRL selects between software (when 0x0) or automatic (when 0x1) control for the WAKE line. The default is software control.
- MODE_VAL defines the following operation modes:
  - Sleep: Specifies whether internal clocks must run and port be operating
  - Stream: Receiver does not use start-bits.
  - Frame: Allows break transmission/reception defined as a longer-than-frame 0 sequence
- FLOW_VAL defines the following data flows:
  - Synchronized flow: The READY signal from the receiver drops after every first frame bit, rising when data are stored, and transmission of a new frame is possible.
  - Pipelined flow: The receiver cannot drop the READY line at some times.
  - Real-time flow: The receiver drops the READY line at the first received bit and raises it at the last one.

NOTE: READY is activated when the module is going into active state (stream or frame mode). The receive mode must be selected at the end of module's configuration, because activates the transfer from the remote side. This will prevent the device from wrong received data, lost of data, fake start of communication.

23.9.4.8.1.2 Other Registers

- The HST_FRAMESIZE_Pp register is kept to offer legacy compatibility. It is a read-only register, returning 0x1F.
- The HST_DIVISOR_Pp[7:0] RX_RATE_DIV_VAL bit field sets the transmission bit rate, with 1 transmitted bit per clock cycle. Bit rate can be changed by software at any time.
- The HST_CHANNELS_Pp[4:0] CHAN_NUM_VAL bit field sets the number of logical channels. It must be a power of 2. The default value is 0x1. This corresponds to only one logical channel, always the same, and in that case, a header is not transmitted; It cannot be changed without stopping the link.
- HST_MAPPINGf contains important settings for each FIFO (one register per FIFO):
  - HST_MAPPINGf[0] ENABLE bit: FIFO is enabled or not.
  - HST_MAPPINGf[4:1] CH_NUMBER and HSR_MAPPINGf[7] PORT_NUMBER bit fields (channel number and port number): FIFO is assigned to an HSI logical channel on a physical port.
  - HST_MAPPINGf[13:10] THRESHOLD bit field is the number of empty TX FIFO locations that will activate interrupt automatically.
- The HST_ARBMODE_Pp[0] ARB_VAL bit allows choosing of the arbitration policy for time allocation to logical channels, when several channels have to transmit. Round-robin algorithm implements a circular scan: the same channel cannot transmit twice if another channel is ready to transmit. Scan proceeds in the same, unspecified direction (design choice). Fixed priority algorithm grants maximum priority to logical channel 0, minimum priority to channel 15. The right to transmit is assigned to the higher priority channel ready to transmit, independently of previous transmissions.

  The choice between algorithms must consider that round-robin sets a maximum wait time for each channel, but it may require a long time to transmit long sequences of frames, on any channel. On the other hand, fixed priority allows limiting of transmission time for high priority channels, while low priority channel may wait for a long time.

  It is important to understand that this register sets the allocation of one port resource (transmission lines) from 2 to 16 vying transmit FIFOs. Allocation of the 16 transmit FIFOs to 32 logical channels is

done by the HST_MAPPINGf register. For this second kind of allocation, no arbitration makes sense, because software is in charge to ensure against more that 16 logical channels transmitting at the same time.

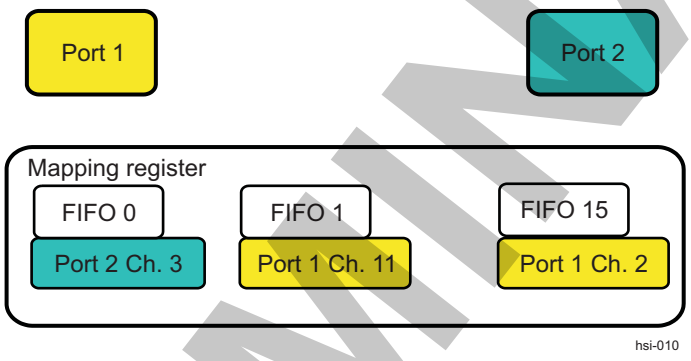
23.9.4.8.2 Mapping

Figure 23-206 shows an example of programming the HST_MAPPINGf register. No limitation is set on the choice of channel/FIFO/port association.

Each port has its HST_ARBMODE_Pp register so that it is also possible to program alternate algorithms on ports.

While the HST_MAPPINGf register cares only about FIFO, the HST_ARBMODE_Pp register is associated to a port and each port has its own one, which only selects a winner between ready-to-transmit channels of this port. For example, suppose that in Figure 23-206 only the three represented channels need to transmit; then a yellow (Port 1) arbiter chooses between channel 11 and channel 2, while the cyan (Port 2) arbiter has no decision to take and lets channel 3 transmit.

Figure 23-206. MAPPING Register



23.9.4.8.3 Transmission Buffer

The transmission buffer holds a frame to be transmitted for each channel. The HST_BUFSTATE_Pp[7:0] BUFSTATE_VAL bit field indicates whether the HST_BUFFER_Pp_CHN_i[31:0] DATA bit field holds significant data, and it is not be cleared until transmit FSM is in IDLE state and arbitration indicates the channel is the next in line to transmit. The HST_BUFSTATE_Pp register is automatically written by hardware.

NOTE: Write access to the register with 0x3 and 0xF byte-enable loads its value into the transmit FIFO. If only 16-bit accesses are used, the upper 2 bytes must be written first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

Some applications need reversed byte ordering of frames. This is supported by the HST_SWAPBUFFER_Pp_CHN_i register. By reading this register instead of the corresponding HST_BUFFER_Pp_CHN_i register on the same channel, byte ordering of the 4 bytes in a frame is reversed (see Section 23.9.4.7.3, *Receive Buffers*).

23.9.4.8.4 Break Pattern Transmission

Break pattern transmission is an alternative to normal transmission mode, and is used when trying to recover lost synchronization. It is started by software by setting the HST_BREAK_Pp[0] BREAK_VAL bit. As soon as transmit FSM is in IDLE state (ready to accept another frame for transmission), a nonzero value on the HST_BREAK_Pp[0] BREAK_VAL bit starts the BREAK sequence, and automatically clears the HST_BREAK_Pp[0] BREAK_VAL bit. A sequence of 0, longer than a frame, is transmitted.

23.9.4.8.5 Transmission Operations

The transmitter adds up to the transmit shift register, loaded from the transmission buffer, and the transmit FSM current state of the FSM can be observed and controlled through the HST_TXSTATE_Pp[2:0] TXSTATEVAL bit field. A functional description of the transmit FSM is shown in Figure 23-205.

After reset, the transmitter is in IDLE state. It starts transmission when there is data in one of the transmission HST_BUFFER_Pp_CHN_i registers, depending on the value of HST_BUFSTATE_Pp[7:0] BUFSTATE_VAL bit field, or when the value of BREAK is not 0.

When transmitting a data frame (not a BREAK sequence), the frame to be transmitted is clocked from the HST_BUFFER_Pp_CHN_i register to the transmission shift register, and the FSM enters WAIT state until it receives READY = 1. At this point, it starts driving the DATA and FLAG lines with a preliminary start-bit at 1, if in STREAM mode, or with the frame, which amounts to header and payload data.

In case of synchronized data flow, the TRANSMIT state is left after one frame is transmitted, because READY always drops after the first transmitted bit. Transmit FSM transitions through IDLE and WAIT states before retransmitting, when READY rises.

In case of pipelined data flow, transmit FSM remains in TRANSMIT state as long as READY = 1, and transmission goes on, always clocking data from the appropriate HST_BUFFER_Pp_CHN_i register, as selected by arbitration. Transmission is stopped by the condition READY = 0, forcing FSM to go into IDLE state. READY must not switch during the last 8 nominal bit times.

23.9.4.8.6 Transmission Exceptions

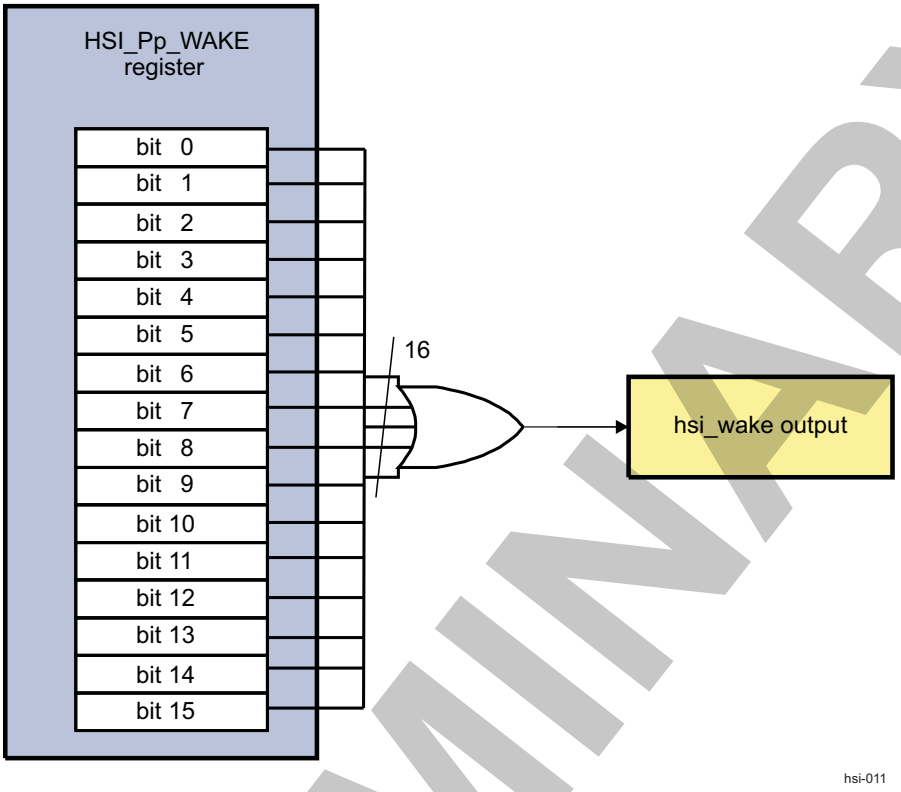
There are no transmission errors. Reception of READY = 0 in the last 8 bits of frames is not flagged. The DATA ACCEPTED interrupt is used to inform software that the HST_BUFFER_Pp_CHN_i[31:0] DATA bit field is empty and to request more data.

23.9.4.9 HSI Wake Generator

The WAKE line is used to create a wake-up event for the external module that interfaces with HSI before a data transfer through the HSI serial interface.

The 16 bits (1 per HSI channel) of the HSI_Pp_WAKE[15:0] WAKE_CHI bit field are ORed together to drive the WAKE line, as shown in Figure 23-207.

Figure 23-207. HSI_Pp_WAKE Control in Case of Managed Wake



The wake generator can be managed by software operations or automatically by hardware. If the wake generator is not managed, the WAKE signal is driven to 0 and the remote transmitter must wake itself upon activity detection on the DATA and FLAG lines.

23.9.4.9.1 Software Management of HSI Wake Generator

Software can get the responsibility to use and manage those bits to create and release wake-up events consistently with HSI use.

Because the HSI_Pp_WAKE[15:0] WAKE_CHI bit field can be managed by different threads/processors, this mechanism allows independent bit management by each thread. Without locking the HSI_Pp_WAKE register (as a read-modify-write does), it avoids one thread to overwrite the register change made by another thread. Each bit of the HSI_Pp_SET_WAKE[15:0] HSI_SET_WAKE_CHI bit field is owned by one thread at a time.

- The thread can set this bit by setting the corresponding bit of the HSI_Pp_SET_WAKE[15:0] HSI_SET_WAKE_CHI bit field to 1. This sets only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).
- The thread can clear this bit by setting the corresponding bit of the HSI_Pp_CLEAR_WAKE[16:0] HSI_HSI_CLEAR_WAKE_CHI bit field to 1. This clears only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).

23.9.4.9.2 Automatic Management of HSI Wake Generator

The wake generator is automatically managed when there is a transmission to be performed. When data are waiting for transmission in a FIFO TX, the hardware sets the corresponding bit of the HSI_Pp_WAKE[15:0] WAKE_CHI bit field, and this raises the WAKE signal on port *p*. Then WAKE is deasserted by the first occurrence of one event between a fixed time-out from the end of the last transfer, a transition to IDLE in idle-req protocol, a software clear of register.

23.9.4.10 FIFO Subsystem

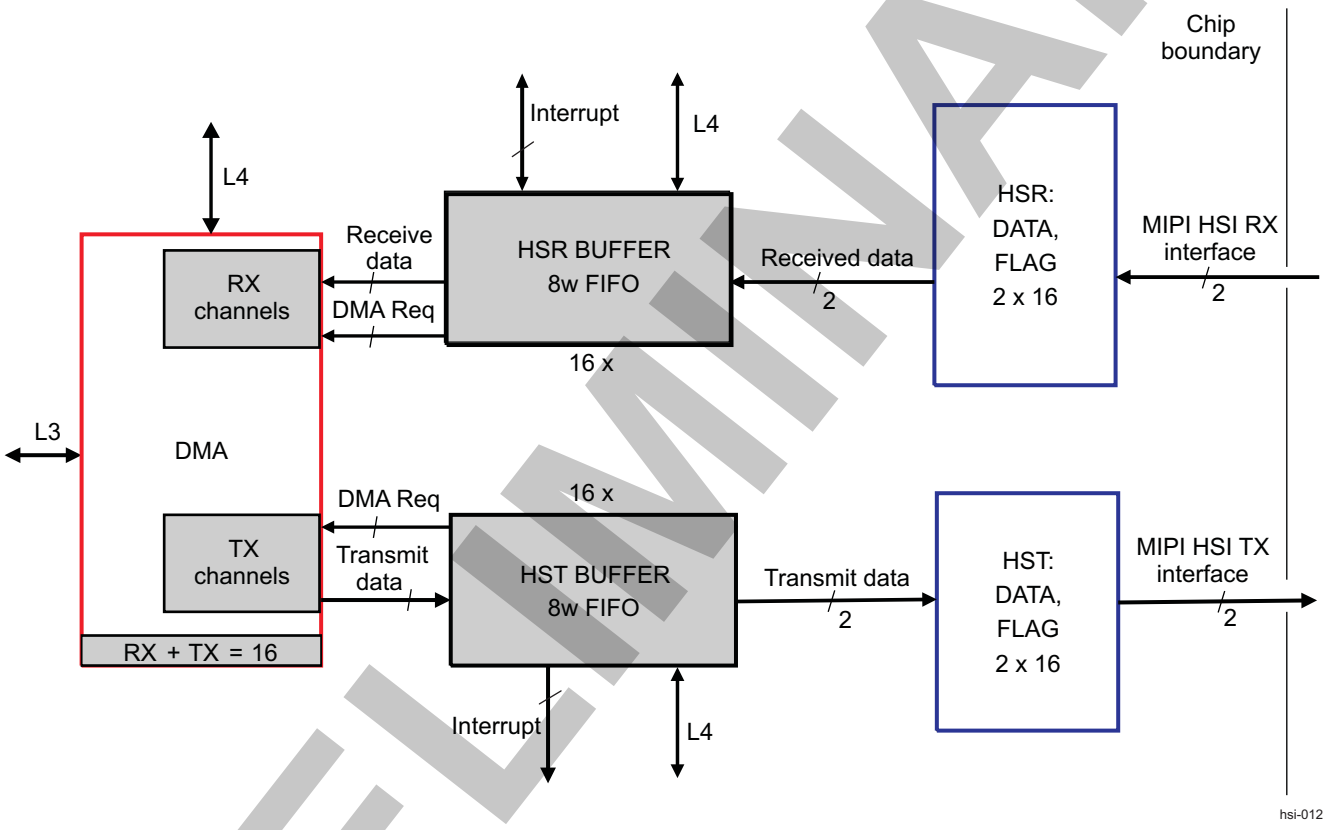
The FIFO subsystem allows temporary buffering while receive data is transferred from the receiver through DMA or the L4 interconnect to main memory, and the storing of transmit data read in main memory through DMA (or written by L4) before transmitting it. The FIFO depth is 8 × 32-bit words for each channel, yielding a total size of 1 KiB with 16 bidirectional channels.

RX FIFOs are clocked by interconnect clock, TX FIFOs are clocked by undivided functional clock.

23.9.4.10.1 FIFO Subsystem Architecture

Figure 23-208 shows the overall FIFO architecture.

Figure 23-208. Overall FIFO Architecture



There are 16 DMA channels available. They can be used for RX or TX in any combination; direction is programmable.

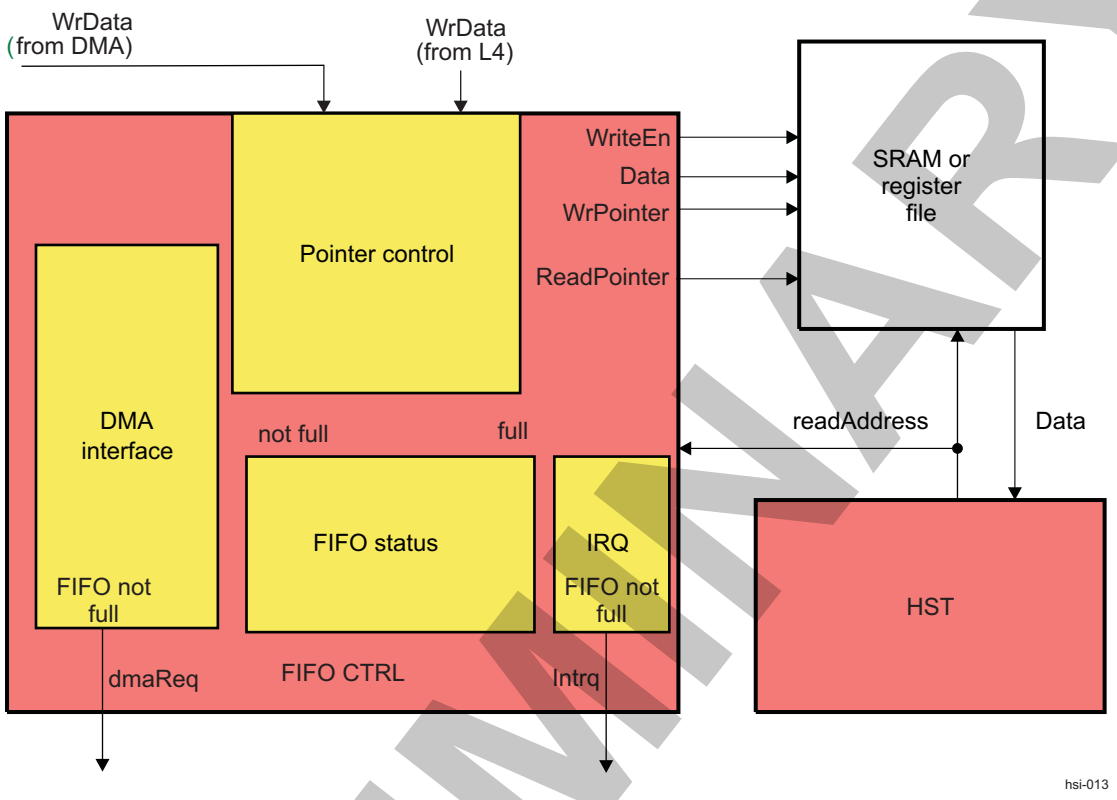
There are 16 RX FIFOs and 16 TX FIFOs. Not all FIFOs can be served by DMA, but all RX FIFOs (or else TX FIFOs) can be served by DMA, if needed. The other FIFOs, if used, must be read/written through the L4_CFG interconnect.

Both HSI ports provide up to 16 × 2 logical channels. This means that only one half of the HSI logical channels can be accommodated on the existing FIFOs. The others must not be used, and their use must flag an error. The 16 HST_MAPPINGf or HSR_MAPPINGf registers specify which HSI logical channel number is allowed to be received on RX FIFOs and/or fed for transmission by TX FIFOs. There is one mapping register for transmission and one for reception. Any attempt to transmit or process received data on HSI logical channels not previously mapped on mapping registers results in an error. In other words, some header values (bits 35 to 32) are not allowed at any given time, and generate an error when received. Software must ensure that the remote side sends payload on the allowed logical channels, specified by header values.

23.9.4.10.2 Transmit FIFO Architecture

Figure 23-209 shows the transmission FIFO architecture.

Figure 23-209. Transmission FIFO Architecture



The FIFO controller flags the condition of "room available in FIFO" or "FIFO not full" at any time when FIFO can host new data for transmission. This condition raises an interrupt request and a DMA request, if enabled. A programmable threshold in the corresponding HST_MAPPINGf[13:10] THRESHOLD bit field reduces the number of requests (they can be sent only when four words can be written in FIFO). The default value for the threshold is 0x0 (that is, a request rises as soon as one word can be written in FIFO). See Table 23-699.

Table 23-699. Threshold for Transmit FIFO Interrupt/DMA Request

HST_MAPPINGf[13:10] THRESHOLD	Number of Words in FIFO	Request
0 (legacy default)	Less than 8	Yes
1	Less than 1	Yes
2	Less than 2	Yes
3	Less than 3	Yes
4	Less than 4	Yes
5	Less than 5	Yes
6	Less than 6	Yes
7	Less than 7	Yes
8	Less than 8	Yes
9 to 15	Any	No

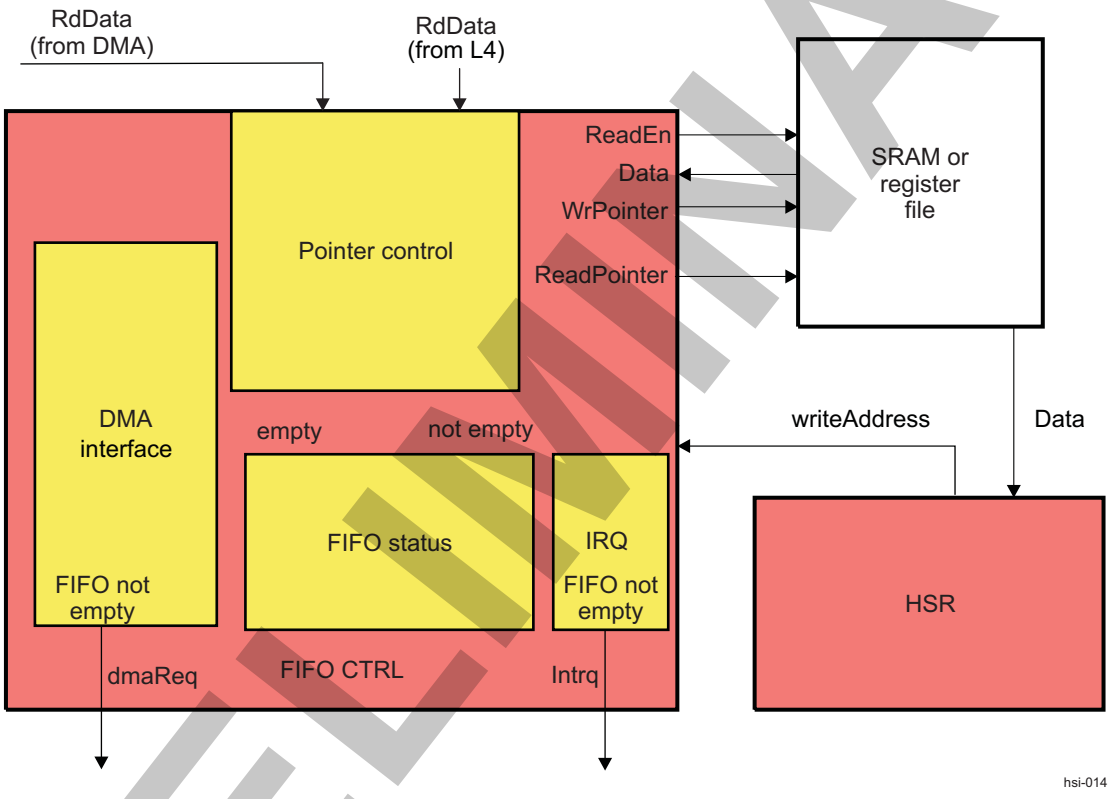
FIFO can be written by DMA and the L4 interconnect configuration port, but the L4 interconnect has fixed priority at any time. Software controls correct access. No hardware mechanism is provided to analyze and block concurrent operation, nor is any hardware control provided on reprogramming DMA registers during a transfer in which they are involved.

The address of FIFO is the corresponding HST_BUFFER_Pp_CHN_i register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when DMA or the L4 interconnect access the HST_BUFFER_Pp_CHN_i address and it manages the read pointer when HST needs a data to transmit.

23.9.4.10.3 Receive FIFO Architecture

Figure 23-210 shows the reception FIFO architecture.

Figure 23-210. Reception FIFO Architecture



FIFO controller flags the condition of "unread data in FIFO" or "FIFO not empty" at any time when a FIFO hosts new data, received and not read. This condition can be simply the misalignment of the read pointer and write pointer. The condition raises an interrupt request and a DMA request, if enabled. The HSR_MAPPINGf[13:10] WORDS bit field informs software how many words must be read.

Unlike transmission, it is not possible here to filter requests through a threshold on the number of received words. If such a threshold is bigger than one, and a last single word is received after the last read, software is unaware that more data waits to be read.

The address of FIFO is the corresponding HSR_BUFFER_Pp_CHN_i register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when HSR has received data, and it manages the read pointer when DMA or the L4 interconnect access the HSR_BUFFER_Pp_CHN_i register.

23.9.4.10.4 FIFO Addressing

From a software point of view, a FIFO is seen at a single address, the corresponding HST_BUFFER_Pp_CHN_i or HSR_BUFFER_Pp_CHN_i register address. The HST_SWAPBUFFER_Pp_CHN_i or HSR_SWAPBUFFER_Pp_CHN_i register address is also provided to invert data endianness with byte granularity. FIFO overflow in RX is extremely unlikely, because of the large difference in HSI and L3_MAIN interconnect bit rate. However, if this occurs, the hardware prevents any loss of data by deasserting (setting to 0) the READY signal to the remote transmitter. FIFO overflow in TX is not flagged and must be avoided by software drivers.

23.9.4.11 Error Reporting

23.9.4.11.1 Detection of Errors

Error detection on the module is limited to the physical layer. No data corruption is checked, and no error is flagged as long as the receiver and transmitter agree on frame boundaries. Because clocking and data are recovered from alternate edges on the DATA and FLAG signals, three kinds of error can appear:

- Simultaneous edges
- Missing edges
- Additional edges

23.9.4.11.1.1 Simultaneous Edges

The transmitter is not supposed to produce simultaneous edges on the DATA and FLAG signals, but they can appear if the transmission rate is far higher than the receiver can handle. Given to the sampling protocol, this event may introduce errors in sampled data. Detecting this error is not easy, because the recovered clock is also affected, and in some configurations no other clock is available. One bit is available in the HSR_ERROR_Pp register, to report any hardware abnormal condition in data reception.

23.9.4.11.1.2 Missing Edges

Missing edges result in missing clock cycles, thus causing the receiver to get less data than expected on a given frame.

In synchronized flow, when the transmit side has completed transmission, the receiver side is still waiting for more data, and does not raise READY, thus stopping the transmitter from going on with more frames. A frame time-out counter (see Section 23.9.4.11.2.1, *Frame Time-Out Counter*) is used to escape this deadlock condition.

In pipelined flow, when the transmit side has completed transmission and has more data to transmit, the receiver accepts and processes this data as if they were part of the previous frame. Frame synchronization is then lost. It may randomly resume when in frame mode, as zeroes at the end of a frame are automatically discarded. But even in this case, a number of frames may be lost or corrupted. When in stream mode, no self-recovery is ever possible, and synchronization is lost forever. A frame burst counter (see Section 23.9.4.11.2.3, *Frame Burst Counter*) is used to limit the number of these potentially corrupted frames, simply by limiting the number of frames a transmitter can send back-to-back in a pipelined mode. A tailing bit counter (see Section 23.9.4.11.2.2, *Frame Tailing Bit Counter*) is used to check that the receiver and transmitter agree on being at the end of frame.

23.9.4.11.1.3 Additional Edges

Additional edges result in additional clock cycles, thus causing the receiver to get more data than expected on a given frame.

In synchronized flow, when the receive side thinks the frame is over, the transmitter keeps sending data until the end of frame is reached. In frame mode, if these additional bits are all 0s, they are discarded by the receiver, the transmission stops, and the receiver raises READY when it is available to receive a new frame. The transmit side starts a new frame and synchronization is recovered. But if at least one of the additional bits is set to 1, this can misguide the receiver that a new frame has already started and READY

stays at 0. The transmit side stops, waiting for READY = 1, a never occurring condition, because the receiver has lost synchronization. In this case, the link is stuck. This is also the case in stream mode, when the receiver wrongly thinks that a new frame is started, so it is not available to receive a full new frame, and it does not set READY = 1. A frame time-out counter (see Section 23.9.4.11.2.1, *Frame Time-out Counter*) is used to escape this deadlock condition.

23.9.4.11.2 Error Counters

Clocks for these three counters are provided through a division of the functional clock. These counters can be set to a value and can be stopped when some events occur. Events flag errors and set a corresponding bit in the HSR_ERROR_Pp register.

23.9.4.11.2.1 Frame Time-Out Counter

This counter is clocked by the functional clock, divided by the factor specified in the HSR_DIVISOR_Pp[7:0] RX_RATE_DIV_VAL bit field, to provide a clock at receive bit rate. Receive bit rate is always communicated by the remote transmitter through the protocol layer. This counter starts when the first bit of the frame is found and stops when 36 (or 37 depending on the mode) bits are correctly received by the receiver. If the counter overflows, an error is generated (the HSR_ERROR_Pp[1] FTE bit is set to 0). In OPP reduction of the functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when the receive rate is outside the full error detection rate range.

23.9.4.11.2.2 Frame Tailing Bit Counter

This counter can be clocked by the same clock as the frame time-out counter, which has the receiver bit rate frequency. It starts after the last bit of a frame is received, and READY = 0; in pipelined flow, this counter is started only after the end of the last frame received. No event stops the counter, except its own overflow. It counts up to 8. An error is logged (the HSR_ERROR_Pp[4] TBE bit is set to 0) if a 1 bit is received in frame mode before counter overflow, or any bit is received in stream mode before counter overflow. In OPP reduction of functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when receive rate is outside the full error detection rate range.

23.9.4.11.2.3 Frame Burst Counter

Differently from previous counters, this counter is clocked by a frame-sync signal obtained directly by received data. Its goal is to reduce the number of contiguous frames sent in pipelined flow. As explained in Section 23.9.4.11.1, *Detection of Errors*, in some cases after missing/additional clock cycles, synchronization is lost and these pipelined frames can be corrupted. Software sets the count value, which can be as high as 256 (no higher values are supported by hardware). If READY is dropped to 0, for reasons other than counter expiration, the counter is stopped and restarted as soon as transmission resumes. At the end of the count, READY drops to 0. The tailing bit counter is started, and if it overflows without error detection and the receiver has enough room for another frame, READY is reset to 1. No error and no interrupt are generated on this counter.

23.9.4.11.3 Error Registers

One error register per port is provided to check the error source that issued an interrupt, with more details than the error bit in the interrupt status register.

- The HSR_ERROR_Pp[0] SIG bit: Signal error bits are kept for legacy reasons, and they can be used for any abnormal situation the hardware wants to flag.
- The HSR_ERROR_Pp[1] FTE bit: Frame time-out error bits flag the situation when not even a frame has been received in the time corresponding to two or more frames, depending on the FTE counter software setting.
- The HSR_ERROR_Pp[4] FBE bit: Tailing bit error bits flag the situation when at least one spurious bit is received after the end of a frame, in the time corresponding to two or more bit times.

- The HSR_ERROR_Pp[7] RME bit: Receive mapping error bits flag the situation when data are received on a channel that is not mapped to any enabled FIFO.
- The HSR_ERROR_Pp[11] TME bit: Transmit mapping error bits flag the situation when DMA tries to access a FIFO that is not mapped to any logical channel, or is not enabled.

These two registers each have a companion HSR_ERRORACK_Pp register, where software must set the corresponding error bit to 1 to clear it.

23.9.5 HSI Programming Guide

23.9.5.1 HSI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the HSI module.

23.9.5.1.1 Global Initialization

23.9.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HSI.

For more information, see Section 23.9.3, *HSI Integration*.

Table 23-700. Global Initialization of Surrounding Modules for HSI

Surrounding Modules	Comments
PRCM	HSI functional and interface clocks must be enabled. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing must be set in the control module. For more information, see Chapter 18, *Control Module*.
(Optional) Interrupt controller	The MPU, IPU, or DSP INTC must be configured to enable the interrupt request generation to the MPU, IPU, or DSP subsystem. For information about enabling interrupts, see *Chapter 17, Interrupt Controller*.
(Optional) Interconnect	For information about the L4 interconnect configuration, see Chapter 14, *Interconnects*. For information about L3_MAIN interconnect configuration, see *Chapter 14, Interconnects*.

23.9.5.1.1.2 HSI Global Initialization

23.9.5.1.1.2.1 Main Sequence – HSI Global Initialization

This procedure initializes the HSI module after a power-on reset (POR) or software reset.

Table 23-701. HSI Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform an HSI software reset.	HSI_SYSCONFIG[1] SOFTRESET	0x1
WAIT UNTIL HSI reset is complete.	HSI_SYSSTATUS[0] RESETDONE	= 0x1
Set standby mode configuration.	HSI_SYSCONFIG[13:12] MIDLEMODE	0x-
Set idle mode configuration.	HSI_SYSCONFIG[4:3] SIDLEMODE	0x-
Clock auto gating.	HSI_SYSCONFIG[0] AUTOIDLE	0x-
Set the transmit data rate.	HST_DIVISOR_Pp[7:0] TX_RATE_DIV_VAL	0x-
(Optional) Enable DMA.	DMA_GCR[0] SWITCH_OFF	0x0

23.9.5.1.2 HSI Operational Modes Configuration

23.9.5.1.2.1 HSI Transmit Mode/Receive Mode

23.9.5.1.2.1.1 Main Sequence – Configure HSI Transmitter

Table 23-702. HSI Configure HSI Transmitter

Step	Register/Bit Field/Programming Model	Value
Set the mode.	HST_MODE_Pp[1:0] MODE_VAL	0x-
Set the data flow type.	HST_MODE_Pp[3:2] FLOW_VAL	0x-
Set the hsi_wake line control.	HST_MODE_Pp[4] WAKE_CTRL	0x-
Set the transmission bit rate	HST_DIVISOR_Pp[7:0] TX_RATE_DIV_VAL	0x-
Set the arbitration mode.	HST_ARBMODE_Pp[0] ARB_VAL	0x-
Set the number of active HSI logical channels.	HST_CHANNELS_Pp[4:0] CHAN_NUM_VAL	0x-
Set the TX FIFO threshold.	HST_MAPPINGf[13:10] THRESHOLD	0x-
Associate the TX FIFO to an HSI port.	HST_MAPPINGf[7] PORT_NUMBER	0x-
Associate the TX FIFO to an HSI logical channel.	HST_MAPPINGf[4:1] CH_NUMBER	0x-
Enable the TX FIFO.	HST_MAPPINGf[0] ENABLE	0x-

23.9.5.1.2.1.2 Main Sequence – Configure HSI Receiver

Table 23-703. HSI Configure HSI Receiver

Step	Register/Bit Field/Programming Model	Value
Set a clock frequency for the error detection counters.	HSR_DIVISOR_Pp[7:0] RX_RATE_DIV_VAL	0x-
Set the number of active HSI logical channels.	HSR_CHANNELS_Pp[4:0] CHAN_NUM_VAL	0x-
Set the frame timeout error counter.	HSR_COUNTERS_Pp[19:0] FT	0x-
Set the tailing bit error counter.	HSR_COUNTERS_Pp[23:20] TB	0x-
Set the frame burst error counter.	HSR_COUNTERS_Pp[31:24] FB	0x-
Associate the RX FIFO to an HSI port.	HSR_MAPPINGf[7] PORT_NUMBER	0x-
Associate the RX FIFO to an HSI logical channel.	HSR_MAPPINGf[4:1] CH_NUMBER	0x-
Enable the RX FIFO.	HSR_MAPPINGf[0] ENABLE	0x-
Set the mode in receive mode.	HSR_MODE_Pp[1:0] MODE_VAL	0x-
Set the data flow type in receive mode.	HSR_MODE_Pp[3:2] FLOW_VAL	0x-

23.9.5.1.2.1.3 Main Sequence – HSI Polling Method

23.9.5.1.2.1.3.1 Sub-sequence – HSI Transmit in Polling Method

23.10 High-Speed Multiport USB Host Subsystem

This section describes the high-speed (HS) multiport universal serial bus (USB) host subsystem of the device.

23.10.1 High-Speed Multiport USB Host Subsystem Overview

NOTE:

The HS USB host subsystem is composed of:

- HS multiport USB host controller module
- USB TLL module
- Three HSIC digital front end (DFE) modules

The HS USB host subsystem consists of several ports delivered outside the device and several modes per port. These modes are:

- UTMI+ low pin-count interface (ULPI) for external PHY
- ULPI transceiverless link (TLL)
- Serial TLL
- High-speed interchip (HSIC)

The HS USB host controller module contains two quasi-independent host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*, is responsible for HS traffic (480 Mbps), over ULPI/USB 2.0 transceiver macrocell interface (UTMI).
- The OHCI controller, based on the *Open Host Controller Interface (OHCI Specification for USB Release 1.0a*, is responsible for full-speed (FS)/low-speed (LS) traffic (12/1.5 Mbps, respectively), over a serial interface.

Each of the three external ports of the HS USB host controller module is owned by one of the controllers (EHCI or OHCI) at a given time. Each port can work in several modes:

- When the port is owned by the OHCI (FS) host, a 6-pin internal serial interface to the TLL is used.
- When the port is owned by the EHCI (HS) host, UTMI internal interface to the TLL or through ULPI to external PHY is used.

  See USB controller module internal architecture in Section 23.10.4.1, *USB Host Controller Functionality*.

The current subsystem does not support all dynamic USB speed negotiations, as expected from a standard USB host port at the same time. It supports:

- HS-only (with external HS physical layer [PHY]/HS TLL mode, or HSIC) on the EHCI
- FS-/LS-only (with external FS PHY/FS TLL mode) on the OHCI

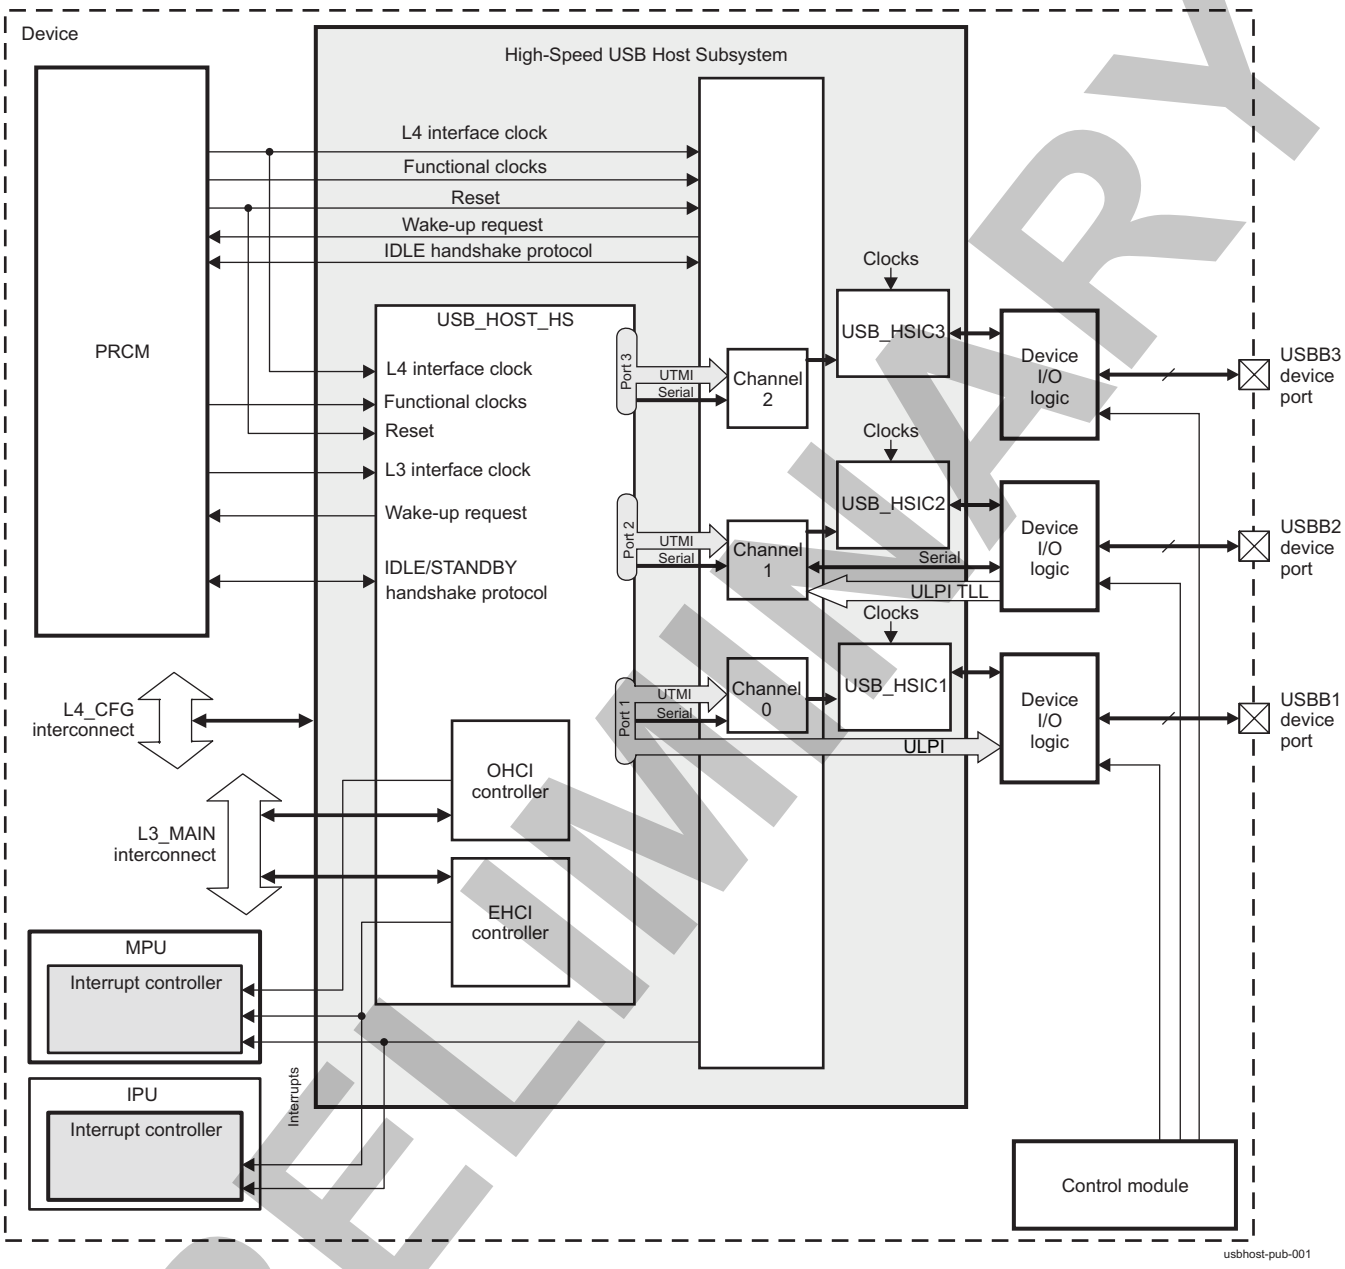
The USB TLL module is the adapter on the host ports. It consists of two channels that are seen as emulating a pair of back-to-back PHYs and has:

- UTMI port, connected to the host controller module
- ULPI port, connected to a ULPI peripheral

The three HSIC digital front-ends (DFE) plug into the UTMI port of the host controller module and control HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

Figure 23-214 shows the HS USB host subsystem.

Figure 23-214. HS USB Host Subsystem Overview



23.10.1.1 Main Features

The HS multiport USB host subsystem supports the following features:

- **HS USB host controller module:**
  - One initiator on level 3 (L3)
  - One target on level 4 (L4)
  - Two IRQs
  - No DMA request
  - Implements a USB 2.0 HS host controller:
    - HS (480 Mbps) communication with HS USB peripherals or hubs
    - FS (12 Mbps) communication with FS USB peripherals or hubs

    - LS (1.5 Mbps) communication with LS USB peripherals
  - Support for suspend, resume, remote wakeup
  - Three downstream ports (3-port root hub)
  - Heterogeneous port configuration (that is, different HS/FS PHYs with different clocking methods on different ports, supported simultaneously)
  - Single FS host controller, compliant with OHCI software application programming interface (API), per-port power switching support
  - Interface with UTMI PHYs (that is, the TLL module) on all ports (but only one is mapped on device balls)
    - 8-bit data path
    - Synchronous (on-chip) interface, independent clock input per port (that is, the TLL module provides clock to the host controller and to the remote USB controller).
    - HSIC front-end (after appropriate internal configuration)
  - Interface with ULPI PHYs (external transceivers) on all ports (but only one is mapped on device balls)
    - 8-bit bidirectional data bus (SDR mode)
    - 12-pin interface
    - Independent clock input per port (ULPI PHY in output mode)
    - Supports only HS data transactions

    NOTE: The HS USB host subsystem can support only the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

  - Interconnect initiator for built-in DMA operation of EHCI/OHCI
  - Interconnect target for configuration
  - Link power management (LPM) support in OHCI and EHCI hosts
- **USB TLL module:**
  - One interconnect target on L4
  - One IRQ
  - No DMA request
  - Three HS USB channels, each of them with four ports (A to D) (Not all C and D ports are mapped on device balls):
    - Port A: Host module UTMI+ port. Connects to the local link controller (host module). The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports. The port complies with UTMI+ version 1.0 and supports:
      - 8-data-bit, UTMI (HS/FS-capable)
      - UTMI+ L3 extensions
      - Vcontrol/Vstatus (from UTMI)
      - Serial FS 6-pin mode
    - Port B: Link-side UTMI+ port. Connects to HSIC front-end module.
    - Port C: PHY-side ULPI slave port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
      - SDR ULPI mode (8-bit data width)
    - Port D: Serial multimode port.
      - Supports 6-pin unidirectional and 4-/3-/2-pin bidirectional modes
      - All modes are supported for TLL or PHY interface configuration, except 2-pin mode (which is TLL-only).
      - Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

- **HSIC module:** HSIC Digital Front-End (DFE) module is interfacing between:
  - one downstream port of a (multiport) HS link controller
    - 8-bit, 60 MHz UTMI
  - one set of bidirectional IOs (data + strobe)
    - HSIC electrical characteristics, as per *High Speed Inter-Chip (HSIC) Electrical Specification*
    - strobe is a 240 MHz clock-like signal
    - data is 480 Mbit/s, aligned with both strobe edges.

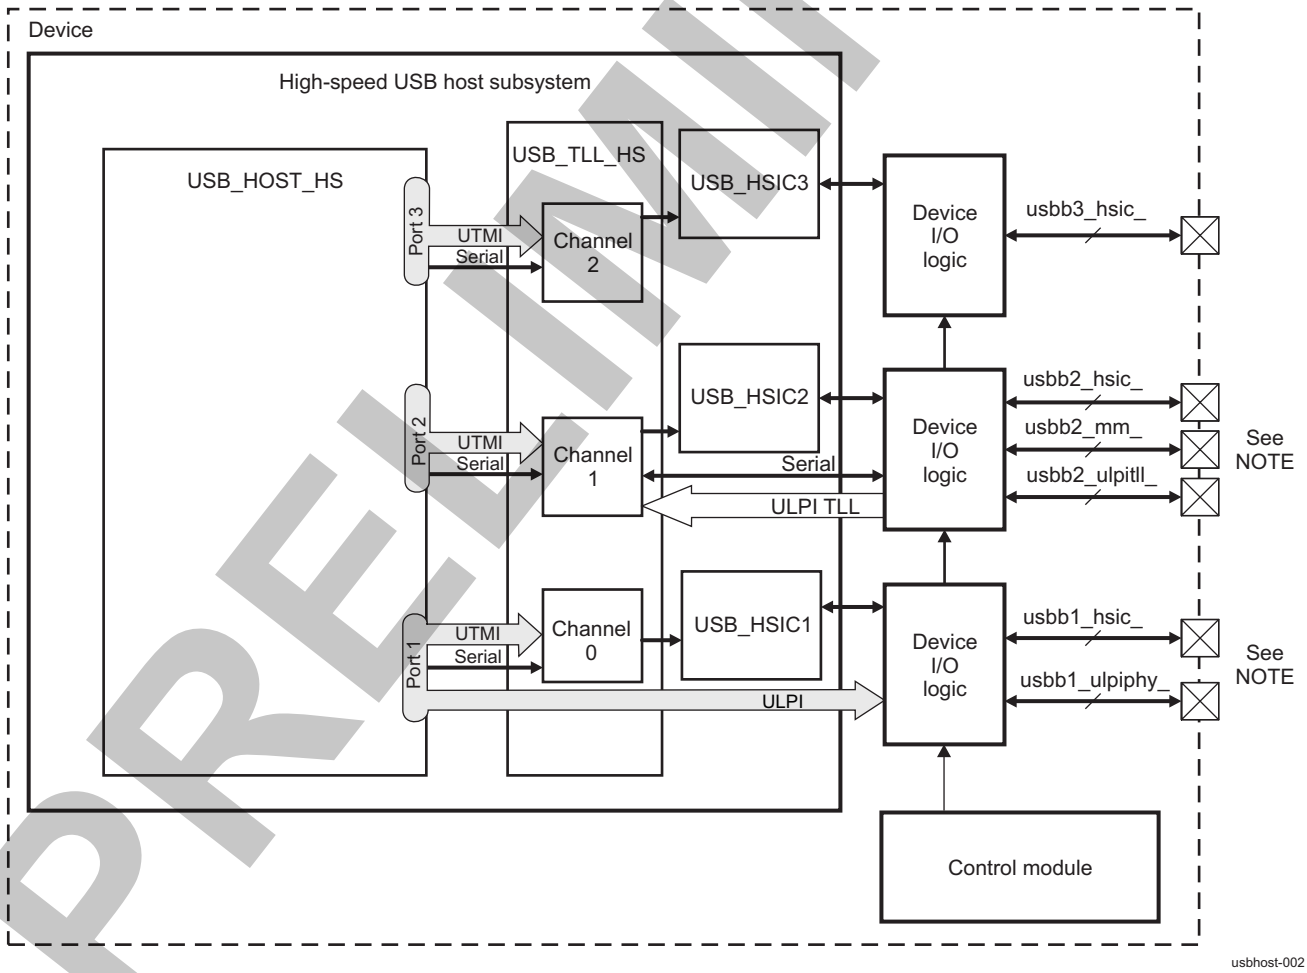
23.10.2 HS Multiport USB Host Subsystem Environment

The HS USB host subsystem provides three kinds of interfaces for connection:

- ULPIs for HS data transactions (up to 480 Mbps) (see Section 23.10.2.1, *ULPIs*)
- Serial interfaces, using the USB TLL module, for FS and LS data transactions (up to 12 Mbps) (see Section 23.10.2.2, *FS/LS Serial Interfaces*)
- HSIC interface to two HSIC lines over HSIC-capable I/O drivers (see Section 23.10.2.3, *HSIC Interface*)

Figure 23-215 is an overview of the environment of the HS USB host subsystem.

Figure 23-215. HS Multiport USB Host Subsystem Environment



NOTE: For more information about device-level signal names in different modes, see Section 23.10.2.1, *ULPIs*); Section 23.10.2.2, *FS/LS Serial Interfaces*; and Section 23.10.2.3, *HSIC Interface*.

NOTE: Ports are configured independently and can be in different modes.

Even though all signals can be routed to independent device pads (that is, all port signals can be available simultaneously), port modes are mutually exclusive and are selected through USB Host controller and USB TLL module. See Section 23.10.5.2*Operational Modes Configuration (Selecting and Configuring USB Connectivity)*

For more information how the USB pins are multiplexed on device pads, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*.

23.10.2.1 ULPIs

The HS USB host subsystem supports the following configurations with the ULPIs:

- External USB transceiver:
  - ULPIs: 12-pin/8-bit data SDR version
- TLL:
  - SDR ULPI mode (12-pin/8-bit data width)

The HS USB host subsystem supports USB ports that use the ULPI mode to connect to an off-chip HS ULPI transceiver (12-pin/8-bit data SDR mode) for data transactions (up to 480 Mbps). FS and LS are not supported over the ULPI.

The device supports TLL logic interfaces on its ports in ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port.

The external USB transceiver ULPIs and ULPI TLL interfaces cannot be used together on the same port. It is possible for one port to use ULPI and the other port to use ULPI TLL.

Figure 23-216 and Figure 23-217 show typical applications using the HS USB host subsystem with ULPI and the ULPI TLL interface, respectively.

Figure 23-216. External USB Transceiver ULPIs

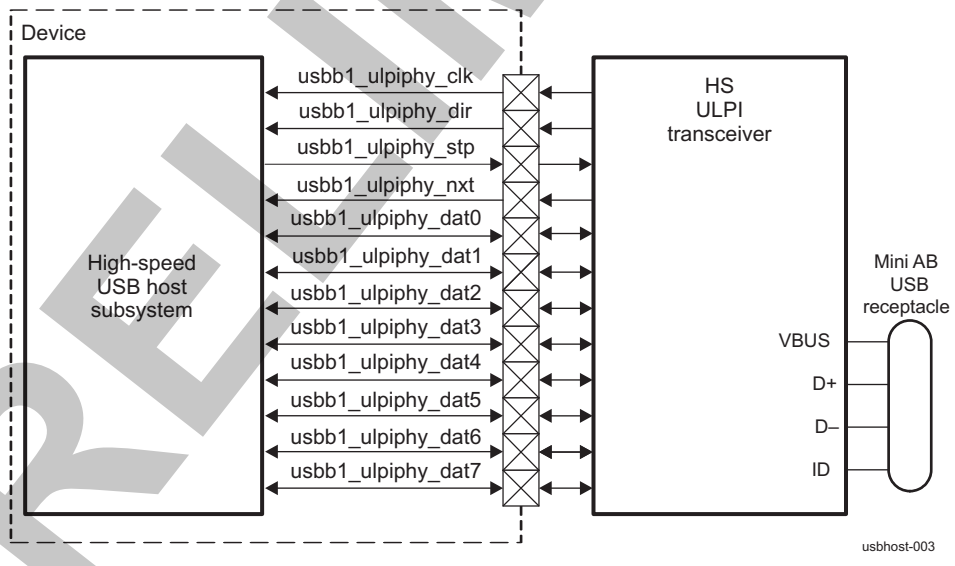


Figure 23-217. ULPI TLL Interfaces

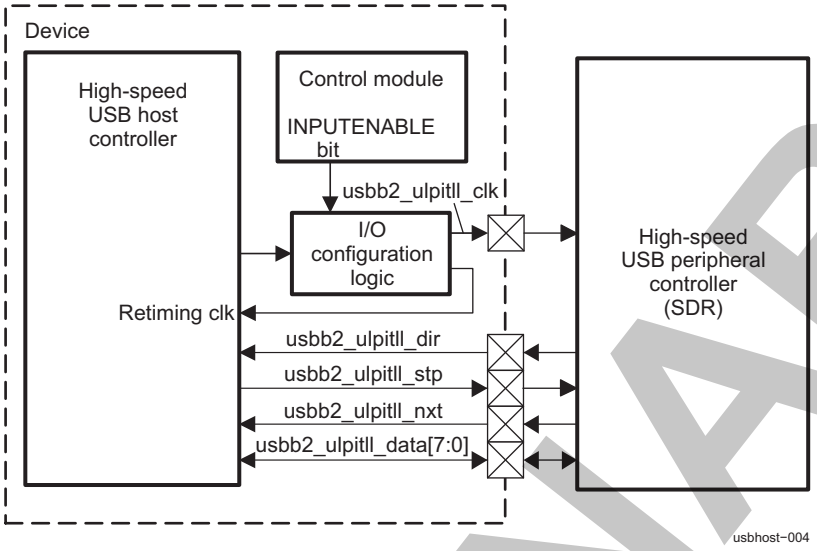

The 12-pin ULPI uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode).

NOTE: The recommended slew rate is not set by default and must be set in the respective CONTROL_SMART2IO_PADCONF_x registers. For more information, see Table 18-85 and Table 18-89 in Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

23.10.2.1.1 Transceiver Interface Configuration in ULPI Mode

The HS USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI mode.

Figure 23-218 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Figure 23-218. ULPIs – 12-Pin/8-Bit Data SDR Version

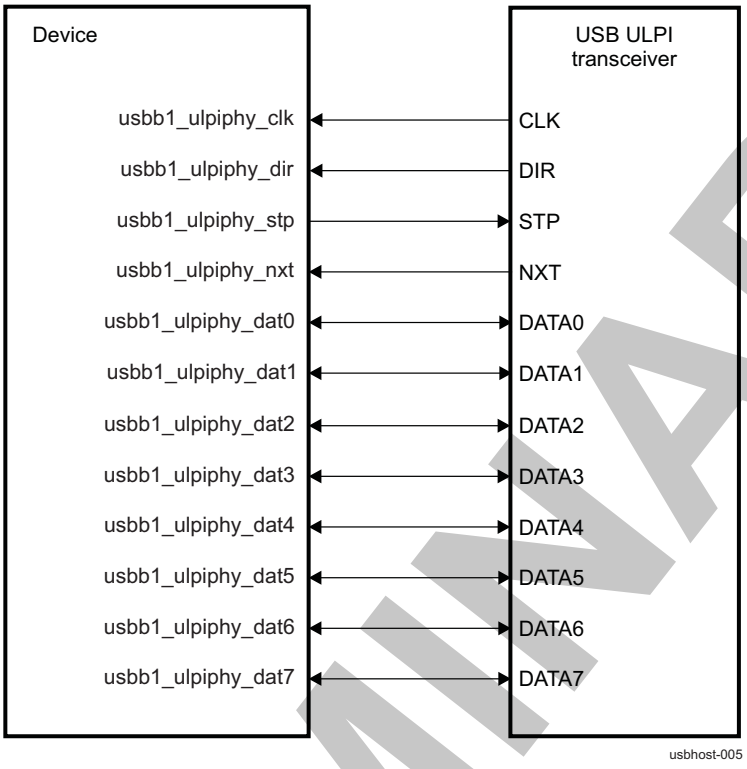

Table 23-830 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Table 23-830. ULPI – 12-Pin/8-Bit Data SDR Version I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value
HS USB Host Controller Port 1 (Device port USBB1)				
CLK	usbb1_ulpiphy_clk	I	Clock input from remote PHY IC	HiZ
DIR	usbb1_ulpiphy_dir	I	Data direction control from remote PHY IC	HiZ
STP	usbb1_ulpiphy_stp	O	Stop signal to remote PHY IC	1
NXT	usbb1_ulpiphy_nxt	I	Next signal from remote PHY IC	HiZ
DAT0	usbb1_ulpiphy_dat0	I/O	Bidirectional 8-bit data bus	HiZ
DAT1	usbb1_ulpiphy_dat1	I/O	Bidirectional 8-bit data bus	HiZ
DAT2	usbb1_ulpiphy_dat2	I/O	Bidirectional 8-bit data bus	HiZ
DAT3	usbb1_ulpiphy_dat3	I/O	Bidirectional 8-bit data bus	HiZ
DAT4	usbb1_ulpiphy_dat4	I/O	Bidirectional 8-bit data bus	HiZ
DAT5	usbb1_ulpiphy_dat5	I/O	Bidirectional 8-bit data bus	HiZ
DAT6	usbb1_ulpiphy_dat6	I/O	Bidirectional 8-bit data bus	HiZ
DAT7	usbb1_ulpiphy_dat7	I/O	Bidirectional 8-bit data bus	HiZ

(1) I = Input; O = Output

23.10.2.1.2 TLL Interface Configuration in ULPI Mode

The HS USB host controller is coupled with the USB TLL module to compose the ULPI TLL interface modes.

Figure 23-219 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Figure 23-219. ULPI TLL Interfaces – 12-Pin/8-Bit Data SDR Version

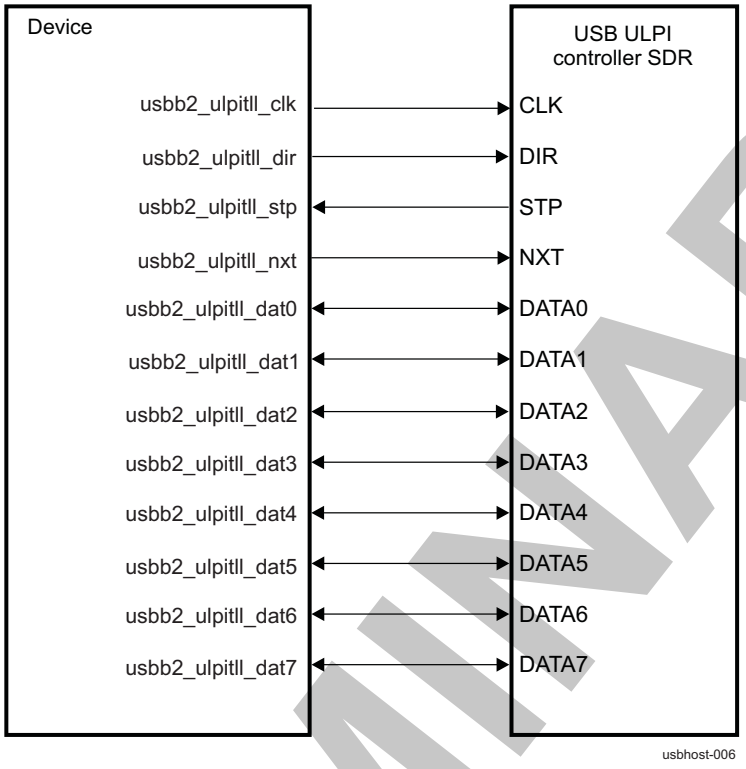

Table 23-831 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

Table 23-831. ULPI TLL Interface – 12-Pin/8-Bit Data SDR Version I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value
HS USB Host Controller Port 2 (Device port USBB2)				
CLK	usbb2_ulpitll_clk	O	Clock output to remote ULPI link controller [2]	0
DIR	usbb2_ulpitll_dir	O	Data direction control from remote ULPI link controller	0
STP	usbb2_ulpitll_stp	I	Stop signal to remote ULPI link controller	HiZ
NXT	usbb2_ulpitll_nxt	O	Next signal from remote ULPI link controller	0
DAT0	usbb2_ulpitll_dat0	I/O	Bidirectional 8-bit data bus	0
DAT1	usbb2_ulpitll_dat1	I/O	Bidirectional 8-bit data bus	0
DAT2	usbb2_ulpitll_dat2	I/O	Bidirectional 8-bit data bus	0
DAT3	usbb2_ulpitll_dat3	I/O	Bidirectional 8-bit data bus	0
DAT4	usbb2_ulpitll_dat4	I/O	Bidirectional 8-bit data bus	0
DAT5	usbb2_ulpitll_dat5	I/O	Bidirectional 8-bit data bus	0
DAT6	usbb2_ulpitll_dat6	I/O	Bidirectional 8-bit data bus	0
DAT7	usbb2_ulpitll_dat7	I/O	Bidirectional 8-bit data bus	0

(1) I = Input; O = Output
(2) This signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

23.10.2.2 FS/LS Serial Interfaces

The HS USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver (see Section 23.10.2.2.3, *External USB Transceiver Interface Configurations in Serial Modes*)
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional

mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)

- TLL (see Section 23.10.2.2.4, *TLL Interface Configurations in Serial Modes*)
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

CAUTION

Only FS and LS data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or external transceiver configuration, the serial interface follows the same principles: it is limited to FS/LS, and HS requires a parallel interface.

23.10.2.2.1 Encoding in Serial Mode

23.10.2.2.1.1 Unidirectional

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in Table 23-832 is used.

Table 23-832. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D– when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D–
			0	0	0	0	1
			0	1	0	1	0
			0	X	1	0	0
			1	X	X	Undriven	Undriven
RCV	Input	Output	Output from transceiver differential receiver				
			D+	D–	RCV		
			0	0	X		
			0	1	0		
			1	0	1		
			1	1	X		
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+	DP			
			0	0			
			1	1			
DM	Input	Output	Output from transceiver single-ended D- signal receiver				
			D–	DM			
			0	0			
			1	1			

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DP/DM encoding mode, the encoding described in Table 23-833 is used.

Table 23-833. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D– when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D–
			0	0	1	0	1
			0	1	0	1	0
			0	0	0	0	0
			1	X	X	Undriven	Undriven
RCV	Input	Output	Output from transceiver differential receiver				
			D+	D–	RCV		
			0	0	X		
			0	1	0		
			1	0	1		
			1	1	X		
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+	DP			
			0	0			
			1	1			
DM	Input	Output	Output from transceiver single-ended D-signal receiver				
			D–	DM			
			0	0			
			1	1			

23.10.2.2.1.2 Bidirectional

When an external USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in Table 23-834 is used.

Table 23-834. Signaling Between HS USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.				
DAT and SE0	Output	Input	When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D– based on the values of DAT and SE0.				
	Output	Input	TXEN	DAT	SE0	D+	D–
			0	0	0	0	1
				1	0	1	0
				X	1	0	0
	Input	Output	TXEN	D+	D–	DAT	SE0
			1	0	0	0	1
				0	1	0	0
				1	0	1	0
				1	1	Undefined	0

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When an external USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in Table 23-835 is used.

Table 23-835. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.		
DM	Output	Input	Value driven to or received from D–		
			TXEN	DM	D–
			0	0	0
			0	1	1
	Input	Output	TXEN	D–	DM
			1	0	0
			1	1	1
DP	Output	Input	Value driven to or received from D+		
			TXEN	DP	D+
			0	0	0
			0	1	1
	Input	Output	TXEN	D+	DP
			1	0	0
			1	1	1
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D–	RCV
			0	0	X
			0	1	0
			1	0	1
			1	1	X

23.10.2.2.2 Sideband Signals for Serial Modes

Serial interfaces carry only the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end, etc.)
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I^2C) UART, etc.)

Figure 23-220 and Figure 23-221 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration and one in TLL configuration. Although the sideband (purple) arrows are oriented from the controller to the transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from the controller to the transceiver [control] and from the transceiver to the controller [status]).

Figure 23-220 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USB TLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USB TLL module) are decoded from the standard UTMI+ interface.

- The software-driven VBUS reporting procedure is described in Section 23.10.4.2.5.1.1, *VBUS*

Management in Serial Transceiver Configurations.

Figure 23-220. Serial Interface Sideband Integration – Transceiver Configuration

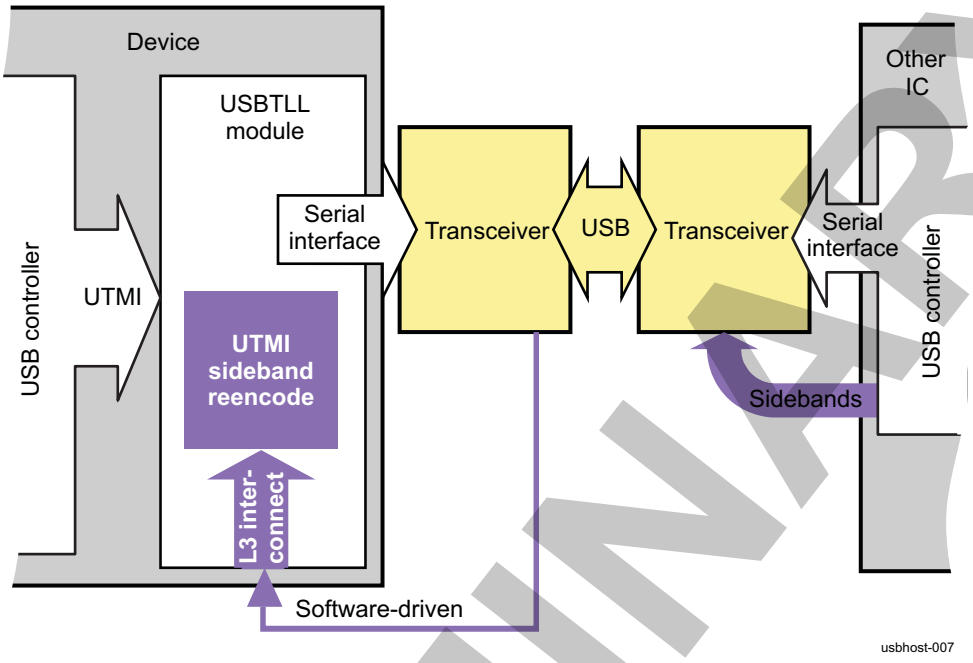

Figure 23-221 shows the TLL configuration, where both transceivers are emulated inside the USB TLL module.

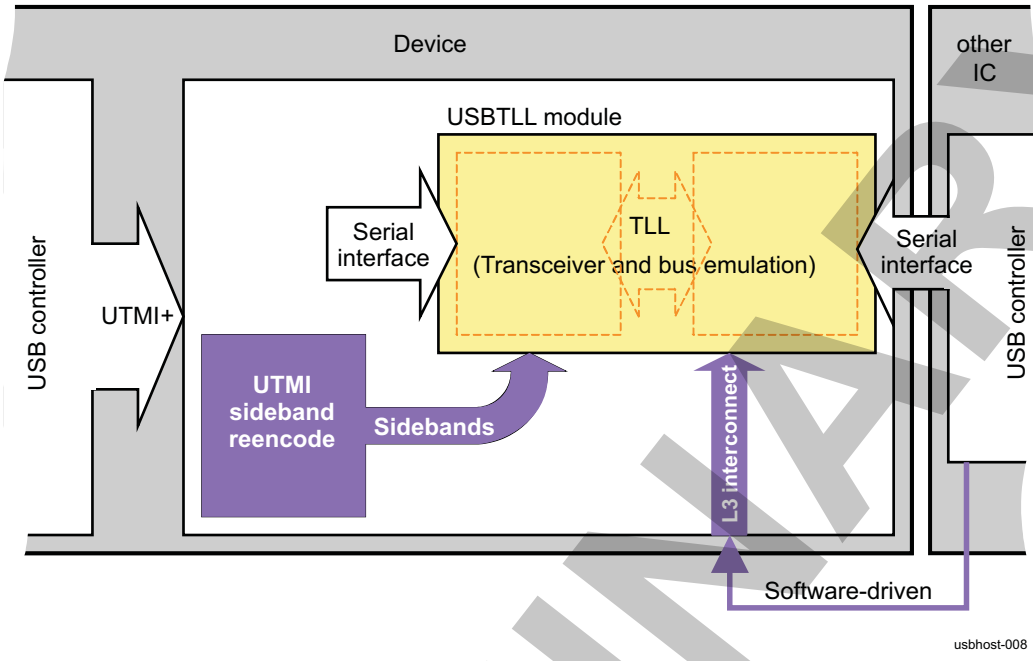
- The transceiver of the local controller (left side of the figure) is working with the sideband information to/from the UTMI+ port. This is internal to the USB TLL module.
- The transceiver of the remote controller (right side of the figure) must communicate with its controller, which is on another IC. This is done in two ways:
  - The sideband input signals at the TLL module boundary (tllpuen, tlldrvvbus, tllvbusvalid, etc.)
  - The software-driven VBUS control procedure described in Section 23.10.4.2.5.2.2, *VBUS Emulation in Serial TLL Modes*)

Figure 23-221. Serial Interface Sideband Integration – TLL Configuration



23.10.2.2.3 External USB Transceiver Interface Configurations in Serial Modes

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the HS USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the HS USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to two external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the HS USB subsystem in serial interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided by additional signals or through an I^2C link.

The following subsections describe the transceiver interface modes supported by the HS USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of the USB lines (D+/D–).

23.10.2.2.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

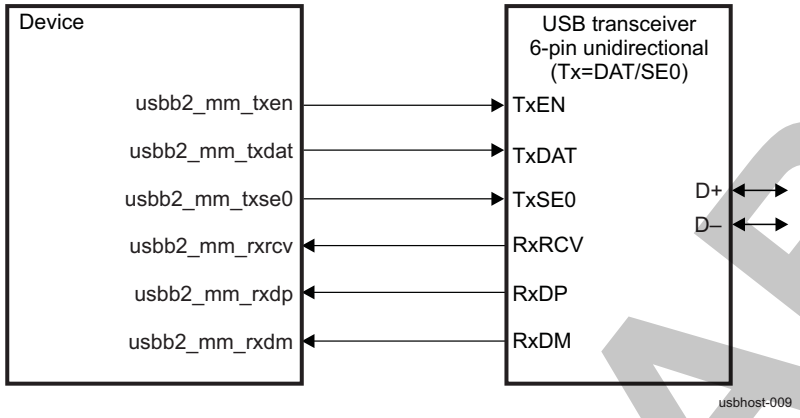
The 6-pin modes are the "natural" transceiver interface modes for the FS transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 and DP/DM.

When an external USB is connected to the device and is used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in Table 23-832 is used.

Figure 23-222 shows a USB port using DAT/SE0 encoding.

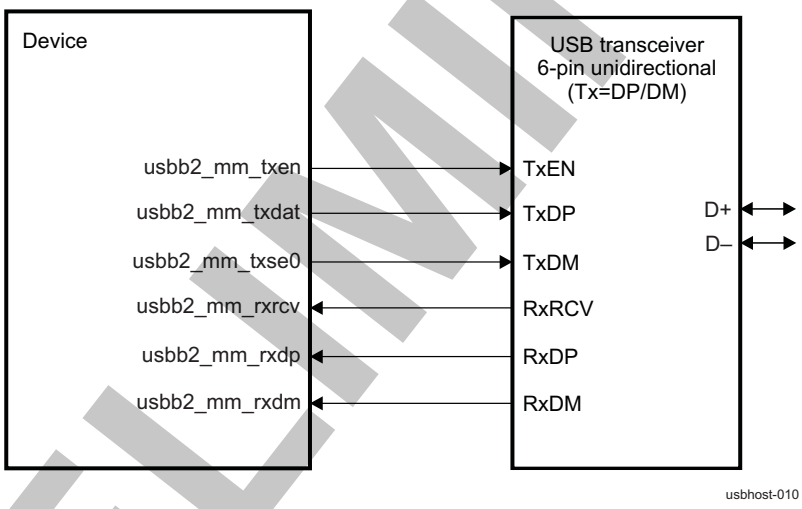
Figure 23-222. 6-Pin Unidirectional Using DAT/SE0 Signaling



When a USB is connected to the device and is used in 6-pin unidirectional DP/DM signaling mode, the signaling described in Table 23-833 is used.

Figure 23-223 shows a USB port using DP/DM encoding.

Figure 23-223. 6-Pin Unidirectional Using DP/DM Signaling



23.10.2.2.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

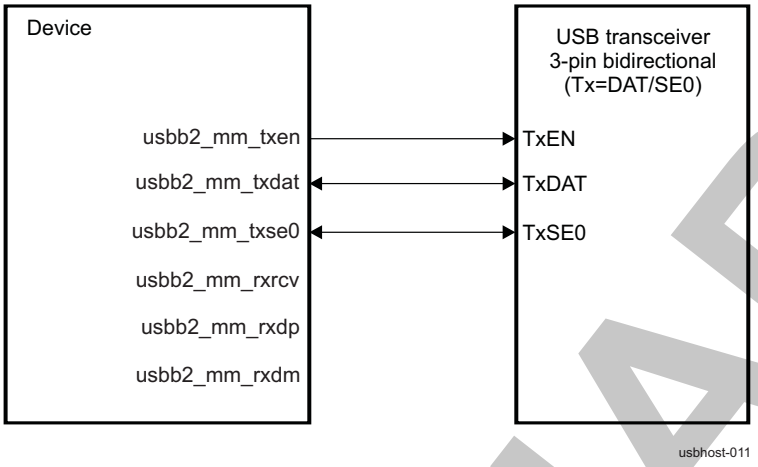
The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling described in Table 23-834 is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

Figure 23-224 shows a USB port using DAT/SE0 encoding.

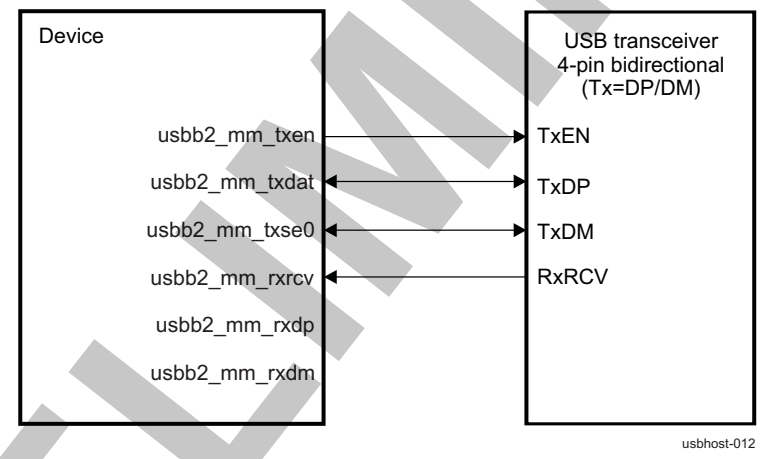
Figure 23-224. 3-Pin Bidirectional Using DAT/SE0 Signaling



The signaling described in Table 23-835 is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

Figure 23-225 shows a USB port using DP/DM encoding.

Figure 23-225. 4-Pin Bidirectional Using DP/DM Signaling



23.10.2.2.4 TLL Interface Configurations in Serial Modes

The HS USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are FS or LS only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

23.10.2.2.4.1 Unidirectional TLL Serial Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-226 shows an external device using DAT/SE0 encoding.

Figure 23-226. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

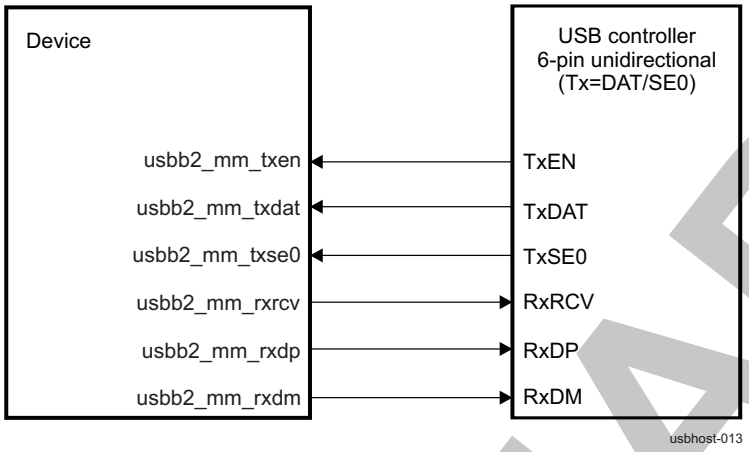


Figure 23-227 shows an external device using DP/DM encoding.

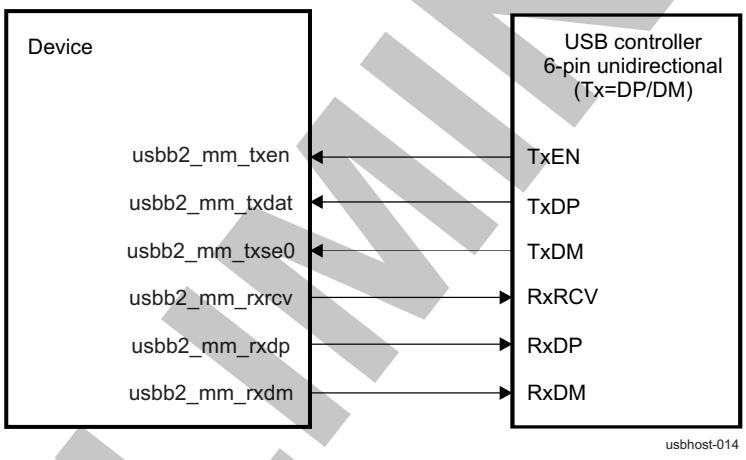
Figure 23-227. 6-Pin Unidirectional TLL Using DP/DM Signaling



23.10.2.2.4.2 Bidirectional TLL Serial Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-228 shows an external device using DAT/SE0 encoding.

Figure 23-228. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

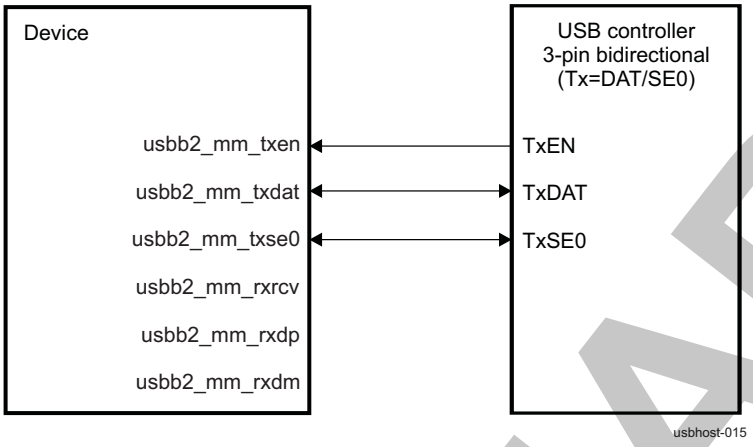


Figure 23-229 shows an external device using DP/DM encoding.

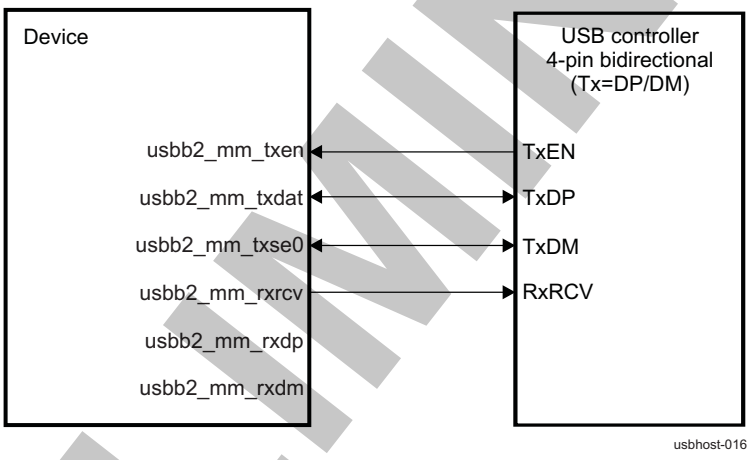
Figure 23-229. 4-Pin Bidirectional TLL Using DP/DM Signaling



The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described previously. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 23-230 shows a USB port using DP/DM encoding.

Figure 23-230. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

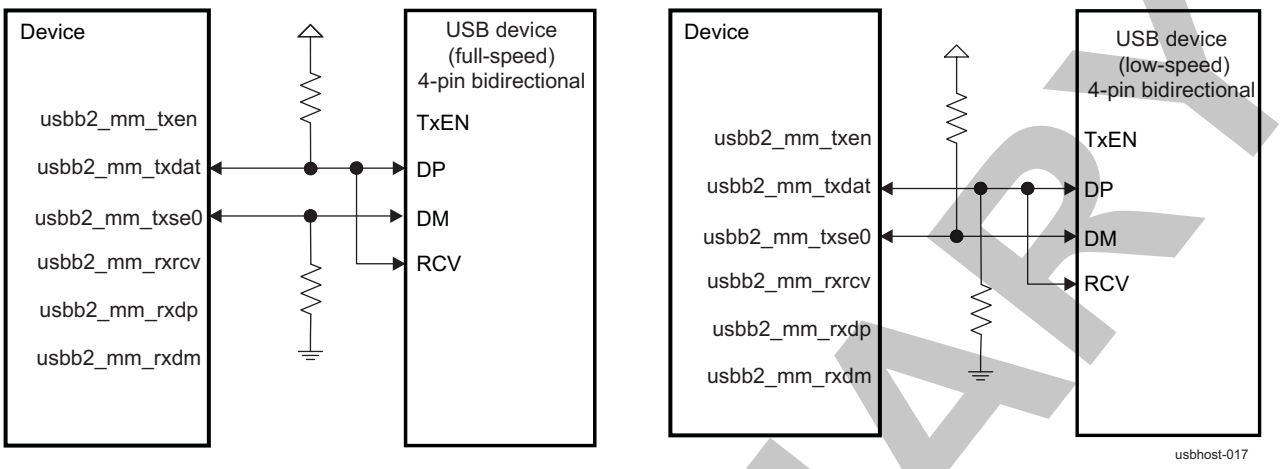


Table 23-836 shows the pullup/pulldown configuration for DP/DM encoding.

Table 23-836. Pullup/Pulldown Configuration for DP/DM Encoding

	Nonconnected Device (Any Speed)	Connected LS Device	Connected FS Device
DP	Pulldown	Pulldown	Pullup
DM	Pulldown	Pullup	Pulldown

Figure 23-231 shows a USB port using DAT/SE0 encoding.

Figure 23-231. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device

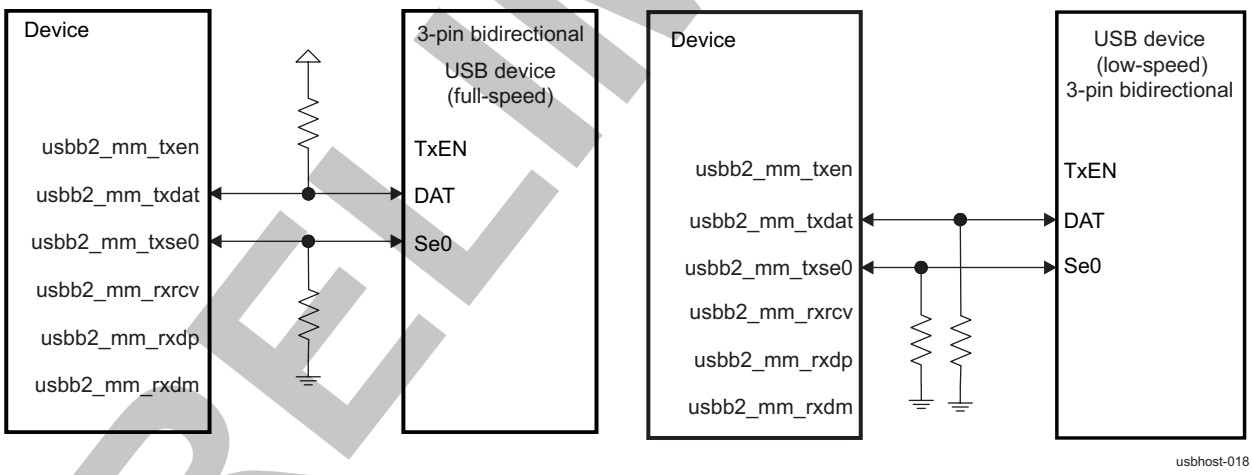

Table 23-837 shows the pullup/pulldown configuration for DAT/SE0 encoding.

Table 23-837. Pullup/Pulldown Configuration for DAT/SE0 Encoding

	Nonconnected Device (Any Speed)	Connected LS Device	Connected FS Device
DAT	Pulldown	Pulldown	Pullup
SE0	Pullup	Pulldown	Pulldown

23.10.2.2.5 Interface Description in Serial Modes

Table 23-838 describes the I/O of the HS USB host subsystem serial interface.

Table 23-838. Multiple-Mode FS/LS Serial Interface I/O Description

Device Signal Name	I/O[1]	Description	Value at Reset
HS USB Host Controller Port 2 (Device port USBB2)			
usbb2_mm_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode	
	I/O	SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DM-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txdat	I/O	DAT function in 3-pin bidirectional DAT/SE0 mode	HiZ
	I/O	DP function in 4-pin bidirectional DP/DM mode	
	O	DAT output in 6-pin unidirectional DAT/SE0 mode	
	O	DP output in 6-pin unidirectional DAT/SE0 mode	
	I/O	DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DP-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txen	O	Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes	1
	I	Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes)	
usbb2_mm_rxrcv	I	Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode)	HiZ
	O	Differential receiver signal output in the 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdp	I	Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes)	HiZ
	O	Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes)	HiZ
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	

[1] I = Input; O = Output

NOTE: ULPI (PHY) interfaces and ULPI TLL interfaces cannot be used together: either the ULPI (PHY) interfaces or the ULPI TLL interfaces are selected

23.10.2.3 HSIC Interface

The HS USB host subsystem supports the configurations with the HSIC interfaces shown in Figure 23-232.

Figure 23-232. HSIC Interface

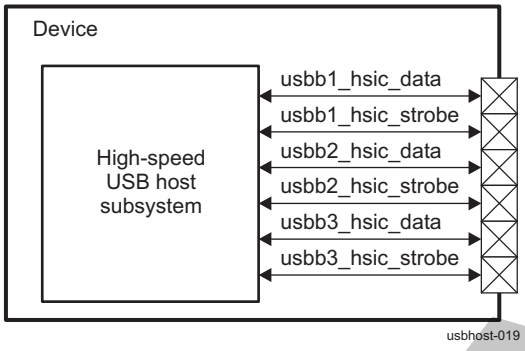

Table 23-839 describes the I/O of the HSIC interface of the HS USB host subsystem.

Table 23-839. HSIC Interface I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value
HS USB Host Controller Port 1 (Device port USBB1)				
DATA	usbb1_hsic_data	I/O	HSIC1 module data signal	HiZ
STROBE	usbb1_hsic_strobe	I/O	HSIC1 module strobe signal	HiZ
HS USB Host Controller Port 2 (Device port USBB2)				
DATA	usbb2_hsic_data	I/O	HSIC2 module data signal	HiZ
STROBE	usbb2_hsic_strobe	I/O	HSIC2 module strobe signal	HiZ
HS USB Host Controller Port 3 (Device port USBB3)				
DATA	usbb3_hsic_data	I/O	HSIC3 module data signal	HiZ
STROBE	usbb3_hsic_strobe	I/O	HSIC3 module strobe signal	HiZ

(1) I = Input; O = Output

23.10.3 HS Multiport USB Host Subsystem Integration

This section describes the integration of the HS USB host subsystem, including information about clocks, resets, and hardware requests.

The USB host controller module includes other modules and additional logic attached to the UTMI/ULPI ports. The HS USB host controller is connected to the L3 interconnect master (initiator) and L4_CFG interconnect slave (target) interfaces.

The elements of the USB HS host subsystem are:

- The multiport USB host controller. Each port uses one of the following modes:
  - ULPI, to a ULPI PHY (typically, off-chip)
  - UTMI, to a local UTMI (typically, on-chip) PHY or emulation of a PHY
- A local phase-locked loop (PLL), able to provide the USB-grade 48-, 60-, 480-MHz clocks
- Three TLL channels, bundled inside a USB TLL module. Each HS TLL channel can be seen as emulating a pair of back-to-back PHYs, and has:
  - A UTMI port, connected to a controller port (the host, in this case)
  - A ULPI port, connected to a (typically, off-chip) ULPI controller (peripheral, in this case)
- Three HSIC DFEs. The DFE plugs into the UTMI port of an HSIC-capable controller (the host, in this case), and controls HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

Figure 23-233 shows the HS USB subsystem integration.

Figure 23-233. HS USB Subsystem Integration

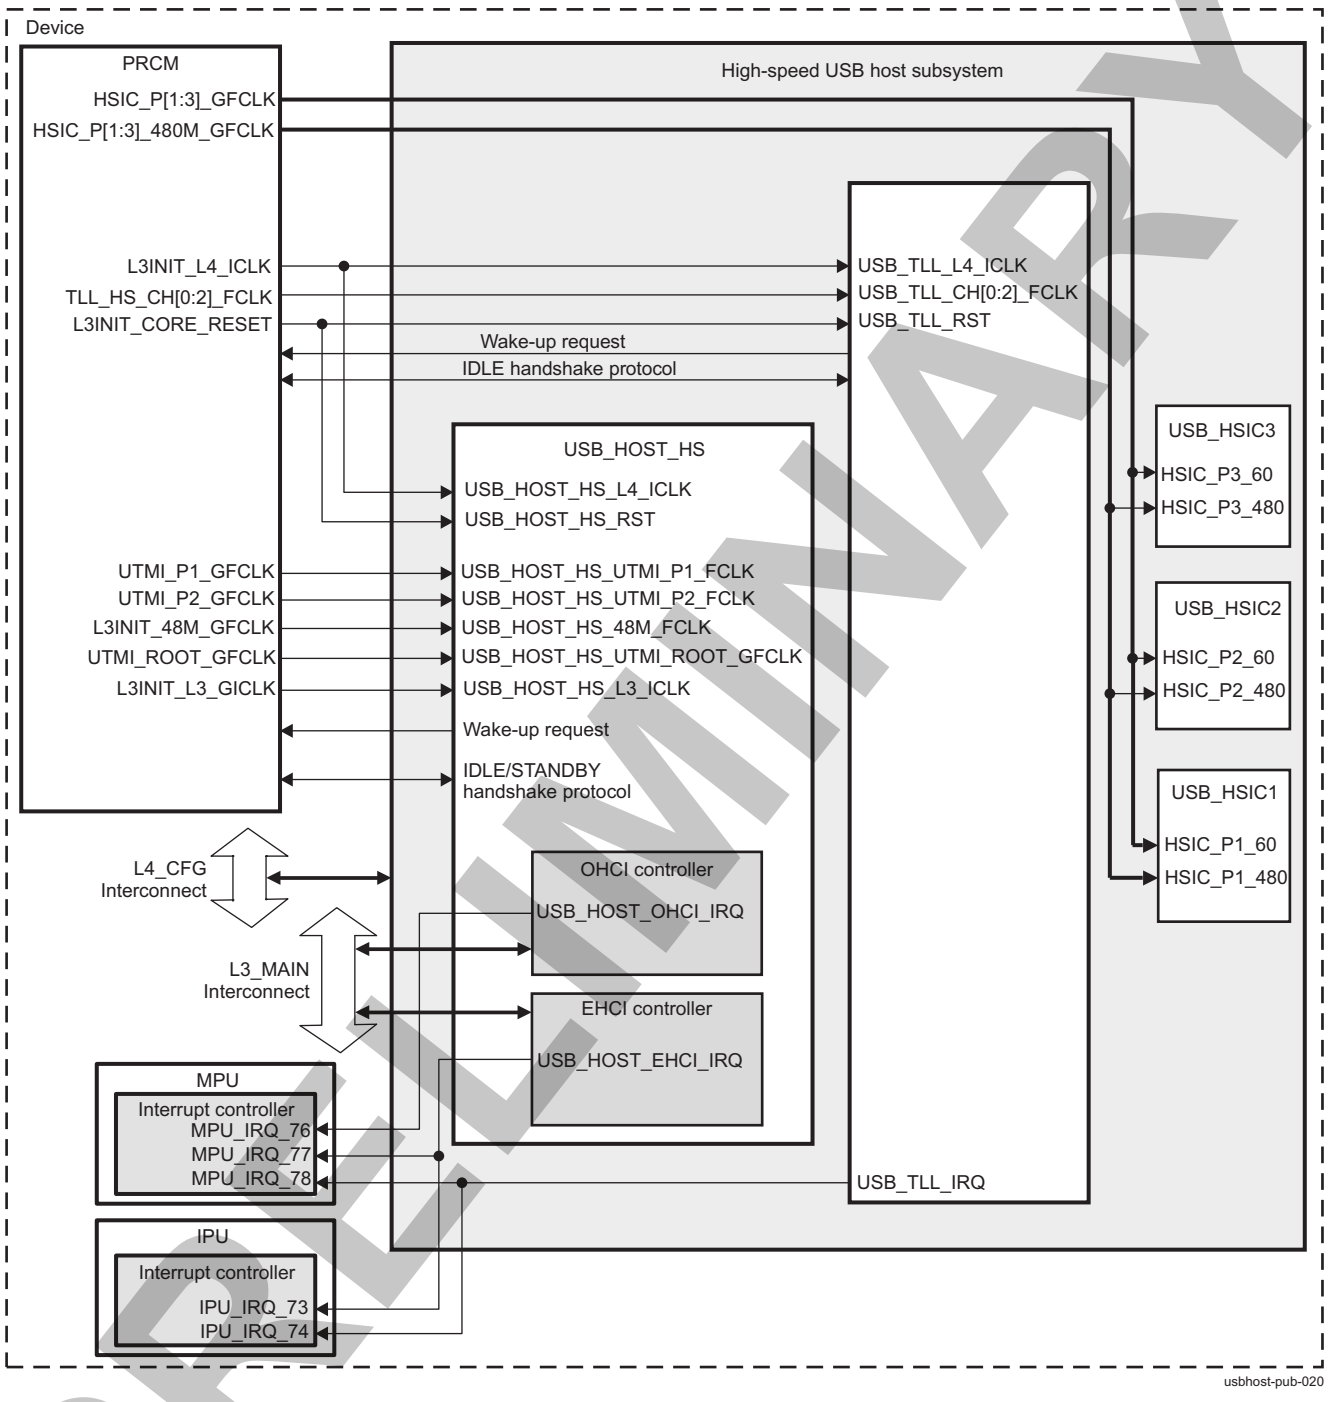

Table 23-840 through Table 23-842 summarize the integration of the module in the device.

Table 23-840. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB_HOST_HS	L3INIT	L3_MAIN L4_CFG
USB_TLL_HS	L3INIT	L4_CFG

Table 23-841. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB_HOST_HS	USB_HOST_HS_L4_ICLK	L3INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see Section 3.6.3.2)
	USB_HOST_HS_L3_ICLK	L3INIT_L3_ICLK	PRCM	L3 interconnect clock for the L3 master port interface (see Section 3.6.10)
	USB_HOST_HS_UTMI_P1_FCLK	UTMI_P1_GFCLK	PRCM	Port 1 UTMI interface functional clock (see Section 3.6.10 and Section 3.6.3.2.2)
	USB_HOST_HS_UTMI_P2_FCLK	UTMI_P2_GFCLK/usbb2_ulpiphy_clk	PRCM/external PHY IC	Port 2 UTMI interface functional clock (see Section 3.6.10 and Section 3.6.3.2.2)
	USB_HOST_HS_INIT_48M_FCLK	INIT_48M_GFCLK	PRCM	48-MHz functional clock for OHCI and EHCI (see Section 3.6.10)
	USB_HOST_HS_UTMI_ROOT_GFCLK	UTMI_ROOT_GFCLK	PRCM	60-MHz root hub clock (see Section 3.6.10)
USB_HSIC1	HSIC_P1_60	HSIC_P1_GFCLK	PRCM	60-MHz clock for the USB HSIC 1 (see Section 3.6.10)
	HSIC_P1_480	HSIC_P1_480M_GFCLK	PRCM	480-MHz clock for the USB HSIC 1(see Section 3.6.10)
USB_HSIC2	HSIC_P2_60	HSIC_P2_GFCLK	PRCM	60-MHz clock for the USB HSIC 2(see Section 3.6.10)
	HSIC_P2_480	HSIC_P2_480M_GFCLK	PRCM	480-MHz clock for the USB HSIC 2(see Section 3.6.10)
USB_HSIC3	HSIC_P3_60	HSIC_P3_GFCLK	PRCM	60-MHz clock for the USB HSIC 3 (see Section 3.6.10)
	HSIC_P3_480	HSIC_P3_480M_GFCLK	PRCM	480-MHz clock for the USB HSIC 3(see Section 3.6.10)
USB_TLL_HS	HS_USB_HOST_INIT_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see Section 3.6.3.2)
	TLL_CH0_FCLK	TLL_CH0_FCLK	PRCM	Functional clock for channel 0 (see Section 3.6.10)
	TLL_CH1_FCLK	TLL_CH1_FCLK	PRCM	Functional clock for channel 1 (see Section 3.6.10)
	TLL_CH2_FCLK	TLL_CH2_FCLK	PRCM	Functional clock for channel 2 (see Section 3.6.10)

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB_HOST_HS	USB_HOST_HS_RST	L3INIT_CORE_RST	PRCM	The signal resets the USB_HOST_HS module.
USB_TLL_HS	USB_TLL_HS_RST	L3INIT_CORE_RST	PRCM	The signal resets the USB_TLL_HS module.

The HS USB host controller and TLL module are attached to the CORE reset domain. The L3INIT_CORE_RST signal resets the HS USB host controller and TLL module (see Chapter 3, *Power, Reset, and Clock Management*).

23.10.4 HS Multiport USB Host Subsystem Functional Description

This section describes the functionality of the HS USB host subsystem by describing the HS USB host controller, USB TLL module.

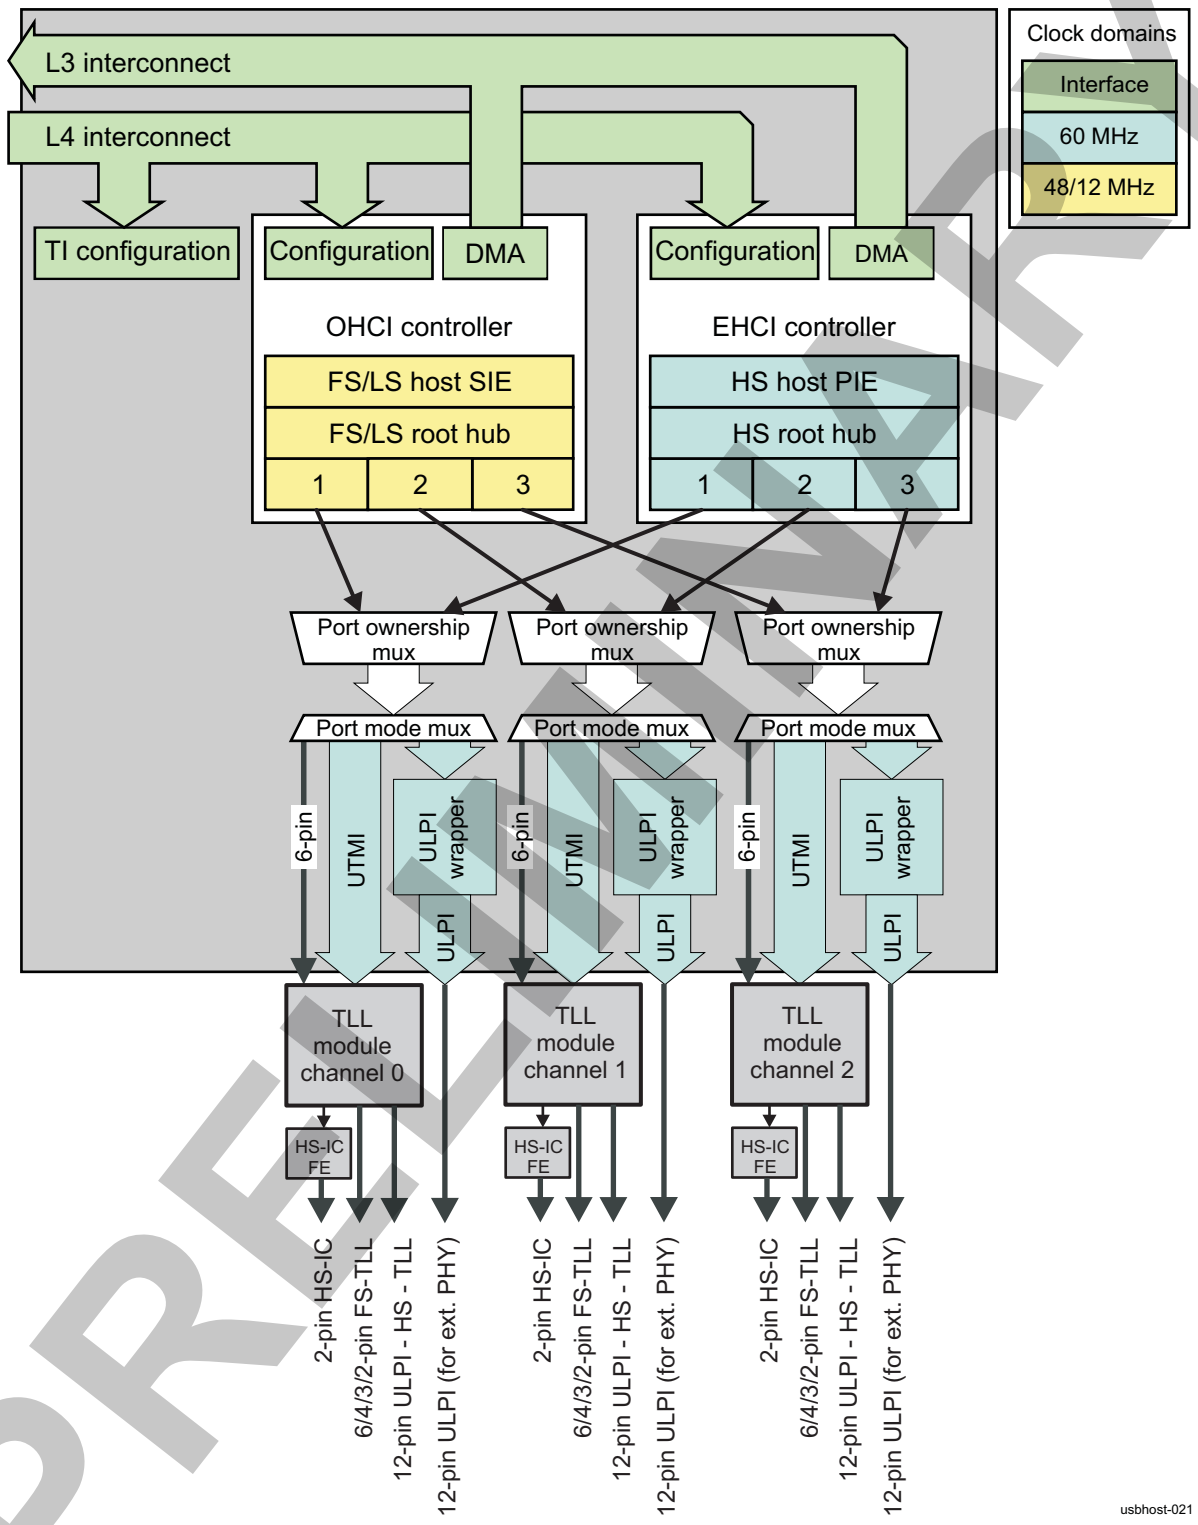
23.10.4.1 USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*

Figure 23-234 is an overview of the HS USB host controller internal architecture. It contains two independent, 3-port host controllers (OHCI and EHCI) that operate in parallel.

Figure 23-234. HS USB Host Controller Internal Architecture



23.10.4.1.1 HS USB Host Controller Software Reset

The HS USB host controller has its own software-reset function through the UHH_SYSCONFIG[0] SOFTRESET bit. Setting this bit to 0x1 resets the HS USB host controller. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

23.10.4.1.2 HS USB Host Controller Power Management

The USB protocol defines power-saving modes, where clocks can be shut down. The host asynchronously detects ULPI/UTMI events and asserts the wake-up output, which causes the clocks to restart.

To reduce dynamic power consumption, an efficient idle scheme in the device is based on:

- Efficient local autoclock gating for each module
- Implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without complex software intervention. In both cases, the HS USB host controller power management is applied only to the interface clock domain.

The HS USB host controller has master (initiator) and slave (target) interfaces:

- As an initiator, the HS USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the HS USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

NOTE: When the ULPI PHY interface is used and a FS/LS device is connected and suspended, the host controller places the ULPI interface in a mode where the ULPI clock (provided to OMAP by the external discrete USB PHY) is stopped.

23.10.4.1.2.1 Standby Handshake Protocol

The HS USB host controller can go into standby mode, in which case it stops generating transactions on the interconnect. To save power, the module standby leads the PRCM module to disable the USB clocks.

The HS USB host controller has an Mstandby/Mwait handshake mechanism with the PRCM module (see Chapter 3, *Power, Reset, and Clock Management*).

The module is ready to enter standby mode (indicated by the Mstandby signal to the PRCM module asserted) when there is no USB activity and the module is idle. It means:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go into standby mode based on the UHH_SYSCONFIG[5:4] STANDBYMODE bit field.

Table 23-843 lists the settings of standby mode.

Table 23-843. HS USB Host Controller Standby Mode Settings

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The HS USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally).
0x1	No-standby	The HS USB host controller never enters standby mode (Mstandby is never asserted).
0x2	Smart-standby	The HS USB host controller is ready to enter standby mode (Mstandby is asserted) when there is no more activity on the USB master interface of the interconnect.

Table 23-843. HS USB Host Controller Standby Mode Settings (continued)

MIDLEMODE Value	Selected Mode	Description
0x3	Smart-standby + wakeup	The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled.

23.10.4.1.2.2 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the HS USB host controller. The IDLE handshake protocol lets the PRCM module requiring the HS USB host controller to enter idle mode. Although this handshake is completely hardware and out of any software control, the way in which the HS USB host controller acknowledges the PRCM IDLE request is configurable through the UHH_SYSCONFIG[3:2] SIDLEMODE bit field. Table 23-844 lists the settings of SIDLEMODE and the related acknowledgment modes.

Table 23-844. HS USB Host Controller SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. Because such a mode does not prevent the loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.
0x3	Smart-idle + wakeup	The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled.

23.10.4.1.2.3 Wake-Up Request

The wake-up request signal USBHOST_SWAKEUP is generated by the HS USB host controller to the PRCM module.

23.10.4.1.3 HS USB Host Controller Port Status

The USB port status is given through the UHH_HOSTCONFIG[8] P1_CONNECT_STATUS, [9] P2_CONNECT_STATUS, and [10] P3_CONNECT_STATUS bits. The default value of these bits is 0x0 indicating that peripheral is disconnected.

23.10.4.1.4 HS USB Host Controller Burst Control

To avoid buffer underflow, bursts must be enabled by setting the UHH_HOSTCONFIG[4:2] bit field to 0x7, and the UHH_HOSTCONFIG[5] ENA_INCR_ALIGN bit to 1.

23.10.4.1.5 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the HS USB host controller, are described in the following list and are reflected in the register descriptions (see Section 23.10.6.5, *OHCI Registers*). For all standard features, see the *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*.

- HCFMINTERVAL[30:16] FSMPS bit field (FullSpeedMaxPacketSize) = 0x0000: The host stops scheduling new packets 0 bit times before the end of the frame (that is, by default, there is no scheduling overrun protection). To be updated by the software driver.
- HCRHDESCRIPTORA[7:0] NDP bit field (NumberDownstreamPorts) = 0x03 = three ports

- HCRHDESCRIPTORA[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- HCRHDESCRIPTORA[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- HCRHDESCRIPTORA[31:24] POTPG bit field (PowerOnToPowerGood) = 0x0A = 10: Power ramp-up time is 10 x 2 ms = 20 ms.
- HCRHDESCRIPTORB[15:0] DR bit field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- HCRHDESCRIPTORB[31:16] PPCM bit field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

23.10.4.1.6 UTMI Interface

The host controller supports three ports. Each host controller port is configured to be in UTMI or ULPI mode (see the UHH_HOSTCONFIG[21:16] Px_MODE bit field).

In UTMI mode, a port has its UTMI signal set broadcasting the outgoing packets (from the host to the peripherals) and gathering the incoming ones (from the addressed peripheral to the host). ULPI signals for that port are undefined/don't care on all ports.

The UTMI ports between the HS USB host controller and the USB TLL module are on-chip and remain invisible.

UTMI transparent mode is used to connect with the HSIC modules. (UHH_HOSTCONFIG[17:16] P1_MODE or [19:18] P2_MODE [21:20] or P3_MODE bit fields must be set to 0x3).

23.10.4.1.7 ULPI Interface

The host supports two ports. Each host controller port is configured to be either in UTMI or in ULPI mode (see the UHH_HOSTCONFIG[21:16] Px_MODE bit fields).

In ULPI mode, a port has its ULPI signal set broadcasting the outgoing packets (that is, from the host to the peripherals) and gathering the incoming packets (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

NOTE: The ULPI clock (part of the 12-wire ULPI interface) is expected to be routed by the system from the ULPI CLK input I/O pad to the clock input used by all HS modes (ULPI and UTMI) for the current port.Section 3.6.3.2.2

23.10.4.2 USB TLL Module Functionality

23.10.4.2.1 USB TLL Software Reset

Writing 0x1 to the USBTLL_SYSCONFIG[1] SOFTRESET bit resets the USB TLL module. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

23.10.4.2.2 USB TLL Power Management

The USB protocol defines power-saving modes, where clocks can be shut down.

23.10.4.2.2.1 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the USB TLL module. The IDLE handshake protocol lets the PRCM module require the HS USB TLL module to enter idle mode.

The way in which the HS USB TLL module acknowledges the PRCM IDLE request is configurable through the USBTLL_SYSCONFIG[4:3] SIDLEMODE bit field. Table 23-845 lists related acknowledgment modes.

Table 23-845. HS USB TLL Module SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request, basing its decision on its internal activity.

23.10.4.2.3 USB TLL Channels and Ports

Following the same convention as UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL, and not with respect to the link controller): An input goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USB TLL module). Reciprocally, an output goes from the TLL (transceiver) to the link controller (that is, it is an output for the USB TLL module).

By convention, the local link controller is the controller integrated on the same IC as the USB TLL module: This is the HS USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other is the USB peripheral, and they communicate through the USB TLL module.

A channel is defined as a independent USB path through the USB TLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the HS USB host controller in the device). There are two channels of the USB TLL module in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at the same time, depending on the configuration of the channel. The mode remains static throughout the USB operation.

23.10.4.2.4 USB TLL Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USB TLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. Table 23-846, lists the modes.

All configurations connect the PHY UTMI port (attached to the HS USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pad side).

Table 23-846 describes the available modes and the software settings required for each. Channel i has the following settings:

- CHANMODE: TLL_CHANNEL_CONF_i[2:1] CHANMODE bit field
- FSLSMODE: TLL_CHANNEL_CONF_i[27:24] FSLSMODE bit field
- FSLSSERIALMODE_3PIN/6PIN: Either the ULPI PHY-side INTERFACE_CTRL_i[1] FSLSSERIALMODE_3PIN bit or the INTERFACE_CTRL_i[0] FSLSSERIALMODE_6PIN bit (only one at a time can be set to 1)

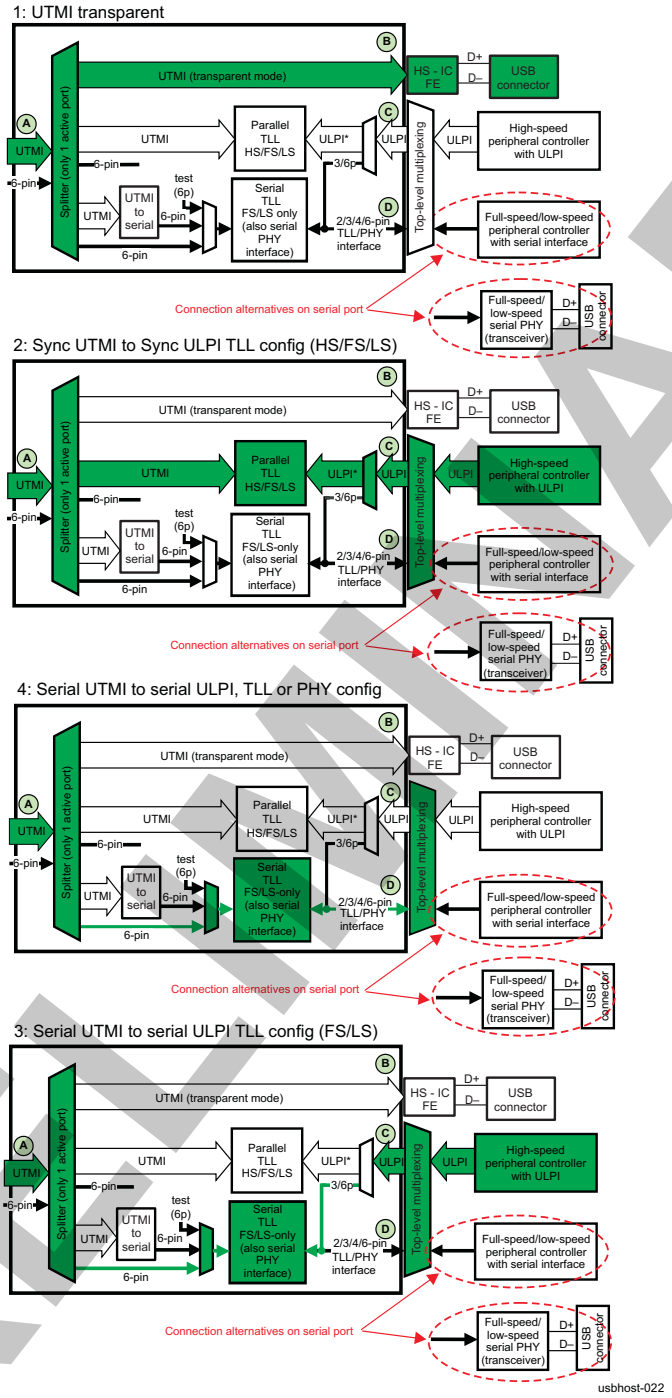
Table 23-846. USB TLL Channel Configuration

Configuration	Mode	CHANMODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
1	UTMI transparent	0	N/A	–	A-B	–	UTMI transparent
2	ULPI synchronous TLL	0	N/A	FSLSSERIALMODE_3PIN/6PIN = 0	A-C	HFL	ULPI link (peripheral controller)
3	Serial UTMI to serial ULPI TLL	0	N/A	FSLSSERIALMODE_3PIN/6PIN = 1	A-C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode

Table 23-846. USB TLL Channel Configuration (continued)

Configuration	Mode	CHANMODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
4	Serial UTMI to serial TLL	1	0x4-0x7; 0xA-0xB	–	A-D	FL	Serial link (2-/3-/4-/6-pin)
4	Serial UTMI to serial PHY	1	0x0-0x3	–	A-D	FL	Serial transceiver (2-/3-/4-/6-pin)

Figure 23-235. Per-Configuration Data Path Through USB TLL



23.10.4.2.5 USB TLL VBUS Management and Emulations

In transceiver configurations, a USB cable is present, including a 5-V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power savings compared to a simple suspend.

- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see Figure 23-220 and Figure 23-221 and the related explanations.

23.10.4.2.5.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to and from the VBUS manager IC (typically, the transceiver).

Only serial transceiver configurations are concerned in the case of the HS USB host subsystem in the device.

23.10.4.2.5.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described in the following list (also see Figure 23-220).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge," VBUS pulldown "discharge") is assumed to be handled separately from the USB TLL module (that is, by software and straight to the power IC, which can be the transceiver, especially in OTG cases).
- The status of VBUS must be sampled by the appropriate hardware (again, most often the transceiver) and reported by software to the USB TLL module, using the TLL_CHANNEL_CONF_i[16] DRVVBUS and TLL_CHANNEL_CONF_i [15] CHRGVBUS bits, as indicated in Table 23-847.

Table 23-847 lists the values to write to the TLL_CHANNEL_CONF_i register depending on the status of VBUS observed by the transceiver on the VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations, the signification of the fields is:

- DRVVBUS: Set to 1 to report a VBUS level greater than VBUS valid.
- CHRGVBUS: Set to 1 to report a VBUS level greater than session valid.

Table 23-847. VBUS Level Software Reporting for Serial Transceiver Configuration

VBUS Status	TLL_CHANNEL_CONF_i[16] DRVVBUS	TLL_CHANNEL_CONF_i[15] CHRGVBUS
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

23.10.4.2.5.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line and obtains a voltage level, which is reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas an actual VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The charge feature is used for VBUS-pulsing SRP and is enabled long enough to go over the session valid threshold, but without reaching VBUS valid. In the TLL, the transition to session valid is immediate, and VBUS valid is never reached even if the charge is intentionally kept active.
- The discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS toward the session-end level. For TLL, therefore, this is useless (although the UTMI input/ULPI register bit does exist, for compatibility), and is always don't care.

23.10.4.2.5.2.1 VBUS Emulation in ULPI TLL Modes

Table 23-848 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 23-848. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

VBUS Controls (Actions)			VBUS Level	VBUS Status		
OTG_CTRL_i[5] DRVVBUS	OTG_CTRL_i[4] CHRGVBUS	OTG_CTRL_i[3] DISCHRGVBUS		USB_INT_STATUS_i[1] VBUSVALID bit	USB_INT_STATUS_i[2] SESSVALID bit	USB_INT_STATUS_i[3] SESSEND bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

23.10.4.2.5.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad hoc sideband signals (see Figure 23-221).

VBUS control can be done in software by writing to the following fields of the TLL_CHANNEL_CONF_i register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pull up VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session-end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (The DRVVBUS bit and input signal are OR-ed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at the top level, a software alternative is to use the voltage status reported on the interface (through the standard UTMI+ sideband signals) of the local controller (the HS USB host controller in the device) and to pass it to the remote controller (a peripheral controller) by means of an ad hoc software-controller interface other than the USB. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

23.10.4.2.6 USB TLL Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the TLL_CHANNEL_CONF_i[27:24] FSLSMODE bit field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are FS/LS only (that is, HS is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, RXDP, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output-enable signal associated with it on the USB TLL entity.

Table 23-849 lists the function of each pad in each mode. USB TLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 23-849. Serial Mode Description, Signal Functionality

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
TLL_CHANNEL_CONF_i[27:24] FSLSMODE bit field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DP/DM/RCV	DP/DM/RCV	DAT/SE0	DP/DM/RCV	DAT/SE0	DP/DM
Pin use	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5[1]	6 or 5[1]	3	4 or 3[2]	2	2
I/O Pad Function Per Mode										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDP	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDP	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

(1) RXRCV and RXDP carry the same information: RXDP can drive both inputs of the remote controller, and RXRCV can be kept unused.

(2) Same remark for TXDAT (for outputs) and RXRCV: TXDAT only is enough.

23.10.4.2.7 USB TLL Attach/Connect Emulation for Serial Modes

This section applies to all serial TLL modes in the following circumstances:

- In UTMI-to-serial mode (TLL_CHANNEL_CONF_i[2:1] CHANMODE = 0x1) for all TLL values of the TLL_CHANNEL_CONF_i[27:24] FSLSMODE bit field (0x4–0x7; 0xA–0xB)
- In UTMI-to-ULPI TLL mode (TLL_CHANNEL_CONF_i[2:1] CHANMODE = 0x0) when the ULPI bus is switched to 6-pin or 3-pin serial modes

In those modes, the USB bus lines are emulated by USB TLL internal logic and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one is implemented:

- The TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable:
  - When this bit is cleared, the local controller RX path shows only the local controller (the HS USB host controller) actions on the bus: TX driving, pullups, pulldowns. The same applies for the remote controller RX path (except that test override is not available).
  - When the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- The TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5-kΩ resistor]), which causes the line state to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USB TLL module input signal; the connect control can be software (L4_CFG interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit.
- The TLL_CHANNEL_CONF_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as previously defined) results in the pulling up of D+ (1 = full speed) or D– (0 = low speed) (see Table 23-850).
- The 15-kΩ pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require additional control.

NOTE: Sideband control and status actions such as pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require custom additions.

Table 23-850. Pullup Enable Emulation in Serial TLL Modes

TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D– Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	On	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

23.10.5 HS Multiport USB Host Subsystem Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the HS USB host subsystem.

23.10.5.1 Global Initialization

23.10.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HS USB host subsystem is used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HS USB host subsystem.

Table 23-851 describes the global initialization of surrounding modules.

Table 23-851. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	All required clocks must be enabled. For ULPI PHY mode, mux the UTMI_P1_GFCLK from the external pad. See Section 3.6.3.2, *CM Clock Source*, in Chapter 3, *Power, Reset, and Clock Management*.
MPU INTC or IPU INTC	The MPU or IPU INTC must be configured to enable the interrupts when interrupt requests are generated by the HS multiport USB host subsystem. See the respective functional description in Chapter 17, *Interrupt Controllers*, for the MPUs.
Interconnect (L3 and L4)	For more information, see Section 14.2, *L3 Interconnect*, and Section 14.3, *L4 Interconnect*.

23.10.5.1.2 HS Multiport USB Host Subsystem Global Initialization

This procedure in Table 23-852 initializes the HS multiport USB host subsystem after a power-on or software reset.

Table 23-852. HS Multiport USB Host Subsystem Global Initialization

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the TLL module.	USBTLL_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is finished.	USBTLL_SYSSTATUS[0] RESETDONE	=0x1
Enable IRQ event for the TLL module.	USBTLL_IRQENABLE[1] FCLK_END_EN	0x1
Enable IRQ event for the TLL module.	USBTLL_IRQENABLE[0] FCLK_START_EN	=0x1
Perform a software reset on the HS USB controller.	UHH_SYSCONFIG[0] SOFTRESET	0x1
Wait until the EHCI HS host is out of reset.	UHH_SYSSTATUS[2] EHCI_RESETDONE	=0x0
Wait until the OHCI HS host is out of reset.	UHH_SYSSTATUS[1] OHCI_RESETDONE	=0x0
Enable IRQ event for the OHCI HS host.	HCINTERRUPTENABLE[31] MIE	0x1
Enable IRQ event for the EHCI HS host.	USBINTR[0] USBIE	0x1

23.10.5.2 Operational Modes Configuration (Selecting and Configuring USB Connectivity)

Figure 23-236 shows how to select and configure the HS USB host subsystem connectivity.

Figure 23-236. Selecting and Configuring HS USB Host Subsystem Connectivity

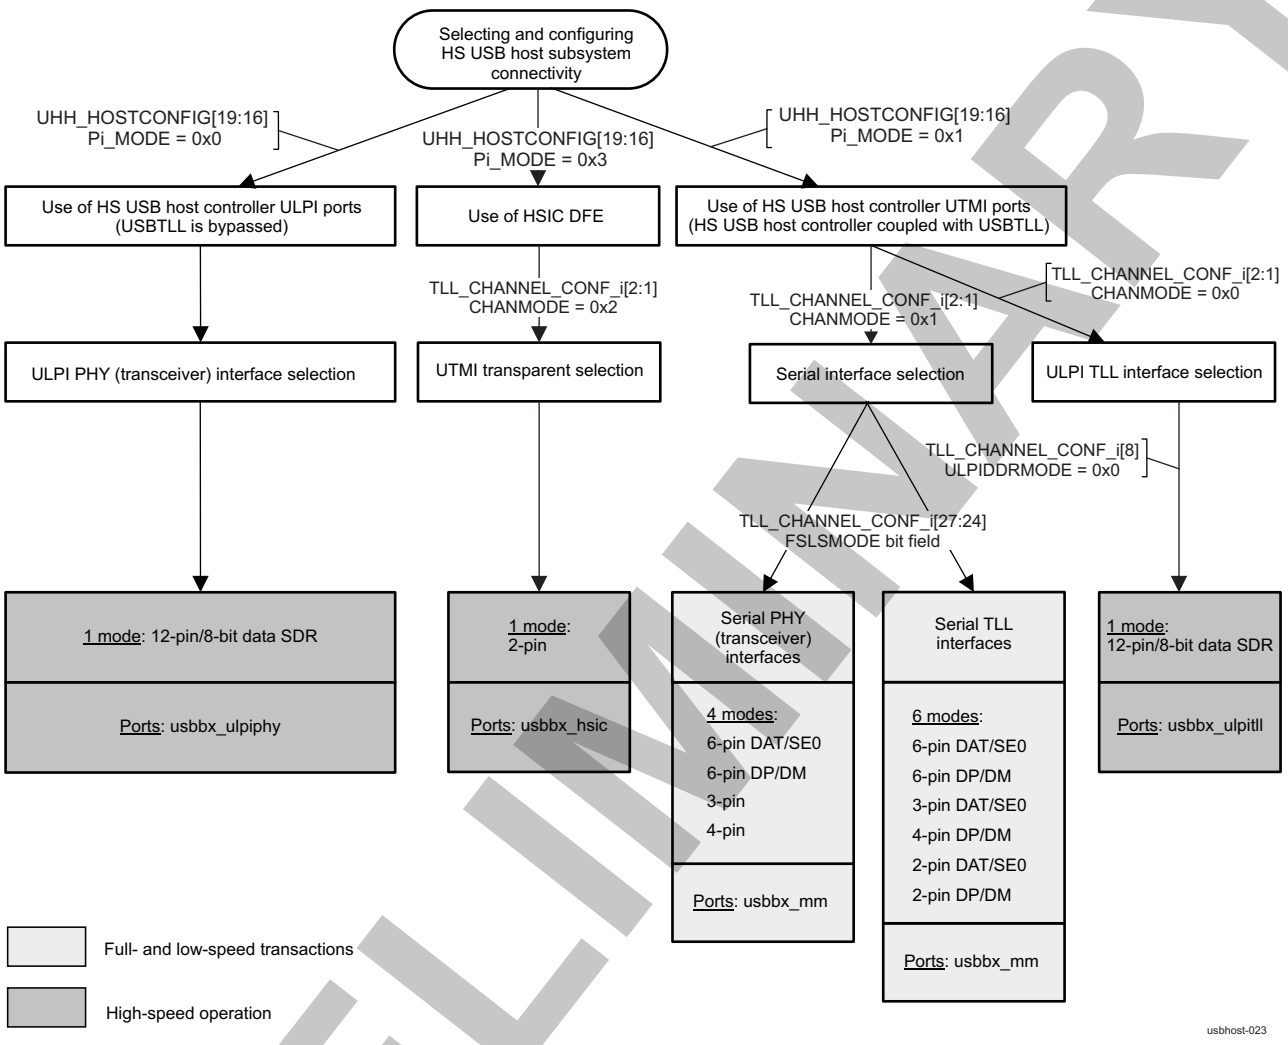


Table 23-853. Register Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

Register Name	
UHH_HOSTCONFIG	TLL_CHANNEL_CONF_i

23.10.5.3 USB TLL Registers

The USB TLL module contains two types of software-programmable registers: TLL control and status registers and ULPI PHY-side registers.

23.10.5.3.1 TLL Control and Status Registers

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4_CFG interconnect. They are used primarily before USB activity starts. The registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

23.10.5.3.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and therefore contains this set of 8-bit PHY-side registers, per ULPI specification. The registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in the ULPI specification

These registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

They are accessible by the L4_CFG interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4_CFG interconnect address space, where they can be accessed through byte accesses. If a conflict occurs between the two access modes, access over ULPI has priority, but both accesses eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4_CFG interconnect accesses can compromise proper USB operation. The L4_CFG interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USB TLL module can be switched off to save power. When the module is switched on again, the ULPI register contents, which have been lost, can be restored over the L4_CFG interconnect before USB operations restart, provided they were saved elsewhere beforehand.

23.10.6 HS USB Host Subsystem Register Manual

This section provides the register description of the subsystem.

23.10.6.1 HS USB Host Subsystem Instance Summary

Table 23-854 summarizes the HS USB Host Subsystem instance.

Table 23-854. HS USB Host Subsystem Instance Summary

Module Name	L4_CFG Base Address	Size

TX encoding is Dat/Se0 (default). 0x1: 6-pin unidirectional PHY i/f mode. TX encoding is Dp/Dm. 0x2: 3-pin bidirectional PHY i/f mode 0x3: 4-pin bidirectional PHY i/f mode 0x4: 6-pin unidirectional TLL mode. TX encoding is Dat/Se0. 0x5: 6-pin unidirectional TLL mode. TX encoding is Dp/Dm. 0x6: 3-pin bidirectional TLL mode 0x7: 4-pin bidirectional TLL mode 0xA: 2-pin bidirectional TLL mode. Encoding is Dat/Se0. 0xB: 2-pin bidirectional TLL mode. Encoding is Dp/Dm.	RW	0x0
23:21	RESERVED		R	0x0
20	TESTTXSE0	Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (TX = hiz) 0x0: drive differential value on TX according to TestTxDat 0x1: drive SE0 on TX	RW	0
19	TESTTXDAT	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (TX = hiz) or TestSe0 = 1 (TX = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1	RW	0

Bits	Field Name	Description	Type	Reset
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive Tx according to TestTxDat/Se0 0x1: Drive Tx Hiz (no drive: pullups determine line state)	RW	0
17	TESTEN	Enable manual test override for serial mode TX path (from local controller UTMI port) 0x0: No override. Tx is from local link controller 0x1: Override enabled	RW	0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5 V	RW	0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0
14:12	RESERVED		R	0x0
11	ULPINOBITSTUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (nonstandard)	RW	0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMII goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	1
8	RESERVED		R	0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode. Hardcoded, for legacy only. Read 0x1: ULPI clock provided by PHY side (i.e. TLL, from functional clock). ULPI clock is output	R Rreturns 1s	1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tllpuen, register field TllConnect. 0x0: Connect is Low-speed: D– pullup 0x1: Connect is Full-Speed: D+ pullup	RW	1
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D– pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected	RW	0

Bits	Field Name	Description	Type	Reset
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: Cable detach emulated on serial TLL 0x1: Cable attach emulated on serial TLL	RW	1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, i.e. the emulated USB cable's orientation. The host must always be on A-side, peripheral on B-side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unclocked and kept under reset. 0x0: Channel i disabled 0x1: Channel i enabled	RW	0

Physical Address	0x4A06 2833 + (0x100 * i)	**Instance**	USB_TLL_HS_ULPI
Description	Part of nonstandard UTMI-to-ULPI mailbox system. UTMI-standard Vcontrol vector byte is sent by the UTMI controller (other side of TLL) to its PHY (emulated here by the TLL). Alternatively, data can be also written directly into the register. Can contain any user-defined data. Vcontrol bit changes can be used to assert the ULPI ALT interrupt. Lowest 4 bits are implemented, others are always-0, read-only. (UTMI standard is 4-bit).

Table 23-935. UTMI_VCONTROL_LATCH_i

Address Offset	0x0000 0034 + (0x100 * i)	**Index**	i = 0 to 2
Physical Address	0x4A06 2834 + (0x100 * i)	**Instance**	USB_TLL_HS_ULPI
Description	Part of nonstandard UTMI-to-ULPI mailbox system. Set by unmasked changes on the corresponding vcontrol_status bits to generate the ULPI ALT interrupt. Cleared upon read, and when low-power mode, serial mode or carkit mode are entered. Lowest 4 bits are implemented, others are always-0, read-only.		
Type	R

CAUTION

The OHCI registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

OHCI register descriptions conform to the OHCI USB standard: *Open Host Controller Interface Specification for USB, Release 1.0a*. For more information about these registers or for new specification releases, search OHCI on www.usb.org.

23.10.6.5.2 OHCI Register Description

through describe the OHCI registers.

Table 23-971. HCREVISION

Address Offset	0x0000 0000		
Physical Address	0x4A06 4800	**Instance**	OHCI
Description	OHCI revision number		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								REV							

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved	R	0x000000
7:0	REV	OHCI specification revision the OHCI revision number upon which the USB host controller is based. Examples: 0x10 for 1.0, 0x21 for 2.1	R	0x10

Table 23-973. HCCONTROL

Address Offset	0x0000 0004		
Physical Address	0x4A06 4804	**Instance**	OHCI
Description	HC operating mode register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																					RWE	RWC	IR	HCFS		BLE	CLE	IE	PLE	CBSR	

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Reserved	R	0x000000
10	RWE	Remote wake-up enable This bit is used to enable or disable the remote wakeup feature upon detection of upstream resume signaling.	RW	0
9	RWC	Remote wake-up connected. This bit indicates whether the host controller supports remote wakeup signaling.	RW	0
8	IR	Interrupt routing This bit determines the routing of interrupts generated by events registered in HCINTERRUPTSTATUS. 0x0: All interrupts are routed to the normal host bus interrupt mechanism.. 0x1: Interrupts are routed to the system management Interrupt.	RW	0
7:6	HCFS	Host controller functional state 0x0: HCFS: USB reset 0x1: HCFS: USB resume 0x2: HCFS: USB operational 0x3: HCFS: USB suspend	RW	0x0
5	BLE	Bulk list processing enable 0x0: Bulk ED list is not processed after the next SOF. 0x1: Enables processing of bulk ED list in the next frame.	RW	0
4	CLE	Control list processing enable 0x0: Control ED list is not processed after the next SOF. 0x1: Enables processing of control ED list in the next frame.	RW	0
3	IE	Isochronous ED processing enabled by host controller driver 0x0: Isochronous EDs are not processed. 0x1: Enables processing of isochronous EDs	RW	0
2	PLE	Periodic list enable 0x0: Periodic ED lists are not processed after the next frame. 0x1: Enables processing of periodic ED lists in the next frame.	RW	0
1:0	CBSR	Control/bulk service ratio. Specifies the ratio between control and bulk EDs processed in a frame. 0x0: One control ED per bulk ED 0x1: Two control ED per bulk ED 0x2: Three control ED per bulk ED 0x3: Four control ED per bulk ED	RW	0x0

Table 23-975. HCCOMMANDSTATUS

Address Offset	0x0000 0008		
Physical Address	0x4A06 4808	**Instance**	OHCI
Description	HC command and status		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														SOC		RESERVED												OCR	BLF	CLF	HCR

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R	0x0000
17:16	SOC	Scheduling overrun count This is used to monitor any persistent scheduling problems. These bits are incremented on each scheduling overrun error. It is initialized to 0x0 and wraps around at 0x3.	R	0x0
15:4	RESERVED	Reserved	R	0x000
3	OCR	Ownership change request. This bit is set to request a change of control of the host controller.	RW	0
2	BLF	Bulk list filled This bit is used to indicate whether there are any TDs on the bulk list. It is set whenever it adds a TD to an ED in the bulk list.	RW	0
1	CLF	Control list filled This bit is used to indicate whether there are any TDs on the control list. It is set whenever it adds a TD to an ED in the control list.	RW	0
0	HCR	Host controller reset (software reset). Set this bit to initiate a USB host controller reset. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this register returns a 0. 0x0: No effect 0x1: USB host controller is reset.	RW	0

POTPG								RESERVED											NOCP	OCPM	DT	NPS	PSM	NDP							

Bits	Field Name	Description	Type	Reset
31:24	POTPG	Power-on to power-good time. Defines the minimum amount of time (2 ms * POTPG) between the USB host controller turning on power to a downstream port and when the USB host can access the downstream device.	RW	0x0A
23:13	RESERVED	Reserved	R	0x0
12	NOCP	No overcurrent protection. This function is not supported at the device level. 0x0: Overcurrent status is reported collectively for all downstream ports. 0x1: The USB host controller does not implement overcurrent protection inputs.	RW	0x0
11	OCPM	Overcurrent protection mode. This function is not supported at the device level.	RW	0x1
10	DT	Device type Always reads 0x0: Indicates that the USB host controller implemented is not a compound device.	R	0
9	NPS	No power switching 0x0: VBUS power switching is supported, either per-port or all-port switched per the power. 0x1: VBUS power switching is not supported; power is available to all downstream ports.	RW	0
8	PSM	Power switching mode 0x0: Indicates that all ports are powered at the same time 0x1: Individual port power switching is supported.	RW	1
7:0	NDP	Number of downstream ports These bits specify the number of downstream ports supported by the root hub. It is implementation-specific. The minimum number of ports is 1. The maximum number of ports supported by OHCI is 15.	R	0x03

Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPCM																DR															

Bits	Field Name	Description	Type	Reset
31:16	PPCM	Port power control mask. Each bit defines whether a corresponding downstream port has port power controlled by the global power control. When set, the port's power state is only affected by per-port power control. When cleared, the port is controlled by the global power switch. If the device is configured to global switch mode this field is not valid. Bit 0: Reserved, bit 1: Ganged-power mask on port 1, ..., bit 15: Ganged-power mask on port 15.	RW	0x0000
15:0	DR	Device removable. Each bit defines whether a corresponding downstream port has a removable device. When cleared, the attached device is removable. When set, the attached device is not removable. Bit 0: Reserved, bit 1: Device attached to port 1, ... bit 15: Device attached to port 15.	RW	0x0000

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved	R	0x000
20	PRSC	Port 1 reset status change. This bit is set when the port 1 port reset status bit has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
19	RESERVED		R	0
18	PSSC	Port 1 suspends status change. Set when the port leaves the suspend state; that is, after the full resume sequence has completed. Write 0x0: No effect Read 0x0: No resume completed (since either the last software clear, or the last port reset). Read 0x1: Resume completed on the port Write 0x1: Clears the bit	RW	0
17	PESC	Port 1 enable status change. This bit is set when the port 1 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
16	CSC	Port 1 connect status change. This bit is set when the port1 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit **Note:** If the HCRHDESCRIPTORB[1] DR bit is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00

Bits	Field Name	Description	Type	Reset
9	LSDA_CPP	Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. Read 0x0: A full-speed device is attached to port 1. Read 0x1: A low-speed device is attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port power status	RW	0
8	PPS_SPP	Port 1 port power status/set port power Read 0x0: Port 1 power is enabled. Read 0x1: Port 1 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 1 port power status bit	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 1 port reset status/set port reset Read 0x0: USB reset is not being sent to port 1. Read 0x1: Port 1 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 1 port reset status bit and causes the USB host controller to begin signaling USB reset to port 1	RW	0
3	POCI_CSS	Port 1 overcurrent indicator (not implemented)/clear suspend status. Read 0x0: no port 1 port overcurrent condition has occurred. Read 0x1: a port 1 port overcurrent condition has occurred. Write 0x0: no effect. Write 0x1: when port 1 port suspend status is 1 causes resume signalling on port 1. When port 1 port suspend status is 0 has no effect.	RW	0
2	PSS_SPS	Port 1 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 1 is not in the USB suspend state. Read 0x1: Port 1 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 1 current connect status is 1, sets the port 1 port suspend status bit and places port 1 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 1 port enable status/set port enable. This bit is automatically set at completion of port 1 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 1 is not enabled. Read 0x1: Port 1 is enabled. Write 0x0: No effect Write 0x1: When port 1 current connect status is 1 sets the port 1 port enable status bit. When port 1 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 1 current connection status/clear port enable Read 0x0: No USB device is attached to port 1. Read 0x1: A USB device is currently attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port enable bit Note: This bit is set to 1 if the HCRHDESCRIPTORB[1 DR bit] is set to indicate a nonremovable device on port 1.	RW	0

19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of companion controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: There are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.	R	0x1
11:8	N_PCC	Number of ports per companion controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port routing rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.	R	0
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port power control This field indicates whether the host controller implementation includes port power control.	R	1

Bits	Field Name	Description	Type	Reset
		0x0: The ports do not have port power switches. 0x1: The ports have port power switches.		
3:0	N_PORTS	Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R	0x0000
17	LPM	Link power management capability 0: Link power management not supported 1: Link power management supported	R	1
16	RESERVED	Reserved	R	0
15:8	EECP	EHCI extended capabilities pointer This field indicates the existence of a capabilities list. 0x0: No extended capabilities are implemented. Others: The offset in PCI configuration space of the first EHCI extended capability.	R	0x00
7:4	IST	Isochronous scheduling threshold This field indicates where software can reliably update the isochronous schedule in relation to the current position of the executing host controller. The host controller can hold one microframe of isochronous data structures before flushing the state.	R	0x1
3	RESERVED	Reserved	R	0
2	ASPC	Asynchronous schedule park capability 0x1: The host controller supports the park feature for high-speed queue heads in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using the USBHOST.USBCMD[11]ASPME bit and the USBHOST.USBCMD[9:8] ASPMC bit field.	R	1
1	PFLF	Programmable frame list flag 0x0: System software must use a frame list length of 1024 elements with this host controller.	R	1

Bits	Field Name	Description	Type	Reset
		0x1: System software can specify and use a smaller frame list and configure the host controller through the USBHOST.USBCMD[3:2] FLS bit field. The frame list must always be aligned on a 4-K page boundary.		
0	BIT64AC	64-bit addressing capability This field documents the addressing range capability of this implementation. 0x0: Data structures using 32-bit address memory pointers 0x1: Data structures using 64-bit address memory pointers	R	0

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	R	0x0
27:24	HIRD	Host-initiated resume duration. If LPM is enabled, this field is RW; otherwise, it is R. The minimum for K-state during resume from LPM: 0x0: 50 µs Each increment adds 75 µs.	RW	0x0
23:16	ITC	Interrupt threshold control This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. 0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined	RW	0x08
15:12	RESERVED	Reserved	R	0x0

Bits	Field Name	Description	Type	Reset
11	ASPME	Asynchronous schedule park mode enable 0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous schedule park mode count It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0x1 to 0x3. Software must not write 0 to this bit when park mode enable is 1 because this may result in undefined behavior.	RW	0x3
7	LHCR	Light host controller reset It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0
6	IAAD	Interrupt on async advance doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Write 0x1: Ring the doorbell. Software must not write 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0
5	ASE	Asynchronous schedule enable This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule.	RW	0
4	PSE	Periodic schedule enable This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule.	RW	0
3:2	FLS	Frame list size This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list current index. 0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved	RW	0
1	HCR	Host controller reset This control bit is used by software to reset the host controller. Write 0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values. This bit is set to 0 by the host controller when the reset process is complete.	W	0

Bits	Field Name	Description	Type	Reset
0	RS	Run/stop 0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. 0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts.	RW	0

RESERVED																ASS	PSS	REC	HCH	RESERVED				IAA	HSE	FLR	PCD	USBEI	USBI		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	Asynchronous schedule status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled.	R	0
14	PSS	Periodic schedule status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host controller halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on async advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by setting the USBHOST.USBCMD[6] IAAD bit to 1. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host system error	RW	0

Bits	Field Name	Description	Type	Reset
		The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.		
3	FLR	Frame list rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port change detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from 0 to 1 or a USBHOST.PORTSC_i[6] FPR bit transition from 0 to 1. This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by setting the USBHOST.PORTSC_i[13] PO bit to 1.	RW	0
1	USBEI	USB error interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

DEVICEADDRESS								SUSPENDSTATUS	RESERVED	WDE	WCE	PTC				PIC		PO	PP	LS		SUSPENDL1	PR	SUS	FPR	RESERVED			PEDC	PED	CSC	CCS

Bits	Field Name	Description	Type	Reset
31:25	DEVICEADDRESS	The USB device address for the device attached to and immediately downstream from the associated root port. R/W only if LPM is enabled; otherwise, R.	RW	0x00
24:23	SUSPENDSTATUS	Addition for LPM support. Indicates status of L1 suspend request: 0x0: Success 0x1: Not yet 0x2: Not supported 0x3: Time-out/error	R	0x0
22	RESERVED	Reserved	R	0
21	WDE	Wake on disconnect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device disconnects as wake-up events.	RW	0
20	WCE	Wake on connect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device connects as wake-up events.	RW	0
19:16	PTC	Port test control The port is operating in specific test modes as indicated by the specific value. The encoding of the test mode bits are: 0x0: Test mode not enabled 0x1: Test J_STATE 0x2: Test K_STATE 0x3: Test SE0_NAK 0x4: Test Packet 0x5: Test FORCE_ENABLE Others: Reserved	RW	0x0
15:14	PIC	Port indicator control (not implemented)	R	0x0
13	PO	Port owner This bit unconditionally goes to 0x0 when the USBHOST.CONFIGFLAG[0] CF bit makes a transition from 0 to 1. This bit unconditionally goes to 0 whenever the USBHOST.CONFIGFLAG[0] CF bit is 0. 0x1: A companion host controller owns and controls the port.	RW	1
12	PP	Port power The function of this bit depends on the value of the USBHOST.HCSPARAMS[4] PPC bit. The behavior is as follows: **PPC** / **PP** / **Operation** 0x0 / 0x0 / Forbidden 0x0 / 0x1 / Host controller does not have port power. control switches. Each port is hardwired to power. 0x1 / 0x0 / Host controller has port power control switches. Current switch state is off. 0x1 / 0x1 / Host controller has port power control switches. Current switch state is on. When an overcurrent condition is detected on a powered port and the USBHOST.HCSPARAMS[4] PPC bit is a 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0.	RW	0
11:10	LS	Line status These bits reflect the current logical levels of the D+ (bit 11) and D– (bit 10) signal lines. This field is valid only when the port enable bit is 0 and the current connect status bit is set to 1. The encoding of the bits is:	R	0x0

Bits	Field Name	Description			Type	Reset
		Bits[11:10]	**USB State**	**Interpretation**		
		0x0	SE0	Not low-speed device, perform EHCI reset.		
		0x2	J-state	Not low-speed device, perform EHCI reset.		
		0x1	K-state	Low-speed device, release ownership of port.		
		0x3	Undefined	Not low-speed device, perform EHCI reset.		
9	SUSPENDL1	When this bit is set to 1, an LPM token is generated. 0: Suspend using L2 1: Suspend using L1 (LPM)			RW	0
8	PR	Port reset This field is 0 if the PP bit is 0. 0x0: Port is not in reset. 0x1: Port is in reset. Write 0x0: Terminate the bus reset sequence. Write 0x1 when at 0x0: The bus reset sequence is started.			RW	0
7	SUS	Suspend This field is 0 if the PP bit is 0. 0x0 when PED = 0x1: Port enabled 0x1 when PED = 0x1: Port in suspend state When PED = 0x0: Port disabled			RW	0
6	FPR	Force port resume This field is 0 if the PP bit is 0. 0x0: No resume (K-state) detected/driven on port 0x1: Resume detected/driven on port			RW	0
5:4	RESERVED	Reserved			R	0
3	PEDC	Port enabled/disabled change This field is 0 if the PP bit is 0. Read 0x0: No change. Read 0x1: Port enabled/disabled status has changed. Write 0x1: Clears this bit to 0.			RW	0
2	PED	Port enabled/disabled Software cannot enable a port by setting this bit to 1. The host controller only sets this to 1 when the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by host software. This field is 0 if the PP bit is 0. 0x0: Disable 0x1: Enable			RW	0
1	CSC	Connect status change Indicates a change has occurred in the port CCS bit. This field is 0 if the PP bit is 0. Read 0x0: No change Read 0x1: Change in current connect status Write 0x1: Clears this bit to 0			RW	0
0	CCS	Current connect status This value reflects the current state of the port, and may not correspond directly to the event that caused the CSC bit to be set. This field is 0 if the PP bit is 0.			R	0

Bits	Field Name	Description	Type	Reset
		0x0: No device is present. 0x1: Device is present on port.

23.11 Super-Speed USB OTG Subsystem

This section describes the SuperSpeed (SS) USB On-The-Go (OTG) subsystem of the device.

NOTE:

23.11.1 SuperSpeed USB OTG Subsystem Overview

The SS USB controller is a USB3 OTG dual-role-device (DRD) link controller supporting the following modes:

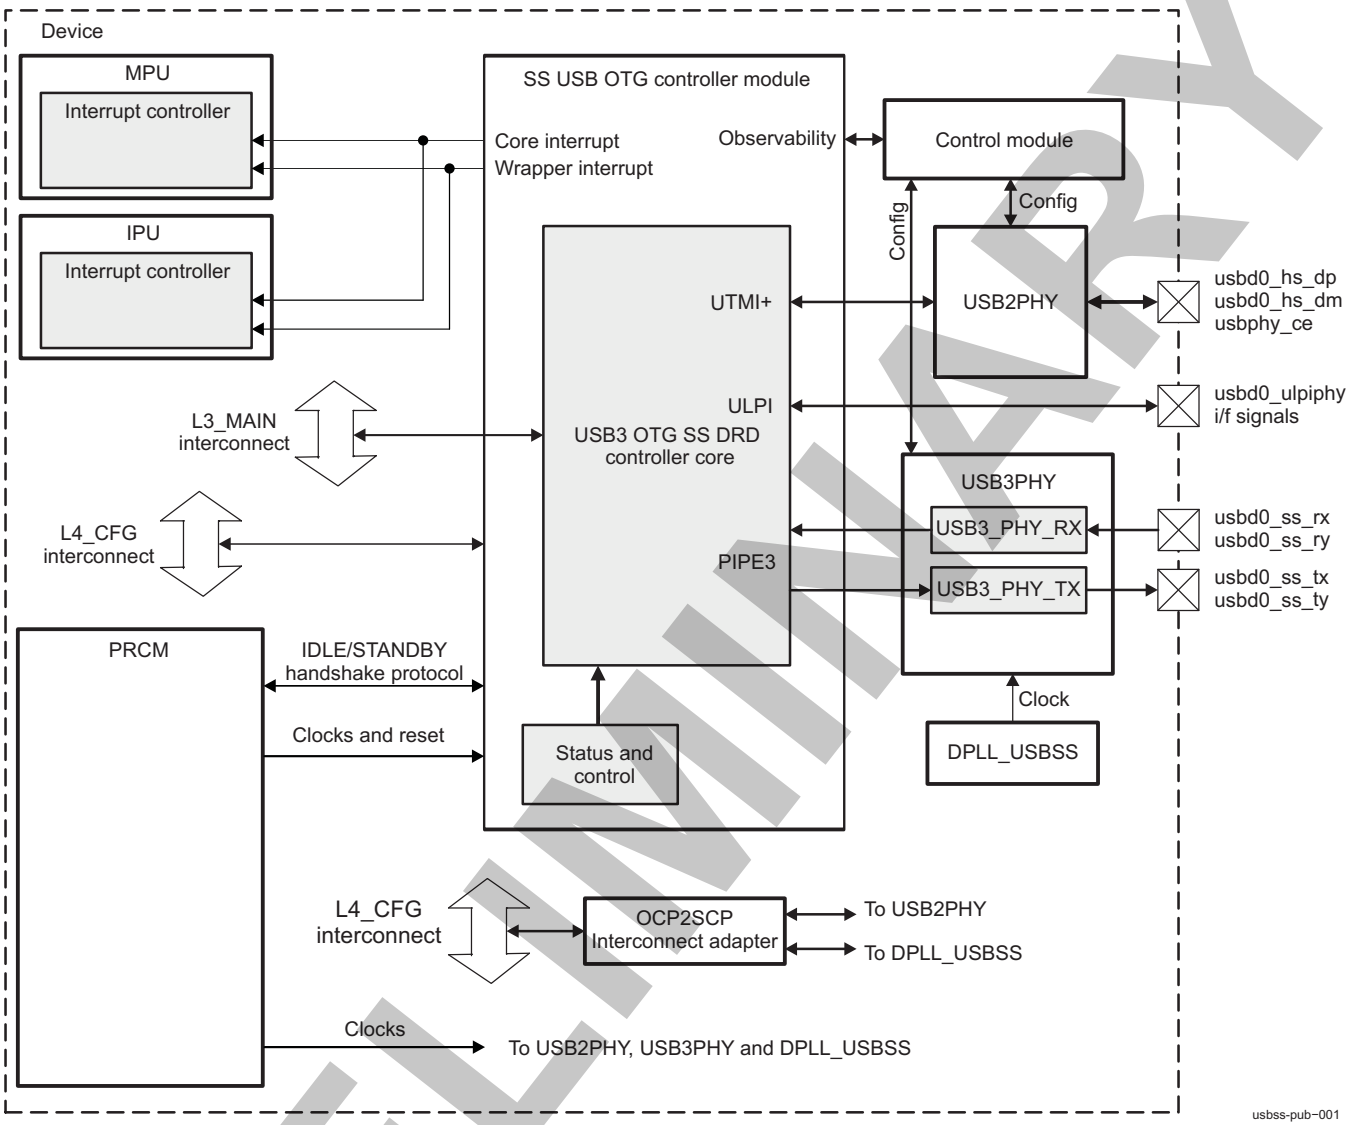
- USB 2.0 peripheral (function controller) in full- and high-speed (12 and 480 Mbps, respectively)
- USB 2.0 host in low-, full-, and high-speed (1.5, 12, 480 Mbps, respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 3.0 peripheral (function controller) in super speed (5 Gbps)
- USB 3.0 host in super speed with one downstream port but multipoint capability when a hub is connected to it

The SuperSpeed USB OTG controller supports a single USB port that uses the ULPI interface mode to connect to an off-chip transceiver (12-pin, 8-bit data SDR mode) and to a USB 2.0/3.0 bus using an embedded USB 2.0 PHY and embedded USB 3.0 RX/TX PHYs.

NOTE: The current implementation of the SuperSpeed USB OTG subsystem does not support the dynamic role switching, that is, OTG protocols HNP, SRP, and ADP.

Figure 23-237 shows the SuperSpeed USB subsystem overview.

Figure 23-237. SuperSpeed USB OTG Subsystem Highlight



23.11.1.1 Main Features

The SuperSpeed USB controller features:

- Dual-role device (DRD) capability:
  - Peripheral (device role) operation in SS, high-speed (HS), full speed (FS)
  - Host role operation (single port with xHCI software API) in all speeds (SS, HS, FS, and low speed [LS])
- UTMI+ port for USB2.0 PHY interface (8 bit data @60 MHz)
- ULPI port for alternative, off-chip USB2 PHY interface (12-pin, 8-data-bit, SDR)
- PIPE port for USB3.0 SS PHY interface (32-bit data @125 MHz by default)
- Link power management (LPM)
- Logic retention for fast power transitions
- USB-HS OTG PHY (USB2PHY): contains the USB functions, drivers, receivers, and pads correct D+/D– signalling and battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable) to control external battery charger.

- USB3PHY. The USB3PHY is embedded in the device and contains:
  - USB3_PHY_RX deserializer to receive data at SuperSpeed mode
  - USB3_PHY_TX serializer to transmit data at SuperSpeed mode
  - Power sequencer that contains a power control state machine, generating the sequences to power up/down the USB3_PHY_RX/USB3_PHY_TX
  - Dedicated DPLL (DPLL_USBSS)

23.11.2 SuperSpeed USB OTG Subsystem Environment

23.11.2.1 SuperSpeed USB OTG Subsystem I/O Interfaces

Figure 23-238 describes the I/O signals of the SuperSpeed USB subsystem interfaces.

Figure 23-238. SuperSpeed USB Subsystem Environment

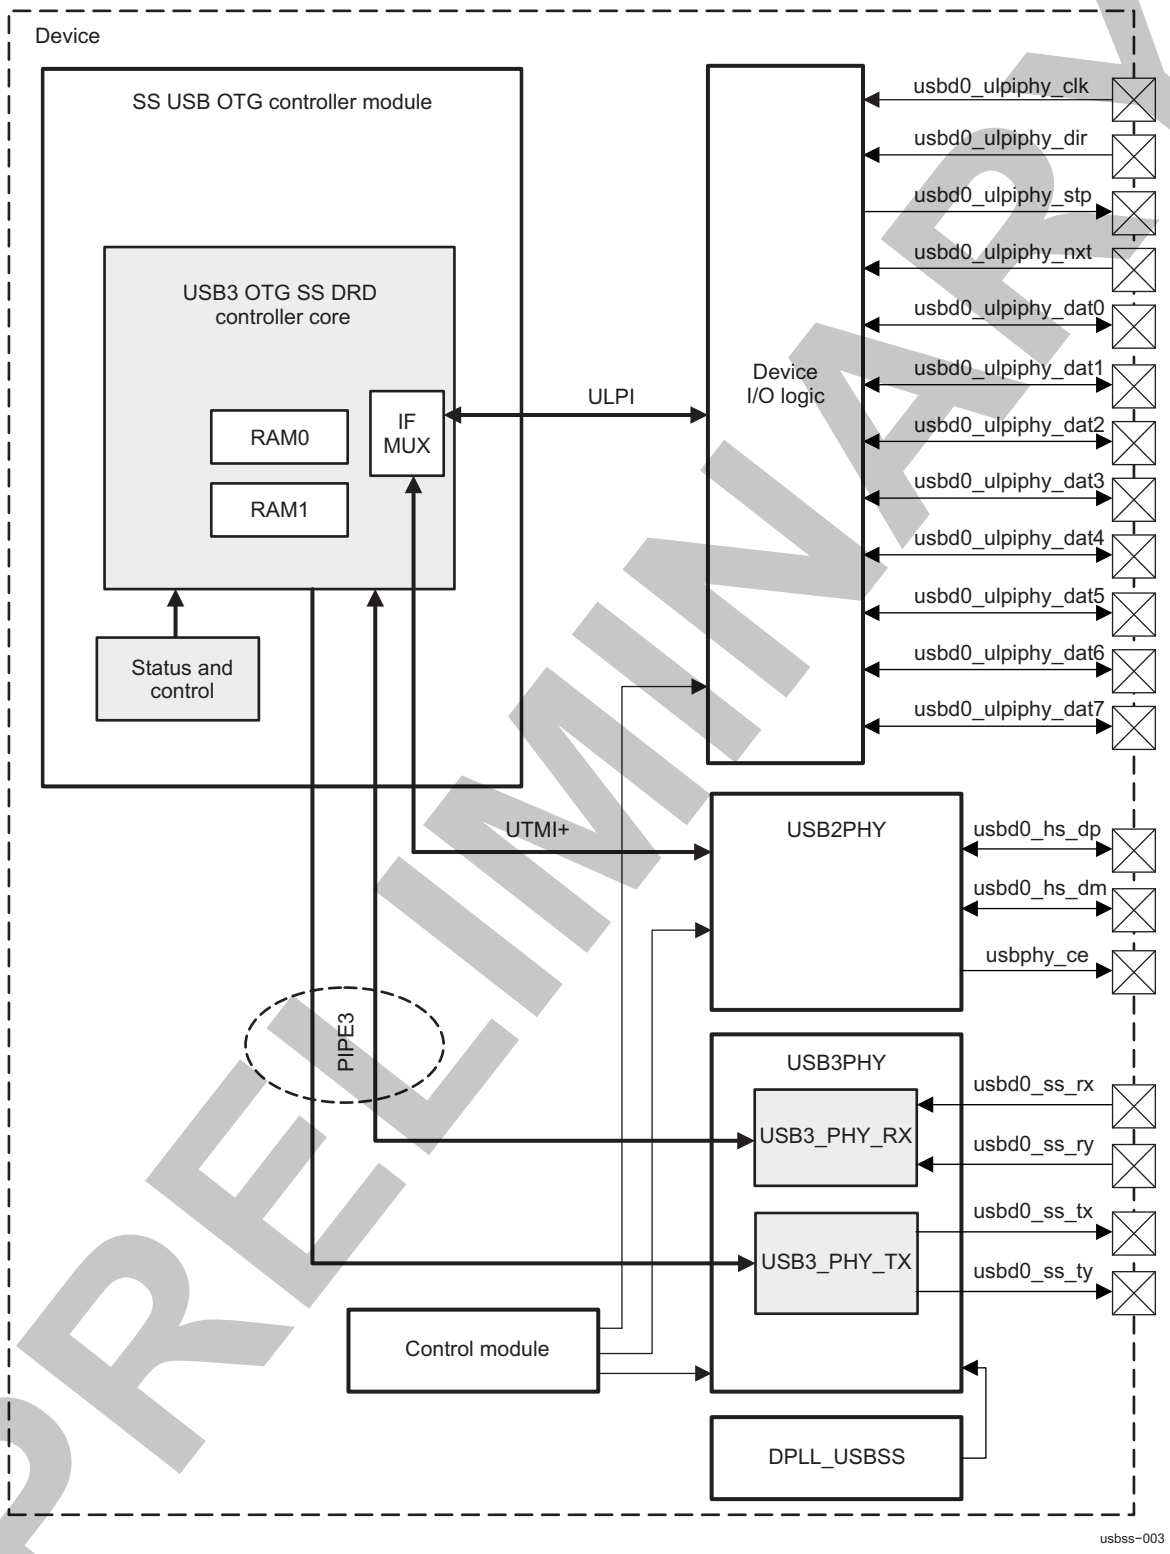


Table 23-1064 describes the I/O signals of the SuperSpeed USB subsystem interfaces shown in Figure 23-238

Table 23-1064. Input/Output Description

Module Pin	Device-Level Signal Name	I/O[1]	Description	Reset Value
ULPI interface				
ULPI_CLK	usbd0_ulpiphy_clk	I	Clock input from external transceiver	HiZ
ULPI_DIR	usbd0_ulpiphy_dir	I	Data direction control from external transceiver	HiZ
ULPI_STP	usbd0_ulpiphy_stp	O	Output to external transceiver to stop data stream	1
ULPI_NXT	usbd0_ulpiphy_nxt	I	Next signal control from external transceiver	HiZ
ULPI_DATA0	usbd0_ulpiphy_data0	I/O	Data bit 0 to/from external transceiver	HiZ
ULPI_DATA1	usbd0_ulpiphy_data1	I/O	Data bit 1 to/from external transceiver	HiZ
ULPI_DATA2	usbd0_ulpiphy_data2	I/O	Data bit 2 to/from external transceiver	HiZ
ULPI_DATA3	usbd0_ulpiphy_data3	I/O	Data bit 3 to/from external transceiver	HiZ
ULPI_DATA4	usbd0_ulpiphy_data4	I/O	Data bit 4 to/from external transceiver	HiZ
ULPI_DATA5	usbd0_ulpiphy_data5	I/O	Data bit 5 to/from external transceiver	HiZ
ULPI_DATA6	usbd0_ulpiphy_data6	I/O	Data bit 6 to/from external transceiver	HiZ
ULPI_DATA7	usbd0_ulpiphy_data7	I/O	Data bit 7 to/from external transceiver	HiZ
USB2PHY				
CE	usbphy_ce	O	Charging enable signal	0
DP	usbd0_hs_dp	I/O	USB2 half-duplex differential pair	HiZ
DM	usbd0_hs_dm	I/O		HiZ
USB3PHY				
TX	usbd0_ss_tx	O	USB3 transmitter differential pair	HiZ
TY	usbd0_ss_ty	O		HiZ
RX	usbd0_ss_rx	I	USB3 receiver differential pair	HiZ
RY	usbd0_ss_ry	I		HiZ
USB frame sync output				
SYNC_USOF_ITP_CLK	sync_usof_itp_clk	O	4-kHz clock output, each edge locked to ITP/uSOF sync packets of SS/HS USB	0
SYNC_SOF_CLK	sync_sof_clk	O	0.5-kHz clock output, each edge locked to SOF sync packets of FS USB	0

(1) I = Input; O = Output; I/O = Bidirectional

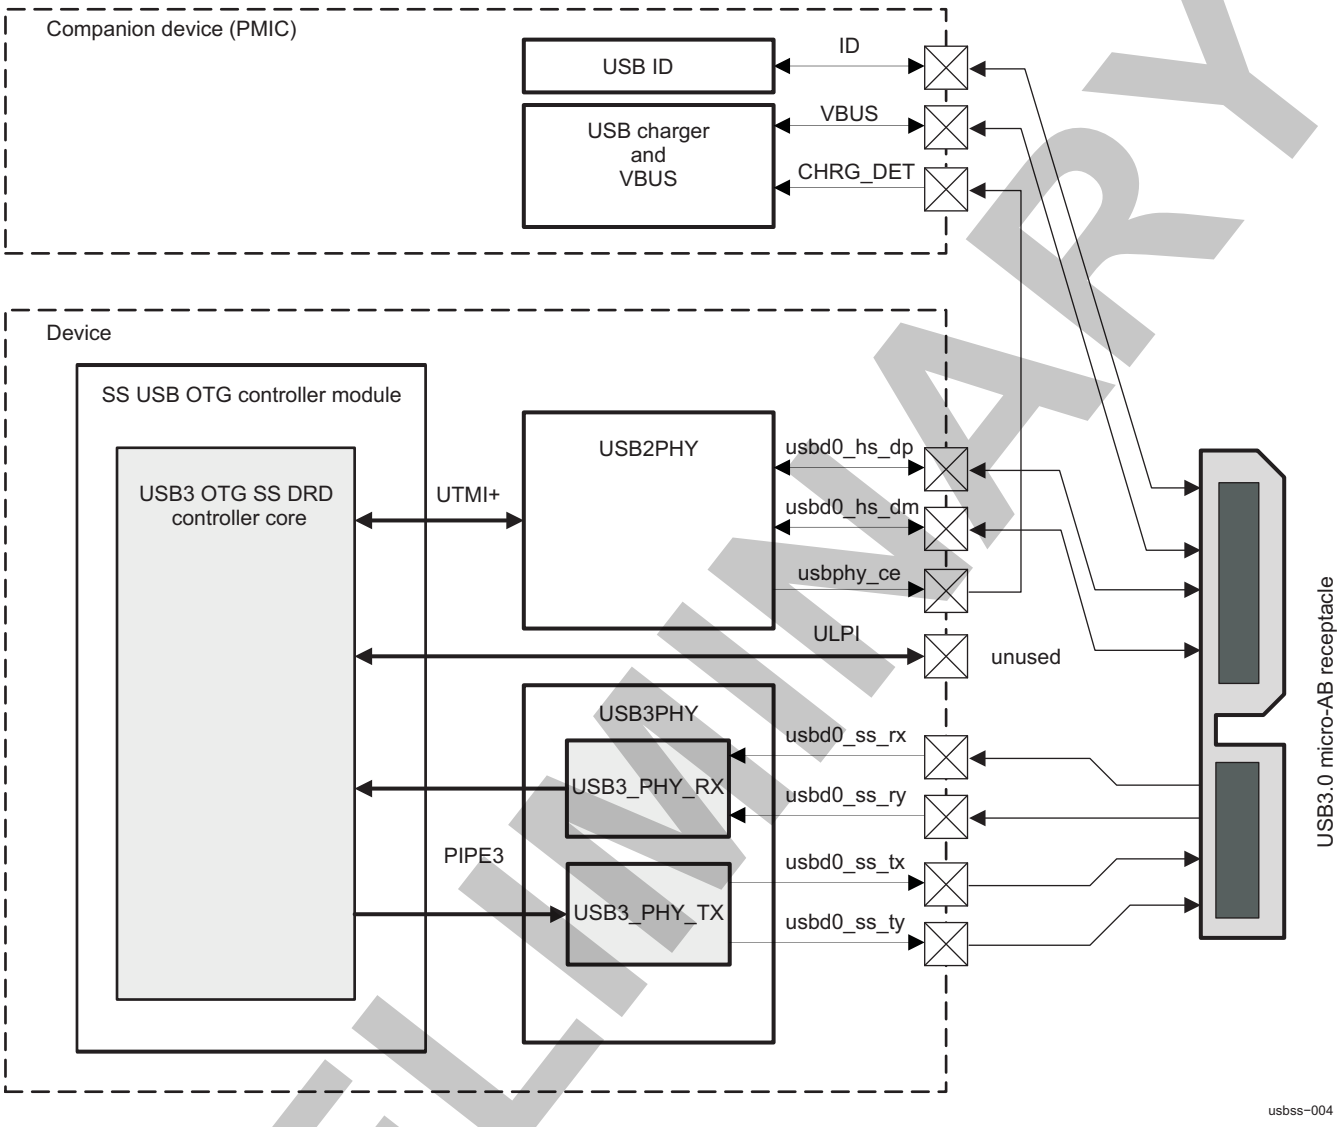
NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, of *Chapter 18, Control Module*.

23.11.2.2 SuperSpeed USB OTG Subsystem Application

23.11.2.2.1 USB3.0 OTG DRD Application

Figure 23-239 shows a typical application using the SuperSpeed USB subsytem. The application represents a full-featured integration and allows all of the capabilities of the controller used. The companion IC can actually be split in two, with a power IC either supplying (driver) or drawing (charger) power on VBUS, and a control IC performing the VBUS and OTG ID control functions, such as pulling, sensing, etc.

Figure 23-239. SuperSpeed USB Controller Application: USB3.0 OTG DRD



The USB3.0 micro-AB receptacle characterizes a USB3.0 OTG DRD, and allows the following attachments:

- Micro-A-type plugs, to attach to a USB peripheral/hub upstream port (or to another DRD, as host)
- Micro-B-type plugs, to attach to a USB host/hub downstream port (or to another DRD, as peripheral)
- To USB3.0 devices: The USB3.0 micro plug covers all contacts of the receptacle.
- To USB2.0 devices: The USB2.0 micro plug occupies only the wider, USB2.0 half of the receptacle. SuperSpeed signal pairs remain floating.

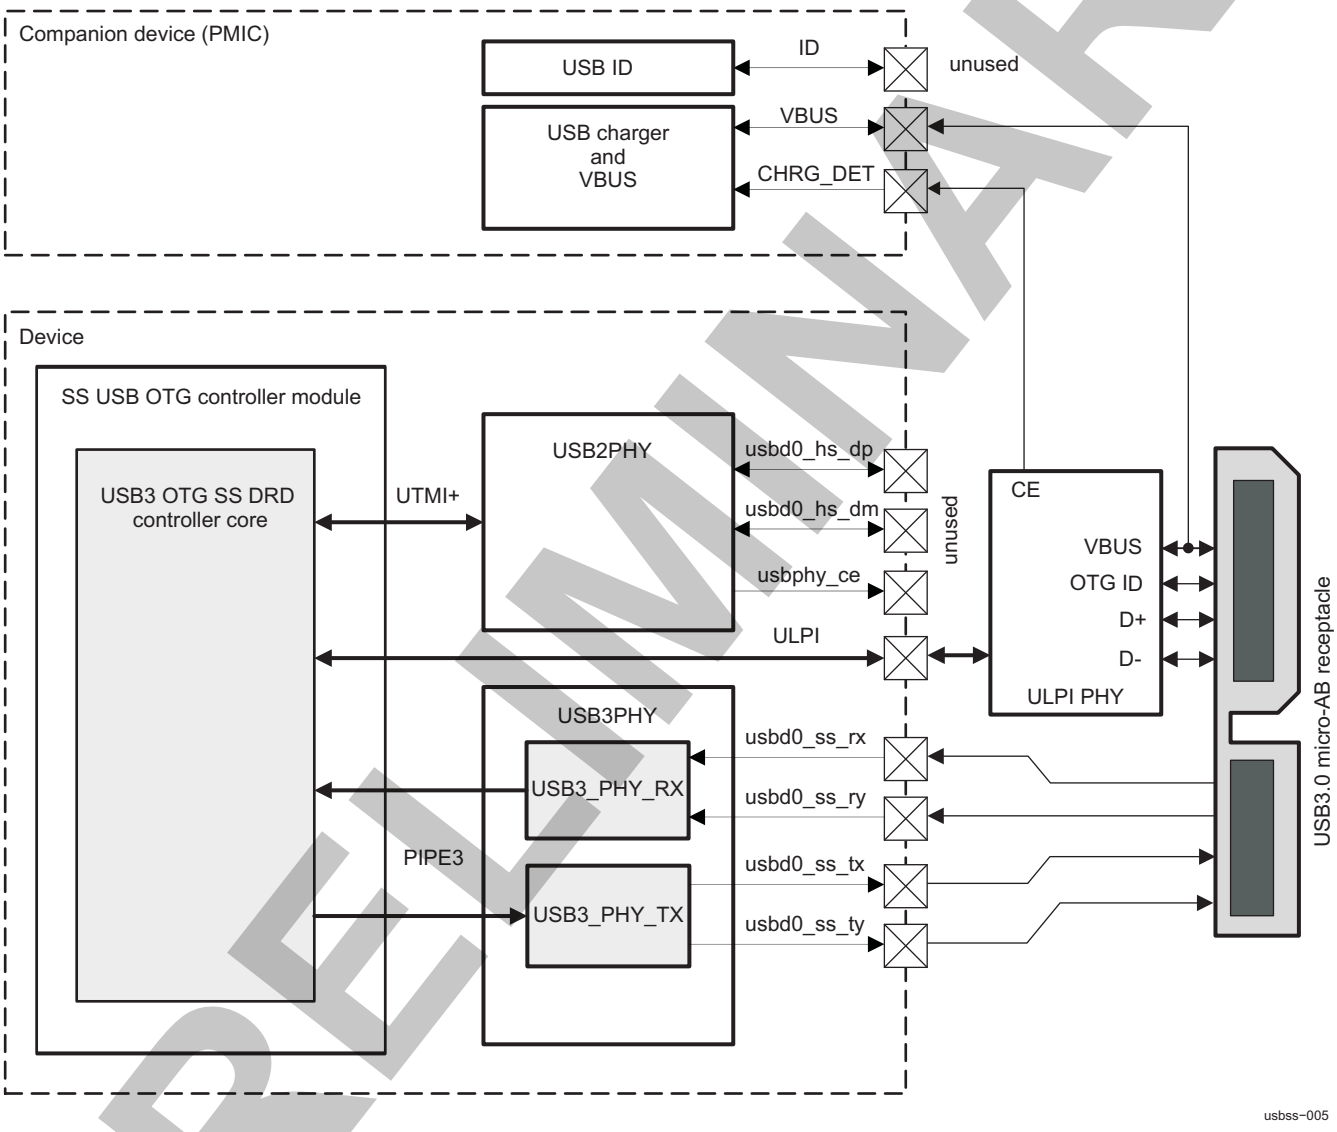
23.11.2.2.2 USB3.0 OTG DRD Alternative

NOTE: External ULPI PHY interface is used mostly for debug and test purposes. During normal operation, the internal USB2 PHY must be used.

Figure 23-240 shows an alternative to Figure 23-238 (that is, a USB3.0 integration) in which an external ULPI PHY IC is used instead of the on-chip UTMI PHY (USB2PHY). Seen from outside the system, both integrations are functionally equivalent. Internally, the functions of the OTG ID and VBUS are taken over by the ULPI PHY. However, the (now optional) companion IC still can be required to draw (charger) power on VBUS or supply it with more than the ULPI PHY is capable of.

The external (ULPI) PHY interface is selected through USBOTGSS_GUSB2PHYCFG[4] ULPI_UTMI_SEL bit set to 0x1.

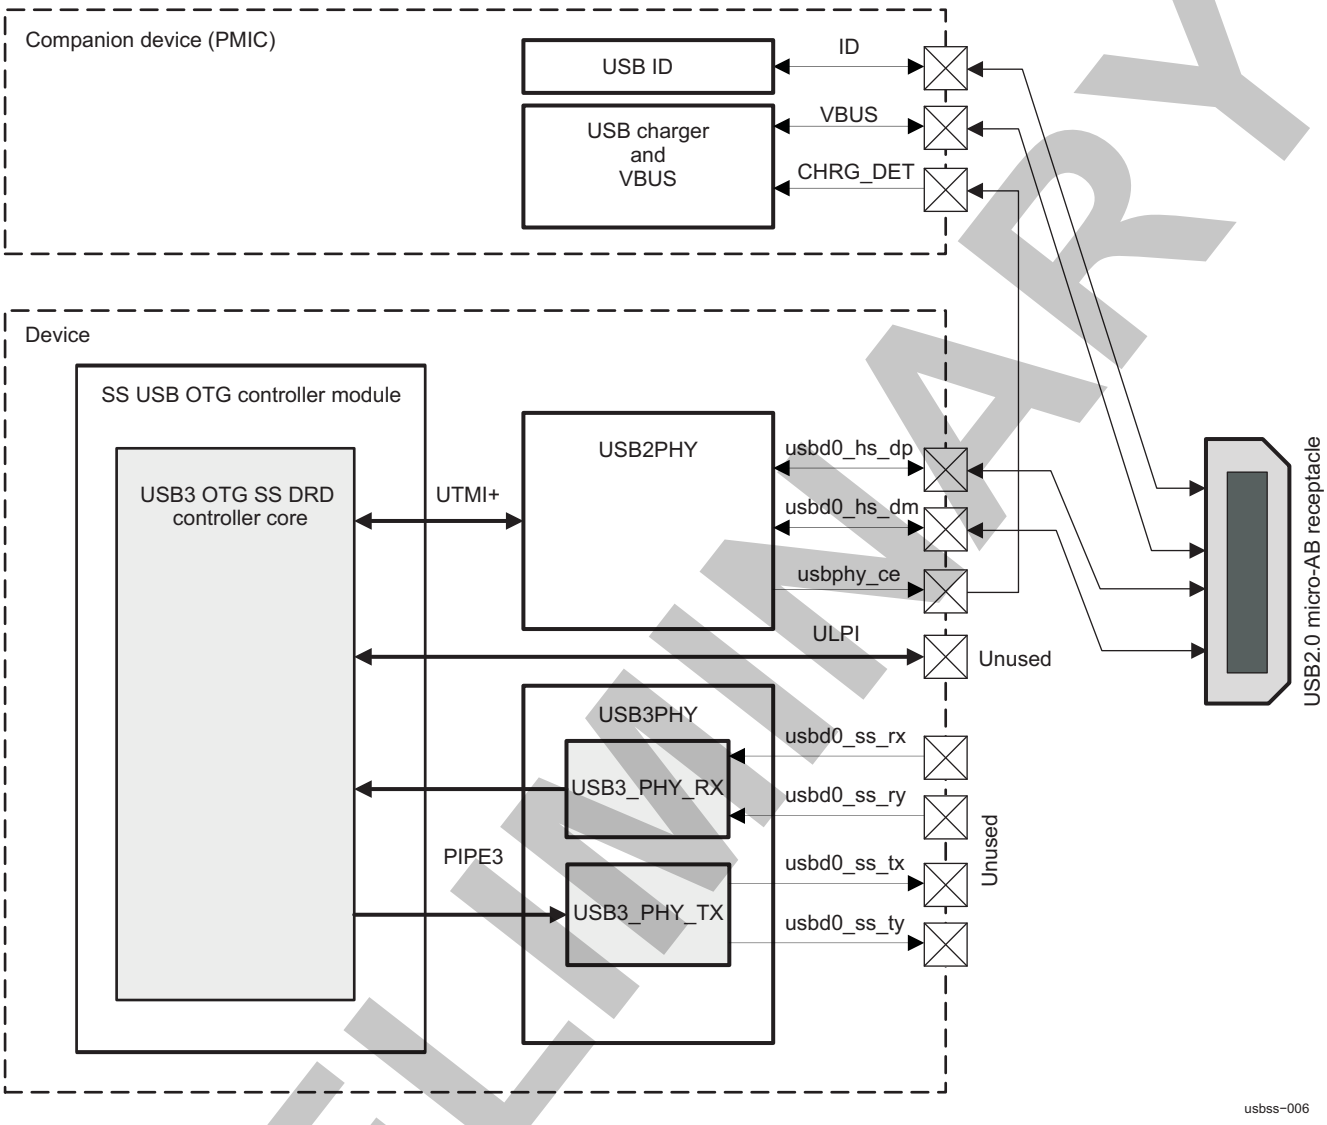
Figure 23-240. SuperSpeed USB Controller Application: USB3.0 OTG DRD (ULPI PHY)



23.11.2.2.3 USB2.0 OTG DRD

Figure 23-241 shows a USB2.0-only integration in which the USB3.0 capability is not available. Similarly to Figure 23-238, the companion IC can be split in two, with a power IC either supplying (driver) or drawing (charger) power on VBUS, and a control IC providing the VBUS and OTG ID control functions, such as pulling, sensing, etc.

Figure 23-241. SuperSpeed USB Controller Application: USB2.0 OTG DRD



The USB2.0 micro-AB receptacle characterizes a USB2.0 OTG DRD and accepts the following:

- Micro-A-type plugs, which attach to a USB peripheral/hub upstream port (or another DRD, as host)
- Micro-B-type plugs, which attach to a USB host/hub downstream port (or another DRD, as peripheral)
- USB2.0 devices only: The USB2.0 micro plug covers all contacts of the receptacle.
- Not USB3.0 devices: The USB3.0 micro plug is incompatible and the SuperSpeed signal pairs of the cable remain floating.

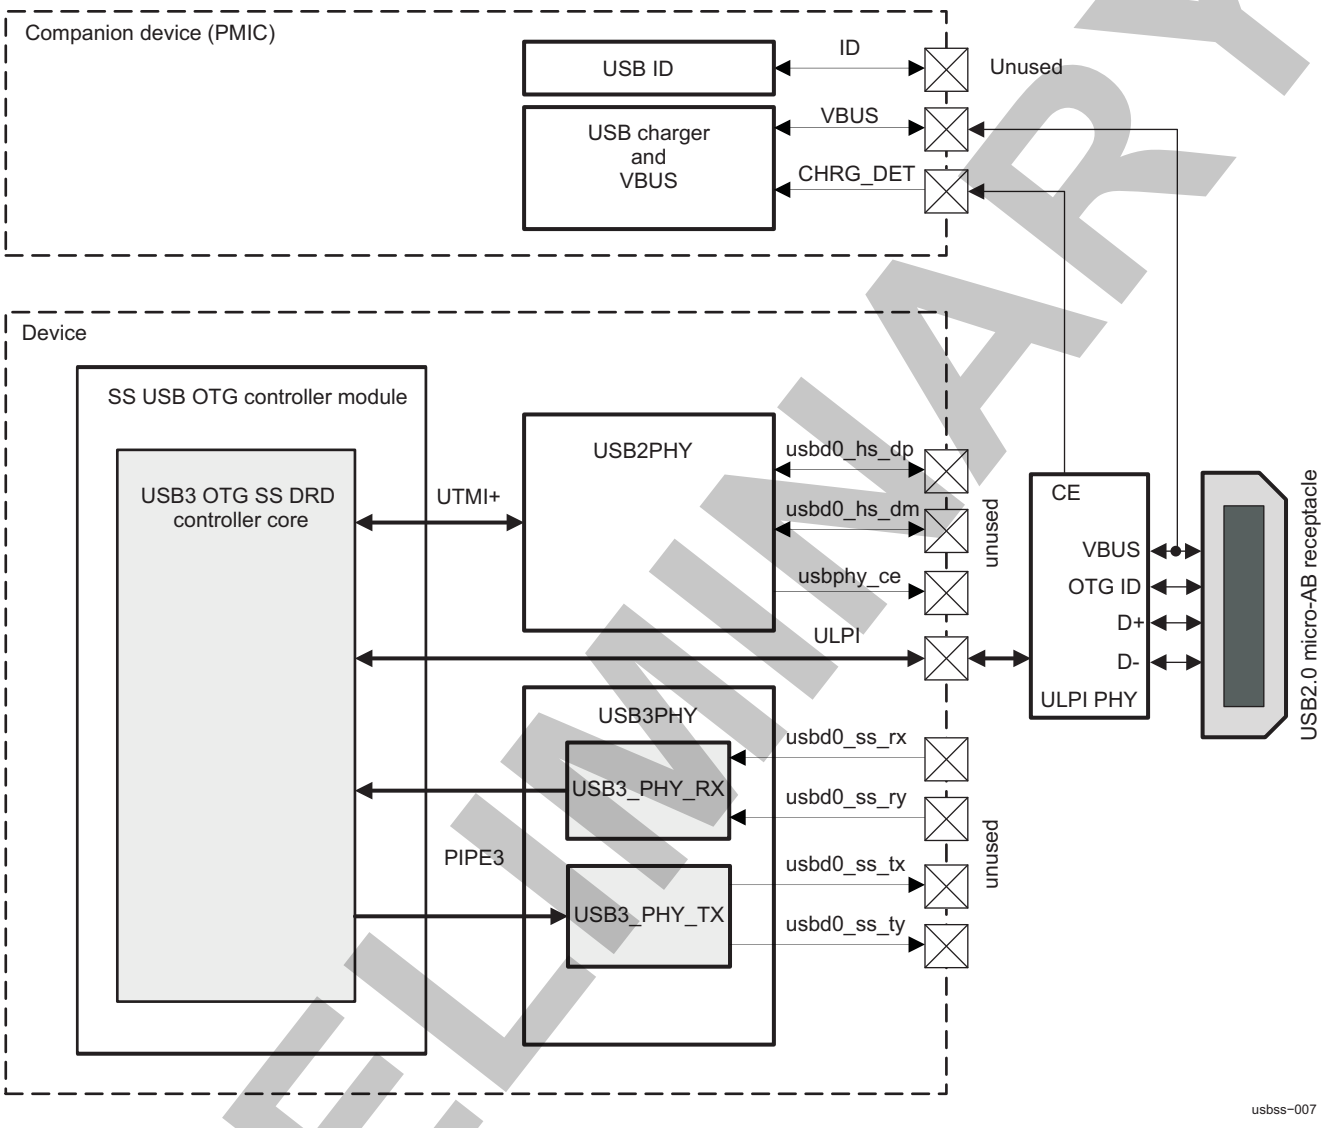
23.11.2.2.4 USB2.0 OTG DRD Alternative

NOTE: External ULPI PHY interface is used mostly for debug and test purposes. During normal operation, the internal USB2 PHY must be used.

Figure 23-242 shows an alternative to Figure 23-241 (that is, a USB2.0-only integration) in which an external ULPI PHY IC is used instead of the on-chip UTMI USB2PHY. Seen from outside the system, both integrations are functionally equivalent. Internally, the functions of OTG ID and VBUS are taken over by the ULPI PHY. However, the (now optional) companion IC can still be required to draw (charger) power on VBUS or supply it with more than the ULPI PHY is capable of.

The external (ULPI) PHY interface is selected through USBOTGSS_GUSB2PHYCFG[4] ULPI_UTMI_SEL bit set to 0x1.

Figure 23-242. SuperSpeed USB Controller Application: USB2.0 OTG DRD (ULPI PHY)



23.11.3 SuperSpeed USB OTG Subsystem Integration

The L3 (master) interconnect generates data traffic within the device. The L4 (slave) interconnect is a configuration port for register setting.

Figure 23-243 shows the SuperSpeed USB subsystem integration in the device.

Figure 23-243. SuperSpeed USB Subsystem Integration

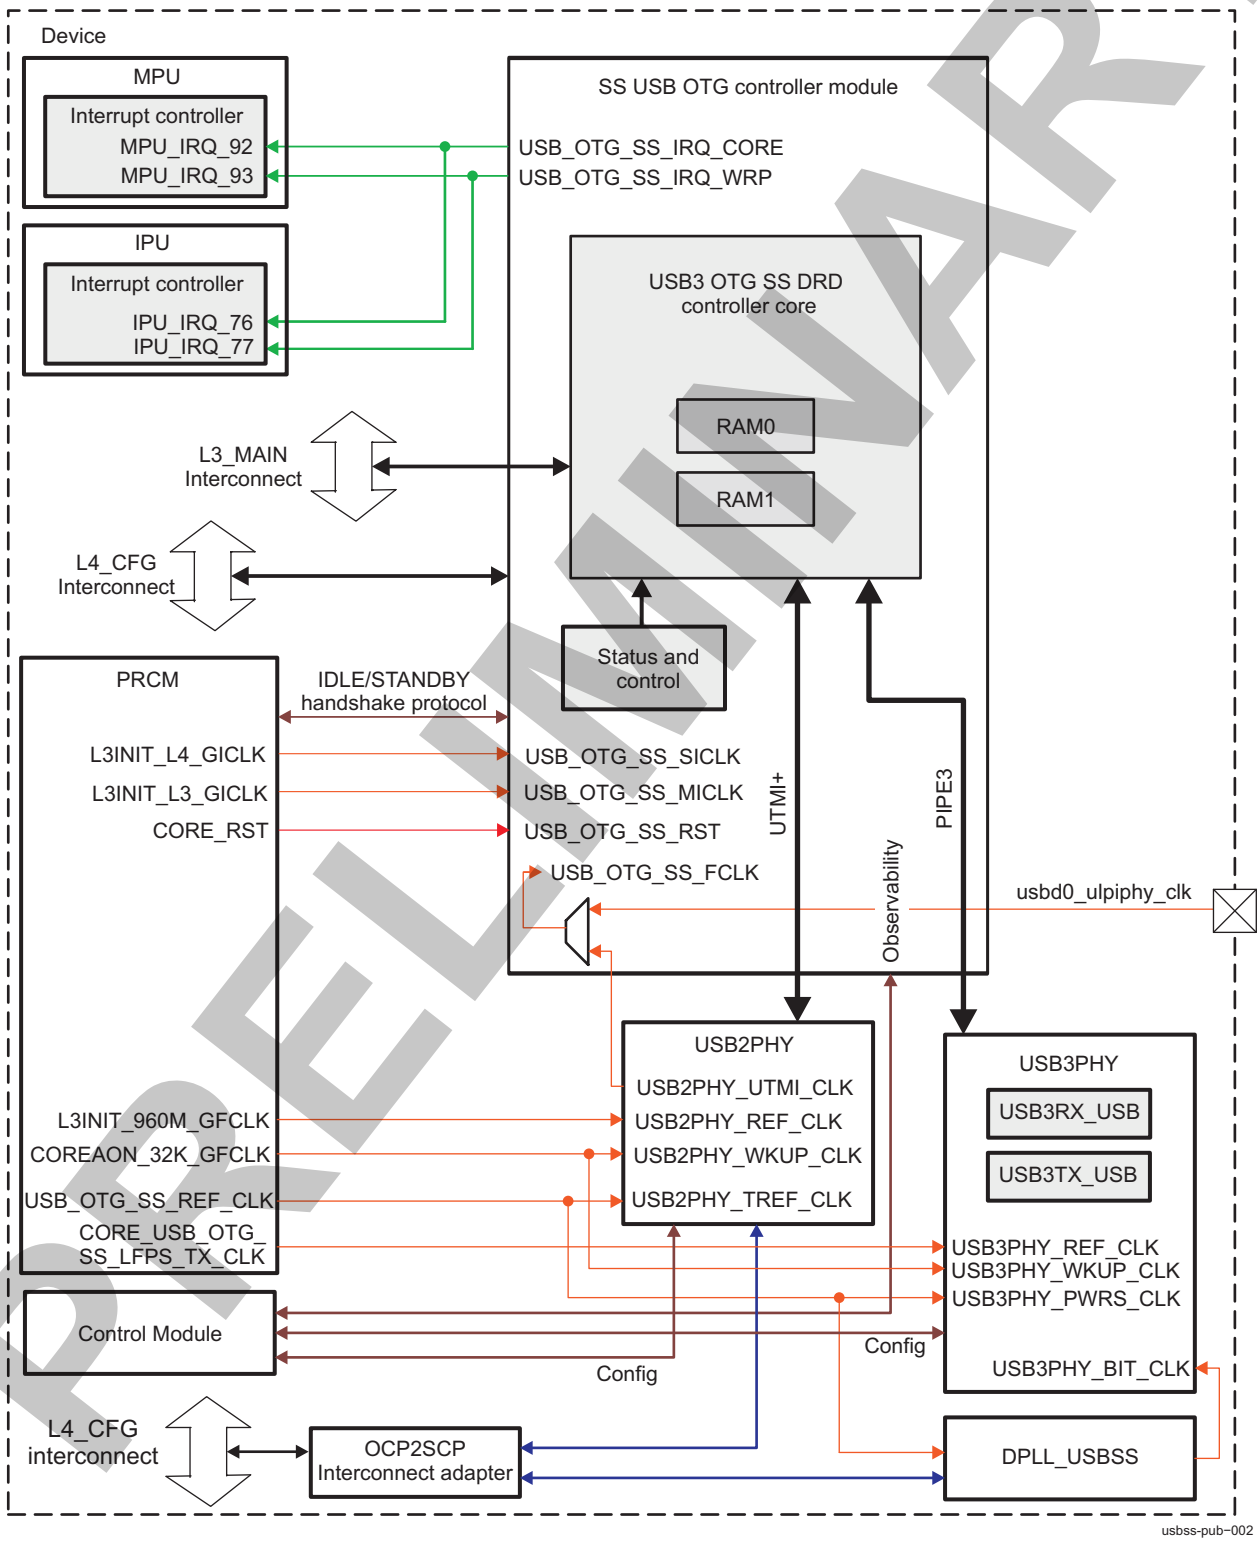


Table 23-1065 through Table 23-1067 summarize the integration of the module in the device.

Table 23-1065. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
USB_OTG_SS	PD_L3INIT	L3_MAIN L4_CFG
USB2PHY	PD_L3INIT	L4_CFG
USB3PHY	PD_L3INIT	L4_CFG

Table 23-1066 lists the clocks provided to the SuperSpeed USB subsystem.

Table 23-1066. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
USB_OTG_SS	USB_OTG_SS_FCLK	OTG_60M_FCLK	USB2PHY or ULPI PHY	60-MHz UTMI/ULPI clock

USB_OTG_SS_IRQ_WRP	MPU_IRQ_93	MPU INTC	USB_OTG_SS wrapper interrupt request
	IPU_IRQ_77	IPU_INTC	

23.11.4 SuperSpeed USB OTG Controller Functional Description

23.11.4.1 Reset

23.11.4.1.1 Software Reset

Software can perform a reset on SS USB OTG controller by following the sequence:

1. Write 1 to USBOTGSS_FLADJ[31] CORE_SW_RESET to assert the software reset to the core. This bit is not self-clearing. All core registers will be cleared to their default value. Wrapper registers will not be affected.
2. Write 0 to USBOTGSS_FLADJ[31] CORE_SW_RESET to deassert the software reset of the core.
3. Poll register field USBOTGSS_USBSTS[11] CNR until controller is ready (=0), before accessing the other core registers (the reset of the RAM-stored core registers can take several cycles to complete, see Section 23.11.4.1.2, *Active RAM Reset*).
4. USBOTGSS_WRAPPER registers can be reset by writing 1 to USBOTGSS_SYSCONFIG[17] WRAPRESET. Wrapper reset is completed when this bit is cleared back to 0 by hardware.

23.11.4.1.2 Active RAM Reset

The lower part of RAM0 contains some register values and descriptor cache (from RAM0 address 0 to DWC_USB3_DCACHE_DEPTH_INFO-1) that must be initialized. For that purpose, the core automatically writes all-0 words to a section of RAM0 immediateley after coming out of reset. This sequential process takes time (over 1000 interconnect clock cycles), during which functional read and write to the RAM-mapped registers are stalled. To avoid the stalls, the xHCI status bit USBOTGSS_USBSTS[11] CNR (controller not ready) can be polled until cleared (= 0).

Although this is a standard USB-host mode status bit, the method also works to access RAM-mapped registers of the USB-device.

23.11.4.2 Interrupts

Two interrupt lines come out from the USB controller module:

- USB_OTG_SS_IRQ_CORE: for SS USB OTG controller events
- USB_OTG_SS_IRQ_WRP: for SS USB OTG wrapper events

23.11.4.2.1 Core Events

The main interrupt line carries all events from the DRD core related to the USB device and USB host (xHCI). Those high-frequency events are associated with actual USB traffic. Since core IRQ is the only source event for that interrupt, and the status bit (USBOTGSS_IRQSTATUS_0[0] COREIRQ_ST) is self-clearing, the software does not actually need to access USBOTGSS_IRQSTATUS_0. Prior to the assertion of IRQ line USB_OTG_SS_IRQ_CORE, the core DMA (master) accesses main memory to write IRQ events to the IRQ event queue. If the master is in standby mode, an interrupt event brings it out of standby, as explained in Section 23.11.4.3.2, *System Power Management*.

For a description of core interrupts, see Synopsys® *Designware Cores SuperSpeed USB 3.0 Controller Databook*.

23.11.4.2.2 Wrapper Events

USB_OTG_SS_IRQ_WRP interrupt line is triggered by:

- VBUS and OTG ID controls changes in the mailbox mechanism (when UTMI is used, as opposed to

ULPI)

- OTG events from the core
- The DMA (master's) port automatic reenabling, to allow new read/write accesses.

Table 23-1068 lists the event flags, and their mask, that can cause module interrupts.

Table 23-1068. SS USB OTG Wrapper Events

Event Flag	Event Mask	Description
USBOTGSS_IRQSTATUS_1[17] DMADISABLECLR	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[17] DMADISABLECLR_EN	DMA-disable self-clear IRQ. USBOTGSS_SYSCONFIG[17] DMADISABLE hardware-cleared (to 0) because of DMA access. Not triggered by a software clear.
USBOTGSS_IRQSTATUS_1[16] OEVT	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[16] OEVT_EN	OTG event in controller. The event is in status register USBOTGSS_OEVT.
USBOTGSS_IRQSTATUS_1[13] DRVVBUS_RISE	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[13] DRVVBUS_RISE_EN	Drive VBUS control rise
USBOTGSS_IRQSTATUS_1[12] CHRGVBUS_RISE	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[12] CHRGVBUS_RISE_EN	Charge VBUS control rise
USBOTGSS_IRQSTATUS_1[11] DISCHRGVBUS_RISE	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[11] DISCHRGVBUS_RISE_EN	Discharge VBUS control rise
USBOTGSS_IRQSTATUS_1[8] IDPULLUP_RISE	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[8] IDPULLUP_RISE_EN	ID pullup control rise
USBOTGSS_IRQSTATUS_1[5] DRVVBUS_FALL	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[5] DRVVBUS_FALL_EN	Drive VBUS control fall
USBOTGSS_IRQSTATUS_1[4] CHRGVBUS_FALL	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[4] CHRGVBUS_FALL_EN	Charge VBUS control fall
USBOTGSS_IRQSTATUS_1[3] DISCHRGVBUS_FALL	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[3] DISCHRGVBUS_FALL_EN	Discharge VBUS control fall
USBOTGSS_IRQSTATUS_1[0] IDPULLUP_FALL	USBOTGSS_IRQENABLE_SET_1/ USBOTGSS_IRQENABLE_CLR_1[0] IDPULLUP_FALL_EN	ID pullup control fall

23.11.4.3 Power Management

23.11.4.3.1 Overview

The high-speed USB controller has both master (initiator) and slave (target) interfaces:

- As an initiator, the high-speed USB OTG controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB OTG controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

23.11.4.3.2 System Power Management

The standard idle request/acknowledge handshake is associated with the interconnect slave port. The default idle mode is smart-idle and is used for most operations.

Table 23-1069 describes the high-speed USB idle mode settings. For more information, see Section 3.1.1, *Power, Reset, and Clock Management*.

Table 23-1069. USBOTGSS Controller Idle Mode Settings

USBOTGSS_SYSCONFIG[3:2] IDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HSUSBOTG host controller acknowledges unconditionally the idle request from the PRCM, regardless of its internal operations.
0x1	No-idle	The HSUSBOTG host controller never acknowledges any idle request from the PRCM.
0x2	Smart-idle	The HSUSBOTG host controller acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions and IRQ requests are treated.
0x3	Smart-idle wakeup	The HSUSBOTG host controller enters smart mode with wakeup enabled. Controller may generate wakeup events when in idle state.

The standby/wait handshake is associated with the interconnect master port. The DMA is under direct software control. The software driver ensures that the master is shut down correctly when shutdown is required.

The default standby mode is smart-standby. USBOTGSS_SYSCONFIG[5:4] STANDBYMODE is 0x2 after reset and is used for most operations. Because there is no asynchronous wakeup source for the master, smart-standby and smart-standby/wakeup are functionally equivalent.

The master interface is controlled by a semi-automatic disable bit mapped in USBOTGSS_SYSCONFIG[16] DMADISABLE. To use this bit, the standby mode must be a smart-standby mode as follows:

- When the DMA must perform read/write accesses, the following sequence takes place entirely in hardware: The disable bit is cleared (USBOTGSS_SYSCONFIG[16] DMADISABLE = 0); and the controller comes out of standby (mstandby = 0) and waits for the PRCM handshake (mwait = 0) before the access can occur.
- When the DMA must stop for power management, software must place USB operation (transfer request block [TRB] processing) on hold and set the USBOTGSS_SYSCONFIG[16] DMADISABLE bit back to 1. This places the controller in standby (mstandby = 1).
- Core interrupts on the USB_OTG_SS_IRQ_CORE line must remain enabled even during low-power periods. The DMA can therefore write new events to the memory-mapped interrupt event queue at any time and clear the DMADISABLE bit to 0. For the software driver to keep track of DMADISABLE, the hardware clearing of DMADISABLE triggers another interrupt, USBOTGSS_IRQSTATUS_1[17] DMADISABLECLR.

To keep track of the DMADISABLE value, the system software is expected to have a single piece of code managing:

- The clearing to 0 of DMADISABLE through the DMADISABLECLR interrupt event
- The setting to 1 of DMADISABLE, by direct software write.

NOTE: This operation might require to be repeated, if the transition to idle is interrupted by a DMA access on the master.

NOTE:

- The aforementioned procedure is guaranteed only in smart-standby modes. In force-standby and no-standby modes, the requirements of the internal DMA and the DMADISABLE setting are overridden in the generation of mstandby to PRCM.
- The USBOTGSS_SYSCONFIG[16] DMADISABLE can also be cleared (written to 0) by software at any time, but this is redundant with the hardware's action and therefore must not used under normal circumstances.

Table 23-1070 describes the high-speed USB standby mode settings.

Table 23-1070. USBOTGSS Controller Standby Mode Settings

USBOTGSS_SYSCONFIG[5:4] STANDBYMODE Value	Selected Mode	Description
0x0	Force-standby	The USBOTGSS controller enters standby mode unconditionally.
0x1	No-standby	The USBOTGSS controller never enters standby mode.
0x2	Smart-standby	The USBOTGSS controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect.
0x3	Smart-standby wakeup	Equivalent to smart-standby

23.11.4.4 Software API Interface

23.11.4.4.1 xHCI USB Host Software API

The eXtensible Host Controller Interface for USB (see *eXtensible Host Controller Interface for USB (xHCI) revision 1.0 with errata (errata files 1.7)*) is a standarsized interface between a USB host controller (HC) and system software (HCD, for Host Controller Driver), based on a dedicated DMA (implemented over the master interface) and a standard control and status register set (mapped in the slave address space). The HC and HCD communicate through interrupts, memory-mapped registers and data structures mapped in system memory.

The xHCI software API is used to control the DRD:

- When in USB host mode (aka OTG A-host, OTG B-host).
- When the DRD is in USB device mode (aka peripheral, OTG A-peripheral, OTG B-peripheral, function), the xHCI interface is unused.
- xHCI does not control OTG functionality (even when in OTG-host mode) .
- additionally, some implementation-specific configuration are required (in non-xHCI so called global registers) before xHCI operation proper can start.

xHCI controls all USB speeds of the host mode, that is, Super-Speed (through the USB3PHY) but also High-, Full-, and Low- speed (through the HS/FS/LS USB2PHY or ULPI PHY). xHCI replaces and supersedes all previous host HCIs (HS-only EHCI, FS/LS OHCI and UHCI), and is therefore not backwards compatible with any of them.

The xHCI standard supports a number of options (so called capabilities) and configurations (port count), all of which are self-described in the controller's memory-mapped register. The software driver must read the options and act accordingly. The main characteristics of the controller are:

- USBOTGSS_HCSPARAMS1[31:24] MAXPORTS = 2 xHCI ports (this corresponds to a single USB2 plus USB3 physical port)
  - USBOTGSS_SUPTPRT2_DW2[15:8] CPC = 1: one xHCI USB2-capable port (HS/FS/LS)
  - USBOTGSS_SUPTPRT2_DW2[7:0] CPO = 1: USB2-capable port is xHCI port 1
  - USBOTGSS_SUPTPRT3_DW2[15:8] CPC = 1: one USB3-capable port (super-speed)
  - USBOTGSS_SUPTPRT3_DW2[7:0] CPO = 2: USB3-capable port is xHCI port 2
- USBOTGSS_HCSPARAMS1[18:8] MAXINTRS = 1: One interrupter (IRQ line)

The current implementation is configured by default for xHCI version 1.0 mode. A legacy mode is also available, which implements xHCI version 0.96 (*eXtensible Host Controller Interface for USB (xHCI) revision 0.96*).

- Default mode: xHCI 1.0 (USBOTGSS_CAPLENGTH[31:16] HCIVERSION = 0x0100).
- Legacy mode: xHCI 0.96 (HCIVERSION = 0x0096)

NOTE: The following procedure must be used to switch the xHCI mode to the legacy version (xHCI 0.96):

1. Write 1 to USBOTGSS_FLADJ[31] CORE_SW_RESET to assert the software reset to the core. This bit is not self-clearing. All core registers will be cleared to their default value. Wrapper registers will not be affected.
2. Write 0 to USBOTGSS_FLADJ[29] XHCI_REVISION to select xHCI 0.96 (or to 1 to go back to xHCI 1.0 mode)
3. Write 0 to USBOTGSS_FLADJ[31] CORE_SW_RESET to deassert the software reset of the core.
4. Poll xHCI register field USBOTGSS_USBSTS[11] CNR until controller is ready (=0), before accessing the other core registers (the reset of the RAM-stored core registers can take several cycles to complete).

The host has the same extended capabilities regardless of the xHCI version, as described in the extended capability registers (Section 23.11.4.14.2, *xHCI Host Mapping*), as per the xHCI standard:

- Legacy support (not related to xHCI version)
- USB2.0 protocol support
- USB3.0 protocol support.

23.11.4.4.2 xHCI USB Device Software API

The device software API is used to control the DRD when in device mode (aka peripheral, OTG A-peripheral, OTG B-peripheral, function). The API is not standardized. It reuses some of the xHCI features, by using descriptors mapped in main memory, but relies more on register accesses.

The device software API controls all USB speeds of the device mode, that is, Super-Speed (through the SS USB3PHY) but also high and full speed (on the HS/FS/LS USB2PHY).

When the DRD is in USB host mode (aka OTG A-host, OTG B-host), the device API is unused.

23.11.4.4.3 OTG Control Software API

NOTE: The current implementation of the SuperSpeed USB OTG subsystem does not support the dynamic role switching, that is, OTG protocols HNP, SRP, and ADP.

23.11.4.5 UTMI+ USB2 HS/FS/LS PHY Interface

The USB Transceiver Macrocell Interface (UTMI+) is the de-facto standard interface to an on-chip HS/FS/LS PHY attached to the bidirectional D+/D- twisted pair. The default mode is 8-bit (datawidth) 60 MHz UTMI. Even though 16-bit, 30 MHz is also available through software reconfiguration, the lower clock frequency brings higher latencies in the protocol FSM and in cross-domain resynchronizations, which can cause maximum USB turnaround times to be exceeded, depending on the PHY characteristics: 16-bit mode must not be preferred without a good justification.

Activity on UTMI+ and ULPI is mutually exclusive. When the on-chip UTMI PHY is used, ULPI interface typically is not utilized.

23.11.4.5.1 Mailbox VBUS/ID Management

The UTMI+ sideband signals to manage VBUS and OTG ID lines can be routed to a mailbox logic. See also Figure 23-244,*SuperSpeed USB Subsystem Operation Diagram* for an illustration of the process :

- Any change on an OTG control output (drive, charge or discharge VBUS, pull up ID: utmi_drvvbus, utmi_chrgvbus, utmi_dischrgvbus, utmi_idpullup outputs respectively) trigger an interrupt. The software must read the new output value from USBOTGSS_UTMI_OTG_CTRL and transfer it to the companion device (PMIC).
- In the other direction, any status change in the companion (VBUS valid, A/B session valid, session end, ID dig: utmi_vbuvalid, utmi_avalid, utmi_bvalid, utmi_sessend, utmi_iddig inputs, respectively) is expected to trigger an interrupt , and the software to write the new status to the controller's OTG status

mailbox (USBOTGSS_UTMI_OTG_STATUS), from where it will enter the controller's inputs.

- Note that ADP (which also involves VBUS) is expected to be handled directly through the core's API, with no mailbox required and no associated UTMI+ signal.

The PIPE powerpresent is the VBUS status used in USB3 mode. It monitors the same VBUS line as the USB2 mode, with the following relationship.

- In host mode, USB3 powerpresent = USB2 VBUS valid (that is, the VBUS drive by the local host is sufficient for remote devices / hubs to start)
- In device mode, USB3 powerpresent = USB2 B-Session valid (that is, VBUS provided by remote host is sufficient to start operation)

Because PIPE powerpresent has a different meaning in host and in device mode, and because of the redundancy with the UTMI signals, the controller ORes together the appropriate PIPE and UTMI inputs to create its internal VBUS status. For that reason, it is recommended to leave field USBOTGSS_UTMI_OTG_STATUS[9] POWERPRESENT at its default value (=0), and only to fill in the USB2 VBUS status fields in the same register.

23.11.4.5.2 UTMI Power Management for LPM

To the standard utmi_suspendm output used in "plain" USB, the current controller adds two non-standard outputs for the Link Power Management extension (see *USB 2.0 Link Power Management (LPM) Addendum*): utmi_l1_suspend_n and utmi_l1_sleep_n.

LPM relabels the two USB power states of plain USB as L0 (active) and L2 (suspended), and introduces third, intermediate state L1 (sleep). In L1, resume latencies are shorter than in L2, and are configurable by the host through the HIRD parameter (Host Initiated Resume Duration). The USB device will typically attempt to go to the lowest-power mode compatible with the HIRD, that is, which can be exited in time to respect the HIRD. This includes the potential suspension of the UTMI interface.

The state referred to as "idle" below is the state where all clocks in the module can be stopped, in order to perform power management operations (isolation, voltage scaling, retention, power gating, etc.), and is characterized by output sidleack = 2'b11 (idle).

As explained in Table 23-1071, *LPM Power Management On UTMI+*, each of the three UTMI signals is asserted (=0) when entering a specific low-power mode:

- utmi_suspendm: asserted (=0) when the UTMI clock needs to be stopped, potentially to put the controller in idle:
  - when entering L2/suspend ("plain" suspend) or
  - when entering L1/sleep + the HIRD is high enough.
- utmi_l1_suspend_n: asserted (=0) when entering L1/sleep + HIRD value is high enough to suspend.
- utmi_l1_sleep_n: asserted (=0) when entering L1/sleep + HIRD value is too low to suspend, that is, the UTMI clock cannot be stopped and the controller cannot go to idle.

Table 23-1071, *LPM Power Management On UTMI+*shows the value of each output depending on the mode. All three signals are active-low.

Table 23-1071. LPM Power Management On UTMI+

Link state	L0 (Active)	L1 (Sleep)	L1 (Sleep), Suspended	L2 (Suspend)	Idle = Reset = Isolation
utmi_suspendm	1	1	0	0	0
utmi_l1_suspend_n	1	1	0	1	0
utmi_l1_sleep_n	1	0	1	1	1

NOTE:

- Following the assertion (=0) of utmi_suspendm, the UTMI clock is stopped by the PHY and the controller may go to idle. When in idle, the controller forces both utmi_suspendm and utmi_l1_suspend_n to 0 (active). In other words, the PHY will see the same input values, whether in L2/suspend or in "suspended L1/sleep" receive the same input is expected to remember which mode it must be in, by following the signal that is asserted first.
- As a consequence of the above, the controller blocks the deassertion (to 1) of utmi_suspendm and utmi_l1_suspend_n caused by for example a UTMI linestate change. The goal of that is to delay the restart of the UTMI clock until the controller is out of idle and ready to resume activity.

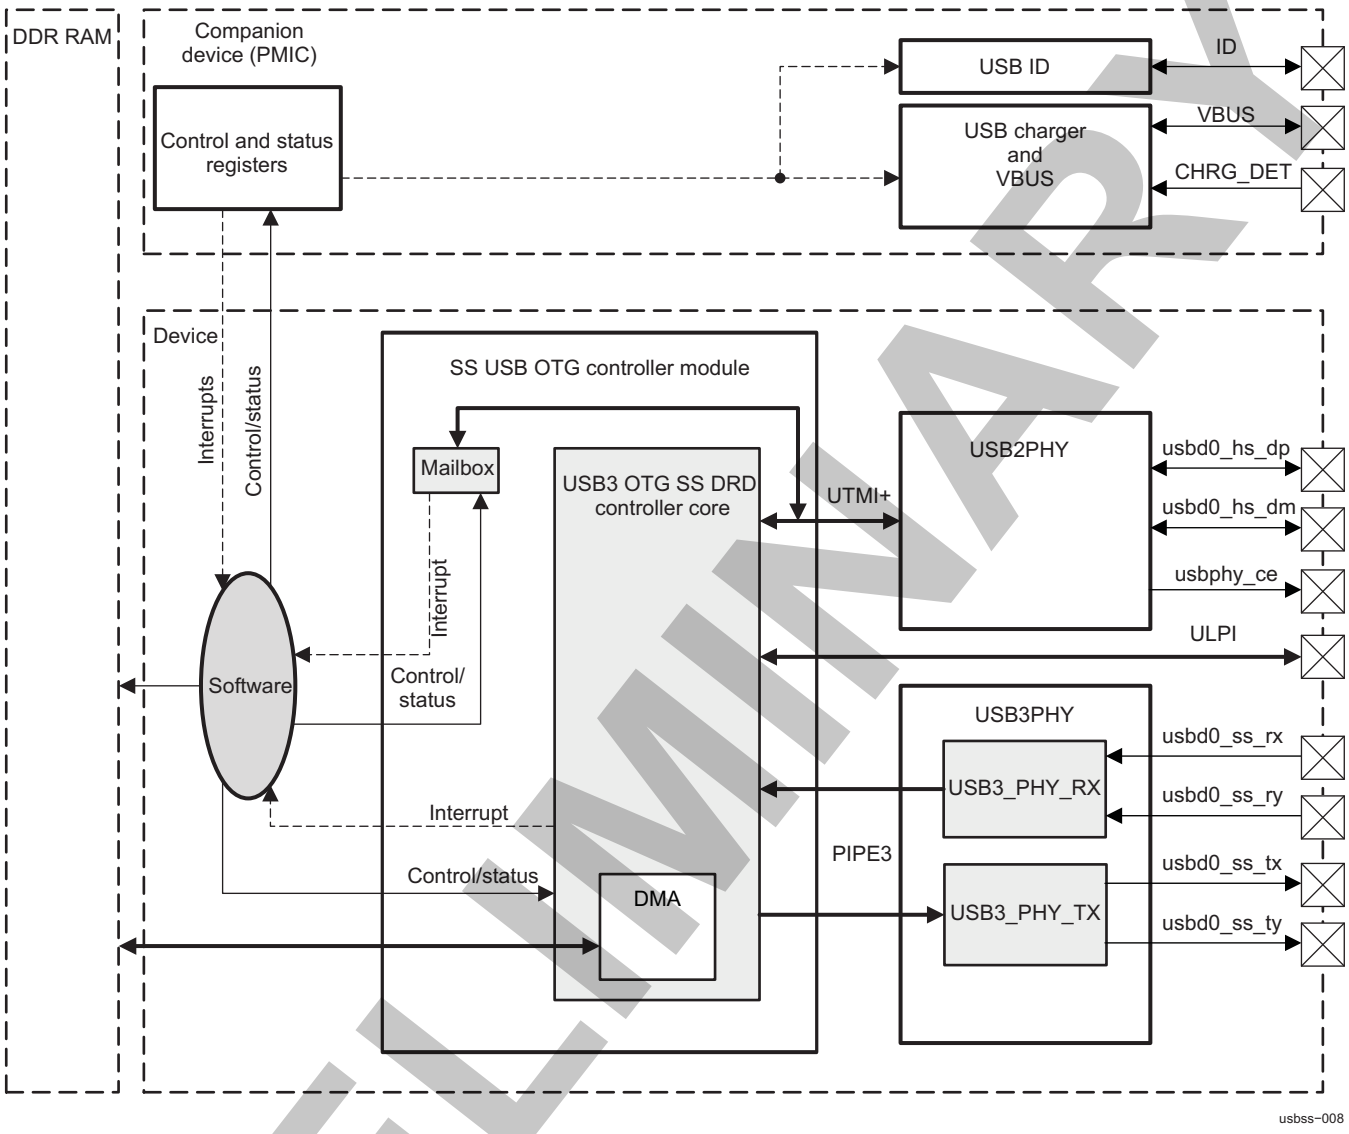
23.11.4.6 Operation Theory

This section provides an overview of the USB_OTG_SS controller basic operation.

For information about the complete programming sequence, see *Designware Cores SuperSpeed USB 3.0 Controller Databook*.

Figure 23-244 shows the operation of the complete subsystem: The USB_OTG_SS controller together with a USB2.0 PHY (HS/FS/LS-capable) and USB3.0 PHY (SS-capable); the MPU subsystem running software and connected to the main memory; and a companion IC (TWL6035) managing the VBUS and OTG ID.

Figure 23-244. SuperSpeed USB Subsystem Operation Diagram



The eight USB I/O signals can be routed to a connector receptacle (for example USB3.0 micro-AB) to create a single USB3.0 OTG2 port. Alternatively, the four I/Os of the SS PHY can be left unconnected, with the remaining four routed to a connector receptacle (for example, the USB2.0 micro-AB) to create a single USB2.0 OTG2 port.

Data transfers proceed as follows:

1. USB software allocates blocks of the main memory for operation.
2. USB software issues commands to the controller (USB transmit, receive, etc.) together with the allocated addresses of the blocks.
3. The built-in DMA of the USB controller then executes the commands by either transmitting (read from memory, sent though USB PHY) or receiving (received through USB PHY, written to memory). The PHY used (either USB2 or USB3 PHY) depends on the configuration and context.
4. The USB controller returns a status to the software (using interrupts).

Operations involving:

- VBUS (from the simple drive/detection for the non-OTG host/peripheral to the more complex OTG control and status) and
- The OTG ID (DRD role determination)

are expected to take place off-chip (that is, without a dedicated hardware link). Instead, the various control and status operations are expected to use ad-hoc channels supported by interrupts and miscellaneous communication interfaces. (For example, the TWL6035 PMIC is accessed through the I2C1 interface.). From a USB protocol standpoint, the latency associated with those ad-hoc channels is acceptable, because none of those operations is timing-critical. See Section 23.11.4.5.1, *Mailbox VBUS/ID Management* for more details on the mailbox mechanism.

23.11.4.7 External Buffer Control (EBC) Mode Operation

When the DMA is fetching (or writing) data to/from system memory, the assumption is that the data/free space is available as soon as the descriptors, that is, the TRBs, are filed to the controller. However, there are cases where the data is not really memory-mapped but stored in a FIFO, called below the EB for external buffer, and for which additional flow control is required.

The External Buffer Control (EBC) is a hardware interface that provides such a data flow control (throttling) with no additional software intervention. It is supported with the following limitations:

- Device mode only (not supported for host mode)
- BULK protocol, with EP size = bulk maximum packet size (64 bytes for FS, 512 for HS, 1024 for SS)
- Available on only two endpoints, one in each direction: EP15 IN (Tx), EP15 OUT (Rx)
- Large TRBs (multiple packets per descriptor)
- No multi-segment TRBs

NOTE:

- EBC-capable endpoints can be used in non-EBC mode as well: as long as the appropriate bit in USBOTGSS_DEV_EBC_EN has not been set, the endpoint retains its default behaviour, that is, Tx data (or space for Rx data) is available in system memory as soon as the TRB is given to the controller.
- EBC-operated endpoints must be configured (in the DEPCFG command) with command bitfield DEPCMDPAR1.LimitOutstandingTxDMA set to 1, to prevent several outstanding transactions from accessing the EB out of order, which is not allowed as the EB is a FIFO.
- EBC can operate in parallel with other device endpoints working in the regular, non-EBC mode.
- EBC mode provides standard and correct behaviour on the USB wire, even if the retries are not handled by the external buffer system, that is, even if data is not actually repeated upon retries.

23.11.4.7.1 IN (Tx) EP Operation In EBC Mode

Enabling procedure for the IN (transmit) EP in EBC mode:

1. Prepare the EB FIFO to handle the EBC hardware interface signals (described in Section 23.11.4.8.2, *Device-Mode Endpoint Commands*)
2. Write to 1 bitfield USBOTGSS_DEV_EBC_EN[15] INEP15 to enable the hardware interface on the controller side
3. Configure IN EP15 with the following requirements:
   - DEPCMDPAR1.LimitOutstandingTxDMA = 1 in DEPCFG command
   - TRB transfer descriptors pointing at the EB's memory mapping
   - (Optional) TRB structure can be a (linked list) loop stored in a special, read-only zone. This provides infinite recycling by preventing the DMA from upgrading TRBs and passing them to the software. This allows the transfer to proceed without any software intervention. Note that such a memory zone is not included in the controller, and requires specialized logic. For instance, it cannot use
     (a) a write-protected block of RAM, as the DMA writes would trigger MMU errors, or
     (b) a ROM, as the DMA writes would trigger system bus errors. Writes to this zone should be allowed to "fail silently", that is, have no effect and trigger no error.

- EP size = maximum bulk packet size

4. Proceed like a non-EBC endpoint

Disabling the EP: If less than one packet-size of data is available in the EB, it is by construction invisible to the controller, and will never be fetched and transmitted (unless it is "pushed" over the threshold by more data). It is the responsibility of the system to ensure that no relevant data is stuck in the EB when the EP is disabled.

23.11.4.7.2 OUT (Rx) EP Operation in EBC Mode

Enabling procedure for the OUT (receive) EP in EBC mode:

1. Prepare the EB FIFO to handle the EBC HW interface signals (described in Section 23.11.4.8.2, *Device-Mode Endpoint Commands*)
2. Write to 1 bitfield USBOTGSS_DEV_EBC_EN[31] OUTEP15, to enable the hardware interface on the controller side
3. Configure OUT EP15 with the following requirements:
   - DEPCMDPAR1.LimitOutstandingTxDMA = 1 in DEPCFG command
   - TRB transfer descriptors pointing at the EB's memory mapping
   - EP size = maximum bulk packet size.
4. Proceed like a non-EBC endpoint

23.11.4.8 USB Device (Peripheral) Operation

The current section describes elements of device-mode operation. The controller in device-mode uses a dedicated set of programming registers, prefixed with a D, and described in Section 23.11.5.2, *DWC_USB3 registers*. For the complete programming model, refer to *DWC superspeed USB3 controller databook*.

Operation in USB device mode is controlled using the following tools:

- Device endpoint command registers: CSRs, accessed by the software driver through the controller slave (L4_CFG) interface. Commands pass the address in main memory of the transfer request block (TRB) to the controller DMA.
- TRBs: Mapped in main memory, TRBs describe the data buffers also located in main memory. Initially created by the software driver, read and updated by the controller DMA.
- Data buffers: Areas of main memory containing USB data to transmit or make available for received USB data. Data buffers are defined in the TRBs.
- Event buffer: Mapped in main memory, the event buffer is a circular buffer containing USB events written by the device controller and read by the device software driver.
- Interrupt line: flags core events

23.11.4.8.1 Device TRBs

Transfer request blocks (TRBs) are mapped in main memory as linked lists. They describe the data buffers also located in main memory. Initially created by the software driver, they are read by the controller DMA and updated by it, depending on USB activities.

Even through device TRBs are inspired by and similar to the host TRBs defined by the *Extensible Host Controller Interface (xHCI) for USB* specification, they are not identical. The main difference is that device TRBs are updated (written) by the controller DMA, unlike host TRBs, which are written only by the software driver and are read-only for the controller DMA.

NOTE: TRBs are structures implemented in the main memory.

Table 23-1072 through Table 23-1077 describe the 128 bits of the TRB as four 32-bit words.

Table 23-1072. Device TRB Word Structure

Name	Address Offset

Table 23-1076. STATUS

Bits	Field Name	Description	Type	Reset
31:28	TRBSTS	TRB status. Updated by hardware transfer status information before releasing the TRB. 0x0: OK 0x1: MissedIsoc: Isochronous interval missed or incomplete. 0x2: SetupPending: Another SETUP was received during current control transfer data/status phase.	RW	0x0
27:26	Reserved		RO	0x0
25:24	PCM1	Packet count minus 1: Total number of packets in the buffer descriptor for high-speed, high-bandwidth isochronous IN endpoints in an Isoc-First TRB. 0x0: 1 packet 0x1: 2 packets 0x2: 3 packets 0x3: 4 packets	RW	0x0
23:0	BUFSIZ	Buffer size. Remaining size in bytes (to be sent/which can be received) in the TRB data buffer. Decremented by hardware after data is transferred. 0x000000: No remaining bytes in buffer 0xFFFFFF: 16 MiB – 1 remaining byte in buffer (maximum size)	RW	0x000000

Table 23-1077. CONTROL

Bits	Field Name	Description	Type	Reset
31:30	Reserved		R	0x0
29:14	SID_SOFN	Stream ID/SOF number Stream-based bulk EP: The stream ID of the transfer. Isochronous EP: (micro)frame number in which the last packet of the buffer is transmitted (debug).	RW	0x0000
13:12	Reserved		R	0x0
11	IOC	Interrupt on complete. Applicable only when LST = 0, for a) IN EP or b) OUT EP when CSP = 1. Read-only for the USB controller DMA (hardware) Read 0: No action Read 1: XferInProgress event issued (with IOC bit set) on completion of buffer transfer.	R	0
10	ISP_IMI	Interrupt on short packet/interrupt on Missed ISOC. Controls the generation of the XferInProgress event. Read-only for the USB controller's DMA (hardware). Read 0: No action Read 1: XferInProgress event when: a) Receiving an unexpected short packet (OUT EP, LST = 0, CSP = 1) or b) The missed Isoc status is given (isochronous EP).	R	0
9:4	TRBCTL	TRB control. Type of TRB. Read-only for the USB controller DMA (hardware) Read 0x01: Normal (Bulk/Interrupt/Control-Data-n with n1) Read 0x02: Control-Setup Read 0x03: Control-Status-2 Read 0x04: Control-Status-3 Read 0x05: Control-Data-1 Read 0x06: Isochronous-1 (First TRB of Service Interval) Read 0x07: Isochronous-n (with n1) Read 0x08: Link TRB	R	0x0
3	CSP	Continue on short packet. Reaction of an OUT endpoint on reception of a short packet. Read-only for the USB controller DMA (hardware) Read 0: Generate XferComplete event and remove the stream. Read 1: Continue to the next buffer descriptor.	R	0
2	CHN	Chain buffers. Associates this TRB with the next in the same buffer descriptor. Always 0 in the last TRB of a buffer descriptor. Read-only for the USB controller DMA (hardware) Read 0: End of the current buffer descriptor. Read 1: Next TRB is part of the same buffer descriptor	R	0
1	LST	Last TRB. Indicates the last TRB in a list, that is, in a transfer for the endpoint/bulk-stream. Read-only for the USB controller DMA (hardware) Read 0: TRB list not complete Read 1: Last TRB	R	0
0	HWO	Hardware owner. TRB ownership. Set to 1 by software when creating the TRB. Software cannot modify the TRB again until cleared to 0 by hardware. There are exceptions for short packets on OUT endpoints and link TRBs. 0: Software-owned TRB 1: Hardware-owned TRB	RW	0

23.11.4.8.2 Device-Mode Endpoint Commands

Current subsection describes the endpoint commands passed by the device controller driver (software) to the device controller (hardware) through the appropriate memory-mapped control and status registers. The command is passed to endpoint i through register USBOTGSS_DEPCMD_i, with additional parameters passed through USBOTGSS_DEPCMDPAR0_i, USBOTGSS_DEPCMDPAR1_i and USBOTGSS_DEPCMDPAR2_i in case the 16-bit USBOTGSS_DEPCMD_i[31:16] CMDPARAM_EVTPARAM is not sufficent, depending on the command.

Table 23-1078, *Device-mode Endpoint Commands Summary* is a summary of the EP commands, and which parameter registers are used (Y) in each case. Unused parameter registers are reserved. Each command is described in Section 23.11.4.8.2.1 through Section 23.11.4.8.2.9.

Table 23-1078. Device-mode Endpoint Commands Summary

	Command	Command full name	Parameter	PAR0	PAR1	PAR2
1	DEPCFG	Set EP configuration	64-bit	Y	Y	
2	DEPXFERCFG	Set EP transfer resource configuration	32-bit	Y		
3	DEPGETDSEQ	Get data sequence number	none			
4	DEPSETSTALL	Set stall	none			
5	DEPCSTALL	Clear stall	none			
6	DEPSTRTXFER	Start transfer	64-bit	Y	Y	
7	DEPUPDXFER	Update transfer	none			
8	DEPENDXFER	End transfer	none			
9	DEPSTARTCFG	Start new configuration	none			

23.11.4.8.2.1 Set EP Configuration (DEPCFG) Command

This command sets the configuration of the physical endpoint.

DEPCFG.CommandParam: unused (when USBOTGSS_DEPCMD_i register is written)

Additional parameters: 64-bit, stored in USBOTGSS_DEPCMDPAR0_i and USBOTGSS_DEPCMDPAR1_i, with the fields detailed in Table 23-1079 and Table 23-1080. Register USBOTGSS_DEPCMDPAR2_i is reserved.

Table 23-1079. USBOTGSS_DEPCMDPAR1_i Fields for DEPCFG Command

Bits	Field Name	Description	Type	Reset
31	FIFOBASED_EBCBASED	Isoc EP: TRBs never written back by the core, for FIFO-based data buffers. Bulk EP: Limit outstanding DMA transfers to 1 read + 1 write, required for EBC operation. 0: DISABLED Default EP behaviour (EBC not functional) 1: ENABLED Enable FIFO-based (for isoc EP) / EBC-based (for bulk EP) mode	RW	0x0
30	BULKBASED	Set to 1 for an isochronous EP to ignore intervals programmed in the TRBs, like a bulk EP. 0: DEFAULT Normal behaviour for isochronous EP 1: BBISOC Bulk-based isochronous EP	RW	0x0
29:26	EPNUMBER	Endpoint number for this physical EP. Control EP 0 OUT must be assigned to physical EP0 Control EP 0 IN must be assigned to physical EP1	RW	0x0
25	EPDIRECTION	Endpoint Direction for this physical endpoint Control EP 0 OUT must be assigned to physical EP0 Control EP 0 IN must be assigned to physical EP1 0: OUT direction (receive) 1: IN direction (transmit)	RW	0x0
24	STRMCAP	Stream Capable 0: NOTCAP EP is not stream-capable 1: CAP EP is stream-capable	RW	0x0
23:16	BINTERVAL_M1	bInterval value minus one, as reported in the EP descriptor. Set to 0 when operating in FS.	RW	0x0
15	LimitOutstandingTxDMA			
14	Reserved		RO	0x0
13	STREAMEVTEN	Stream Event DEPEVT enable 0: DIS event disabled 1: EN event enabled	RW	0x0
12	Reserved		RW	0x0

Table 23-1079. USBOTGSS_DEPCMDPAR1_i Fields for DEPCFG Command (continued)

Bits	Field Name	Description	Type	Reset
11	RXTXFIFOEVTEN	RxTxFifoEvt DEPEVT event enable IN EP: FIFO underrun enable OUT EP: FIFO underrun enable 0: DIS event disabled 1: EN event enabled	RW	0x0
10	XFERNRDYEN	XferNotReady DEPEVT event enable 0: DIS event disabled 1: EN event enabled	RW	0x0
9	XFERINPROGEN	XferInProgress DEPEVT event enable 0 DIS event disabled 1 EN event enabled	RW	0x0
8	XFERCMPLEN	XferComplete DEPEVT event enable 0: DIS event disabled 1: EN event enabled	RW	0x0
7:5	Reserved		RW	0x0
4:0	INTRNUM	Interrupt/Event Buffer number on which interrupts for this EP are generated. Must be 0 if a single interrupter HW configuration. 0x00: INT0 Interrupt 0	RW	0x0

Table 23-1080. USBOTGSS_DEPCMDPAR0_i Fields for DEPCFG Command

Bits	Field Name	Description	Type	Reset
31	IGNORESEQNUM	Ignore Sequence Number: avoids resetting the sequence number upon DEPCFG command. Used to modify the DEPEVTEN event enable bits on the fly 0: RESET Sequence Number shall be reset to 0 1: IGNORE Sequence Number shall not change	RW	0x0
30:26	DSEQNUM	Data Sequence Number. Must be zero at initial EP configuration.	RW	0x0
25:22	BRSTSIZ	Burst Size minus 1 0x0: MIN 1-beat burst 0xF: MAX 16-beat burst	RW	0x0
24	STRMCAP	Stream Capable 0: NOTCAP EP is not stream-capable 1: CAP EP is stream-capable	RW	0x0
21:17	FIFONUM	FIFO number assigned to this EP. Control EP must have the same value for IN and OUT EP. OUT: use Rx FIFO number 0 IN: use only the lower 16 Tx FIFOs.	RW	0x0
16:14	Reserved		RW	0x0
13:3	MPS	Maximum Packet Size, in bytes	RW	0x0
2:1	EPTYPE	Endpoint type 0x0: CTRL Control EP 0x1: ISOC Isochronous EP 0x2: BULK Bulk EP 0x3: INT Interrupt EP	RW	0x0
0	Reserved		RW	0x0

23.11.4.8.2.2 Set EP Transfer Resource Configuration (DEPXFERCFG) Command

Command assigns a transfer resource to the endpoint. Resource is actually used between the start (Start Transfer) and the end (End Transfer command or XferComplete) of the transfer.

DEPCFG.CommandParam: unused (when USBOTGSS_DEPCMD_i register is written)

Additional parameters: 32-bit, stored in USBOTGSS_DEPCMDPAR0_i, with the fields detailed inTable 23-1081, *USBOTGSS_DEPCMDPAR0_i Fields for DEPXFERCFG Command*. Register USBOTGSS_DEPCMDPAR1_i and USBOTGSS_DEPCMDPAR2_i are reserved.

Table 23-1081. USBOTGSS_DEPCMDPAR0_i Fields for DEPXFERCFG Command

Bits	Field Name	Description	Type	Reset
31:16	Reserved		RW	0x0
15:0	NUMXFERRES	Number of transfer resources allocated to this EP. Must be set to 1. 0x01: One resource	RW	0x0

23.11.4.8.2.3 Get Data Sequence Number (DEPGETDSEQ) Command

For non-isochronous EP only. Returns the current data sequence number for the EP, allowing it to be saved, and later restored using the DEPCFG command.

DEPCFG.CommandParam: unused (when USBOTGSS_DEPCMD_i register is written)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i, USBOTGSS_DEPCMDPAR1_i and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.2.4 Set Stall (DEPSETSTALL) Command

Stalls all tokens to the EP, including if the EP is in NRDY state.

- OUT EP: ongoing packet completes normally, next OUT DP or token is stalled.
- IN EP, SS: current burst completes normally, next ACK TP is stalled.
- IN EP, HS/FS/LS: current packet completes normally, next IN token is stalled.
- Control EP: only the OUT direction shall be stalled
- Isochronous EP: not applicable, do not use

DEPCFG.CommandParam: unused (when USBOTGSS_DEPCMD_i register is written)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i, USBOTGSS_DEPCMDPAR1_i, and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.2.5 Clear Stall (DEPCSTALL) Command

Clears the previously applied stall for the EP.

- Control EP: stall cannot be cleared by software: Hardware clears the stalls automatically when the next SETUP token is received.
- Non-Control EP: stall must be cleared by software. This also resets the DSeqNum to 0.
- Isochronous EP: not applicable, do not use

DEPCFG.CommandParam: unused (when USBOTGSS_DEPCMD_i register is written)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i, USBOTGSS_DEPCMDPAR1_i, and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.2.6 Start Transfer (DEPSTRTXFER) Command

Indicates that a Transfer Descriptor (TD), that is, a list of TRBs that comprise one or more transfers, is ready to be processed. A pointer to the TD is recorded and is kept until the transfer ends (XferComplete event or DEPENDXFER command)

Hardware assigns the transfer a resource index number (XferRscIdx), returned in the USBOTGSS_DEPCMD_i register and in the Command Complete event, for use in subsequent Update and End Transfer commands.

Non-stream capable EP:

- StreamID must be set to 0
- HighPri is reserved

Stream-capable EP:

- StreamID must be non-zero and match the StreamID in the TRB at the Transfer Descriptor Address

- HighPri may be set for one or more streams.
- Commands is issued for multiple streams, until the resources in DEPXFERCFG.NumXferRes are used up

DEPCFG.CommandParam:

- For isoc EP: CommandParam = StartMicroFramNum: 16-bit Frame / microframe number to which the first TRB of the transfer applies
- For stream-capable EP: CommandParam = StreamID: 16-bit USB stream ID associated to this transfer.

Additional parameters: 64-bit, stored in USBOTGSS_DEPCMDPAR0_i and USBOTGSS_DEPCMDPAR1_i, with the fields detailed in Table 23-1082 and Table 23-1083. Register USBOTGSS_DEPCMDPAR2_i is reserved.

Table 23-1082. USBOTGSS_DEPCMDPAR1_i Fields for DEPSTRTXFER Command

Bits	Field Name	Description	Type	Reset
31:0	TDADDR_LOW	Transfer Descriptor Address, lower 32 bits. Since TRBs must be aligned on a 16-byte boundary, the 4 LSBs of this field must be 0.	RW	0x0

Table 23-1083. USBOTGSS_DEPCMDPAR0_i Fields for DEPSTRTXFER Command

Bits	Field Name	Description	Type	Reset
31:0	TDADDR_HIGH	Transfer Descriptor Address, upper 32 bits. All 0 in 32-bit-address architectures.	RW	0x0

23.11.4.8.2.7 Update Transfer (DEPUPDXFER) Command

In the case of a circular TRB buffer, causes the hardware to re-cache the TRB following a TRB update by the software. Update includes the setting of HWO bit back to 1. The indicated resource transfer index identifies the updated TRB. It must have been previously started, then have completed its transfer (XferComplete event or an DEPENDXFER command)

Special No Response Update Transfer command is issued by setting CmdAct=0 and CmdIOC=0. In this case, no command complete (EpCmdCmplt) event is generated, CmdAct never changes, and another command may be issued to the same EP immediately. Do not use when software depends on the XferNotReady event to setup TRBs.

DEPCFG.CommandParam: CommandParam[6:0] = USBOTGSS_DEPCMD_i[22:16] = XferRscIdx: 7-bit Transfer resource index, assigned by the hardware to the transfer when it is started (DEPSTRTXFER command)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i , USBOTGSS_DEPCMDPAR1_i , and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.2.8 End Transfer (DEPENDXFER) Command

Request DMA to stop for the EP/stream, because of an error condition. TRB is identified by its transfer resource index. ForceRM bit (USBOTGSS_DEPCMD_i[11] HIPRI_FORCERM) must be set to 1 to remove transfers from the queue. CmdIOC bit (USBOTGSS_DEPCMD_i[8] CMDIOC) must be set to 1 in order to an EP Command Complete event is generated after the transfer ends, to synchronize the conclusion of system bus traffic before the End Transfer command is completed.

Effect of the command:

- IN EP: A packet being transmitted may be truncated with the DPPABORT ordered set, any pending ACKs from the USB are ignored.
- OUT EP: Any data in the receive FIFO is moved to the corresponding memory buffer, until a packet boundary.
- TD processing stops, TRB status is not updated.

- No XferComplete event is generated upon transfer end, only a CommandComplete event.

Use the command in the followng cases:

- To close EP when handling USBReset or SetConfiguration
- After receiving a ClearFeature (STALL) control transfer, before issuing Clear Stall, then Start Transfer
- After a XferInProgress event when the TRB after the one that caused the XferInProgress event has HWO=0
- For isochronous EP, if the host stops moving data for many intervals, to wait for the host to restart.

DEPCFG.CommandParam: CommandParam[6:0] = USBOTGSS_DEPCMD_i[22:16] = XferRscIdx: 7-bit Transfer resource index, assigned by the hardware to the transfer when it is started (DEPSTRTXFER command)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i , USBOTGSS_DEPCMDPAR1_i , and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.2.9 Start New Configuration (DEPSTARTCFG) Command

Command issued to start a new configuration, in the following cases :

- Only to EP 0 (USBOTGSS_DEPCMD_i (i = 0))
- After power-on-reset with XferRscIdx=0 before starting to configure EP 0 and 1. CmdIOC bit (USBOTGSS_DEPCMD_i[8] CMDIOC) must be set to 0 and CmdAct bit CmdIOC bit (USBOTGSS_DEPCMD_i[10] CMDACT) must be polled because EP 0 is not yet configured with a valid interrupt number at that point.
- With XferRscIdx=2 when it receives SetConfiguration before starting to configure EP > 1.

Transfer resource allocation gets reset to the value in the XferRscIdx parameter (must be 0 or 2).

DEPCFG.CommandParam: CommandParam[6:0] = USBOTGSS_DEPCMD_i[22:16] = XferRscIdx: 7-bit Transfer resource index, assigned by software when the new configuration is started (DEPSTARTCFG command)

Additional parameters: None. Registers USBOTGSS_DEPCMDPAR0_i , USBOTGSS_DEPCMDPAR1_i , and USBOTGSS_DEPCMDPAR2_i are reserved.

23.11.4.8.3 Device-Mode Events

The current subsection describes the status events passed by the device controller (hardware) to the device controller driver (software) though the event buffer(s) mapped in system memory. Most events fit in a single (32-bit) dword. The one exception is the Vendor device test LMP received event, which takes 3 dwords.

Table 23-1084 gives a summary of all possible events

- Events are decoded from right to left (LSbits to MSbits)
- Each line is a different category of event, described in Section 23.11.4.8.3.1, *Endpoint Events (DEPEVT)* and Section 23.11.4.8.3.2, *Device events (DEVT)*. The number in the first column is a link to the corresponding event description table.
- Short field names (a1, a2, b1, etc.) are described in Table 23-1088.

Table 23-1084. Device-Mode Events Summary

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Vendor-Defined Data (dword 2/2)																															

Table 23-1085 lists the event types, as used in the event buffer (dword 0 bits [7:0])

Table 23-1085. Event Type

bit [7:1]	bit [0]	Name	Comments
don't care	0	DEPEVT	Device-mode, Endpoint-specific event
don't care	1	non-EP	Device-mode, non-endpoint-specific event
0000000	1	DEVT	Device-mode, Device event

Table 23-1086 lists the 4-bit endpoint events (DEPEVT), as used in the buffer (dword 0 bits [9:6]).

Table 23-1086. Endpoint Event (DEPEVT) Types

DEPEVT	Name	Comments
0x0	reserved	
0x1	XferComplete	Transfer complete
0x2	XferInProgress	Transfer in progress
0x3	XferNotReady	Transfer not ready
0x4	RxTxFifoEvt	Receive/Transmit FIFO event
0x5	reserved	
0x6	StreamEvt	Stream Event
0x7	EpCmdCmplt	Endpoint Command Complete
0x8 to 0xF	reserved	

Table 23-1085 lists the 4-bit device-specific events (DEVT), as used in the buffer (dword 0 bits [11:8]).

Table 23-1087. Device-Specific Event (DEVT) Types

DEVT	Name	Comments
0x0	DisconnEvt	Disconnect detected
0x1	UsbRst	USB reset detected
0x2	ConnectDone	Connect done event
0x3	ULStChng	USB or Link state change event.
0x4	WkUpEvt	Host resume (wakeup) detected
0x5	reserved	
0x6	EOPF	End of periodic frame
0x7	SOF	Start of (micro-)frame
0x8	reserved	
0x9	ErrticErr	Erratic error
0xA	CmdCmplt	Generic command complete
0xB	EvntOverflow	Event buffer overflow
0xC	VndrDevTstRcved	Vendor device test LMP received from link partner.
0xD to 0xF	reserved	

Table 23-1088. Device-Mode Events Encoding, Short Fields

Field	Bits	Description
d1	12	XferComplete/XferInProgress EP event: 1'b1: Bus error occurred.
c1	13	XferComplete/XferInProgress EP event: 1'b1: TRB completed with short packet reception or last packet of isoc interval.
b1	14	XferComplete/XferInProgress EP event: 1'b1: IOC bit of the TRB that completed.
a1	15	XferComplete EP event: 1'b1: LST bit of the completed TRB.
a2	15	XferInProgress EP event: MissedIsoc: 1'b1: Interval did not complete successfully.
b3	13:12	XferNotReady EP event: requested stage when (control) transfer was not ready: 2'b00: Control SETUP request 2'b01: Control data request 2'b10: Control status request
a3	15	XferNotReady EP event: 1'b0: XferNotActive: Host initiated a transfer not present in the hardware. 1'b1: XferActive: Host initiated a transfer that is present but no valid TRBs are available.
a5	15:12	StreamEvt EP event (only for bulk EP that supports streams): 4'h2: StreamNotFound: No active, ready stream found in transfer resource cache. 4'h1: StreamFound: Active and ready stream found, traffic to the host initiated for that stream.
a7	15:12	EpCmdCmplt EP event, DepXferCfg command: 4'h1: Error: Software requesting more transfer resources than are configured in the hardware.
a9	15:12	EpCmdCmplt EP event, DepStrtXfer command:
b13	19:16	ULStChng device-specific event: Link state upon event. See DSTS register for encoding.
a13	20	ULStChng device-specific event: SS event. 1'b1: SS 1'b0: non-SS

23.11.4.8.3.1 Endpoint Events (DEPEVT)

Category of events is specific to data endpoints (EP). Several types of EP events exist, with different field structures.

Table 23-1089. Endpoint Events (DEPEVT)

Description	
Endpoint event (DEPEVT)	
Size in event buffer:	1 dword
Key:	Event type = evt[0] = DEPEVT
Subfields:	Physical EP number = evt[5:1]
	EP event type = evt[9:6]
	EventStatus = evt[15:12]
	EventParam = evt[31:16]

Table 23-1090. Transfer complete EP event (XferComplete)

Description	
Type of endpoint event generated upon completion (sucessful or not) of a IN or OUT USB transfer.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = XferComplete
Other fields:	EventParam = Stream ID = (if applicable, i.e. BULK EP with stream support)
	EventStatus = Bus Error flag + last isoc / short packet flag + IOC of TRB + LST of TRB
	Physical EP number

Table 23-1091. Transfer in progress EP event (XferInProgress)

Description	
Type of endpoint event generated during the processing of a still-ongoing transfer.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = XferInProgress
Other fields:	EventParam = IsocMicroFrameNum
	EventStatus = Missed isoc flag + last isoc / short packet flag + IOC of TRB + LST of TRB
	Physical EP number (0 to 31)

Table 23-1092. Transfer not ready EP event (XferNotReady)

Description	
Type of endpoint event that indicates receipt of a transaction when no TRBs are available for the EP. For isochronous IN endpoints, a zero-length packet is sent. For non-isochronous endpoints, an NRDY is sent.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = XferNotReady
Other fields:	EventParam = Stream ID = (if applicable, i.e. BULK EP with stream support)
	EventStatus = Xfer active flag + control phase (status/data)
	Physical EP number (0 to 31)
Generation of the event:	For stream-capable EP, generated each time the host attempts a transaction.
	For non-stream-capable EP, generated only on the first transaction attempt after an EP command to this EP.
	For isochronous EP, generated only once prior to the Start Transfer command to communicate the current bus time.

Table 23-1093. FIFO EP event (RxTxFIFOEvt)

Description	
Type of endpoint event generated upon FIFO underrun / overrun, for debug only.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = RxTxFIFOEvt
Other fields:	Physical EP number (0 to 31)
Generation of the event:	Only possible when thresholding is enabled
	FIFO underrun for IN EP = USB transmission
	FIFO overrun for OUT, non-isochronous EP = USB reception

Table 23-1094. Stream EP event (StreamEvt)

Description	
Type of EP event indicating that a stream-capable EP initiated a search within its transfer resource cache. The result of the search is in the EventStatus field.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = StreamEvt
Other fields:	EventParam = Stream ID = (if applicable)
	EventStatus = Found / NotFound flag
	Physical EP number (0 to 31)

Table 23-1095. Device EP command complete event (EpCmdCmplt)

Description	
Category of EP events generated upon completion of an EP command. Several sub-types exist depending on the command. Those with specific field structures are listed in the chapters below.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = EpCmdCmplt
Other fields:	EventParam (contains the Command type, and more depending on the command)
	EventStatus (depending on the command)
	Physical EP number (0 to 31)

Table 23-1096. Device EP command complete event (EpCmdCmplt): set transfer resource

Description	
Type of EP event generated upon completion of the Set transfer resource command	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = EpCmdCmplt
	Command type = EventParam[11:8] = evt[27:24] = DepXferCfg
Other fields:	EventStatus = Error flag for the command
	Physical EP number (0 to 31)

Table 23-1097. Device EP command complete event (EpCmdCmplt): get data sequence

Description	
Type of EP event generated upon completion of the Get data sequence command	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT

Table 23-1097. Device EP command complete event (EpCmdCmplt): get data sequence (continued)

Description	
	EP event type = evt[9:6] = EpCmdCmplt
	Command type = EventParam[11:8] = evt[27:24] = DepGetDSeq
Other fields:	EventParam[4:0] = CurDatSeqNum : current data sequence number
	Physical EP number (0 to 31)

Table 23-1098. Device EP command complete event (EpCmdCmplt): start transfer

Description	
Type of EP event generated upon completion of the Start transfer command	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = DEPEVT
	EP event type = evt[9:6] = EpCmdCmplt
	Command type = EventParam[11:8] = evt[27:24] = DepStartXfer
Other fields:	EventParam[7:0] = XferRscIdx : resource index number
	EventStatus = Error flag for the command
	Physical EP number (0 to 31)

23.11.4.8.3.2 Device events (DEVT)

All non-EP events are listed in Table 23-1100 through Table 23-1110. Note that the only type of non-EP event is the device event, that is, an event that applies to the entire device, as opposed to only an EP.

NOTE: DEVT described here must not to be confused with device-mode events, that is, all events generated by the controller when in USB device mode, including the EP events (DEPEVT) described in the previous section.

Table 23-1099. Device events (DEVT)

Description	
Device event (DEVT)	
Size in event buffer:	1 or 3 dword depending on event
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
Other fields:	device event type = evt[11:8]
	EvtInfo = evt[23:16]

Table 23-1100. Disconnect DEVT event (DisconnEvt)

Description	
Device event generated upon disconnect detection.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = DisconnEvt
Other fields:	none (EvtInfo is unused)

Table 23-1101. USB reset DEVT event (UsbRst)

Description	
Device event generated upon USB reset detection.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = UsbRst
Other fields:	none (EvtInfo is unused)

Table 23-1102. Connect done DEVT event (ConnectDone)

Description	
Device event generated upon USB connect detection.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = ConnectDone
Other fields:	none (EvtInfo is unused)

Table 23-1103. USB / link status change DEVT event (ULStChng)

Description	
Device event generated upon USB / Link status change. In superspeed, generated only when entering the following USB3 LTSSM states: Rx.Detect, SS.Disabled, Polling, U1, U2, U3, or Recovery (only from U1, U2, U3).	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = WkUpEvt
Other fields:	EvtInfo[4] = SuperSpeed flag
	EvtInfo[3:0] = Link State

Table 23-1104. Wakeup DEVT event (WkUpEvt)

Description	
Device event generated upon detection of USB resume from the remote host. WARNING: Event is not generated by the device's own remote wakeup, or by the resume normally transmitted by the host in reply to that.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = WkUpEvt
Other fields:	none (EvtInfo is unused)

Table 23-1105. End of periodic frame DEVT event (EOPF)

Description	
Device event generated at the end of periodic frame.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = EOPF
Other fields:	none (EvtInfo is unused)

Table 23-1106. Start of frame DEVT event (SOF)

Description	
Device event generated at the start of (micro-)frame.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = SOF
Other fields:	none (EvtInfo is unused)

Table 23-1107. Erratic error DEVT event (ErrticErr)

Description	
Device event generated upon erratic error event: Rxvalid / rxactive signals incorrectly asserted (by the USB2 PHY) for more than 2 ms on UTMI interface. Device then goes to Suspended, with a ULStChng event generated. Recovery from that error requires a soft disconnect.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = ErrticErr
Other fields:	none (EvtInfo is unused)

Table 23-1108. Command Complete DEVT event (CmdCmplt)

Description	
Device event generated upon (non-EP) command completion.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = CmdCmplt
Other fields:	none (EvtInfo is unused)

Table 23-1109. Event buffer overflow DEVT event (EvntOverflow)

Description	
Device event generated upon event buffer overflow: One or more events may have been dropped after this event, when buffer became full.	
Size in event buffer:	1 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = EvntOverflow
Other fields:	none (EvtInfo is unused)

Table 23-1110. Vendor device test LMP received DEVT event (DevTstRcved)

Description	
Device event generated upon receipt of vendor device test LMP from link partner	
Size in event buffer:	3 dword
Key fields:	Event type = evt[0] = non-EP
	non-EP event type = evt[7:1] = DEVT
	device event type = evt[11:8] = DevTstRcved
Other fields:	EvtInfo = LMP's Vendor-Specific Device Test Field
	LMP's Vendor-defined data (2 dwords = 64 bits total)

23.11.4.9 USB Host Operation

The host operates in all speeds (SS, HS, FS, LS) per the standard xHCI API (see *Extensible Host Controller Interface [xHCI] for USB)*. It uses a dedicated set of programming registers (with no specific prefix, unlike the G, D, and O prefixes used for the global, device and OTG registers).

Optional xHCI features implemented by the controller are described by the memory-mapped capability descriptors, as per the standard.

23.11.4.9.1 Manual Far-end Receiver Detection in USB3 Host Mode

As per the USB3 standard (see LTSSM operation in *Universal Serial Bus 3.0 Specification*), an idle USB3 host (downstream) port must periodically check the status of its own transmitter regarding the presence of a connected receiver (far-end receiver detection a.k.a. TxDetectRx) in two cases:

- When the port is enabled (VBUS is supplied) but not connected yet, in order to check every 12 ms for a possible new connection.
- When the port is enabled, has connected, then suspended (to U3), in order to verify every 100 ms that the connection has not been broken.

Accordingly, the host controller's hardware state machine must periodically go and check the USB3 connection.

- This is not optimal because the host is constantly clocked and powered, while spending most of the time waiting. As a result, virtually all the time not spent transferring actual data will be spent in one of the two infinite loops above.
- On the other hand, note that the DRD controller is only in USB host mode if a USB peripheral device is connected to it, or at least the (A-side) cable of a USB device attached to it. By default, that is, with the connector receptacle empty, the DRD is in USB peripheral device mode.
- Also, note that the DRD is also required to drive VBUS (5V) whenever it is in USB host mode: the power spent to poll the connection status must be compared to the power spent to drive the VBUS, to decide if the optimizations described below are worth the effort. This is highly implementation-dependent.

The following low-power, software-controlled connection status polling alternative is available:

- Automatic hardware-controlled polling is disabled.
- An external, software-controller ad hoc timer is programmed for the desired polling period (12 or 100 ms).
- Whenever the timer rolls over, the software manually triggers the far-end receiver detection
- Between two detections, the USB core is placed in a low-power mode
- This continues until the connection status changes (during polling interval), or until another wakeup event occurs (at any time, as per USB protocol).

Section 23.11.4.9.1.1 through Section 23.11.4.9.1.3 describe this alternative, lower-power manual procedure in detail.

NOTE: The procedures in the subsequent sections:

- Relevant in USB host-mode only (hence the reliance on xHCI features). Unlike host mode where far-end termination on DSP repeats (and consumes power) forever, device-mode far-end termination on USP times out after 8 retries when in Rx.Detect state, and is not required at all when in U3 state: provided the adequate wakeup mechanism is in place, a USB peripheral device can eventually be placed in a low-power mode. Accordingly, the automatic detection procedure shall be active regardless when in USB device mode.
- Relevant in USB3 mode only. When operating as a USB2-only host (HS/FS/LS on the USB2 lines), far-end receiver detection (on the USB3 lines) does not apply.

23.11.4.9.1.1 Manual receiver detection enabling

Manual mode is enabled (default hardware-driven mode is disabled) by writing field USBOTGSS_GUSB3PIPECTL[22] DISRXDETU3RXDET to 1. This can be done early in the controller's initialization, for example, even before the host/device role has been determined, since the setting has no effect in the default device mode.

From that point on, and assuming no change on the USB bus, the behaviour of the hardware core's LTSSM in host mode changes as follows:

- After reaching Rx.Detect.Quiet, stay in that state indefinitely (do no receiver detection) instead of exiting after a 12 ms timeout to Rx.Detect.Active state (and do receiver detection).
- While in U3 state, never do receiver detect, instead of doing so every 100 ms with infinite retries.

The recommended method to detect a connection change in manual mode is the LTSSM state readout in register USBOTGSS_PORTSC1/2[8:5] PLS

- A disconnection is characterized by a transition out of U3 (to Rx.Detect, etc…)
- A connection by a transition out of Rx.Detect (to Polling, etc…).

The procedure is to wait the appropriate time, then read the state. If the state has changed, the controller should be allowed to proceed normally. In the opposite case (no change), the controller can return to a low-power mode. In other words, it's not the specific state that the LTSSM has gone to that is of interest, it's the fact that the state has changed at all.

Another method is to use xHCI port state change events. However, the granularity of that method is not as good as, both in terms of LTSSM state (the PORTSC) time (the interrupt can be further delayed by moderation) LTSSM state granularity xHCI programming registers do not give access to the

23.11.4.9.1.2 Manual receiver detect procedure, waiting for connection (Rx.Detect)

Once manual receiver detect has been enabled (USBOTGSS_GUSB3PIPECTL[22] DISRXDETU3RXDET = 1, see Section 23.11.4.9.1.1), the following procedure is required in USB host mode to remain USB3 compliant. On the other hand, it must not be applied in USB device mode, as the automatic receiver detect is always enabled in that mode.

Whenever entering the (default) Rx.Detect LTSSM state (from any other state), the controller proceeds as usual through Rx.Detect.Reset and enter Rx.Detect.Active. In that last state, it automatically performs the expected receiver detect, once. Note that this first detection takes place with the PIPE interface in P2 state (that is, with PIPE clock running). The following detections (below) take place in P3 (PIPE clock stopped).

If the detection succeeds (USB3 device is connected), the LTSSM proceeds to Polling state as usual. No additional intervention is required.

If the detection fails (no USB3 device connected yet), the LTSSM proceed to Rx.Detect.Quiet as usual, and stays there forever, preventing any further receiver detection. The manual procedure starts then.

- The transition to Rx.Detect.Quiet can be detected by actively polling USBOTGSS_GDBGLTSSM[25:22] LTDBLINKSTATE and [21:18] LTDBSUBSTATE. Encoding is indicated in Table 23-1114, *LTSSM State/Substate Encoding* (core_ltdb_substate[3:0]). In any case, the transition to low-power mode (below) must first ensure that all clocks are stopped, which implies that PIPE is in P3, which in turn implies that the LTSSM sub-state is Rx.Detect.Quiet.
- An always-on timer (ad hoc, located outside the current USB controller) must be set to interrupt the software every 12 ms. The first interval must be made smaller to take the first wakeup latency into account.
- The USB controller must be placed in low-power mode. Details may vary depending on the transceiver/PLL properties.
  - all interrupts/software events cleared
  - system bus initiator in standby mode
  - system bus target in idle mode
  - all clock inputs stopped (including suspend clock that would normally run the 12-ms counter)
  - logic placed in retention mode (outputs isolated, etc…)
  - PIPE interface in P3 mode with the PIPE clock stopped. The controller goes to P3 state

automatically after the first Rx detection (above) fails.

- When the timer rolls over (after 12 ms), bring the module back out of low-power mode. This includes restarting the interface and suspend clock. The PIPE interface remains in P3 (unclocked).
- Trigger the receiver detect by writing 1 to USBOTGSS_GUSB3PIPECTL[22] DISRXDETU3RXDET
- Wait for the receiver detection to take place. The delay depends on the provided suspend clock speed and on the PHY's response time.
- Poll the LTSSM state in xHCI register USBOTGSS_PORTSC1/2[8:5] PLS
- When the delay elapses (or if a connect event happens before that):
  - If the LTSSM state is still Rx.Detect, no receiver has been detected: port must return to Rx.Detect.Quiet substate. The controller can be placed back into low-power mode (see above). Procedure loops indefinitely until a receiver is detected.
  - If the LTSSM is different from Rx.Detect, a receiver has been detected: port advances to Polling state and proceed with USB3 polling as in the regular mode. Manual detection is over, and always-on 12-ms timer can be disabled and released.

The procedure above will be interrupted by any other state change on the bus, local or remote, as per xHCI: power-on reset, host mode exit, etc…

23.11.4.9.1.3 Manual receiver detect procedure, checking the connection (U3)

Once manual receiver detect has been enabled (USBOTGSS_GUSB3PIPECTL[22] DISRXDETU3RXDET = 1, see Section 23.11.4.9.1.1), the following procedure is required in USB host mode to remain USB3 compliant. On the other hand, it must not be applied in USB device mode, as the automatic receiver detect is always enabled in that mode.

A disconnection is characterized by a transition out of U3 (to Rx.Detect, etc…)

After entering the U3 LTSSM state (from U0), the controller stays there forever until a wakeup is issued by either side, and does not perform any receiver detection. The manual procedure starts there.

- The transition to U3 can be detected by actively polling USBOTGSS_PORTSC1/2[8:5] PLS. In any case, the transition to low-power mode (below) must first ensure that all clocks are stopped, which implies that PIPE is in P3, which in turn implies that the LTSSM sub-state is P3.
- An always-on timer (ad hoc, located outside the current USB controller) must be set to interrupt the software every 100 ms. The first interval must be made smaller to take the first wakeup latency into account.
- The USB controller must be placed in low-power mode. Details may vary depending on the transceiver / PLL properties.
  - all interrupts/software events cleared
  - system bus initiator in standby mode
  - system bus target in idle mode
  - all clock inputs stopped (including suspend clock that would normally run the 100 ms counter)
  - logic placed in retention mode (outputs isolated, etc…)
  - PIPE interface in P3 mode with the PIPE clock stopped, as implied by the U3 LTSSM state.
- When the timer rolls over (after 100 ms), bring the module back out of low-power mode. This includes restarting the interface and suspend clock. The PIPE interface remains in P3 (unclocked).
- Trigger the receiver detect by writing 1 to USBOTGSS_GUSB3PIPECTL[22] DISRXDETU3RXDET
- Wait for the receiver detection to take place. The delay depends on the provided suspend clock speed and on the PHY's response time.
- Poll the LTSSM state in xHCI register USBOTGSS_PORTSC1/2[8:5] PLS
- When the delay elapses (or if a connect event happens before that)
  - If the LTSSM state is still U3, the receiver is still connected. The controller can be placed back into low-power mode (see above). Procedure loops indefinitely unless the receiver connection is lost.
  - If the LTSSM is different from U3, the receiver detection has been lost: port advances to Rx.Detect state. Manual detection is over, and always-on 100 ms timer can be disabled and released.

The procedure above will be interrupted by any other state change on the bus, local or remote, as per xHCI: USB wakeup, USB reset, power-on reset, host mode exit, etc…

23.11.4.10 USB OTG Operation

USB on-the-go (OTG) operation uses a dedicated set of programming registers, prefixed with an O (the letter). It generates a number of interrupt events, all of which are routed to IRQ line USB_OTG_SS_IRQ_WRP. Unlike the device and the host's operation, the OTG does not write interrupt status events to system memory through its master interface. Instead, the status must be read out directly from internal status registers. For the complete programming model, refer to the *DWC superspeed USB3 controller databook*

23.11.4.11 Trace Export Over USB

The current section describes a method to use a (USB3) bulk IN endpoint (EP) to export a stream of trace data to a remote (USB3) host. As such, it does not describe any specific feature of the existing core, only a guaranteed method to exploit the USB device for a specific purpose.

23.11.4.11.1 Trace Export Requirements

Trace data is a stream of data generated by monitoring the activity of a processor (CPU), and to be exported to a specialized equipment for analysis. The requirements are the following:

- Minimum or no software intervention while in continuous operation. The goal of that is not only to avoid polluting the trace (as any software operation runs on the CPU, and appears on trace), but also to avoid any perturbation on the observed (and potentially troublesome) software execution.
- Data integrity is preferred. For that reason, bulk (that is, retries) is preferred to retry-less isochronous, even though it has no bandwidth reservation.
- Simultaneous operation on other endpoints. It must be possible to run functional EPs of the USB device, while transmitting trace data. This assumes that the functional operation to be preserved is USB-device mode, the only one compatible with trace export.
- Sufficient bandwidth. This depends on the MPU type and count, but typically requires USB3 speed. The same method is also valid for USB2 speeds.

The current section focuses on the bulk IN EP's continuous operation, that is, the transmission of data from the current controller to a remote host, following initial configuration. A bulk OUT EP may also be used to control trace operations, but this is outside the scope of this section.

NOTE: The present method requires the following from the system:

- A memory-mapped buffer where the trace data is available, as advertised by the TRBs, and where it can be fetched by the USB controller's DMA engine.
- A dataflow pacing mechanism to control the DMA's fetching of trace data. Without this mechanism, the infinite, instantaneous TRB recycling explained below would cause the USB controller to (try and) saturate the available USB bandwidth. This would happen regardless of the availability of actual trace data.
- A way to write-protect a block of TRBs, so that they are never updated by the DMA: this will create an automatic (without software intervention) recycling of the TRBs, since they cannot be handed over to the software driver by the DMA, and will remain hardware-owned forever. The write protection causes "silent failures" on writes, that is, writes will not change the TRB value (have no effect) but that wil not trigger an error, either. For instance, storing predetermined TRBs in a ROM will not work if write accesses to the ROM are rejected by the interconnect.

23.11.4.11.2 Trace Export Procedure

The system relies on a TRB list mapped in a read-only block, as explained in Section 23.11.4.11.1, *Trace export requirements*. The list is turned into an infinite loop by a link TRB. An example is shown in Table 23-1111, *TRB Block Example For Trace Export*:

- Three TRBs are mapped in a contiguous block.
- The first two TRBs (TRB1 and TRB2) are identical.
  - Normal TRB, chain bit set
  - TRB points at the trace data buffer (64-bit address 0x0000 0000 3300 0000)
  - Buffer has the maximum size that is a multiple of the maximum packet size (1 KiB)
- The reason there are two TRBs instead of only one is to allow the DMA's list processor to prefetch one while executing the other.
- The third and last TRB (TRB3) loops back to TRB1 (64-bit address 0x0000 0000 1234 ABC0)

For more information on the TRB data structure, see Section 23.11.4.8.1, *Device TRBs*.

Table 23-1111. TRB Block Example For Trace Export

Address	Data (32-bit)	Access	Comments
0x1234 ABC0	0x3300 0000	R	TRB1: debug-buffer pointer low
0x1234 ABC4	0x0000 0000	R	TRB1: debug-buffer pointer high
0x1234 ABC8	0x00FF FC00	R	TRB1: buffer size = 16Mbyte-1kbyte
0x1234 ABCC	0x0000 0015	R	TRB1: normal TRB, CHN=1
0x1234 ABD0	0x3300 0000	R	TRB2: debug-buffer low
0x1234 ABD4	0x0000 0000	R	TRB2: debug-buffer high
0x1234 ABD8	0x00FF FC00	R	TRB2: buffer size = 16Mbyte-1kbyte
0x1234 ABDC	0x0000 0015	R	TRB2: normal TRB, CHN=1
0x1234 ABE0	0x1234 ABC0	R	TRB3: TRB1 pointer low
0x1234 ABE4	0x0000 0000	R	TRB3: TRB1 pointer high
0x1234 ABE8	0x0000 0000	R	TRB3:
0x1234 ABEC	0x0000 0081	R	TRB3: link TRB

Initiating the trace export

1. Configure the controller in device mode (if not already done)
2. Configure a bulk IN endpoint for maximum performance: maximum packet size (1 KiB), bursting support, etc. Note that streaming is not relevant here, as there is only one stream of data.
3. Make sure no interrupt is enabled for the trace export endpoint, to prevent any software intervention during the (steady-state) transmission.
4. Configure the linked loop of TRBs as described in Section 23.11.4.11.1, *Trace export requirements*, and write-protect them against the USB controller's DMA
5. Start the transfer by linking to the first TRB of the loop.

Trace export steady-state (no software intervention)

1. Assuming that the dataflow pacing mentioned in the previous chapter is in place, the EP transmits data continuously.
2. Once a TRB is executed (that is, described trace data has been transmitted over USB), the DMA updates it by clearing the Hardware Owner (HWO) bit to 0, to hand it back to the software driver.
3. The TRB write fails silently, that is, HWO remains 1
4. When the DMA loops the TRB loop and reloads the same TRB, it is executed again, as if it had been refreshed by the software driver.

Stopping the trace export

- Done by ending the USB transfer by software. One possible method is to clear one of the HWO bits to 0, which will cause the list processor to stop when it reaches that point.

23.11.4.12 Observability Debug Interface

The USBOTGSS_DEBUG_DATA register and the 32-bit debug_data output signal (to the device debug subsystem) allow observation of a selection of signals that are not otherwise available at the system boundary (device pads). The mode is controlled by the USBOTGSS_DEBUG_CFG and USBOTGSS_GDBGLSPMUX registers. By default, the observability system is in mode 0 and all bits of USBOTGSS_DEBUG_DATA are consequently tied low (= 0).

Table below summarizes the different modes.

Table 23-1112. DEBUG_DATA observability modes summary

USBOTGSS_DEBUG_CFG[2:0] SEL	USBOTGSS_GDBGLSPMUX[21:16] TRACEPORTMUXSEL	USBOTGSS_DEBUG_DATA
0x0	don't care	all-0
0x1	don't care	UTMI signals (see table below)
0x2	don't care	PIPE signals (see table below)
0x3	don't care	CORE signals (see table below)
0x4 or 0x5	0x3F	all-0
0x4	n	Trace vector n, lower 32 bits
0x5	n	Trace vector n, upper 32 bits

Tables below contain a bit-by-bit description of modes 1, 2 and 3. The value of the trace vector visible through mode 4 and 5 may change depending on the controller core version, and are not documented here.

Table 23-1113. Configurations Of Observability Output

Table 23-1114 shows the encoding used for the link training SuperSpeed state machine (LTSSM) state (ltdb_link_state, 4 bit) and substate (ltdb_substate, 4 bit), which is available in the core observability mode as shown in Table 23-1113. The state and substate are also visible to the software in the USBOTGSS_GDBGLTSSM register. The substate can only be decoded relatively to the state (that is, all 8 bits must be decoded together). There are more substates in the current implementation than there are LTSSM substates defined by the standard (see *Universal Serial Bus Revision 3.0 Specification)*, because the implementation is finer grained than the standard. Table 23-1114 describes the relationship.

Table 23-1114. LTSSM State/Substate Encoding

core_ltdb_link_state[3:0]	core_ltdb_substate[3:0]	LTSSM State	LTSSM Substate	Implementation-Specific Substate Name	Description

The USB controller includes two USB2 media access controller (MAC) instances. Table 23-1116 describes their state. In the current single-port architecture, only one can be operational at a time.

- MAC 0 (core_u2mac_txrx_state_0[4:0]) is the FS/LS instance.
- MAC 1 (core_u2mac_txrx_state_1[4:0]) is the HS instance.

Table 23-1116. USB2 MAC State Encoding

core_u2mac_txrx_state_X[4:0](1)	USB2 MAC State	Note
0x00	IDLE	
0x01	SEND_SPLT	Host mode only

0x1	USB device

23.11.4.13 USB Frame Synchronization

Some systems may require a timing reference synchronized with the USB frames/microframes, as set by the USB host. For example, a USB data streaming application may rely on two clocks generated on either side of the USB interface (one in the USB host, the other in the USB device), and locked over the USB.

For that purpose, the controller generates two timing reference outputs

- SYNC_USOF_ITP_CLK: microframe/ITP LSbit count which toggles at every (125 us-long) HS/SS micro-frame boundary, that is, 8000 transitions per seconds or a 4-kHz square clock
- SYNC_SOF_CLK: frame LSbit count which toggles every (1 ms-long) FS/LS frame, that is, 1000 transitions per seconds or a 0.5-kHz square clock.

The USB protocol defines different bus timing reference depending on the role and speed:

- The timing master is by definition always the USB host, which broadcasts the LSKA/SOF/uSOF/ITP. The USB device, which receives those signals, is the timing slave.
- The reference can only be maintained if the device is receiving the required signals, that is, if it is not suspended (in USB2) or out of U0 (in USB3)
- In low-speed (LS, 1.5 Mbit/s), the host sends an SE0 "Low-Speed Keep-Alive" (LSKA) pulse every 1 ms (frame). Traffic stops before the frame's end and ensures that the LSKA pulse is sent at the exact time. However, note that the current controller is never a LS device (only a LS host): synchronization to the LSKA is not required.
- In full-speed (FS, 12 Mbit/s), the host sends a Start-Of-Frame (SOF) FS packet every 1 ms (frame), containing an frame number incremented by 1 each time. Traffic stops before the frame's end to ensure that the SOF FS packet is sent at the exact time.
- In high-speed (HS, 480 Mbit/s), the host sends a Start-Of-Frame (SOF) packet every 125 us

(microframe), containing a frame number. The same frame number is repeated 8 times, then incremented by 1, etc… (1 frame = 8 micro-frames). Traffic stops before the frame's end to ensure that the SOF HS packet is sent at the exact time.

- In super-speed (SS, 5 Gbit/s), the host send a Isochronous Timestamp Packet (ITP) within each 125 us microframe, containing an ITP number incremented by 1 every microframe. The ITP is not send at exact intervals, but includes a field giving the packet's delay with respect to the ideal microframe boundary. This allows the USB device to resynchronize.

NOTE:

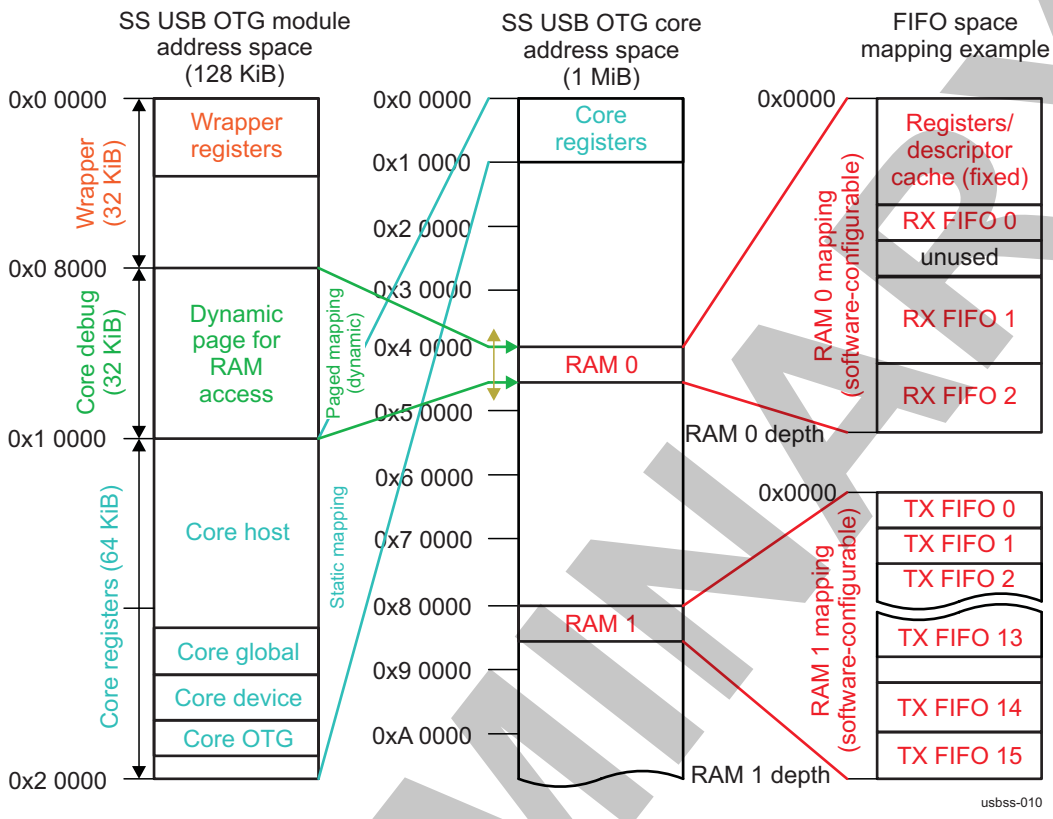
- The reference clock for the sync signals is:
  - The 125-MHz PIPE clock when in SS USB3 device mode
  - The 60-MHz UTMI/ULPI clock (USB_OTG_SS_FCLK) when in HS/FS USB2 device mode
  - The 60-MHz UTMI/ULPI clock (USB_OTG_SS_FCLK) when in host mode (any speed, including SS)
- In case of missing/corrupted SOF/ITP, the device still toggles the sync outputs, after a delay:
  - 128 ns after the expected microframe start in SS USB3 device
  - 200 ns after the expected microframe start in HS USB2 device
  - 3.5 us after the expected frame start in FS USB2 device
- In a FS device, only the frame sync (SYNC_SOF_CLK) toggles. The micro-frame sync (SYNC_USOF_ITP_CLK) is tied to 0.
- In a HS/SS device, both syncs toggle.
- The micro-frame sync SYNC_USOF_ITP_CLK is also available on the debug port (See Section 23.11.4.12, *Observability Debug Interface*).

23.11.4.14 Memory Map

The 128-KiB (17-bit address) address space of the USB SS controller module is split into three main blocks (see Figure 23-245):

- Wrapper registers: Contain the TI-specific registers, including the top-level interrupt management, power management, etc.
- Core registers (static mapping): Provide access to the core functional status and control registers.
- Core debug access (programmable, paged mapping): Provides access to the entire memory space of the core, which is much larger than the core registers. Designed to access the core buffer RAMs, remapped in memory for debug (read/write) access.

Figure 23-245. Module Vs Core Vs RAM Address Spaces And Mapping



23.11.4.14.1 Core Space Remapping

Unless otherwise specified, all offsets mentioned in this chapter are USB byte offsets of the controller module memory space or simply module offsets. However, the logic core embedded within the module also has its own memory space (with core offsets) and each FIFO can also be configured within its respective RAMs using FIFO configuration offsets.

The core space (1 MiB) is remapped within the (128 KiB) address space of the module, as shown in Figure 23-245. All functional registers of the core are located inside a single 64 KiB block and statically remapped inside the core register block of the subsystem (0x1 0000 to 0x1 FFFC). Normal operation does not require access to the rest of core's memory space.

The core memory space also contains the two internal RAM buffers (RAM0 and RAM1). The RAMs contain data and descriptor cache (read out of or written to main memory by the built-in DMA of controller) as well as some register fields (accessed by software through the core register block). The RAM content is accessed for debug purposes only and never directly during normal operation.

The data cache is composed of a number of TX and RX FIFOs mapped in RAM1 and RAM0, respectively. The mapping of each FIFO is programmable through the USBOTGSS_GTXFIFOSIZ0 through USBOTGSS_GRXFIFOSIZ15 and USBOTGSS_GRXFIFOSIZ0 through USBOTGSS_GRXFIFOSIZ2 registers by a base address/FIFO depth configuration pair. Both parameters are expressed in FIFO config physical addresses (that is, 64-bit word addresses) with the RAM base at address 0x0. Software must ensure that FIFOs are within the implemented RAM size, do not overlap each other, and do not encroach on the register/descriptor cache (lower addresses of RAM0)

The core memory space can be accessed by pages of 32 KiB each. Each of the 32 pages can be dynamically mapped to the core debug block of the module (0x0 8000 to 0x0 FFFC) by programming the USBOTGSS_MMRAM_OFFSET register. Each RAM is smaller than 32 KiB (or 4 K × 64-bit words) and fits inside a single page.

NOTE: The core registers (mapped statically) can also be accessed in paged mode, but this feature is only a side effect of paging and must not be used.

Table 23-1119 summarizes the offsets of the structures visible in the (paged) core debug block:

- Core offset column: The byte offset of the structure within the 1-Mbyte core address space
- Page offset (OFFSET_MSB) column: The 32 K page offset of the structure within the core address space, with between parentheses the value of the 5-bit register field USBOTGSS_MMRAM_OFFSET[19:15] OFFSET_MSB.
- Module offset column: Byte offset at which the structure is visible from outside the USB3 subsystem, for the page offset indicated.
- FIFO base parameters are the byte base address of the FIFO structure with respect to the RAM base. FIFO base parameters are software programmable.
- FIFO size parameters are the size of the FIFO structure in bytes. FIFO size parameters are software programmable.
- RAM base/size are the hardcoded byte base address and size in bytes of the RAM structures.
- Cache base/size are the hardcoded byte base address and size in bytes of the descriptor-cache-register-storage structures.

Table 23-1119. Address Offsets Of Memory-Mapped Structures Within Core Debug Block

Memory-Mapped Structure	Core Offset	Page Offset (OFFSET_MSB)	Module Offset
Low core registers, base	0x0 0000	0x0 0000 (0x00)	0x8000
Low core registers, top	0x0 7FFF	0x0 0000 (0x00)	0xFFFF
High core registers, base	0x0 8000	0x0 8000 (0x01)	0x8000
High core registers, top	0x0 FFFF	0x0 8000 (0x01)	0xFFFF
RAM0 base	0x4 0000	0x4 0000 (0x08)	0x8000
RAM0 top	0x4 0000 + (RAM size - 1)	0x4 0000 (0x08)	0x8000 + (RAM size - 1)
Registers/descriptor cache base	0x4 0000	0x4 0000 (0x08)	0x8000
Registers/descriptor cache top	0x4 0000 + (cache size)	0x4 0000 (0x08)	0x8000 + (cache size)
RX FIFO base	0x4 0000 + (FIFO base)	0x4 0000 (0x08)	0x8000 + (FIFO base)
RX FIFO top	0x4 0000 + (FIFO base + FIFO size - 1)	0x4 0000 (0x08)	0x8000 + (FIFO base + FIFO size - 1)
RAM1 base	0x8 0000	0x8 0000 (0x10)	0x8000
RAM1 top	0x8 0000 + (RAM size - 1)	0x8 0000 (0x10)	0x8000 + (RAM size - 1)
TX FIFO base	0x8 0000 + (FIFO base)	0x8 0000 (0x10)	0x8000 + (FIFO base)
TX FIFO top	0x8 0000 + (FIFO base + FIFO size - 1)	0x8 0000 (0x10)	0x8000 + (FIFO base + FIFO size - 1)

Table 23-1120 lists the parameters used in Table 23-1119 and how they are calculated. All values can be retrieved by software from register bitfields. When the bitfield is read-only, the parameter (for example, RAM sizes) is fixed (that is, hardwired). When the bitfield is writable, the parameter is programmable by software. The ×8 mutiplication factor is a consequence of the 64-bit RAM physical addressing.

Table 23-1120. Parameters For Memory-Mapped Structures Offset Calculation

Parameter	Register Bitfield Value (Byte Address/Size)	Type
RAM0 size	8 × USBOTGSS_GHWPARAMS6[31:16] DWC_USB3_RAM0_DEPTH	R
RAM1 size	8 × USBOTGSS_GHWPARAMS7[15:0] DWC_USB3_RAM1_DEPTH	R
Descriptor cache size (in RAM0)	8 × USBOTGSS_GHWPARAMS8[31:0] USBOTGSS_DWC_USB3_DCACHE_DEPTH_INFO	R

Table 23-1120. Parameters For Memory-Mapped Structures Offset Calculation (continued)

Parameter	Register Bitfield Value (Byte Address/Size)	Type
RX FIFO m base (in RAM0) (1)	8 × USBOTGSS_GRXFIFOSIZ0[31:16] RXFSTADDR through USBOTGSS_GRXFIFOSIZ2[31:16] RXFSTADDR	R/W
RX FIFO m size (in RAM0)(1)	8 × USBOTGSS_GRXFIFOSIZ0[15:0] RXFDEP through USBOTGSS_GRXFIFOSIZ2[15:0] RXFDEP	R/W
TX FIFO n base (in RAM1)(2)	8 × USBOTGSS_GTXFIFOSIZ0[31:16] TXFSTADDR through USBOTGSS_GTXFIFOSIZ15[31:16] TXFSTADDR	R/W
TX FIFO n size (in RAM1)(2)	8 × USBOTGSS_GTXFIFOSIZ0[15:0] TXFDEP through USBOTGSS_GTXFIFOSIZ15[15:0] TXFDEP	R/W

(1) m = 0 to 2
(2) n = 0 to 15

23.11.4.14.2 xHCI Host Mapping

The core host block is subdivided based on the *eXtensible Host Controller Interface for USB (xHCI)* specification, with subblocks mapped at specified offsets of the core host base. Table 23-1121 summarizes the offset of each block.

The constant offset primitives are:

- Host offset = 0x1 0000
- CAPLENGTH = 0x20 (readable from hardwired USBOTGSS_CAPLENGTH[7:0] CAPLENGTH register bitfield)
- RTSOFF = 0x440 (readable from hardwired USBOTGSS_RTSOFF[31:0] register)
- DBOFF = 0x480 (readable from hardwired USBOTGSS_DBOFF[31:0] register)
- xECP × 4 = 0x220 × 4 (readable from the hardwired USBOTGSS_HCCPARAMS[31:16] XECP register bitfield)

Table 23-1121. xHCI Host Register Block Offsets

Register Block Name	Block Offset Definition	Block Offset Value	Bottom Register In Block
Capability registers	Host offset	0x1 0000	USBOTGSS_CAPLENGTH
Operational registers	Host offset + CAPLENGTH	0x1 0020	USBOTGSS_USBCMD
Runtime registers	Host offset + RTSOFF	0x1 0440	USBOTGSS_MFINDEX
Doorbell registers	Host offset + DBOFF	0x1 0480	USBOTGSS_DB_j (j =0)
Extended capability registers	Host offset + (xECP × 4)	0x1 0880	USBOTGSS_USBLEGSUP

23.11.4.15 USB2PHY

The device-embedded USB2.0 physical layer (USB2PHY) contains the USB functions, drivers, receivers, and pads for correct D+/D– signaling, and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable [pin usbphy_ce]) to control an external battery charger. It also contains LDO and bandgap to provide voltage reference.

The embedded PHY does not support the OTG features of USB-OTG standards (that is, ID pin detection and VBUS detection). This function is exported to an external companion chip (for example, the TWL6035). See details in Section 23.11.4.5.1, *Mailbox VBUS/ID Management*

The following USB2PHY signal is routed internally to the GPIO module pin to generate interrupts when any of the following events occur:

- CHGDETECTED: This signal indicates the output of the charger detection protocol.

  0: Charger not detected

  1: Charger detected

  The value is latched until the charger protocol is reset.

For information about how to enable this interrupt, see Section 25.1, *General-Purpose Interface*.

23.11.5 USBOTGSS Register Manual

23.11.5.1 USBOTGSS Instance Summary

Table 23-1122. USBSS Instance Summary

Module Name	Module Base Address	Size
USBOTGSS_WRAPPER	0x4A02 0000	64 KiB
DWC_USB3	0x4A03 0000	64 KiB
USB2PHY	0x4A08 4000	124 Bytes

NOTE: For OCP2SCP1, see the OCP2SCP1 register manual in Chapter 27, *Shared PHY Component Subsystems*.

23.11.5.2 DWC_USB3 registers

23.11.5.2.1 DWC_USB3 Register Summary

Table 23-1123. DWC_USB3 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
USBOTGSS_CAPLENGTH	R	32	0x0000 0000	0x4A03 0000

It is only used for SuperSpeed.	RW	0
28	RESERVED		R	0
27:24	USBRXPKTCNT	USB Receive Packet Count: Number of packets that must be available in the RX FIFO before the core can start the corresponding USB RX transaction (burst). Don't care if USBRXPKTCNTSEL=0. 0xF: Maximum value 0x0: Use when and only when disabled (USBRXPKTCNTSEL=0) 0x1: Minimum value (when enabled)	RW	0x0
23:19	USBMAXRXBURSTSIZE	USB Maximum Receive Burst Size. Maxi IN burst size, when USBRXPKTCNTSEL = 1. When the system bus is slower than the USB, RX FIFO can overrun during a long burst. User can program a smaller value to this field to limit the RX burst size that the core can do. Only applies to SS Bulk / Iso / Int IN endpoints in host mode. Don't care if USBRXPKTCNTSEL=0. 0x0: Use when and only when disabled (USBRXPKTCNTSEL=0) 0x1: Burst of up to 1 (minimum value when enabled) 0x10: Burst of up to 16 (maximum value)	RW	0x00
18:16	RESERVED		R	0x0
15	RESERVED	Always write 0, result of writing of a non-zero value is undetermined.	RW	0
14:11	RESERVED		R	0x0
10:0	RESERVED	Always write 0, result of writing of a non-zero value is undetermined.	RW	0x000

Table 23-1218. USBOTGSS_GCTL

Address Offset	0x0000 C110		
Physical Address	0x4A03 C110	**Instance**	DWC_USB3
Description	Global control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PWRDNSCALE													MASTERFILTBYPASS	BYPSSETADDR	U2RSTECN	FRMSCLDWN		PRTCAPDIR		CORESOFTRESET	RESERVED		DEBUGATTACH	RAMCLKSEL		SCALEDOWN		DISSCRAMBLE	RESERVED		DSBLCLKGTNG

Bits	Field Name	Description	Type	Reset
31:19	PWRDNSCALE	Power Down Scale: In P3 state, pipe clock stops and is replaced internally by the suspend clock to create a 16kHz reference. Set field to Fs/16k, rounded up, with Fp suspend clock frequency. Required accuracy is 0-50% 0x2: 32kHz suspend clock (minimum frequency) 0x960: 38.4 MHz suspend clock 0x2EE: 12 MHz suspend clock 0x5DC: 24 MHz suspend clock 0x4B0: 19.2 MHz suspend clock 0x32D: 13 MHz suspend clock 0x659: 26 MHz suspend clock 0x1E85: 125 MHz suspend clock	RW	0x04B0
18	MASTERFILTBYPASS	Master Filter Bypass. Bypasses the double-synchronizers and the 5 ms debounce filters on UTMI+ inputs (the latter are not implemented).	RW	0
17	BYPSSETADDR	Override of the device address, bypassing the SET ADDRESS control transfer. For simulation only. 0x0: Functional mode 0x1: Device's address set directly to USBOTGSS_DCFG[9:3] DEVADDR	RW	0
16	U2RSTECN	If the super speed connection fails during POLL or LMP exchange, the device connects at non-SS mode. If this bit is set, then device attempts three more times to connect at SS, even if it previously failed to operate in SS mode.	RW	0
15:14	FRMSCLDWN	Frame scale-down This field scales down device view of a SOF (FS/LS) / uSOF (HS) / ITP (SS) duration. 0x0: SS/HS interval=125 us, FS interval=1ms (standard) 0x1: SS/HS interval=62.5 us, FS interval=0.5ms 0x3: SS/HS interval=15.625 us, FS interval=0.125ms 0x2: SS/HS interval=31.25 us, FS interval=0.25ms	RW	0x0
13:12	PRTCAPDIR	Port Capability Direction 0x1: Core acts as DRD in host mode 0x3: Core acts as OTG DRD, with the mode set by the ID 0x2: Core acts as DRD in device mode	RW	0x3

Bits	Field Name	Description	Type	Reset
11	CORESOFTRESET	Core Soft Reset. When you reset PHYs (using USBOTGSS_GUSB2PHYCFG or USBOTGSS_GUSB3PIPECTL registers), you must keep the core in reset state until PHY clocks are stable. 0x0: No soft reset 0x1: Soft reset to core	RW	0
10:9	RESERVED		R	0x0
8	DEBUGATTACH	Debug Attach. When this bit is set: a) SS Link proceeds directly to the Polling link state (after RUN/STOP in the USBOTGSS_DCTL register is asserted) without checking remote termination. b) Link LFPS polling timeout is infinite c) Polling timeout during TS1 is infinite (in case link is waiting for TXEQ to finish).	RW	0
7:6	RAMCLKSEL	RAM Clock Select. No action, hardware always uses bus clock (config 2'b00) 0x0: AXI bus clock 0x1: PIPE clock 0x3: MAC clock (125 MHz) 0x2: PIPE/2 clock	RW	0x0
5:4	SCALEDOWN	Scale-Down Mode Enable Switches to shorter, non-standard protocol time intervals to speed up simulation. DO NOT MODIFY ON ACTUAL HARDWARE. 0x0: Disable scale-downs. Legal USB timing values are used. Always use on actual hardware. 0x1: Enables scaled down values of : - HS/FS/LS: all except Device-mode suspend and resume. - SS: Number of TxEq training sequences reduce to 8 - SS: LFPS polling burst time reduce to 100 ns - SS: LFPS warm reset receive reduce to 30 us - SS: more ... 0x3: SS/HS/FS/LS: scale down all the above 0x2: HS/FS/LS: scale-down of Device-mode suspend and resume. SS: No TxEq training sequences are sent.	RW	0x0
3	DISSCRAMBLE	Disable Scrambling. Transmit request to Link Partner on next transition to Recovery or Polling.	RW	0
2:1	RESERVED		R	0x0
0	DSBLCLKGTNG	Disable Clock Gating. When this bit is set to 1 and the core is in Low Power mode, internal clock gating is disabled.	RW	0

Description	Global user control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED										NOEXTRDL	PSQEXTRRESSP			SPRSCTRLTRANSEN	RESBWHSEPS	CMDEVADDR	USBHSTINAUTORETRYEN	RESERVED			DTCT			DTFT								

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		RW	0x000
21	NOEXTRDL	No Extra Delay between SOF and the 1st packet (when host) 0x0: 2 us delay between SOF and first packet. Some bandwith is lost. 0x1: No extra delay. May cause some devices to misbehave.	RW	0
20:18	PSQEXTRRESSP	Protocol Status Queue Extra Reserved Space (Debug only). Additional space in the PSQ reserved before the USB3 protocl transaction layer (U3PTL) initiates a new USB transaction and burst beats. 0x0: 0x1:	RW	0x0
17	SPRSCTRLTRANSEN	Sparse Control Transaction Enable. Valid in host mode only (any speed). 0x0: Feature disabled, no limitation on control transactions 0x1: Host controller schedules transactions for Control transfer in different [micro]frames to prevent incorrect behaviour from device.	RW	0
16	RESBWHSEPS	Reserving (more) Bandwidth for HS Periodic EPs. Valid in host mode only. 0x0: HC reserves 80% of the bandwidth for periodic EPs 0x1: HC reserves 85% of the bandwidth for periodic EPs, which allows 2 high speed, high bandwidth ISOC EPs.	RW	0

Bits	Field Name	Description	Type	Reset
15	CMDEVADDR	Compliance Mode for Device Address. Valid in host mode only. 0x0: Device Address is equal to Slot ID. 0x1: Increment Device Address on each Address Device command. Slot ID may have different value than Device Address if max_slot_enabled < 128.	RW	1
14	USBHSTINAUTORETRYEN	Host IN Auto Retry Enable: host core behaviour upon data packet CRC errors or internal overrun scenarios in non-isochronous IN transfers. 0x0: Auto Retry Disabled: Host core to reply with a terminating retry ACK (Retry=1 and NumP=0) 0x1: Auto Retry Enabled: Host core to reply with a non-terminating retry ACK (Retry=1 and NumP!=0)	RW	0
13:11	RESERVED		RW	0x0
10:9	DTCT	Device Timeout Coarse Tuning: time the host waits for a response from device before timeout. Coarse setting. 0x0: Use DTFT instead 0x1: 500 us 0x3: 6.5 ms 0x2: 1.5 ms	RW	0x0
8:0	DTFT	Device Timeout Fine Tuning: time the host waits for a response from device before timeout. Fine setting. Timer runs on the 125 MHz clock (8 ns period), timeout is DTFT × 256 × 8 ns ~= DTFT × 2 us Don't care unless DTCT=0 0x1: ~ 2 us timeout (2,048 ns) 0x7D: 256 us timeout (maximum, exact value) 0x32: ~ 100 us timeout (102,400 ns) 0x5: ~ 10 us timeout (10,240 ns)	RW	0x010

17	ULPIEXTVBUSDRV	ULPI External VBUS Drive Selects supply source to drive 5V on VBUS, in the ULPI PHY. 0x0: PHY drives VBUS with internal charge pump 0x1: PHY drives VBUS with an external supply.	RW	0
16	ULPICLKSUSM	Sets the ClockSuspendM bit in the Interface Control register on the ULPI PHY. Applicable only in serial FS/LS or Carkit modes. NOT APPLICABLE	RW	0
15	ULPIAUTORES	ULPI Auto Resume. Sets the AutoResume bit in Interface Control register on the ULPI PHY. 0x0: PHY does not use the AutoResume feature. 0x1: PHY uses the AutoResume feature.	RW	0
14	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
13:10	USBTRDTIM	USB 2.0 Turnaround Time, in PHY clock cycles. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM).	RW	0x9
9	RESERVED		R	0
8	ENBLSLPM	Enable UTMI Sleep. Controls assertion of utmi_sleep_n, utmi_l1_suspend_n outputs to the PHY when in the L1 state. 0x0: utmi_sleep_n, utmi_l1_suspend_n assertion from the core not transferred to the external PHY. 0x1: utmi_sleep_n, utmi_l1_suspend_n assertion from the core transferred to the external PHY.	RW	1
7	PHYSEL	PHY Select. (HS vs. serial): Unused, since serial PHY is not supported.	R	0
6	SUSPHY	Suspend enable for USB2.0 HS/FS/LS PHY (ULPI or UTMI). Set to 1 only after core initialization is complete. 0x0: USB2.0 PHY not placed in Suspend mode 0x1: USB2.0 PHY enters Suspend mode if port is suspended or unused.	RW	0
5	FSINTF	Full-Speed Serial Interface Select. UNUSED.	R	0
4	ULPI_UTMI_SEL	ULPI or UTMI+ Select 0x0: UTMI+ Interface 0x1: ULPI Interface	RW	0
3	PHYIF	PHY Interface. DO NOT USE. If UTMI+ is selected, configures 8- or 16-bit interface. If ULPI is selected, configures SDR or DDR mode. 0x0: 8-bit UTMI @60 MHz / SDR (12-pin) ULPI 0x1: 16-bit UTMI @30 MHz, not supported / DDR (8-pin) ULPI, not supported	RW	0
2:0	TOUTCAL	HS/FS Timeout Calibration. The number of PHY clocks, as indicated by the application in this field, is multiplied by a bit-time factor; this factor is added to the high-speed/full-speed interpacket timeout duration in the core to account for additional delays introduced by the PHY. This may be required, since the delay introduced by the PHY in generating the linestate condition may vary among PHYs. The USB standard timeout value for high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of connection. The number of bit times added per PHY clock are: High-speed operation: 8 bit times per 60-MHz PHY clock cycle Full-speed operation: (depending on clock speed) 0.2 bit times per 60-MHz PHY clock cycle 0.25 bit times per 48-MHz PHY clock cycle	RW	0x0

Bits	Field Name	Description	Type	Reset
31	PHYSOFTRST	PHY Soft Reset. Active-high, fully static software reset for PIPE USB3 transceiver. 0x0: Reset inactive. 0x1: Reset active.	RW	0
30:28	RESERVED		RW	0x0
27	UX_EXIT_IN_PX	Workaround for SS PHY injecting a glitch on RxElecIdle while receiving Ux exit LFPS, and PowerDown change is in progress. 0x0: U1/U2/U3 exit done in PHY power state P0 0x1: U1/U2/U3 exit done in PHY power state P1/P2/P3 respectively	RW	0
26	PING_ENHANCEMENT_EN	Ping Enhancement Enable: Extended downstream port U1 ping receive timeout. Invalid for Upstream port. 0x0: U1 ping rx timeout is 300 ms (default) 0x1: U1 ping rx timeout extended to 500 ms	RW	0
25	U1U2EXITFAIL_TO_RECOV	Enhancement to prevent interoperability issue in case of incorrect LFPS handshake by the remote link. 0x0: LTSSM goes to SS Inactive when U1/U2 LFPS handshake fails (default) 0x1: LTSSM goes to Recovery when U1/U2 LFPS handshake fails, and to SS.Inactive only if recovery fails.	RW	0
24	REQUEST_P1P2P3	Control the systematic request of P1/P2/P3 for U1/U2/U3 0x0: No P1/P2/P3 change request upon immediate Ux exit (remotely or locally initiated) 0x1: Always request transition from P0 to P1/P2/P3 on PHY during transition from U0 to U1/U2/U3 on USB.	RW	0
23	STARTRXDETU3RXDET	Manual control for periodic Rx detection required in U3 and Rx.Detect, host mode. Write 0x0: No action Write 0x1: Trigger immediate Rx detection on transmitter.	RW	0
22	DISRXDETU3RXDET	Disable the HW-scheduled periodic Rx detection required in U3 and SS.Disabled, for host mode. 0x0: Rx detection is HW-scheduled every 12/100 ms when in SS.Disabled / U3 LTSSM state, respectively. This requires the suspend clock to run permanently. 0x1: HW-scheduled Rx detection is disabled, and must be SW-controlled using DoRxDetect.	RW	0
21:19	P1P2P3DELAY	If DelayP0toP1P2P3=1, delays the transition to P1/P2/P3 when entering U1/U2/U3 until P1P2P3Delay*8b10b errors occur, or RxValid=0 on PIPE.	RW	0x0

Bits	Field Name	Description	Type	Reset
18	DELAYP0TOP1P2P3	Delay PHY change from P0 to P1/P2/P3 when link state changes from U0 to U1/U2/U3, respectively. 0x0: When entering U1/U2/U3, transition to P1/P2/P3 without checking RxElecIlde, RxValid on PIPE. 0x1: When entering U1/U2/U3, delay the transition to P1/P2/P3 until RxElecIlde=1, RxValid=0 on PIPE	RW	1
17	SUSPENDENABLE	Suspend Enable for USB3.0 SS PHY. Set to 1 only after core initialization is complete. 0x0: USB3.0 PHY not placed in Suspend mode 0x1: USB 3.0 PHY enters Suspend mode when conditions are valid.	RW	0
16:15	DATWIDTH	PIPE Data Width (input from phy: refer to PIPE standard) Field updated to the input's value immediately after reset. Read 0x2: PIPE data is 8 bit @500 MHz Read 0x1: PIPE data is 16 bit @250 MHz Read 0x0: PIPE data is 32 bit @125 MHz	R	0x0
14	ABORTRXDETINU2	Abort Rx Detect in U2. For Downstream port only. 0x0: Receiver detection not aborted 0x1: When in U2, receiver detection will be aborted if U2 exit LFPS is received.	RW	0
13	SKIPRXDET	Skip Rx Detect. When set, the core skips Rx Detection if PIPE signal "RxElecIdle" is low. Skip is defined as waiting for the appropriate timeout, then repeating the operation.	RW	0
12	LFPSP0ALGN	LFPS P0 Align. When set to 1: - The core deasserts LFPS transmission on the clock edge that it requests PHY power state 0 when exiting U1, U2, or U3 low power states. Otherwise, LFPS transmission is asserted one clock earlier. - The core requests symbol transmission two pipe_rx_pclks periods after the PHY asserts PhyStatus as a result of the PHY switching from P1 or P2 state to P0 state. 0x0: Default 0x1: DO NOT USE	RW	0
11	P3P2TRANOK	P3-to-P2 Transitions OK 0x0: P0 is always entered as an intermediate state during transitions between P2 and P3, as defined in the PIPE specification. 0x1: Core transitions directly from PHY power state P2 to P3 or from state P3 to P2. Illegal as per PIPE, use only if PHY cannot do LFPS in P3.	RW	0
10	P3EXSIGP2	PHY power state behaviour upon U3 exit handshake. 0x0: Default behaviour 0x1: Go to P2 before attempting a U3 exit handshake.	RW	0
9	LFPSFILT	LFPS Filter. When set, filter LFPS reception with PIPE "RxValid" signal in PHY power state P0, that is, ignore LFPS reception from the PHY unless both PIPE signals "RxElecIdle" and "RxValid" are deasserted.	RW	0
8:7	RESERVED		R	0x0
6	TXSWING	Tx Swing (output to PHY: refer to PIPE standard)	RW	0
5:3	TXMARGIN	Tx Margin[2:0] (output to PHY: refer to PIPE standard)	RW	0x0
2:1	TXDEEMPHASIS	Tx Deemphasis (output to PHY: refer to PIPE standard) The value driven to the PHY is controlled by the LTSSM during USB3 Compliance mode.	RW	0x1

Bits	Field Name	Description	Type	Reset
0	ELASTICBUFFERMODE	Elastic Buffer Mode (output to PHY: refer to PIPE standard)	RW	0

Table 23-1330. USBOTGSS_DCFG

Address Offset	0x0000 C700		
Physical Address	0x4A03 C700	**Instance**	DWC_USB3
Description	Device configuration: Configures the core in device mode after power-on or after certain control commands or enumeration. Does not change after initial programming.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								IGNORESTREAMPP	LPMCAP	NUMP						INTRNUM					PERFRINT	DEVADDR								DEVSPD	

Bits	Field Name	Description	Type	Reset
31:24	RESERVED		RW	0x00
23	IGNORESTREAMPP	Ignore Packet-Pending for Stream management. From stream-capable bulk endpoints only. 0x0: When Data Packet is received with PP=0 (OUT EP) or ACK is received with NumP=0 and PP=0 (IN EP), search another stream (CStream) to initiate to the host. This is non-optimal a) When host sets PP=0 even though it has not finished with the stream, and b) if the EP is configured with one transfer resource i.e. can't initiate another stream. 0x1: PP is ignored for stream selection, no another stream is searched when DP is received with (PP=0) or ACK with (NumP=0, PP=0), to enhance performance if system bus bandwidth is low or host responds to ERDY quickly.	RW	0

Bits	Field Name	Description	Type	Reset
22	LPMCAP	Link Power Management (LPM) Capability. 0x0: not LPM capable: device cannot respond to LPM transactions. 0x1: LPM capable: device shall respond to LPM transactions.	RW	0
21:17	NUMP	Number of Receive Buffers. Indicates number of receive buffers to be reported in ACK TP. Value based on RxFIFO size, buffer sizes programmed in descriptors, and system latency.	RW	0x04
16:12	INTRNUM	Interrupt Number. Interrupt/EventQ number on which non-endpoint-specific device related interrupts (see DEVT) are generated.	RW	0x00
11:10	PERFRINT	Periodic Frame Interrupt. Time within a (micro)frame when the application must be notified using the End Of Periodic Frame Interrupt, which can be used to determine if all the periodic (isochronous, interrupt) traffic for that (micro)frame is complete. 0x0: 80% of the (micro)frame interval 0x1: 85% of the (micro)frame interval 0x3: 95% of the (micro)frame interval 0x2: 90% of the (micro)frame interval	RW	0x2
9:3	DEVADDR	Device Address. Configure upon set-address USB command, clear to 0 upon USB reset. 0x0: Default address for unenumerated device.	RW	0x00
2:0	DEVSPD	Device Speed: USB speed at which the core should connect. Actual bus speed is determined only after chirp completion, based on the speed of the attached USB host. 0x0: High Speed (HS): 480 Mbit/s 0x1: Full Speed (FS): 12 Mbit/s 0x3: Full Speed (FS): 12 Mbit/s on serial PHY: NOT SUPPORTED 0x4: Super Speed (SS): 5 Gbit/s 0x2: Low Speed (LS): 1.5 Mbit/s on serial PHY: NOT SUPPORTED	RW	0x0

Bits	Field Name	Description	Type	Reset
31	RUNSTOP	Run/Stop 0x0: Stop USB device controller operation and signal disconnect to attached host. Clear only after all active transfers have been removed. For USB 3.0 disconnection, proceed by changing the target state to RX_DET. USBOTGSS_DSTS[22] DEVCTRLHLT is set once disconect is complete and core is idle. 0x1: Start USB device controller operation, after programming the device CSR. Controller will not signal connect to the attached host until the bit is set.	RW	0
30	CSFTRST	Core Soft Reset. Auto-cleared. The reset has the following effect: - Interrupts are cleared. - Registers are cleared except: USBOTGSS_GSTS, USBOTGSS_GSNPSID, USBOTGSS_GGPIO, USBOTGSS_GUID, USBOTGSS_GUSB2PHYCFG, USBOTGSS_GUSB3PIPECTL, USBOTGSS_DCFG, USBOTGSS_DCTL, USBOTGSS_DEVTEN, USBOTGSS_DSTS. TxFIFOs and RxFIFO are flushed. - State machines are reset to the idle state, except the device slave. - Transactions on the device bus Master are terminated after completion. - Transactions on the USB are terminated immediately. Write 0x1: Start reset (self-clearing) Read 0x1: Reset ongoing Read 0x0: No ongoing reset, reset complete.	RW	0
29	RESERVED		R	0
28	HIRDTHRES_4	Host Initiated Resume Duration (HIRD) Threshold, MSbit: See HIRDTHRES_TIME	RW	0
27:24	HIRDTHRES_TIME	Host Initiated Resume Duration (HIRD) Threshold, LSBits = timeout value. utmi_l1_suspend_n is asserted in L1 when : (HIRD value >= HIRDTHRES_TIME) and (HIRDTHRES_4=1) utmi_sleep_n is asserted in L1 when : (HIRD value < HIRDTHRES_TIME) or (HIRDTHRES_4=0) 0x6: 510 us 0x1: 135 us 0xA: 810 us 0x7: 585 us 0x0: 60 us 0x2: 210 us 0x8: 660 us 0x9: 735 us 0xB: 885 us 0x4: 360 us 0x5: 435 us 0xC: 960 us (maximum: higher values are invalid) 0x3: 285 us	RW	0x0
23	APPL1RES	LPM Response Programmed by Application: Handshake response made to LPM token. Note that if USBOTGSS_DCFG[22] LPMCAP = 0, the response is always timeout (no response). 0x0: NYET handshake to correct LPM transaction if data is pending in Tx FIFO or if OUT (Rx) endpoints are in flow controlled state. 0x1: Core shall ACK correct LPM transaction regardless of Tx FIFO status and OUT (Rx) endpoint flow control.	RW	0

Bits	Field Name	Description	Type	Reset
22:20	RESERVED		R	0x0
19	KEEPCONNECT	Used for Save-and-Restore operation. DO NOT USE, SAR NOT IMPLEMENTED 0x0: 0x1: Prevents device disconnection when RUNSTOP is cleared to 0. Enables the "Hibernation Request Event" when the link goes to U3/L2. Prevents LTSSM from automatically going to U0/L0 when host requests resume from U3/L2.	RW	0
18	L1HIBERNATIONEN	DO NOT USE, SAR NOT IMPLEMENTED	RW	0
17	CRS	Controller Restore State. DO NOT USE, SAR NOT IMPLEMENTED Write 0x0: Initiate restore process, sets USBOTGSS_DSTS[25] RSS to 1 Write 0x1:	RW	0
16	CSS	Controller Save State. DO NOT USE, SAR NOT IMPLEMENTED Write 0x0: Initiate save process, sets USBOTGSS_DSTS[24] SSS to 1 Write 0x1:	RW	0
15:13	RESERVED		R	0x0
12	INITU2ENA	Initiate U2 Enable. Cleared to 0 by USB reset. 0x0: May not initiate U2 0x1: May initiate U2	RW	0
11	ACCEPTU2ENA	Accept U2 Enable. Cleared to 0 by USB reset. 0x0: Reject U2 except when Force_LinkPM_Accept bit is set 0x1: Accept transition to U2 state if nothing is pending on the application side	RW	0
10	INITU1ENA	Initiate U1 Enable. Cleared to 0 by USB reset. 0x0: May not initiate U1 0x1: May initiate U1	RW	0
9	ACCEPTU1ENA	Accept U1 Enable. Cleared to 0 by USB reset. 0x0: Reject U1 except when Force_LinkPM_Accept bit is set 0x1: Accept transition to U1 state if nothing is pending on the application side.	RW	0
8:5	ULSTCHNGREQ	USB/Link State Change Request. A new request is indicated by a change of value. To issue the same request back-to-back, a 0 shall be written between the two requests. State change request result is reflected in USBOTGSS_DSTS. 0x6: SS: SS.Inactive 0x8: SS: Recovery HS/FS/LS: Remote wakeup request. Issue only when device is in early suspend or suspend state 0x5: SS: Rx.Detect 0xA: SS: Compliance 0xB: SS: Loopback 0x0: No action 0x4: SS: SS.Disabled	RW	0x0

Table 23-1340. USBOTGSS_DGCMD

Address Offset	0x0000 C714		
Physical Address	0x4A03 C714	**Instance**	DWC_USB3
Description	Device generic command: Generic command interface to send link management packets and notifications.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CMDSTATUS	RESERVED				CMDACT	RESERVED	CMDIOC	CMDTYP							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15	CMDSTATUS	Command Status. Read 0x1: CmdErr: Error while processing the command. Read 0x0: No error	R	0
14:11	RESERVED		R	0x0
10	CMDACT	Command active. Auto-cleared. Write 0x1: Start generic command execution (self-clearing) Read 0x1: Command active (ongoing) Read 0x0: No ongoing command, command complete.	RW	0
9	RESERVED		R	0
8	CMDIOC	Command Interrupt On Complete. Event mapped to interrupt number USBOTGSS_DCFG[16:12] INTNUM. Reads return 0. Write 0x1: Generic Command Completion event to be issued after executing the command.	W	0

Bits	Field Name	Description	Type	Reset
7:0	CMDTYP	Command Type. Reads return 0. Write 0xC: Set Endpoint NRDY: Makes the core think that the given endpoint is in an NRDY state. If buffers are available in that endpoint, an ERDY is immediately transmitted. Parameter[4:0] = Physical Endpoint Number Write 0x3: Transmit Function Wake Device Notification (Notification-only in SuperSpeed) Parameter[7:0] - Interface Number (IntfNum) that caused remote wakeup Write 0x6: Transmit Function Host Role Request Device Notification (Notification-only in SuperSpeed) Parameter[1:0] = RSP Phase (Notification Type Specific) is INITIATE (2'b01) or CONFIRM (2'b10). Write 0xA: All FIFO Flush. (No parameter) Write 0x2: Set Periodic Parameters Parameter[9:0] (SystemExitLatency): Set value programmed by the host through the Set SEL device request, in microseconds. The Set SEL control transfer has 6 bytes of data and contains 4 values; Refer to the USB 3.0 spec, Section 9.4.12. Offset / Name / Meaning: 0 U1SEL Time in us for U1 System Exit Latency 1 U1PEL Time in us for U1 Device to Host Exit Latency 2 U2SEL Time in us for U2 System Exit Latency 4 U2PEL Time in us for U2 Device to Host Exit Latency If the device is enabled for U1 and U2, then the U2PEL should be programmed. If the device is enabled only for U1, then U1PEL should be programmed into this parameter. If the value is greater than 125 us, then the software must program a value of zero into this register. Write 0x1: Transmit Set Link Function LPM. (Reserved in non-SuperSpeed operations) Parameter[0] = [Force_LinkPM_Accept] (0: De-assert 1: Assert) Write 0x9: Selected FIFO Flush Parameter[4:0] = FIFO Number Paramer[5] = TX FIFO (1) or RX FIFO (0) Write 0x10: Run device Bus LoopBack Test: Issue this command first, then the Start Transfer command to EP 0 and 1. Configure EP0 as OUT and EP1 as IN. The core reads data from the IN buffers and writes it back to OUT buffers. The IN and OUT must have an equal amount of data buffer. The endpoint 1 Tx-FIFO default value of (512/8)+2 = 66 should be changed to (1024/8)+2 = 130 for loopback mode. Parameter[0] = enable (1) and disable (0) Loopback mode.	W	0x00

30:25	RESERVED		R	0x00
24	OTGCONIDSTSCHNGEVNT	Connector ID status change event. Set in both A-device and B-device mode. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
23	HRRCONFNOTIFEVNT	Host Role Request Confirm Notifier Event. Set upon reception of HRR Device Notification TP with Confirm field set. Set in OTG3, SS, A-host or B-host mode only. OTG3: NOT IMPLEMENTED Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
22	HRRINITNOTIFEVNT	Host Role Request Initiate Notifier Event. Set upon reception of HRR Device Notification TP with Initiate field set. Set in OTG3, SS, A-host or B-host mode only. OTG3: NOT IMPLEMENTED Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
21	OTGADEVIDLEEVNT	A-device A-IDLE Event. Set when OTG FSM enters A-IDLE state from any other state. Set in A-device mode only. OTG3: NOT IMPLEMENTED Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
20	OTGADEVBHOSTENDEVNT	A-device B-host End Event. Set when connected B-device has completed its B-host role and returns to B-peripheral. Set in A-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
19	OTGADEVHOSTEVNT	A-device Host Event. Set when device enters host role, upon initial connect to B-device as well as upon HNP from A-peripheral to A-host. Set in A-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
18	OTGADEVHNPCHNGDETEVNT	A-device HNP change Detected Event. Set when there is an HNP event. Set in A-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
17	OTGADEVSRPDETEVNT	A-device SRP Detected Event. Set when SRP request from B-device is detected. Set in A-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
16	OTGADEVSESSENDDETEVNT	A-device Session End Detected Event. Set when UTMI input "a-vbus-valid" is deasserted (0). Set in A-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
15:12	RESERVED		R	0x0
11	OTGBDEVHOSTENDEVNT	B-device Host End Event. Set completing B-host role and returning to default B-peripheral role. Set in B-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
10	OTGBDEVHNPCHNGEVNT	B-device HNP Change Event. Set upon (success of failure of an) HNP attempt. Set in B-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
9	OTGBDEVSESSVLDDETEVNT	B-device Session Valid Detected Event. Set when B-device succeeds in starting a session. Set in B-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
8	OTGBDEVVBUSCHNGEVNT	B-device VBUS Change Event. Set when UTMI input "b-session-valid" transitions (to 0 or 1). Set in B-device mode only. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0
7:4	RESERVED		R	0x0
3	BSESVLD	B-Session Valid. Updated when OTGBDevVBUSChngEvnt is set. Read 0x1: B-session is valid on VBUS Read 0x0: B-session is not valid on VBUS	R	0
2	HSTNEGSTS	Host Negociation Status. Updated when OTGADevHNPChngEvnt or OTGBDevHNPChngEvnt is set. Read 0x1: Host negotiation success. Read 0x0: Host negotiation failure. In A-device, indicates imminent end of session indication from core. In B-device, it indicates that the timer used to wait for an A-device to signal a connection (b_ase0_brst_tmout) timed out resulting in B-device staying as B-peripheral.	R	0
1	SESREQSTS	Session Request Status. Updated when OTGBDevSessVldDetEvnt is set. Read 0x1: Session started as a result of successful SRP. Read 0x0: Session not started as a result of SRP.	R	0
0	OEVTERROR	No errors currently defined. Write 0x0: No action Write 0x1: Clear the event Read 0x1: Event was set by core Read 0x0: Event was not set	RW W1toClr	0

Description	Controls various parameters of the master and slave interfaces.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED														WRAPRESET	DMADISABLE	RESERVED								STANDBYMODE		IDLEMODE		RESERVED			

Bits	Field Name	Description	Type	Reset
31:18	RESERVED		R	0x0000
17	WRAPRESET	Software reset for the USBOTGSS_WRAPPER register set. Self-clearing. Does not affect the core register set. Write 0x0: No action Write 0x1: Request wrapper reset Read 0x1: Wrapper reset is ongoing Read 0x0: Wrapper reset is done / inactive	RW	0

Bits	Field Name	Description	Type	Reset
16	DMADISABLE	Disable/Enable control of the DMA master (initiator) to block read/write accesses. Bit is auto-cleared (to 0) by HW in case of outgoing access, but must be set (to 1) manually. Write 0x0: Enable the DMA. The enabling can also be done by the hardware, i.e. bit it auto-cleared. Write 0x1: Disable the DMA. software must ensure that there are no ongoing transactions before setting this bit. The disabling can only be done by software. Read 0x1: DMA is disabled, outgoing read/write accesses are blocked. When in smart-standby mode, standby is requested. Read 0x0: DMA is enabled, outgoing read/write accesses are possible. When in smart-standby mode, standby exit is requested.	RW	1
15:6	RESERVED		R	0x000
5:4	STANDBYMODE	PM mode of local initiator (master). Initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby: initiator is unconditionally placed in standby state. 0x1: No-standby: initiator is unconditionally placed out of standby state. 0x3: Smart-Standby, wakeup-capable: initiator's standby state depends on internal conditions, i.e. the module's functional requirements. Asynchronous wakeup events can be generated. 0x2: Smart-standby: initiator's standby state depends on internal conditions, i.e. the module's functional requirements. Asynchronous wakeup events cannot be generated.	RW	0x2
3:2	IDLEMODE	PM mode of local target (slave). Target shall be capable of handling read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, regardless of the IP module's internal requirements. 0x1: No-idle mode: local target never enters idle state. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
1:0	RESERVED		R	0x0

23.11.5.4 USB2PHY Registers

CAUTION

The USB2PHY registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

Reserved bit fields must not be modified.

NOTE: No USB2PHY register settings need to be done in order USB2PHY to operate in default USB2.0 (HS, FS, or LS mode) condition. Registers are provided only for debug purposes.

23.12 SATA Controller

This chapter describes the features and functions of the device Serial Advanced Technology Attachment (SATA) host controller subsystem.

23.12.1 SATA Controller Overview

The SATA host controller handles data interactions between a local host system memory and a SATA mass storage device with minimal local host (LH) intervention.

In contrast to the parallel 16-bit - ATA (PATA) interface, the SATA interface takes advantage of serial data transmission/reception over a differential pair of conductors. SATA uses the command set from the ATA/ATAPI-6 standard augmented with native command queuing (NCQ) commands optimized for the serialized interface.

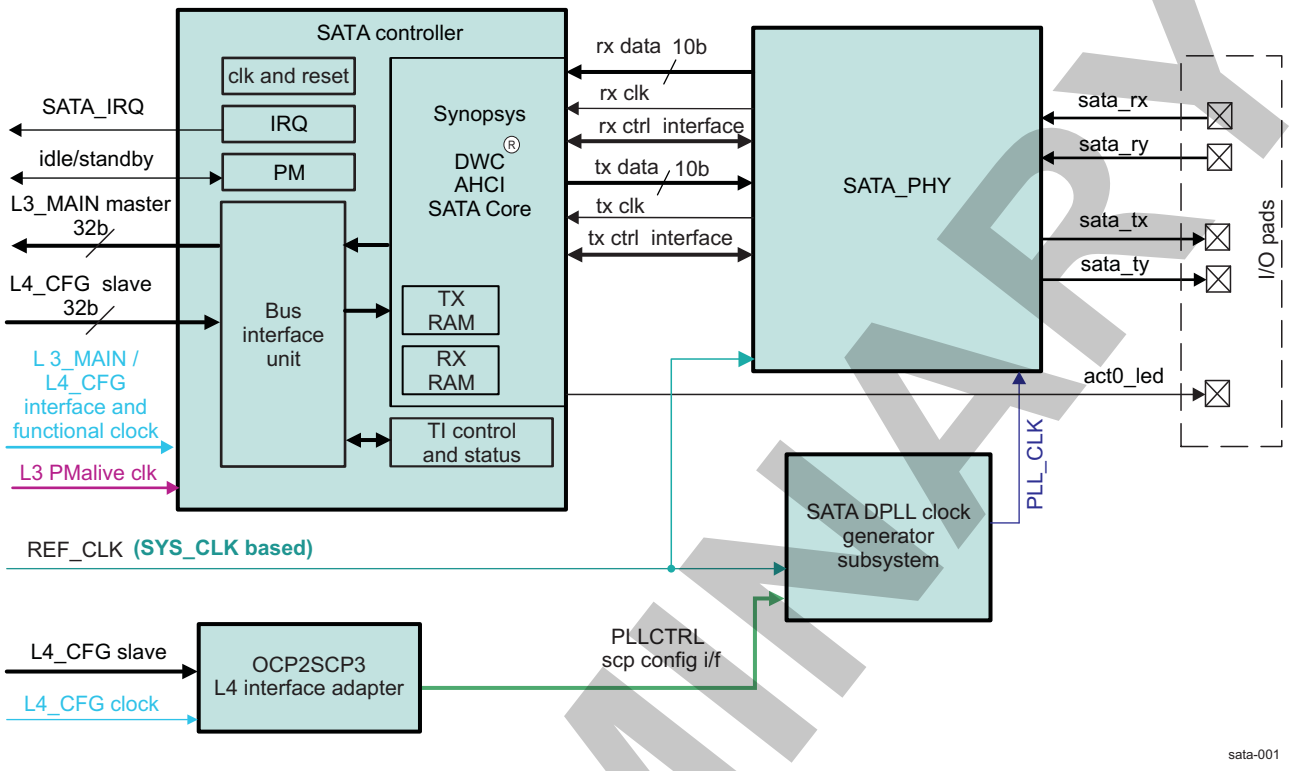
The device has one embedded SATA host bus adapter (HBA) controller with a single port. The device SATA host subsystem is composed of several functional components (see Figure 23-246):

- The core component of the SATA host controller subsystem (signified as SATA controller on the Figure 23-246) implements the transport and link layers of the SATA interface protocol ,i.e. all SATA media access control (MAC) functionalities.
- SATA_PHY encompasses the physical layer (PHY) components - serializer, de-serializer, etc. which adapt the generated by the SATA controller MAC logic parallel 10-bit output data stream for serial electrical transmission and reception.
- DPLL_SATA is a programmable (through registers of the integrated PLL controller - PLLCTRL_SATA) DPLL clock source that provides a high-speed clock to the SATA_PHY serializer/de-serializer components.
- An L4_CFG interface adapter - OCP2SCP3, which enables accessing the PLLCTRL_SATA registers via L4_CFG interconnect accesses.

For details regarding the device SATA host subsystem components - SATA_PHY, PLLCTRL_SATA, DPLL_SATA and interface adapter), see Section 27.1.1, *SATA PHY Subsystem Overview*, in Chapter 27, *Shared PHY Component Subsystems*.

Figure 23-246 shows an overview of the device-embedded SATA host controller subsystem.

Figure 23-246. SATA Host Controller Subsystem Overview



23.12.1.1 SATA Controller

The SATA controller is the main functional component of the device-embedded SATA (Host Bus Adapter) HBA and is based on the Synopsys DesignWare® SATA Core advanced host controller interface (AHCI) module. The SATA controller handles data transactions at the link and transport layers of the SATA interface using the advanced host controller interface (AHCI) mechanism. The SATA controller core engine is a generation 2-compliant host (supporting 3 Gbps transfer speed) with integrated DMA and FIFO RAM buffers .

The SATA controller AHCI-based interactions involve extensive DMA processing of both data and command transfers, reducing much of the user overhead associated with standard ATA task file register servicing. The SATA HBA port programmable DMA acts as a master on the device L3_MAIN interconnect, which facilitates direct command/data transfers between host system memory and attached SATA storage devices.

The SATA controller has a slave configuration port accessible on the device L4_CFG interconnect. This port provides the user with an appropriate register interface for HBA setup, control and status, interrupt settings, DMA configuration, etc.

23.12.1.1.1 AHCI Mode Overview

The SATA core supports the AHCI hardware mechanism, which provides the user software with a suitable HBA register interface to manage SATA interface operations. Generally, the AHCI introduces a system memory structure that includes some generic control and status area and a list of command entries (which can have a depth from 1 up to 32 entries) assigned per HBA port. Each of the command list entries contains information necessary to program a SATA device and pointers to data transfer descriptors.

The AHCI mode of operation disregards the master/slave communication model. A certain SATA AHCI host controller port establishes a point-to-point connectivity with only a single SATA peripheral device at a time, which is always a master device.

23.12.1.1.2 Native Command Queuing

The SATA AHCI engine supports NCQ and is capable of command queued protocol interactions with NCQ-compliant SATA mass storage devices. The NCQ commands generated by a SATA HBA port are loaded into command queues maintained at the peripheral device. The commands are stored in a queue and subsequently fetched and processed by peripheral device controller in sequences, which imply more native and highly-optimized for the device order of execution. The synchronization between an NCQ-aware SATA HBA and an NCQ-aware peripheral storage device involves implementation of the so called FPDMA queued command protocol, which ensures that HBA posts NCQ commands to the target SATA device in its demanded NCQ order.

23.12.1.1.3 SATA Transport Layer Functionalities

The SATA controller handles all of the transport layer functions of the SATA protocol. During reception it receives a frame information structure (FIS) from its link layer through the RX FIFO, decodes the type, and routes it to the proper location through the port DMA. During transmission it transfers a FIS constructed by the port DMA to the link layer through the TX FIFO. It also passes link layer errors and checks for transport layer errors to pass up to the system. The transport layer also contains the TX and RX FIFOs. These FIFOs are used as asynchronous data buffers between the serial domain and the bus clock domain. The size of these FIFOs affects the subsystem ability to buffer data before flow control must be asserted. It also affects the maximum transaction size that can be programmed into the port DMA.

23.12.1.1.4 SATA Link Layer Functionalities

The link layer maintains the link and supports all SATA link layer functionality, including:

- Out-of-band (OOB) transmit signaling
- Frame negotiation and arbitration
- Envelope framing/deframing
- Cyclic redundancy check (CRC) calculation (receive and transmit)
- 8b/10b encoding/decoding
- Flow control
- Frame acknowledgment and status
- Data width conversion
- Data scrambling/descrambling
- Primitive transmission
- Primitive detection and dropping
- Power management

23.12.1.2 SATA Controller Features

This section describes the features supplied by the SATA controller module. The SATA controller complies with the following standards:

- *Serial ATA Standard* specification (revision 2.6)
- *Serial ATA Advanced Host Controller Interface* specification (revision 1.1). The device SATA host controller also complies with the *Serial ATA Advanced Host Controller Interface* specification (revision 1.3), excluding support for the port multiplier FIS-based switching feature.

The main features of the SATA host controller are:

- Serial ATA 1.5-Gbps and 3-Gbps speeds (SATA-1 and SATA-2)
- Integrated RxFIFO and TxFIFO RAM data buffers
- Support of all SATA power management features
- AHCI support of 64-bit addressing mode (see device limitation note below)
- HBA port associated Internal DMA engine
- Hardware-assisted NCQ for up to 32 entries

- Command completion coalescing (CCC) interrupts
- Activity LED generation

Additionally, link layer supports:

- 8b/10b encoding and decoding functionality
- RX elasticity buffer
- TX OOB sequence generation
- RX OOB sequence generation
- The differences between the SATA host controller and a standard SATA host controller defined by the *Serial ATA Gold Standard* specification (v2.6) are:
- Staggered spin-up is not supported (only one HBA AHCI port embedded).
- Only one port is supported by the device-embedded SATA HBA from up to 32 possible, according to the standard.
- The SATA controller is AHCI-mode compliant only and does not support standard ATA legacy modes of operation.
- Cold presence detection signals are not available. The SATA controller targets support for permanently attached SATA drives only.

The following features are not supported by the SATA host subsystem:

- Far-end analog loopback
- Cold presence detect (CPD) signal is not available at the system level. As a consequence, the SATA device hot-plug operation is not supported.
- Port multiplier feature is not supported by the device SATA controller port.
- Mechanical presence switch signal is not available at system level.
- Message signaled interrupts
- PHY layer functionalities of SATA controller are not integrated. These are assigned to the SATA_PHY transceiver integrated at the device level (outside SATA controller module itself).

NOTE: A save and restore mechanism is not supported for SATA. The SATA host controller must be restarted and reprogrammed every time it exits OFF mode or RETENTION mode.

The SATA controller master (DMA) interface features:

- 32-bit data
- 36 bits of the AHCI master address bus (byte-aligned addressing) implemented in the device. See device limitation note below.
- 1-bit tag-ID port, but the tag value is 1 on all accesses (that is, the feature is not used)
- Sequential burst support (16 x 32 bit – Dwords)

NOTE: Even though the SATA AHCI Controller supports 64-bit -addressing mode, only 36-lower bits of the 64-bit address bus are integrated (meaningful) in the device. This defines a 64-GiB AHCI master address space.

The SATA controller slave interface features:

- 32-bit data, 13-bit (byte-aligned) address
- Single access (no burst support)
- All accesses are expected to be 4 bytes wide, 32-bit aligned.

NOTE: Accesses smaller than 4 bytes wide (that is, byte enable patterns different from 4'b1111) are functional and do not generate an error. Misaligned addresses do not generate an error.

23.12.2 SATA Controller Environment

Apart from the SATA communication-dedicated electrical connections to the SATA_PHY component, there is an additional SATA-defined-led drive generation signal that can be output at the device pad: uart3_cts_rctx. For more information about this signal pad configuration register mapping, see section Section 18.4.8, *Pad Functional Multiplexing and Configuration* in Chapter 18, *Control Module*. For more details regarding the behavior of activity LED generation, see Section 23.12.4.9, *Activity LED Generation Functionality*.

Table 23-1410. SATA Controller I/O Signals

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
TXP[2]	sata_tx	O	TX output of the SATA PHY differential transmission line	0
TXN[2]	sata_ty	O	TY output of the SATA PHY differential transmission line	0
RXP[2]	sata_rx	I	RX input of the SATA PHY differential reception line	Hi-Z
RXN[2]	sata_ry	I	RY input of the SATA PHY differential reception line	Hi-Z
ACT0_LED	sata_actled	O	HBA port activity LED indication	Hi-Z

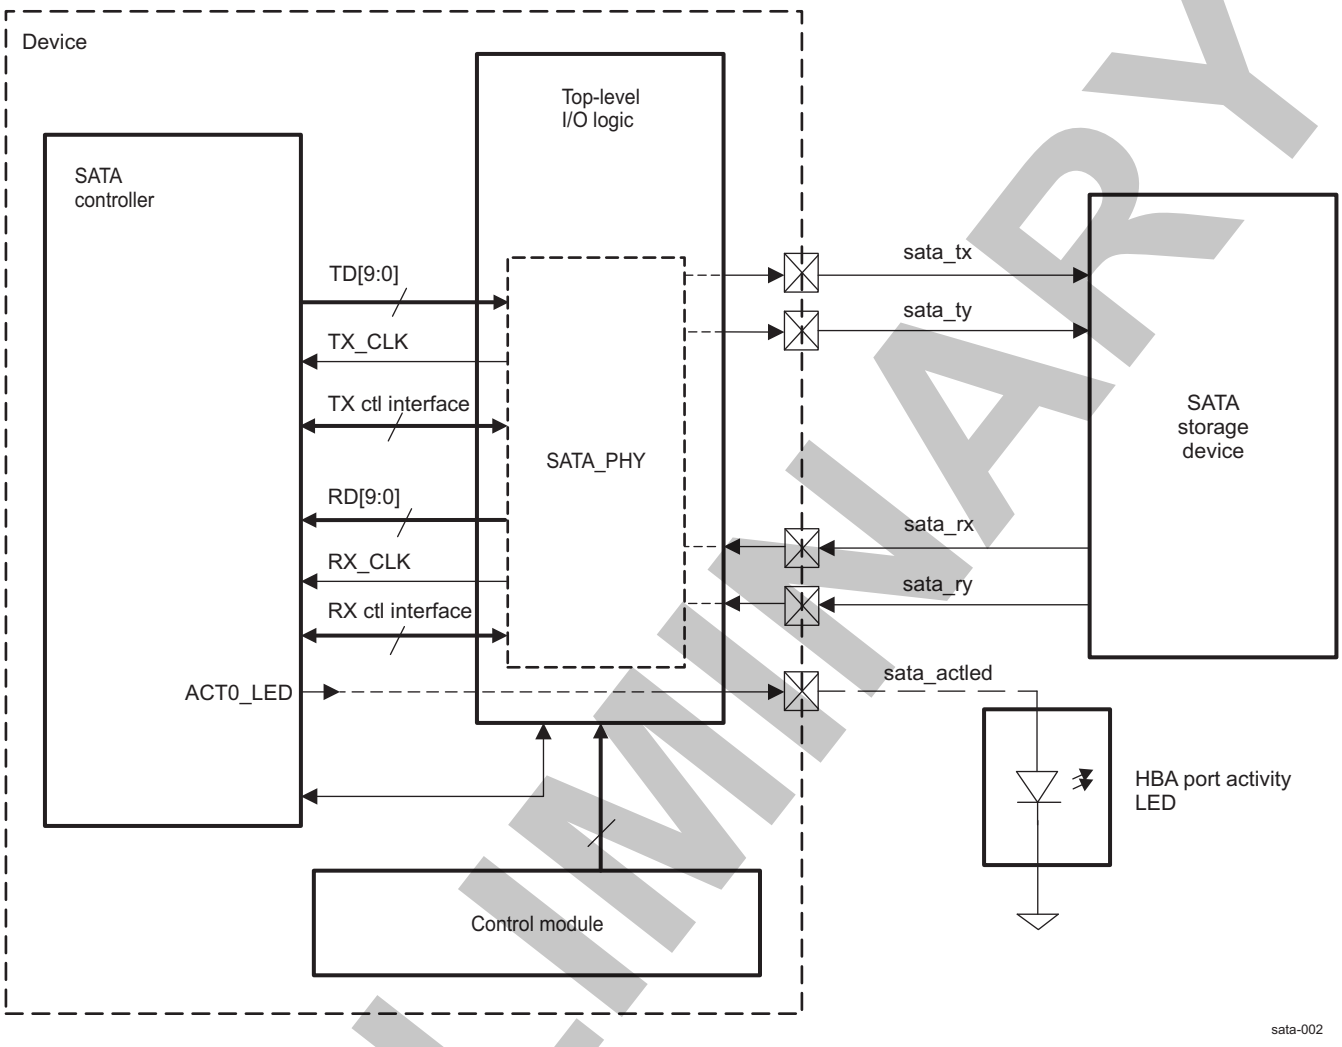
(1) I = Input; O = Output

(2) These signals are part of the interface between SATA PHY serializer / de-serializer and the externally attached SATA storage device.

NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the sections Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*, for more information.

The Figure 23-247 shows the SATA host controller subsystem environment summarizing the interface signals exported directly from SATA controller at the device boundary, as well as those exported after SATA_PHY processing at the device boundary. For more information on the interface between the SATA controller and SATA_PHY, seeChapter 27, *Shared PHY Component Subsytems*.

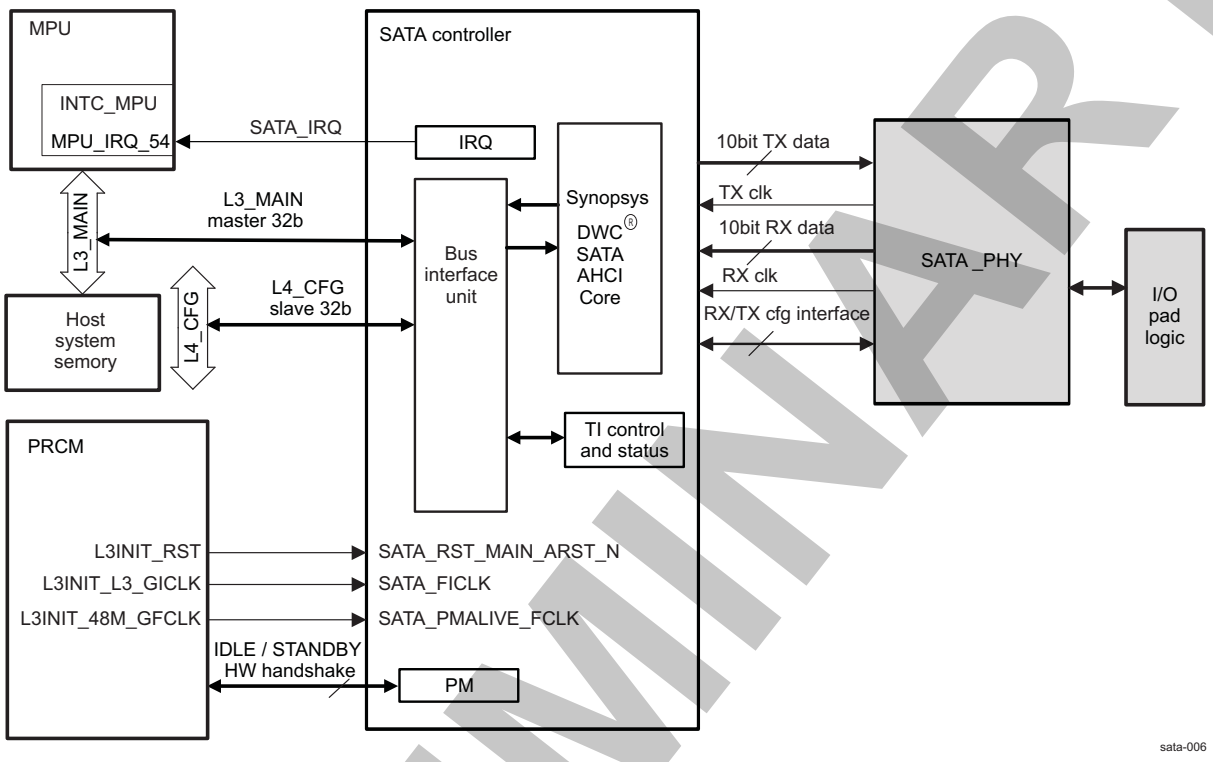
Figure 23-247. SATA Subsystem Environment



23.12.3 SATA Controller Integration

This section describes the SATA AHCI host controller integration in the device, including information about clocks, resets, and hardware requests. Figure 23-248 shows the SATA controller integration.

Figure 23-248. SATA Controller Integration



SATA controller integration includes these features:

- A single functional and interface clock (SATA_FICLK, shared between the master and the slave interfaces)
- A functional always-on clock (SATA_PMALIVE_FCLK to support entrance into and exit from the SATA defined low-power modes)
- A single hardware nonretention reset input (SATA_RST_MAIN_ARST_N)
- Idle/standby handshake protocol with the power, reset, and clock management (PRCM) module
- A single interrupt request generation line (SATA_IRQ, mapped to MPU_IRQ_54 of MPU INTC)
- No DMA or wakeup requests generation to surrounding modules
- L3_MAIN master interface
- L4_CFG-configuration slave interface

The SATA encoded symbol transmission/decoded symbol reception relies on two serial clocks , which are supplied indirectly from the DPLL_SATA through the SATA_PHY component.

NOTE: For more information about the IDLE hardware handshake and the wakeup request, see Section 3.1.1.1.2, *Module Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

Table 23-1411 through Table 23-1413 summarize the integration of the module in the device.

Table 23-1411. Integration Attributes

Module Instance	Attributes

- For a description of the interrupt source, see Section 23.12.4.5, *Interrupt Requests*.

NOTE:

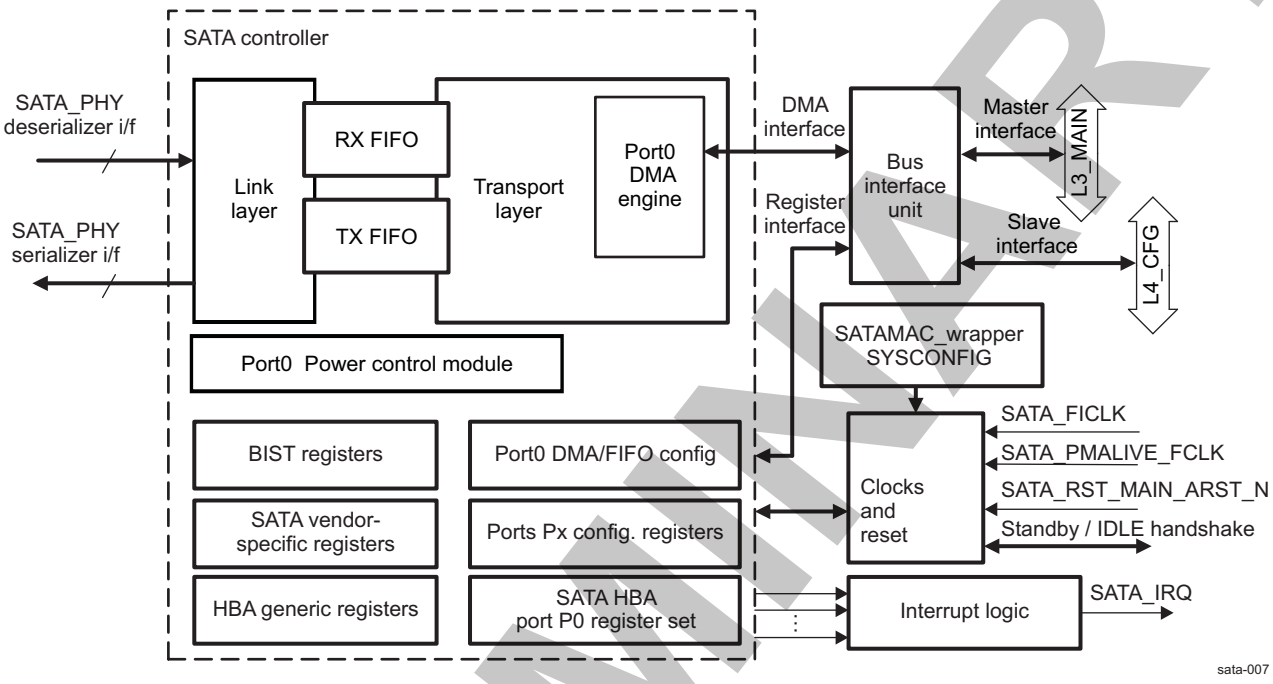
- The SATA HBA does not generate DMA and wakeup hardware requests to the surrounding modules integrated in the device

23.12.4 SATA Controller Functional Description

23.12.4.1 Block Diagram

Figure 23-249 shows a block diagram of the SATA host controller.

Figure 23-249. SATA Controller Functional Block Diagram



The SATA HBA port-associated DMA is a master on the device L3_MAIN interconnect. For a write to the attached storage device, this port reads FISs from the host system memory and pushes them into the transmit FIFO. When frame Dwords are received at RxFIFO, this interface is used to write the data out to the dedicated host system memory area. For details about DMA features and operation, see section Section 23.12.4.8, *DMA Port Configuration*.

The SATA controller has a configuration slave interface used to read and write all system registers. The slave interface includes the following functions:

- Configuring the SATA AHCI core (and indirectly, to a certain extent, the SATA_PHY physical component)
- Configuring the DMA for transmit and receive operations
- Initiating write transfers to the attached storage device
- Responding to interrupts and reads

Both the slave and master interface of the SATA host controller share the same functional and interface clock, that is, operate on the same frequency (see also Section 23.12.3, *SATA Controller Integration*) .

A bus interface unit adapts the SATA controller master and slave buses to the corresponding L3_MAIN and L4_CFG device interconnects.

NOTE: The **SATA controller AHCI Core registers** are part of the instance signified as **DWC_ahsata** inside the Section 23.12.6.1, *SATA Controller Instance Summary*.

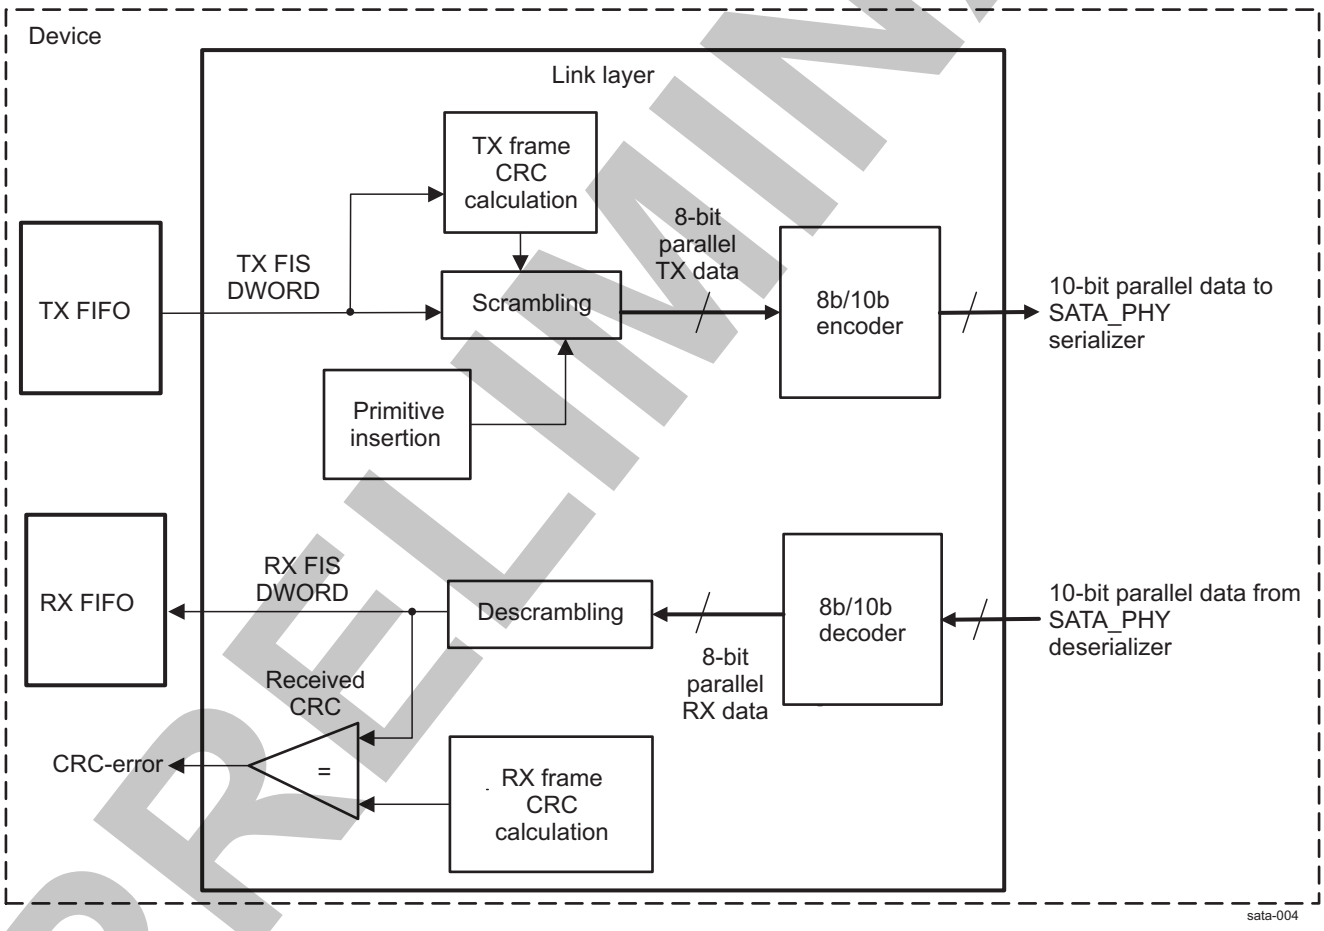
23.12.4.2 SATA Controller Link Layer Protocol and Data Format

One of the main tasks of the SATA HBA Link layer is to perform a parallel 8-bit FIS data to a 10-bit parallel code conversion (8b/10b encoding) . The encoded stream, which is a sequence of 10-bit parallel-encoded characters, is subsequently passed to the SATA_PHY serializer component to adapt to a serial 10-bit character transmission to the SATA peripheral device. For more details, see Section 27.1.1, *SATA PHY Subsystem Overview*, and Section 27.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 27, *Shared PHY Component Subsytems*.

One of the main tasks of the SATA HBA Link receiver is to perform a 8b/10b decoding, in which process the parallel 10-bit characters coming out from the SATA_PHY de-serializer are decoded to parallel data or control bytes. The received symbols with invalid codes are rejected by the link layer and corresponding illegal reception errors are generated. For more details regarding the SATA_PHY de-serializer, see Section 27.1.1, *SATA PHY Subsystem Overview*, and Section 27.1.4, *SATA PHY Subsystem Functional Description,* in Chapter 27, *Shared PHY Component Subsytems*.

There are also other data process stages at the link layer, such as CRC calculation, scrambling/descrambling, primitive insertion/detection, etc. Figure 23-250 shows the primary stages of link Dword data processing.

Figure 23-250. Simplified Schema of Link Dword Processing



23.12.4.2.1 SATA 8b/10b Parallel Encoding/Decoding

The input to the link coder logic is a parallel (unencoded) data byte and an associated control variable: Z with two possible values (K, D). The Z value signifies the byte to be encoded either as a control character (K value) or a data character (D value). The data byte (ABCDEFGH, where A matches the least significant bit [LSB]) is divided into two asymmetric portions: a 5-bit one ABCDE (range: 0 to 31) and a 3-bit one FGH (range: 0 to 7).

The encoding process is performed in two stages. At the first stage, the 5-bit portion is converted to a 6-bit subblock (abcdei); at the second stage, the 3-bit portion is converted to a 4-bit subblock (fghj). An additional parameter called running disparity (rd) is taken into account during code calculation at both the character transmission and reception link sides. It introduces code correlation between adjacent bytes so that the current subblock code can depend on the code of the previous subblock and its associated rd output value. As a consequence, depending on the input rd parameter and the 8b/10b encoded value, the encoding/decoding lookup tables might have two different entries for the same byte.

The 10-bit parallel-encoded character is passed to the 10-bit data input of the SATA_PHY serializer component, which further transmits it serially in a LSB to most significant bit (MSB) order (abcdeifghj). The receiver link receives and decodes the sequence in the same LSB to MSB order (abcdeifghj). While SATA encoder takes the full range of a data byte (0–255) encoding values, it uses only two values to encode control characters. For more information on the 8b/10b encoding/decoding process, see the SATA standard specification.

23.12.4.2.2 SATA Stream Dword Components

The basic unit of SATA information is Dword – a double sized word (32 bits). An encoded Dword has a 40-bit length (4 x 10 bits), but, for simplicity, unencoded Dword lengths are considered here. Each Dword is serially transmitted or received by the SATA_PHY components in LSB character to MSB character order.

- Primitives

  The shortest meaningful component of the SATA stream is the primitive, which consists of a single Dword. Different types of primitive characters are inserted into the SATA stream to maintain synchronization between the host and the SATA peripheral device. Primitives convey real-time state information regarding the SATA communication channel itself. For example, the SATA link layer generates primitives to perform flow control, synchronize power management state transitions, frame enveloping, etc. The transport layer is not aware of the lower level primitive Dwords. They are subject to processing only to the link layer.

- Primitive handshakes

  In some cases, the transmitter of a primitive can require that the receiver send an acknowledge Dword to confirm primitive reception, which is a primitive handshake.

  The first byte of a primitive Dword is always a control character (or Z = K) with two possible encodings. The remaining three data bytes (Z = D) contain the function of the primitive. According to the SATA standard, the transmitter and the receiver are not required to match the number of primitives sent and received.

  Table 23-1414 briefly summarizes the primitives used by SATA.

Table 23-1414. SATA Primitives Summary

Primitive Name	Short Description
ALIGNp	Sent in pairs to PHY component to readjust its internal operations
CONTp	After CONTp insertion, previous primitives are repeated continuously until a different primitive is inserted
DMATp	terminates DMA data transmission
EOFp	End of frame
HOLDp	Inserted to hold data when transmitter doesn't have data ready to transmit
HOLDAp	Acknowledges a HOLDp primitive
PMACKp	Acknowledges a power management request
PMNAKp	A power management request denial
PMREQ_Pp	Power management request to PARTIAL state
PMREQ_Sp	Power management request to SLUMBER state
R_ERRp	Reception error occurred
R_IPp	Current node is receiving data
R_OKp	Reception without error
R_RDYp	Receiver is ready for reception

Table 23-1414. SATA Primitives Summary (continued)

Primitive Name	Short Description
SOFp	Start of frame
SYNCp	Synchronization primitive
WTRMp	Transmitter inserts this primitive while waiting to get the reception status from receiver
XRDYp	Transmitter has data ready for transmission

- SATA data frames

  SATA data frames incorporate data FISs constructed at the transport layer along with some primitives (see Figure 23-251). The maximum number of Dwords between SOFp to EOFp does not exceed 2064 Dwords, including the FIS type and CRC fields described here.

- Frame FIS components

  The FIS contents of a frame incorporate the Dwords that correspond to SATA target data structures. FIS Dwords are output from transport layer TxFIFO to the transmitter link 8b/10b encoder during transmission. In the case of reception, the FIS content is obtained at transport layer RxFIFO after being successfully decoded by the receiver link logic. The commands and data embedded into Frame FISs are generated/interpreted at a higher transport level of the SATA controller and are user software-accessible in the host system memory.

- CRC

  The CRC is the last Dword in a frame, immediately following the last FIS Dword of the frame and preceding the EOFp primitive. The 32-bit CRC calculation is performed only on the FIS Dwords of the frame contents, so that frame-inserted primitives such as HOLDp, CONTp, etc., are not taken into account. The CRC is aligned on a Dword boundary. CRC code computation expects an input of an even number of words and should be Dword-multiple. If an FIS block contains an odd number of words, the last FIS word is padded with 0s to a full Dword before the CRC is calculated.

  – During transmission: The CRC Dword is calculated on original FIS contents, before scrambling and serial 8b/10b encoding are performed.

  – During reception: The CRC Dword is calculated on the 8b/10b decoded and subsequently descrambled 8-bit FIS Dword contents. It is then compared to the CRC received from the source to perform error check analysis.

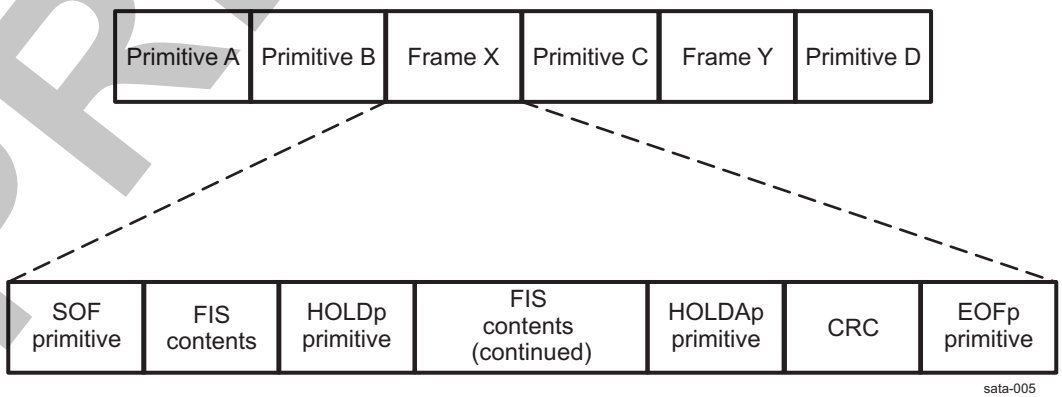
- Frame embedded primitives

  The beginning of a frame is marked with a SOFp primitive, and the end is marked with an EOFp primitive. Some primitives, such as HOLDp and HOLDAp acknowledge, can be inserted into frames between data FISs.

- SATA data stream

  As shown in Figure 23-251, the SATA data stream is composed of frames carrying the target data/command contents combined with various primitives generated to maintain consistency of transfers over the SATA interface.

Figure 23-251. SATA Data Stream Components



23.12.4.2.3 Scrambling/Descrambling Processing

The contents of a frame are scrambled before being passed to the link 8b/10b encoder. Scrambling is performed on Dword quantities by XORing the data to be transmitted with the output of a linear feedback shift register (LFSR). All data words between the SOFp and EOFp are scrambled, including the CRC. Figure 23-250 shows the basic flow.

The SATA controller (as defined by the SATA standard) performs scrambling/descrambling processing for EMI reduction purposes. Two scramblers are instantiated within the SATA controller: The first, the data payload scrambler, scrambles FIS data payload contents (including the calculated CRC Dword); the second, the repeated primitive suppression scrambler, scrambles only the repeated primitive stream contents.

The scrambling runs as follows: A certain data payload Dword located between SOFp and EOFp is XORed with the data payload scrambler output. The resulting scrambled Dword is submitted to the 8b/10b encoder for transmission.

On reception, the Dword is decoded using a 10b/8b decoder, the scrambler output is XORed with the resulting Dword, and the resulting Dword is presented to the link layer. It is then used for CRC computation. The CRC Dword is scrambled in the same way as data payload characters.

For details on the scrambling/descrambling feature, see the *SATA Standard Specification* (rev.2.6).

23.12.4.3 Resets

23.12.4.3.1 Hardware Reset

The module is reinitialized in hardware (for more information about hardware reset, see Section 23.12.3, *SATA Controller Integration*).

For more information on the PRCM.L3INIT_RST hardware reset signal, refer to Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

This reset normally occurs on device power up or during a system bus failure. All components of the SATA AHCI core are initialized, including the HBA port and generic registers. The bus interface unit (BIU) and SATA AHCI core wrapper components are also impacted.

23.12.4.3.2 Software Initiated Resets

The SATA controller supports three levels of software reset, each of which has different impact over the SATA HBA hardware components and AHCI interface registers:

- Software reset (least intrusive)
- Port reset
- HBA reset (most intrusive)

NOTE: It is recommended that user software always starts with the least intrusive reset approach. Software chooses the next most intrusive reset only if the less intrusive reset does not succeed in clearing the condition.

23.12.4.3.2.1 Software Reset

Software reset impacts only the attached to the HBA port SATA peripheral device, without affecting the established communication between physical layers or HBA engine.

To issue a software reset, the user must prepare two H2D register FISs into the emptied command list of the port. The first FIS must have bits SRST = 0b1 and C = 0b0. The first FIS corresponding command header bits C and R are set as follows: C = 0b1 and R = 0b1.The second FIS has bits SRST = 0b0 and C = 0b0. The second FIS corresponding command header bits C and R are set as follows: C = 0b0 and R = 0b0.

However, steps must be taken before issuing the software reset to the peripheral device attached to the port. For details on software reset, see the AHCI specification .

23.12.4.3.2.2 Port Reset

The port reset (also known as COMRESET) must be applied when the HBA port does not function properly after a software reset is issued to the port. The effect is that the SATA HBA port is reinitialized and communication between the phy layers of both the SATA host and the SATA target device is reestablished.

To trigger a COMRESET sequence on the SATA interface, user software must write 0x1 to the SATA_PxSCTL[3:0]DET bit field. The host receives a COMINIT signal sequence, indicating that the peripheral device has successfully reestablished communication. For more information on port reset, see the AHCI specification (revision 1.1).

NOTE: The port reset (COMRESET) method is the preferred AHCI mechanism for error recovery and should be used instead of the software reset.

23.12.4.3.2.3 HBA Reset

Software can globally reset the SATA controller, if a port reset does not clear the conditions successfully. On HBA reset, all SATA AHCI core interface registers are reset, **excluding those from the hardware initialization domain** - the SATA_PxCLB, SATA_PxCLBU, SATA_PxFB and SATA_PxFBU registers. All state machines that relate to data transfers and queuing return to IDLE state, and the port is reinitialized by sending COMRESET. The global reset is triggered when user software sets the SATA_GHC[0]HR = 0b1 bit. The HBA indicates that global reset is finished, deasserting the SATA_GHC[0]HR bit to 0b0 in hardware. Hence, user software must poll the HR bit to detect this condition. For more information, see the mentioned AHCI standard specification.

23.12.4.4 Power Management

The device SATA host controller subsystem power management can be identified at the following levels:

- SATA controller low power-management features (defined also in the SATA standard specification, revision 2.6)
- Idle/standby power-management protocol established between SATA controller and the device PRCM through a SATA AHCI core wrapper interface (signified as SATAMAC_wrapper instance inside the Section 23.12.6.1, *SATA Controller Instance Summary*).

This section describes the relationships that exist between both levels of SATA Controller power management.

23.12.4.4.1 SATA Specific Power Management

The SATA controller core supports both PARTIAL and SLUMBER low-power states, as described in the SATA standard specification (revision 2.6). These modes allow power savings by powering down part of SATA_PHY and gating off the clocks to the link layer. The port power control module is used to enter and exit these modes, which can have the normal functional clocks gated off.

23.12.4.4.1.1 PARTIAL Power Mode

In the PARTIAL power state, the SATA_PHY component transmits electrical IDLE to the device and the receiver is left on to receive OOB signals. This mode can also be used to support near-end analog loopback, if a device is attached.

23.12.4.4.1.2 Slumber Power Mode

In the SLUMBER power state, the transmitter is completely turned off. This allows for greater power savings but near-end analog loopback cannot be performed and there is a longer latency to exit the mode.

23.12.4.4.1.3 Software Control over Low Power States

The user has manual control over low power states through the SATA_PxCMD [31:28]ICC register bit field. This works if the link is in IDLE state; otherwise, writes to this field are ignored.

23.12.4.4.1.4 Aggressive Power Management

Low power modes can be initiated by software when there are no pending transactions, but the SATA AHCI core also supports aggressive power management. In this mode, the subsystem automatically initiates the PARTIAL or SLUMBER state when there are no inflight commands. This is useful for power savings, but the price is increased latency if a low-power mode is entered and a transfer request is made. Software enables aggressive link-layer power management by setting the SATA_PxCMD[26]ALPE bit to 0x1. The link aggressive power management state (PARTIAL or SLUMBER) is selected using the SATA_PxCMD[27]ASP bit.

23.12.4.4.2 Idle/Standby Management Protocol

The idle/standby handshake protocol is implemented between the PRCM and SATA controller, with mode settings located in the SATAMAC_wrapper register (SATA_SYSCONFIG).

- The standard idle request/acknowledge handshake is associated with the L4_CFG slave port. The default idle mode is smart-idle, as indicated by the power-on reset (POR) value: SATA_SYSCONFIG[3:2]IDLEMODE = 0x2.

NOTE: No other mode is expected to be required in normal operation: no-idle and force-idle are used for debugging only. Because the module is not capable of asynchronous wakeup, the smart-idle/wakeup (IDLEMODE = 0x3) is strictly equivalent to smart-idle.

- The standby/wait handshake is associated with the L3_MAIN master port. Software is responsible to keep the DMA operations and the standby status in sync.

The default standby mode is smart-standby, as indicated by the POR value: SATA_SYSCONFIG[5:4]STANDBYMODE = 0x2. However, the SATA controller hardware does not provide any indication about DMA activity that could be used to drive the standby dynamically (that is, the smart mode): Smart-standby is therefore strictly equivalent to the force-standby mode (that is, the module remains in or goes to permanent standby).

The standby control procedures are therefore software-driven.

To exit standby:

1. Change the standby mode to no-standby by setting SATA_SYSCONFIG[5:4] = 0x1.
2. Optional: Confirm the SATA controller standby status through the PRCM. For more information, see Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3. Only then, enable the controller DMA (AHCI list processor). For more information, see the AHCI specification.

To enter standby:

1. Disable the controller DMA (AHCI list processor). For more information, see the AHCI specification.
2. Ensure all pending transactions have completed. For more information, see the AHCI specification.
3. Change the standby mode to smart-standby (or force-standby) by setting SATA_SYSCONFIG[5:4] = 0x2.

CAUTION

The software is responsible to keep the DMA operations and the standby mode status in sync.

NOTE: Because the standby exit is software driven, it is by definition synchronous: the asynchronous wakeup is never activated, which means that the smart-standby and smart-standby/wakeup are equivalent (as well as force-standby).

For more information on the SATA Controller Idle/Standby Management Protocol with the device PRCM , see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

23.12.4.4.3 Clock Gating Synchronization

The bus clock can also be gated off in either the PARTIAL or SLUMBER state, if the software guarantees there is nothing in flight, the clock can be stopped and started without glitches, and the clock can be restarted quickly when activity is initiated from the device side.

The following steps outline the procedure to stop the clock:

1. Put the link in a low power state (either PARTIAL or SLUMBER)
   - SATA MAC link layer can enter low power either manually see Section 23.12.4.4.1.3, *Software Control over Low Power States*) or automatically (see Section 23.12.4.4.1.4, *Aggressive Power Management*)
   - If there is no device attached (making it impossible to enter a low power state), the SATA_SYSCONFIG[16] OVERRIDE0 override bit can be set to 0b1 to stop the interface/functional clock (SATA_FICLK) and save power.
2. Initiate the clock stopping procedure.

CAUTION

If a SATA drive attached to the SATA HBA port has not entered a low power state (PARTIAL or SLUMBER), the user must not set the SATA_SYSCONFIG[16]OVERRIDE0 bit; otherwise, the link layer can be ruined, resulting in indeterminate SATA controller behavior.

Table 23-1415. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	SATA_SYSCONFIG [3:2]IDLEMODE bit field	The available modes are: Force-idle, no-idle, and smart-idle wakeup disabled modes are available.
Master standby modes	SATA_SYSCONFIG [5:4]STANDBYMODE bit field	The available modes are: Force-standby, no-standby, smart-standby wakeup disabled
Clock-gate overriding mode	SATA_SYSCONFIG [16]OVERRIDE0 bit field	Clock stopping override function. Should not be applied when attached to port SATA peripheral device has not entered a Low-power mode.

For more information on the L3INIT_L3_GICLK functional clock gating in the device PRCM , refer to Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

23.12.4.5 Interrupt Requests

This section describes all of the conditions that can generate an interrupt. Each condition is subject to the masking capabilities described in Section 23.12.4.5.4, *Interrupt Condition Control*.

23.12.4.5.1 Interrupt Generation

Both level and pulse interrupts are available. Exercise care when using the pulse interrupt. Because of the synchronization and interrupt aggregation from the internal core, clearing one interrupt as another interrupt occurs can prevent a new pulse from being generated. A new pulse is generated only if the first interrupt is completely cleared (that is, the level interrupt goes away) before the new interrupt event occurs. Thus, an interrupt can occur after the register write is issued to clear the first interrupt but before the interrupt is fully cleared. In this case, a new pulse is not issued and the level interrupt remains asserted. After issuing the write to clear an interrupt, software must read the interrupt status registers to ensure that a new interrupt has not occurred.

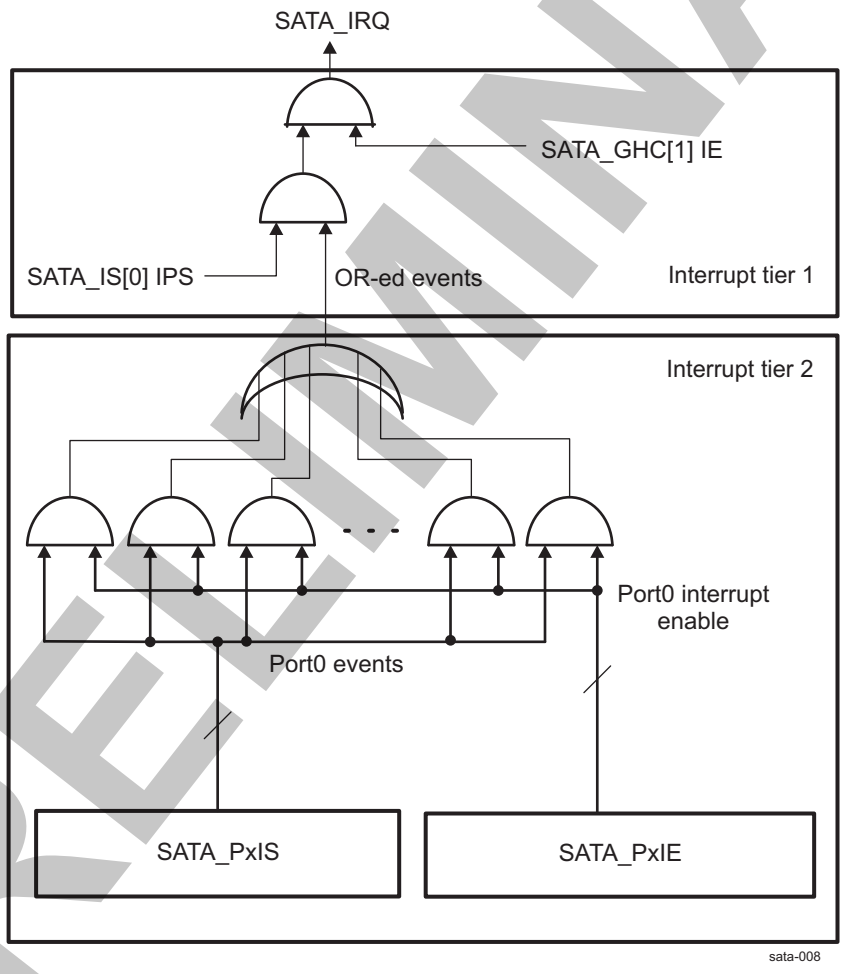
23.12.4.5.2 Levels of Interrupt Control

The AHCI directs that interrupts be indicated in a two-tier structure and thus associated with different HBA ports. Considering the device SATA HBA single-port implementation for the first tier, only the SATA_IS[0] IPS bit should be considered. It indicates if the only port available to the user (HBA port 0) has pending interrupts.

For the second tier, the SATA_PxIS register (where x = 0) indicates which specific interrupt condition(s) occurs to trigger an interrupt on port 0. In most cases, software writes 0x1 (Write One to Clear) to clear these bits, and then writes 0x1 to the SATA_IS [0]IPS bit to clear the interrupt. However, some interrupts in the SATA_PxIS register have alternate methods of being cleared (for details, see Section 23.12.6.2.2, *DWC_ahsata Register Description*). Section 23.12.4.5.3, *Interrupt Events Description*, describes all interrupt generating conditions.

Figure 23-252 shows the SATA controller two-tier interrupt propagation structure. Besides SATA_IS[0], which gates all interrupts at the port 0 level, the tier 1 interrupt is globally gated by the SATA_GHC[1] IE bit.

Figure 23-252. SATA Controller Interrupt Propagation Schema



NOTE: Regardless of the device SATA controller single HBA port implementation, user software must read/write the tier 1 SATA_IS[0] IPS register bit to process interrupts.

23.12.4.5.3 Interrupt Events Description

This section describes the different events that are reflected in the SATA_PxIS register and that cause SATA_IRQ interrupt generation, if enabled, in the SATA_PxIE register. For more information regarding SATA_IRQ handling at the MPU subsystem interrupt controller - INTC_MPU level, see Section 17.3.2, *Interrupt Requests to INTC_MPU* in Chapter 17, *Interrupt Controllers*.

23.12.4.5.3.1 Task File Error Status

This event is registered whenever the SATA_PxTFD[7:0] STS bit field is updated by the device and the error bit SATA_PxTFD[0]STS_ERR is set. SATA_PxTFD[7:0] STS is updated when a new register FIS, PIO setup FIS, or set device bits FIS is received from the device.

23.12.4.5.3.2 Host Bus Fatal Error

This event is registered whenever an error is received by the SATA controller internal DMA master port from the configuration slave port.

23.12.4.5.3.3 Interface Fatal Error Status

This event is registered if an error is generated on the interface. The following conditions can cause this:

- SYNC escape during an H2D register or data FIS transmission
- One of the following errors during a data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Unknown FIS received with a good CRC, but length greater than 64 bytes
- Physical region descriptor (PRD) table byte count of 0

NOTE: This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 23.12.4.3.2, *Software Initiated Resets*.

23.12.4.5.3.4 Interface Non-Fatal Error Status

This event is registered on the following error conditions:

- One or more of the following errors are registered during a non-data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Command list underflow during a read operation when software builds a command table that has more total bytes than the transaction given to the device

NOTE: The conditions previously described are non-fatal and the SATA host controller continues to operate normally.

23.12.4.5.3.5 Overflow Status

This event is registered if command list overflow is detected during read or write when software builds a command table with fewer total bytes than the transaction given to the device.

NOTE: This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 23.12.4.3.2, *Software Initiated Resets*.

23.12.4.5.3.6 PHYReady Change Status

This event is registered when the status of PHYReady changes. Its corresponding status bit (SATA_PxIS[22] PRCS) reflects the SATA_PxSERR[16]DIAG_N bit.

23.12.4.5.3.7 Port Connect Change Status

This event is registered when there was a change in the current connect status as reflected by the SATA_PxSERR[26]DIAG_X bit.

23.12.4.5.3.8 Descriptor Processed

This event is registered when a transaction completes. Its corresponding flag (SATA_PxIS[5] DPS) is set whenever a PRD with the I bit set transfers all of its data.

NOTE: The PRD interrupt is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts can happen close in time so that the second interrupt is missed while the first PRD interrupt is being cleared.

When a PRD entry is exhausted, the HBA can be directed to generate an interrupt through the I bit in the PRD entry (although a PRD is not considered exhausted until all data FISs that transfer data pointed to by that PRD entry is complete). For example, if the data FIS is 8 KiB, and this is covered by three PRD entries, the data is not considered valid at the end of the first or second PRD because the CRC has not been checked, even though the data has been copied to memory or to the device. Therefore, if the I bit is set in the PRD entry, the HBA must hold onto it internally and not set PxIS.DPS until the data FIS is complete and the CRC is correct. Once correct, PxIS.DPS can be set and, if PxIE.DPE and GHC.IE are set, the HBA generates an interrupt.

Conversely, if the PRD entry is 16 KiB and two 8 KiB Data FISS are used to transfer all of the data pointed to by the PRD entry, the PRD interrupt associated with that PRD entry is not signaled until after the second data FIS transfer completes successfully.

23.12.4.5.3.9 Unknown FIS Interrupt

This status event indicates that an unknown FIS is received and copied into system memory.

23.12.4.5.3.10 Set Device Bits Interrupt

This status event indicates that a Set Device Bits FIS is received with the I bit set and copied to system memory.

23.12.4.5.3.11 DMA Setup FIS Interrupt

This status event indicates that a DMA Setup FIS is received with the I bit set and copied into system memory.

23.12.4.5.3.12 PIO Setup FIS Interrupt

This status event indicates that a PIO Setup FIS with the I bit set is copied into system memory and the data related to that FIS is transferred.

23.12.4.5.3.13 Device to Host Register FIS Interrupt

This status event indicates that a D2H Register FIS is received with the I bit set and copied to system memory.

23.12.4.5.4 Interrupt Condition Control

There are several ways for software to control the conditions causing a non - command completion coalescing **(non-CCC)** SATA_IRQ interrupt assertion. The SATA_GHC[1] IE register bit serves as a global mask. If it is 0x0, all interrupts are masked. If it is 0x1, interrupts not masked by the SATA_IS (all interrupts for port 0) and SATA_PxIE registers can trigger an interrupt. The SATA_PxIE register matches the SATA_PxIS register bit for bit. If the corresponding bit in the SATA_PxIE register is set to 0x1, the interrupt is unmasked. If the corresponding is 0x0, the interrupt is masked off.

Table 23-1416 summarizes the SATA controller interrupt status bits and their corresponding interrupt enable bits at the second tier of the SATA controller interrupt generation schema.

Table 23-1416. Interrupt Events Summary

Event Status Flag	Interrupt Event Mask	Mapped to Interrupt Output	Brief Interrupt Event Description
SATA_PxIS [30]TFES	SATA_PxIE [30]TFEE	SATA_IRQ	Task File Error
SATA_PxIS [29]HBFS	SATA_PxIE [29]HBFE		Host Bus Fatal Error
SATA_PxIS [27]IFS	SATA_PxIE [27]IFE		Interface Fatal Error
SATA_PxIS [26]INFS	SATA_PxIE [26]INFE		Interface Non-Fatal Error
SATA_PxIS [24]OFS	SATA_PxIE [24]OFE		Overflow
SATA_PxIS [22]PRCS	SATA_PxIE [22]PRCE		Phy Ready Change
SATA_PxIS [6]PCS	SATA_PxIE [6]PCE		Port Connect Change
SATA_PxIS [5]DPS	SATA_PxIE [5]DPE		Descriptor Processed
SATA_PxIS [4]UFS	SATA_PxIE [4]UFE		Unknown FIS Received
SATA_PxIS [3]SDBS	SATA_PxIE [3]SDBE		Set Device Bits FIS Received
SATA_PxIS [2]DSS	SATA_PxIE [2]DSE		DMA Setup FIS Received
SATA_PxIS [1]PSS	SATA_PxIE [1]PSE		PIO Setup FIS Received
SATA_PxIS[0]DHRS	SATA_PxIE [0]DHRE		Device to Host Register FIS Received

NOTE: To ensure normal generation of the standard (single-event driven, non-CCC) interrupts described in Table 23-1416, the user must ensure that the CCC feature is disabled (that is, the SATA_CCC_CTL[0] EN bit is set to 0x0).

23.12.4.5.5 Command Completion Coalescing Interrupts

The SATA controller supports CCC, which can be thought of as interrupt pacing. Instead of being generated for every command completed, an interrupt can be triggered based on a certain number of commands completed and/or a timer time-out. This significantly reduces the load on the CPU by not allowing software to receive an interrupt every time a command is processed. Software can thus queue many commands or wait for many received FISes and process them as a batch. All CCC functions are controlled by the SATA_CCC_CTL, SATA_CCC_PORTS, and SATA_TIMER1MS registers. Setting SATA_CCC_PORTS[0]PRT = 0x1 makes the only available SATA controller HBA port 0 - CCC-aware. The SATA_CCC_CTL register can be used to program CCC logic to trigger an interrupt whenever a certain number of commands are complete and/or a timeout value (as specified by the TV field of SATA_CCC_CTL and SATA_TIMER1MS registers) occurs. For specific programming instructions, see the SATA_CCC_CTL description.

23.12.4.5.5.1 CCC Interrupt Based on Expired Timeout Value

To trigger a CCC interrupt on a port after an elapsed timer value, the following programming sequence must be implemented by user software:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC = 0x0, which provides that the expired timeout trigger condition is selected.
4. Software defines the 1-ms time-based unit by loading an appropriate number of interface/functional clock cycles into the 20-bit SATA_TIMER1MS[19:0] TIMV bit field. For example, its reset value of 0x186A0 (100 000 x SATA_FICLK cycles) provides that a 1-ms timeout base will be generated if SATA_FICLK = 100 MHz.
5. Software chooses the timeout value as the number of 1-ms intervals through the 16-bit SATA_CCC_CTL[31:16]TV bit field.
6. Software enables the CCC-interrupt feature, asserting SATA_CCC_CTL[0] EN bit to 0b1.

Assertion of bit SATA_CCC_CTL[0] EN to 0x1 is required to start the 1MS TIMER after the above described configuration steps are completed.

NOTE: On CCC event configuration, the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

NOTE: Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL[7:3] INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

23.12.4.5.5.2 CCC Interrupt Based on Completion Count

If the desired method to receive an interrupt is based on the completion of a certain number of commands, the following settings must be performed:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC! = 0x0 to the desired number (1–255) of commands to be completed. The CC! = 0x0 provides that the count completion condition is selected.
4. Software enables the CCC-interrupt feature, asserting the SATA_CCC_CTL[0] EN bit to 0b1.

NOTE: On CCC event configuration , the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

NOTE: Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL [7:3]INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

23.12.4.6 System Memory FIS Descriptors

The SATA AHCI mode supports a command list of from 1 up to 32 entries (command slots) assigned to HBA port 0, which should be allocated and built into host system memory by user software. After receiving command/data messages from the attached port 0 SATA mass-storage drive, the HBA extracts the FIS Dwords, sorts them out, and stores them into different areas of RX FIS-allocated host system memory.

23.12.4.6.1 Command List Structure Basics

Each command list entry has an associated command header (CH) that takes 32 bytes in host system memory, from which only the first 4 Dwords (16 bytes) are used. The CH contains different fields that detail the direction of transfer (H2D or D2H), type of command (ATA/ATAPI), reset behavior, PM ID, byte count and byte length of the PRD table, etc.

A command list slot CH specifies the base address of the underlying command table and information about the associated command FIS length. The command table in system memory has three main areas:

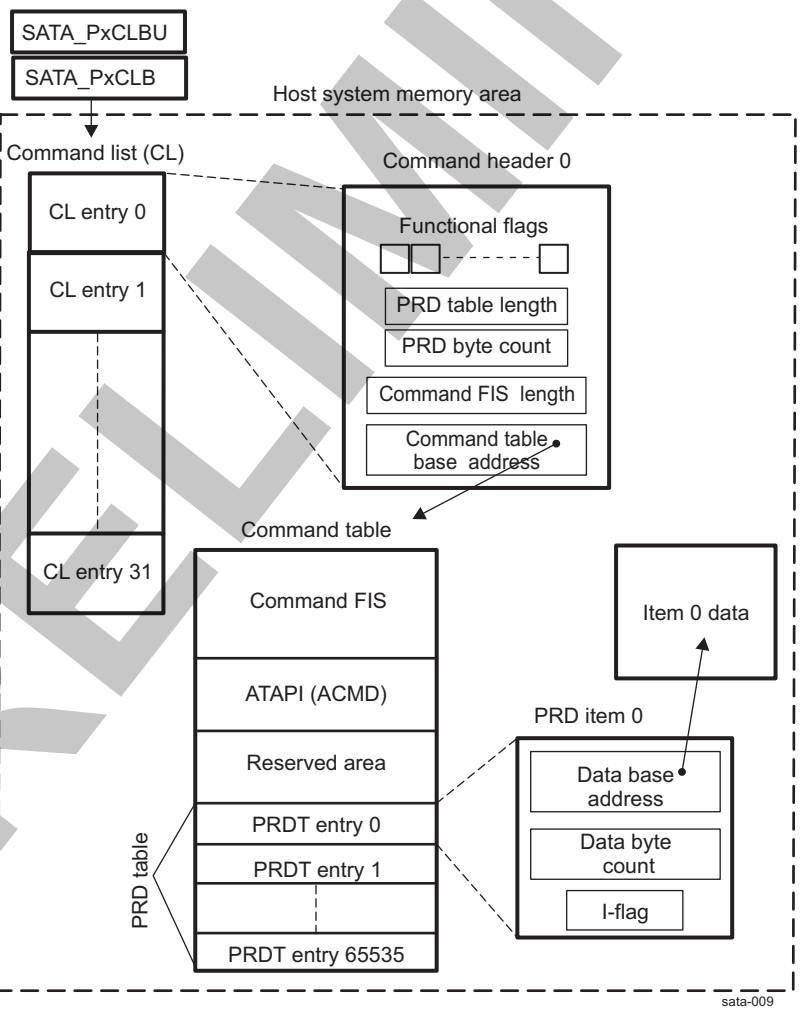
- A 64-byte command FIS area in which the user loads the command-associated FIS contents
- An ATAPI area in which a 12- or 16-byte ATAPI command is loaded, if specified in the CH (through bit A)
- A PRD table area that allows up to 65535 data descriptor entries

An entry of a PRD table (that is, a scatter/gather list item) specifies descriptor parameters of a data block transfer handled by the HBA port DMA.

Figure 23-253 shows the interrelations between the FIS-related structures that user software must allocate and build into the host system memory.

For details on command and data structures in host system memory, see the AHCI and SATA standard specifications.

Figure 23-253. Command List Descriptor Structures



After allocating the necessary portions for the CL, command slots underlying data descriptors, and received FISs into host system memory, the base addresses of these memory locations must be provided by user software to the HBA through the hardware init domain registers: SATA_PxCLB (command list base address - lower bits), SATA_PxCLBU (command list base address-upper bits), SATA_PxFB (received FISs system memory area base address-lower bits) and SATA_PxFBU (received FISs system memory area base address-upper bits) . Thus, the command and data DMA engines can access the transfer context programming structures.

NOTE: SATA_PxCLBU / SATA_PxFBU registers store the upper half of the native 64-bit AHCI addresses. Because only 36-lower bits of the AHCI 64-bit address bus are integrated in the device, actually only the 4-lower bits within SATA_PxCLBU / SATA_PxFBU are meaningful. **The remaining 28-bits must be always written to '0'-s in the descriptors (SATA_PxCLBU[31:4]=0x0 / SATA_PxFBU[31:4]=0x0) .**
Default value for the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

23.12.4.6.2 Supported Types of Commands

The following types commands are supported:

- Standard serial ATA nonqueued commands set.

  As opposed to NCQ, these commands are serviced, acknowledged one by one after a successful completion. The nonqueued SATA CL entries can take advantage of the PRD prefetching option indicated by the P flag in the corresponding CH (for more information, see the SATA specification). The ATA legacy commands are not supported by the SATA AHCI core.
- ATAPI commands
- ATAPI commands are supported by the SATA HBA engine. A request for an ATAPI command service is indicated by setting CH bit A to 0b1. The ATAPI command that the user builds into the ATAPI area of the command table can be 12 or 16 bytes in length and is indicated by the PIO Setup FIS sent by the SATA peripheral storage device requesting the ATAPI command. In addition, the SATA controller supports ATAPI active-LED generation (See Section 23.12.4.9, *Activity LED Generation Functionality*).

NCQ-commands

NCQ-commands are supported by the SATA controller HBA engine, the execution of which can be greatly facilitated by the CCC interrupt feature (for more information, see Section 23.12.4.5.5, *Command Completion Coalescing Interrupts*). As described in Section 23.12.1.1.2, *Native Command Queuing*, the NCQ commands have FPDMA queued command protocol mechanism, which implies that they are treated in a different way then standard SATA commands. The AHCI interface register set include specific registers, such as SATA_PxSACT, etc., to make the HBA aware of the outstanding NCQ slots in a command list. As opposed to standard nonqueued commands, NCQ commands are acknowledged before their actual completion, which accelerates the CL servicing for NCQ slots. The queue tag of the command requested by the SATA peripheral device is indicated to the HBA port by the TAG field in a DMA Setup FIS that an attached SATA peripheral device sends to the SATA controller host . The HBA then uses the tag value to index the NCQ commands updated by user software in the command list. The NCQ command descriptors are not allowed to use the prefetching option in CH because their order of execution is determined by the SATA target device.

23.12.4.6.3 Received FIS Structures

After stream decoding and primitive removal by the link layer, the validated FIS Dwords are extracted from the RxFIFO buffer by the transport layer DMA, and the original SATA storage drive FIS structures are recovered to a dedicated host system memory space. The DMA stores the received FISs into different memory areas based on FIS type. The unknown FIS reception is legal to HBA, as long as the length of the unknown FIS does not overrun the 64-byte size limit of the FIS descriptors. For details on received FISs memory area organization, see the AHCI and SATA standard specifications.

23.12.4.6.4 FIS Descriptors Summary

The FISs that encapsulate SATA target commands and data contents can be divided into:

- FISs transmitted from the host to an attached SATA peripheral device (H2D FISs)
- FISs sent by an attached SATA peripheral device to the host (D2H FISS)

The H2D FISs are constructed by user software into system memory. he H2D FIS types are:

- H2D Register FIS
- H2D DMA Setup FIS
- H2D Data FIS

The D2H FISs are constructed by the attached SATA peripheral device transport layer. The D2H FIS types are as follows:

- D2H Register FIS
- D2H DMA Setup FIS
- PIO Setup FIS
- DMA Activate FIS
- Set Device Bits FIS
- D2H Data FIS

For details on different type of FIS contents, see the SATA standard specification (revision 2.6).

23.12.4.7 Transport Layer FIS-Based Interactions

23.12.4.7.1 Software Processing of the Port Command List

After user software instantiates the CL structures in host system memory, it must maintain them appropriately. The command list is advanced when the BSY, DRQ, and ERR bits of a serial ATA device task file are cleared, which is communicated through a D2H register FIS to HBA port. The HBA port 0 hardware clears the corresponding to the i-th completed command: SATA_PxCI [i] CI (SATA_PxCI [TAG] CI for NCQ) bit to notify user software that the next command FIS can be advanced into the CL. The software then builds the command slot components: CH fields, command table, and associated PRD data descriptors in system memory. Software asserts the SATA_PxCI[i+1] CI (or SATA_PxCI[TAG] CI bit for an NCQ indicated command) to activate the prepared CL command, which is possible only when SATA_PxCMD[0] ST = 0x1. The nonqueued commands in the CL are processed in ascending order of slots (linear processing). The SATA_PxCMD [12:8]CCS read-only field indicates the CL index of the command currently being issued by the HBA port.

The processing of NCQ command slots invokes additional register update/check steps. Before setting the SATA_PxCI[TAG] CI bit to 0b1 and posting an active NCQ command to the SATA HBA port, software must indicate an NCQ outstanding command at the position defined by the SATA peripheral device queue TAG by setting SATA_PxSACT[TAG] DS = 0x1. After the queued command is posted, the peripheral SATA device sends a Set Device Bits FIS to the HBA port to clear the SATA_PxSACT bits corresponding to the successfully completed NCQ commands.

Command-list processing is initially triggered by software setting SATA_PxCMD[0] ST = 0x1, which requires certain conditions to be satisfied.

NOTE: There are some restrictions to setting SATA_PxCMD[0] ST to 0x1. For more information, see the AHCI specification (revision 1.1).

The SATA controller is capable of command list override (CLO) operation. CLO is activated by setting SATA_PxCMD[3] CLO = 0b1, which is expected only when SATA_PxCMD[0] ST = 0x0 (that is, the command list is not processed by the HBA) to avoid HBA-indeterminate behavior. As a consequence of a CLO operation, the SATA_PxTFD register STS_DRQ and STS_BSY flags are cleared. For example, CLO is necessary when the DRQ and BSY flags cannot be cleared by HBA before issuing a software reset (because of some hang condition). For more information on CLO behavior, see the AHCI standard specification.

23.12.4.7.2 Handling the Received FIS Descriptors

The HBA DMA facilitates the reception of the D2H FISs into host system memory. The reception is enabled by the user setting SATA_PxCMD[4] FRE to 0b1. The software is allowed to change the SATA_PxFB / SATA_PxFBU contents and thus move the FIS reception area to different system memory locations, if SATA_PxCMD[14] FR is cleared, which occurs after software writes SATA_PxCMD[4] FRE = 0b0. In this case, further FIS reception is blocked when the internal RxFIFO becomes full. Before setting SATA_PxCMD[4] FRE to 0x1, the user software must ensure that a valid address is programmed into the SATA_PxFB / SATA_PxFBU registers.

NOTE: The HBA port stores the unknown FISs (up to 64 bytes) in system memory but does not have a specified behavior to indicate an error condition on reception. The unknown FISs must be handled specifically by user software.

23.12.4.8 DMA Port Configuration

The SATA controller handles all data operations on its port with an internal DMA integrated in SATA AHCI core.

The SATA controller DMA transfers all information between system memory and the attached SATA peripheral device, as well as configuration and status FISs. The transmit and receive DMA data paths are independently programmable.

The burst size in both directions is fixed to 16 Dwords. The DMA issues transactions of this size or smaller (in Dword increments), depending on programmed transaction size.

NOTE: If the programmed transaction size is lower than 16-Dwords (burst size), then the DMA maxes out at transaction size.

The user can also separately program the transaction size for receive and transmit channels by setting the SATA_PxDMACR[7:4] RXTS and SATA_PxDMACR[3:0] TXTS bit fields. The transaction size is the minimum amount of data on which the DMA works. For example, if a FIS comes from the device to the host, the DMA does not begin transferring data into system memory until there is at least SATA_PxDMACR[7:4] RXTS number of Dwords in the receive FIFO. During transmit, the DMA reads data from system memory in SATA_PxDMACR[3:0] TXTS Dword increments to put into the transmit FIFO. Transactions can be broken up into multiple bursts of 16 Dword - size, crossing of a 1-KiB boundary (boundary between 1-KiB address blocks in memory), or end-of-frame. RXFIFO and TXFIFO transaction sizes are limited to maximum half the size of the integrated RXFIFO and TXFIFO buffers. For more information on maximum transaction sizes and RXFIFO/TXFIFO depths, see the SATA_PxDMACR and SATA_PPARAMR descriptions.

23.12.4.9 Activity LED Generation Functionality

The HBA port drives the device-level sata_actled signal that is active on the following conditions (see also Table 23-1410):

- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b0 (for active nonATAPI commands indication)
- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b1 and SATA_PxCMD[25] DLAE = 0b1 (for active ATAPI commands indication)

When SATA_PxCI and SATA_PxSACT are cleared to 0x0, the LED on the sata_actled signal-associated pad is driven off.

23.12.4.10 Supported Types of SATA Transfers

SATA controller AHCI mode defines two types of transfers between the host system memory and a SATA peripheral device: DMA and PIO data transfers. Whether the transaction is of a DMA type or PIO type, the HBA fetches and stores data to memory, offloading the CPU. No register is implemented for direct user access to the data port.

PIO transfers specified by PIO Setup FISs are strongly discouraged because of their limited support of error indication. PIO commands use is limited to only few cases in which commands support only PIO mechanism, such as execution of the IDENTIFY DEVICE command and ATAPI command transfers in which the PACKET command is invoked. The SATA controller AHCI mechanism allows multiple DRQ blocks of data per PIO command.

23.12.4.10.1 Supported Higher Level Protocols

The following DMA, PIO, FPDMA-queued, and ATAPI command/data protocols are supported by the SATA controller AHCI engine:

- Standard SATA command-related
  - Nondata command protocol
  - PIO write protocol
  - PIO read protocol
  - DMA write protocol
  - DMA read protocol
- NCQ command-related
  - Write FPDMA-queued protocol
  - Read FPDMA-queued protocol
- ATAPI PACKET command-related
  - PACKET Nondata command protocol
  - PACKET PIO read/write protocol
  - PACKET DMA read/write protocol

23.12.4.11 SATA Controller AHCI Hardware Register Interface

Table 23-1417 summarizes the SATA host controller subsystem registers and divides them into functional categories.

Table 23-1417. Summary of SATA Host Subsystem Functional Registers

Register	Functional Category	Brief Register Description
SATA_SYSCONFIG	Device-level registers (wrapper of SATA AHCI core)	TI wrapper idle/standby power management configuration register
SATA_CDRLOCK(1)		TI wrapper register which defines default delay of received data valid information.
SATA_IDR	SATA vendor-specific (VS) register	TI high lander identification register
SATA_CAP	SATA controller generic registers	SATA HBA capabilities set 1
SATA_CAP2		SATA HBA capabilities set 2
SATA_VS		SATA HBA register showing supported AHCI specification revision
SATA_GPARAM1R		SATA HBA global parameters set 1
SATA_GPARAM2R		SATA HBA global parameters set 2
SATA_GHC		SATA HBA global AHCI settings
SATA_PPARAMR	SATA HBA ports-related registers	SATA HBA port x(2) parameter settings
SATA_PI		Enables SATA HBA port x(2) functionalities
SATA_IS		Enables all SATA HBA port x(2) associated interrupts (first tier of interrupt schema)
SATA_CCC_PORTS		Enables SATA CCC feature for the port x(2)
SATA_CCC_CTL		CCC feature parameters control and status
SATA_TIMER1MS		Time base for 1-ms unit of CCC timeout

(1) Under normal conditions, the user is supposed to keep this register at its default (power-on-reset) value.
(2) x = 0, as only SATA HBA port 0 is implemented

Table 23-1417. Summary of SATA Host Subsystem Functional Registers (continued)

Register	Functional Category	Brief Register Description
SATA_PxCLB	SATA HBA Port Px[2] SATA Specification- defined Functional Registers	CL base address (lower-half of AHCI 64-bit address)
SATA_PxCLBU		CL base address (upper-half of AHCI 64-bit address)[3]
SATA_PxFB		Received FISs base address (lower-half of AHCI 64-bit address)
SATA_PxFBU		Received FISs base address (upper-half of AHCI 64-bit address)[3]
SATA_PxIE		Port x[2] non-CCC interrupt enable
SATA_PxIS		Port x[2] non-CCC interrupt event status
SATA_PxCMD		Port x[2] command register
SATA_PxTFD		Port x[2] task file data register
SATA_PxSIG		Port x[2] associated SATA signature register
SATA_PxSSTS		Port x[2] SStatus SATA register (See the SATA standard specification.)
SATA_PxSCTL		Port x [2]SControl SATA register (See the SATA standard specification.)
SATA_PxSERR		Port x [2]SError SATA register (See the SATA standard specification.)
SATA_PxSACT		Port x[2] SActive SATA register (See SATA standard specification.)
SATA_PxCI		Port x [2]command activation/completion indication register
SATA_PxSNTF		Port x[2] SNotification register (See the SATA standard specification.)
SATA_OOBR		OOB detection counters setup
SATA_PxDMACR	Non-standard Port Px[4] Control register	Port x[4] associated DMA configuration register
SATA_TESTR	SATA HBA BIST related registers	Test/normal mode switching
SATA_BISTAFR		BIST FIS-activate register
SATA_BISTCR		BIST control register
SATA_BISTFCTR		BIST FIS count register
SATA_BISTSR		BIST status register
SATA_BISTDECR		BIST Dword error count register

(3) Only the 4-lower bits meaningful in the device, the others must be kept at '0'
(4) x = 0, as only SATA HBA port 0 is implemented

23.12.5 SATA Controller Low Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the SATA host controller.

23.12.5.1 Global Initialization

23.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the SATA host controller is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SATA host controller (for more information, see Section 23.12.2 and Section 23.12.3). Table 23-1418 describes the global initialization of surrounding modules.

Table 23-1418. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled (see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*).
Control Module	Module-specific pad muxing and other PHY power configurations must be set in the control module (see Section 18.4.8, *Pad Functional Multiplexing and Configuration* and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*).
MPU INTC	INTC_MPU must be configured to enable the interrupt from the SATA controller (see Section 17.3.2, *Interrupt Requests to INTC_MPU*, in Chapter 17, *Interrupt Controllers*).
L4_CFG and L3_MAIN interconnects	For more information about the interconnect configuration, see Section 14.2.3.2.1,*L3_MAIN Interconnect Agents* and Section 14.3.1, *L4 Interconnect Overview*, in Chapter 14, *Interconnect.*

NOTE: The MPU INTC configuration is required when using the interrupt communication mode.

23.12.5.1.2 SATA Controller Global Initialization

23.12.5.1.2.1 Main Sequence SATA Controller Global Initialization

Table 23-1419 describes the procedure to initialize the SATA host controller after a POR.

Table 23-1419. SATA Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 adapter for PLLCTRL_SATA.	See Section 27.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 27, *Shared PHY Component Subsytems*.	-
Configure the DPLL_SATA.	See Section 27.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 27, *Shared PHY Component Subsytems*.	-
Configure the SATA_PHY.	See Section 27.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 27, *Shared PHY Component Subsytems*.	-
Perform all firmware capability writes. (1)	See Section 23.12.5.1.2.2, *SubSequence—Firmware Capability Writes*.	-
Set up all appropriate structures in memory per the AHCI standard specification.	See Section 23.12.4.6, *System Memory FIS Descriptors*. See also the AHCI standard specification.	-
Write a valid CL memory base address to the SATA_PxCLB register.	SATA_PxCLB [31:10] CLB	CL Base address (lower-half)
	SATA_PxCLBU [3:0] CLBU	CL Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Write a valid Rx FIS memory base address to the SATA_PxFB register.	SATA_PxFB [31:8] FB	Rx FIS Base address (lower-half)
	SATA_PxFBU [3:0] FBU	Rx FIS Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Issue a software type of reset depending on the error condition.	See Section 23.12.4.3.2, *Software Initiated Resets*.	-
Set the appropriate bits in the SATA_PxCMD register.	See section Section 23.12.4.7.1, *Software Processing of the Port Command List* . See also the AHCI standard specification.	-

(1) This step has an effect only on hardware initialization.

Table 23-1419. SATA Controller Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Program the SATA_PxSCTL register to configure SATA interface capabilities.	See the AHCI standard specification.	-
Program the SATA_PxDMACR register.	See Section 23.12.4.8, *DMA Port Configuration*.	-
Enable the interrupts at port 0.	SATA_IS[0] IPS	0x1
Enable the involved port 0 specific interrupts.	See Section 23.12.4.5.2, *Levels of Interrupt Control*, and Section 23.12.4.5.4, *Interrupt Condition Control*.	-
Enable the FIS reception in the SATA_PxCMD register.	SATA_PxCMD[4] FRE	0x1
Spin up the device (if required).	See the AHCI standard specification and the SATA standard specification.	-

NOTE: The SATA AHCI Controller always manipulates 64-bit memory pointers, and the master interface has 64-bit addresses, but the actual AHCI master interface integration in the device uses ONLY the 36-lower bits. In that case, even though the AHCI support indicates “64-bit” in the SATA_CAP[31] S64A, ONLY the 4-lower bits (SATA_PxCLBU [3:0] / SATA_PxFBU [3:0]) are meaningful in the device.**The upper 28 bits of the address, i.e.** SATA_PxCLBU [31:4] / SATA_PxFBU [31:4] **,must be always SW-programmed to '0'.**

NOTE: Default value of the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

23.12.5.1.2.2 SubSequence – Firmware Capability Writes

Table 23-1420 lists the firmware capability write sequence by which SATA HBA initialization is performed.

NOTE: In the following sequence, SATA controller accesses hardware initialization domain registers that can be written only one time after POR.

Table 23-1420. Firmware Capability Writes

Step	Register/Bit Field/Programming Model	Value
Disable the staggered spin-up support feature.(1)	SATA_CAP[27] SSS	0x0
Enable the SATA controller port 0.	SATA_PI[0] PI	0x1
Disable the mechanical presence detect feature.(1)	SATA_CAP[28] SMPS	0x0
Disable the external signal-only connector.(1)	SATA_PxCMD[22:21] ESP	0x0
Disable the cold presence detect feature. (1)	SATA_PxCMD[20] CPD	0x0
Disable support for the mechanical presence switch.	SATA_PxCMD[19] MPSP	0x0
Disable the hot-plug-capable port feature.	SATA_PxCMD[18] HPCP	0x0
Clear the SATA_PxCMD[17] PMA bit as a notification that a single-target SATA device is attached to port 0.	SATA_PxCMD[17] PMA	0x0

(1) It makes no sense to enable staggered spin-up because only one HBA port is used.

23.12.5.1.3 Issue Command - Main Sequence

The procedure in Table 23-1421 prepares a command list entry and issues its corresponding command.

Table 23-1421. Prepare and Issue a Command

Step	Register/Bit Field/Programming Model	Value
Build command header and command table into host system memory.	For details, see Section 23.12.4.6.1, *Command List Structure Basics*.	-
Create the command corresponding PRD table.		
Queue the command to the command list.	See Section 23.12.4.7.1, *Software Processing of the Port Command List*.	-
Set the SATA_PxCMD[0] ST bit to direct the DMA to start processing the CL.	SATA_PxCMD[0] ST	0x1 (1)
IF a nonNCQ command is issued:		
Set the corresponding SATA_PxCI.CI bit to activate a command already prepared in the i-th slot of the CL .	SATA_PxCI[i] CI	0x-
ELSE		
Indicate the NCQ slot positions through the SATA_PxSACT register. For details on TAG tracking, see Section 23.12.4.7.1.	SATA_PxSACT[TAG] DS	0x-
Set the corresponding SATA_PxCI.CI bit to activate the NCQ command already prepared in the i-th slot of the CL.	SATA_PxCI[TAG] CI	0x-

(1) See the AHCI standard specification for important restrictions when PXCMD[0] ST can be software-asserted to 1.

23.12.5.1.4 Receive FIS—Main Sequence

The procedure in Table 23-1422 is used to handle a FIS reception.

Table 23-1422. FIS Reception

Step	Register/Bit Field/Programming Model	Value
Read SATA_PxIS to determine the type of FIS.	For more information, see Section 23.12.4.7.2, *Handling the Received FIS Descriptors*.	-

23.12.6.2.2 DWC_ahsata Register Description

NOTE: Regardless of the SATA_CAP[17] SPM bit being read as 0b1, command-based switching Port Multiplier (PM) is unsupported by the only device SATA Controller port (Port 0). It is therefore recommended that user always configure attachment of a single mass storage device to device SATA port and disable the PM feature in software.

Table 23-1425. SATA_CAP

Address Offset	0x0000 0000		
Physical Address	0x4A14 0000	**Instance**	DWC_ahsata
Description	Capabilities register: Basic capabilities of the SATA AHCI core. Some fields can be written once after reset, read-only.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31	S64A	Supports 64-bit addressing Read 0x1: 64-bit addressing supported Read 0x0: 32-bit addressing supported	R	1
30	SNCQ	Supports NCQ Controller supports SATA NCQ by handling DMA setup FIS natively. Read 0x1: Supported Read 0x0: Not supported	R	1
29	SSNTF	Supports SNotification register Controller supports SATA_PxSNTF (SNotification) register and its associated functionality. Read 0x1: Supported Read 0x0: Not supported	R	1
28	SMPS	Supports mechanical presence switch Support of a mechanical presence switch for hot plug operation, depending on integration Writable once after power up, read-only afterward 0x0: Not supported 0x1: Supported	RW WSpecial	0
27	SSS	Supports staggered spin-up Controller can support this feature through SATA_PxCMD.SUD Writable once after power up, read-only afterward 0x0: Not supported 0x1: Supported	RW WSpecial	0
26	SALP	Supports aggressive link power management Read 0x1: Supported Read 0x0: Not supported	R	1
25	SAL	Supports Activity LED Read 0x1: Supported Read 0x0: Not supported	R	1

Bits	Field Name	Description	Type	Reset
24	SCLO	Supports command list override Supports the SATA_PxCMD.CLO bit functionality for enumeration of PM devices Read 0x1: Supported Read 0x0: Not supported	R	1
23:20	ISS	Interface speed support Maximum speed the HBA can support Read 0x3: Gen 3 = 6 Gbps Read 0x2: Gen 2 = 3 Gbps Read 0x1: Gen 1 = 1.5 Gbps	R	0x2
19	SNZO	Supports Non-zero DMA offsets Read 0x1: Supported Read 0x0: Not supported	R	0
18	SAM	Supports AHCI mode only SATA controller supports AHCI mode only and does not support legacy, task file-based register interface. Read 0x1: Supported Read 0x0: Not supported	R	1
17	SPM	Supports PM SATA controller supports command-based switching PM on any port. Read 0x1: Supported Read 0x0: Not supported	R	1
16	FBSS	FIS-based switching supported Support of PM FIS-based switching. Read 0x1: Supported Read 0x0: Not supported	R	0
15	PMD	PIO Multiple DRQ Support of multiple DRQ block data transfers for the PIO command protocol Read 0x1: Supported Read 0x0: Not supported	R	1
14	SSC	SLUMBER state capable Support of transitions to the interface SLUMBER power management state Read 0x1: Supported Read 0x0: Not supported	R	1
13	PSC	PARTIAL state capable Support of transitions to the interface PARTIAL power management state Read 0x1: Supported Read 0x0: Not supported	R	1
12:8	NCS	Number of command slots: slots supported by the SATA controller, minus 1 Read 0x1F: 32 command slots	R	0x1F
7	CCCS	Command completion coalescing supported Read 0x1: Supported Read 0x0: Not supported	R	1
6	EMS	Enclosure management supported Read 0x1: Supported Read 0x0: Not supported	R	0
5	SXS	Supports external SATA Read 0x1: Supported Read 0x0: Not supported	R	0

Bits	Field Name	Description	Type	Reset
4:0	NP	Number of ports: ports supported by the SATA controller, minus 1 Read 0x1: 2 ports Read 0x0: 1 port	R	0x00

Table 23-1445. SATA_BISTFCTR

Address Offset	0x0000 00A8		
Physical Address	0x4A14 00A8	**Instance**	DWC_ahsata
Description	BIST frame-information-structure CounT register Received BIST FIS count in the loopback initiator far-end retimed, far-end analog, and near-end analog modes. Updated each time a new BIST FIS is received. Reset by global reset, port reset (COMRESET), or by writing 1 to SATA_BISTCR.CNTCLR Does not roll over and freezes when the FFFF_FFFFh value is reached. It takes approximately 65 hours of continuous BIST operation to reach this value.		
Type	R

30	TFES	Task file error status Set whenever the SATA_PxTFD.STS register is updated by the device and the error bit (bit 0) is set. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
29	HBFS	Host bus fatal error status Set when master (DMA) detects an ERROR response from the slave Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
28	HBDS	Host bus data error status This bit is always cleared to 0. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
27	IFS	Interface fatal error status This bit is set when any of the following conditions is detected: 1) SYNC escape is received from the device during H2D register or data FIS transmission. 2) One or more of the following errors are detected during data FIS transfer: - 10B to 8B Decode Error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 3) Unknown FIS is received with good CRC, but the length exceeds 64 bytes. 4) PRD table byte count is 0. 5) DMA setup FIS is received with a TAG corresponding to inactive (SATA_PxSACT bit is cleared) command slot. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
26	INFS	Interface nonfatal error status Set when any of the following conditions is detected: 1) One or more of the following errors are detected during nondata FIS transfer: - 10b to 8b decode error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 2) Command list underflow during read operation (that is, DMA read) when the software builds a command table that has more total bytes than the transaction given to the device. In both cases port operation continues normally. When an error is detected during nondata FIS transmission, this FIS is retransmitted continuously until it succeeds, or until the software times out and resets the interface. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
25	RESERVED		R	0
24	OFS	Overflow status Set when command list overflow is detected during read or write operation when the software builds command table that has fever total bytes than the transaction given to the device. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
23	IPMS	Incorrect PM status FIS received from a device in which the PM field did not match what was expected May be set during enumeration of devices on a PM due to the normal PM enumeration process Must be used only after enumeration is complete on the PM Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
22	PRCS	PhyRdy change status Reflects the state of SATA_PxSERR.DIAG_N To clear this bit, clear the SATA_PxSERR.DIAG_N bit to 0. Read 0x1: Internal pX_phy_ready signal changed state Read 0x0: Internal pX_phy_ready signal has not changed state since its last reset.	R	0
21:8	RESERVED		R	0x0000

Bits	Field Name	Description	Type	Reset
7	DMPS	Device mechanical presence status Set when the pX_mp_switch input changes its state as a result of a mechanical switch attached to this port opening or closing Valid only when SATA_CAP.SMPS and SATA_PxCMD.MPSP are set Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
6	PCS	Port connect change status This bit reflects the state of the SATA_PxSERR.DIAG_X bit. Cleared only when SATA_PxSERR.DIAG_X is cleared Read 0x1: Change in current connect status Read 0x0: No change in current connect status	R	0
5	DPS	Descriptor processed A PRD with the I bit set has transferred all of its data. Note. This is an opportunistic interrupt and must not be used to definitively indicate the end of a transfer. Two PRD interrupts could occur close enough together that the second interrupt is missed when the first PRD interrupt is cleared. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
4	UFS	Unknown FIS interrupt An unknown FIS was received and has been copied into system memory. Cleared to 0 by the software clearing the SATA_PxSERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the SATA_PxSERR.DIAG_F bit. SATA_PxSERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. The software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync. Read 0x1: IRQ event active Read 0x0: Event inactive	R	0
3	SDBS	Set device bits interrupt A Set Device Bits FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
2	DSS	DMA setup FIS interrupt A DMA Setup FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
1	PSS	PIO setup FIS interrupt A PIO Setup FIS is received with the I bit set, copied into system memory, and the data related to the FIS is transferred. Note: This bit is set even when the data transfer resulted in an error. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
0	DHRS	Device to host register FIS interrupt A D2H register FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Table 23-1479. SATA_PxCMD

Address Offset	0x0000 0118		
Physical Address	0x4A14 0118	**Instance**	DWC_ahsata
Description	Port command		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ICC				ASP	ALPE	DLAE	ATAPI	ATPSE	RESERVED	ESP	CPD	MPSP	HPCP	PMA	CPS	CR	FR	MPSS	CCS					RESERVED			FRE	CLO	POD	SUD	ST

Bits	Field Name	Description	Type	Reset
31:28	ICC	Interface communication control Control of power management states of the interface If the link layer is in the L_IDLE state, writes cause the port to request a transition to a given interface state. If the link layer is not in the L_IDLE state, writes have no effect. When a nonreserved, non-0 (No-Op) value is written, the core performs the action and clears the field back to 0 (Idle) Write 0x0: No-Op 0x6: SLUMBER. SATA device can reject the request and the interface then remains in its current state. 0x1: Active Read 0x0: Port is ready to accept a new interface control command, although the transition to the previously selected state might not have occurred yet. 0x2: PARTIAL. SATA device can reject the request and the interface then remains in its current state.	RW	0x0
27	ASP	Aggressive SLUMBER/PARTIAL 0x0: If SATA_PxCMD.ALPE = 1, the port aggressively enters the PARTIAL state when it clears the SATA_PxCI register and the SATA_PxSACT register is cleared when it clears the SATA_PxSACT register and SATA_PxCI is cleared. 0x1: If SATA_PxCMD.ALPE = 1, the port aggressively enters the SLUMBER state when it clears the SATA_PxCI and the SATA_PxSACT register is cleared or when it clears the SATA_PxSACT register and SATA_PxCI is cleared.	RW	0

Bits	Field Name	Description	Type	Reset
26	ALPE	Aggressive link power management enable 0x0: Aggressive power management state transition is disabled. 0x1: Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of SATA_PxCMD.ASP.	RW	0
25	DLAE	Drive LED on ATAPI enable 0x0: LED is never enabled. 0x1: Port asserts the pX_act_led output when commands are active and SATA_PxCMD.ATAPI = 1.	RW	0
24	ATAPI	Device is ATAPI Used by the port to determine whether or not to assert pX_act_led output when commands are active. 0x0: Connected device is not an ATAPI. 0x1: Connected device is an ATAPI.	RW	0
23	ATPSE	Auto PARTIAL to SLUMBER 0x0: No automatic transition from PARTIAL to SLUMBER 0x1: Link layer transitions from its PARTIAL power management state to SLUMBER state automatically, whether host software-, port (aggressive)-, or device-initiated.	RW	0
22	RESERVED		R	0x0
21	ESP	External SATA port Writable once after power up, read-only afterward 0x0: Port signal-only connector is not externally accessible. 0x1: Port signal-only connector is externally accessible. SATA_CAP.SXS is also set to 1. Mutually exclusive with SATA_PxCMD.HPCP	RW	0x0
20	CPD	Cold presence detect Writable once after power up, read-only afterward 0x0: Platform does not support cold presence detection on this port. 0x1: Platform supports cold presence detection on this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
19	MPSP	Mechanical presence switch attached to port Writable once after power up, read-only afterward 0x0: Platform does not support a mechanical presence switch on this port. 0x1: Platform supports a mechanical presence switch attached to this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
18	HPCP	Hot plug capable port Writable once after power up, read-only afterward 0x0: Port signal and power connectors are not externally accessible. 0x1: Port signal and power connectors are externally accessible through a joint signal-power connector for blindmate device hot plug.	RW	0
17	PMA	PM attached Software is responsible for detecting the presence of a PM. There is no autodetection. 0x0: No PM is attached to this port. 0x1: PM is attached to this port.	RW	0

Bits	Field Name	Description	Type	Reset
16	CPS	Cold presence state Reports whether a device is currently detected on this port as indicated by the pX_cp_det input state (assuming SATA_PxCMD.CPD = 1). Read 0x1: Device detected Read 0x0: No device detected	R	0
15	CR	Command list running For details, see the AHCI state-machine in Section 5.3.2 of the AHCI specification. Read 0x1: Command list DMA engine for this port is running. Read 0x0: Command list is stopped for this port.	R	0
14	FR	FIS receive running For details, see Section 10.3.2 of the AHCI specification. Read 0x1: FIS receive DMA engine for the port is running. Read 0x0: FIS receive DMA engine for the port is stopped.	R	0
13	MPSS	Mechanical presence switch state Reports the state of a mechanical presence switch attached to this port as indicated by the pX_mp_switch input state (assuming SATA_CAP.SMPS = 1 and SATA_PxCMD.MPSP = 1) Cleared to 0 when SATA_CAP.SMPS = 0 Read 0x1: Switch is open. Read 0x0: Switch is closed.	R	0
12:8	CCS	Current command slot This field is valid when SATA_PxCMD.ST is set to 1 and is set to the command slot value of the command currently issued by the port. When SATA_PxCMD.ST transitions from 1 to 0, this field is reset to 0x00. After SATA_PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command is issued, the highest priority slot to issue from next is SATA_PxCMD.CCS + 1. For example, after the port issues its first command, if CCS = 0x00 and SATA_PxCI is set to 0x3, the next command issued is from command slot 1.	R	0x00
7:5	RESERVED		R	0x0
4	FRE	FIS receive enable Must not be set until SATA_PxFB / SATA_PxFBU is programmed with a valid pointer to the FIS receive area Base can be moved after clearing FRE and waiting for FR to clear to 0. 0x0: Received FISes are not accepted by the port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. 0x1: Port can post received FISes into the FIS receive area pointed to by SATA_PxFB and SATA_PxFBU.	RW	0
3	CLO	Command list override Write 0x0: No effect Write 0x1: Request to clear SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ to 0. Use only immediately prior to setting SATA_PxCMD.ST bit to 1 from a previous value of 0. Any other case results in indeterminate behavior. Read 0x1: Override is active, SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ are being cleared. Read 0x0: Override is inactive.	RW	0

Bits	Field Name	Description	Type	Reset
2	POD	Power-on device Writable if SATA_PxCMD.CPD = 1 (cold presence detection enabled), otherwise read-only -1. 0x0: Disabled 0x1: Port asserts the pX_cp_pod output pin so that it can be used to provide power to a cold-presence detectable port.	RW	0
1	SUD	Spin-up device Writable if SATA_CAP.SSS = 1 (staggered spin-up supported), else read-only 1. Read-only-0 on power-up until SATA_CAP.SSS bit is written with the required value. 0x0: Clearing the bit from 1 to 0 causes no action on the interface. 0x1: On edge-detect from 0 to 1, the port starts a COMRESET initialization sequence to the device.	RW	0
0	ST	Start 0x0: Port does not process the command list. On transition from 1 to 0, the SATA_PxCI register is cleared by the port on transition to an IDLE state. 0x1: Port processes the command list. On transition from 0 to 1, the port starts processing the command list at entry 0. SATA_PxSERR must be cleared prior to setting ST to 1. For important restrictions on when ST can be set to 1, See Section 10.3.1 of the AHCI specification.	RW	0

Table 23-1487. SATA_PxSCTL

Address Offset	0x0000 012C		
Physical Address	0x4A14 012C	**Instance**	DWC_ahsata
Description	Port SATA control Control of SATA interface capabilities. Writes to this register result in action taken by the port PHY interface. Reads from the register return the last value written to it. Reset on global reset. Wait for at least seven periods of the slower clock (OCP or parallel serdes clock) between writes, due to the internal clock domain crossing between the transport (OCP) and link (serdes I/F) layers.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												PMP				SPM				IPM				SPD				DET			

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x000
19:16	PMP	PM port: This field is not used by the AHCI.	R	0x0
15:12	SPM	Select power management: This field is not used by the AHCI.	R	0x0
11:8	IPM	Interface power management transitions allowed: Indicates which power states the HBA is allowed to transition to. If an interface power management state is disabled, the HBA is not allowed to initiate that state and the HBA must PMNAK_P any request from the device to enter that state. The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No interface power management state restrictions 0x1: Transitions to the PARTIAL state disabled 0x3: Transitions to both PARTIAL and SLUMBER states disabled 0x2: Transitions to the SLUMBER state disabled	RW	0x0
7:4	SPD	Speed allowed: Highest allowable speed of the interface The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No speed negotiation restrictions 0x1: Limit speed negotiation to generation 1 communication rate. 0x2: Limit speed negotiation to a rate not greater than generation 2 communication rate.	RW	0x0
3:0	DET	Device detection initialization: Controls the HBA device detection and interface initialization. Can be modified only when SATA_PxCMD.ST = 0. Must have a value of 0x0 when SATA_PxCMD.ST = 1. MSB is always 1'b0 (not writable), as for all unreserved field values. 0x0: No device detection or initialization action requested 0x1: Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications reinitialized. While this field is 1h, COMRESET is transmitted on the interface. Software must leave the DET field set to 1h for a minimum of 1 ms to ensure that a COMRESET is sent on the interface. 0x4: Disable the serial ATA interface and put PHY in offline mode.	RW	0x0

Table 23-1488. Register Call Summary for Register SATA_PxSCTL

Bits	Field Name	Description	Type	Reset
31:27	RESERVED		R	0x00
26	DIAG_X	Exchanged: PHY COMINIT signal detected. Reflected in SATA_PxIS.PCS.	RW W1toClr	0
25	DIAG_F	Unknown FIS type: One or more FISes were received by the transport layer with good CRC, but had a type field that was not recognized/known and the length was = 64 bytes. Note: If the unknown FIS length exceeds 64 bytes, DIAG_F is not set and DIAG_T is set instead.	RW W1toClr	0
24	DIAG_T	Transport state transition error: Transport Layer protocol violation detected.	RW W1toClr	0
23	DIAG_S	Link sequence error: One or more Link state machine error conditions encountered, including device doing SYNC escape during FIS transmission.	RW W1toClr	0
22	DIAG_H	Handshake error: One or more R-ERRp received in response to frame transmission. May be the result of a CRC error detected by the device, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame.	RW W1toClr	0
21	DIAG_C	CRC error: One ore more CRC errors detected by the link layer during FIS reception.	RW W1toClr	0
20	DIAG_D	Disparity error: Not used by AHCI, always 0.	R	0
19	DIAG_B	10bit-to-8bit decode error: Errors detected by the 10b8b decoder. Note: Set only when an error is detected on the received FIS data word. Not set when an error is detected on the primitive, regardless of whether it is inside or outside the FIS.	RW W1toClr	0
18	DIAG_W	Comm wake: Comm wake signal detected by the PHY.	RW W1toClr	0
17	DIAG_I	PHY internal error: Internal error detected by the PHY. Note: If the PHY does not support any errors, this bit is never set.	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
16	DIAG_N	PhyRdy change: Indicates that the PHY Ready signal changed state. Reflected in SATA_PxIS.PRCS.	RW W1toClr	0
15:12	RESERVED		R	0x0
11	ERR_E	Internal error: One or more errors detected on the master (DMA) or the slave (MMR access) interfaces.	RW W1toClr	0
10	ERR_P	Protocol error: Any of the following conditions: - Transport state transition error (DIAG_T) - Link sequence error (DIAG_S) - RxFIFO overflow - Link bad end error (WTRM instead of EOF received)	RW W1toClr	0
9	ERR_C	Nonrecovered persistent communication error: PHY Ready signal is negated due to loss of communication with the device or problems with the interface, but not after transition from ACTIVE to PARTIAL or SLUMBER power management state.	RW W1toClr	0
8	ERR_T	Nonrecovered transient data integrity error: Any of the following conditions are set during data FIS transfer: - ERR_P (Protocol) - DIAG_C (CRC) - DIAG_H (Handshake) - ERR_C (PHY Ready negation)	RW W1toClr	0
7:2	RESERVED		R	0x00
1	ERR_M	Recovered communication error: PHY Ready condition is detected after interface initialization, but not after transition from PARTIAL or SLUMBER power management state to ACTIVE state.	RW W1toClr	0
0	ERR_I	Recovered data integrity error: Any of the following conditions are set during non-data FIS transfer: - ERR_P (Protocol) - DIAG_C (CRC) - DIAG_H (Handshake) - ERR_C (PHY Ready negation)	RW W1toClr	0

DS																															

Bits	Field Name	Description	Type	Reset
31:0	DS	Device status: Field is bit-significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. Set by Software prior to issuing a native queued command for a particular command slot. Prior to writing SATA_PxCI[TAG] to 1, software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits by sending a set device bits FIS to the port. The port clears bits in this field that are set to 1 in the SActive field of the set device bits FIS. The port only clears bits that correspond to native queued commands completed successfully. Write only when SATA_PxCMD.ST bit is set to 1. Cleared when SATA_PxCMD.ST is written from 1 to 0. Not cleared by a port reset (COMRESET) or a software reset.	RW	0x0000 0000

Description	This register controls the idle and standby modes of Highlander 08 modules.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															OVERRIDE0	RESERVED										STANDBYMODE		IDLEMODE		RESERVED		

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0000
16	OVERRIDE0	Override for clock stopping. Normally the functional clock can be stopped only if the link is put into PARTIAL or SLUMBER power state. However, if there is no device attached (such as in a removable media situation) or the device is not started, the user can stop the functional clocks but not be able to enter a low-power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low-power state WARNING: If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low-power state it ruins the link and causes undetermined behavior. A port reset or full SATASS reset might be required to recover. 0x0: Normal mode 0x1: Override mode	RW	0
15:6	RESERVED		R	0x000
5:4	STANDBYMODE	Configuration of the local initiator-state management mode. By definition, the initiator can generate a read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: Local initiator is unconditionally placed in STANDBY state. Backup mode, for debug only 0x1: No-standby mode: local initiator is unconditionally placed out of STANDBY state. Backup mode, for debug only. 0x3: Smart-Standby wakeup-capable mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module can generate (master related) wakeup events when in STANDBY state. Mode is relevant only if the appropriate IP module mwakeup output is implemented. 0x2: Smart-standby mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module does not generate (initiated-related) wakeup events.	RW	0x2
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, the target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: The local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the internal requirements of th e IP module. Backup mode, for debug only. 0x1: No-idle mode: The local target never enters IDLE state. Backup mode, for debug only. 0x3: Smart-idle wakeup-capable mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module can generate (IRQ- or DMA-request-related) wakeup events when in IDLE state. Mode is only relevant if the appropriate IP module swakeup output(s) is (are) implemented. 0x2: Smart-idle mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module does not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
1:0	RESERVED		R	0x0

MMC/SDIO

This chapter describes the features and functions of the multimedia card (MMC/SDIO) interface of the device.

NOTE: Some of the MMC/SDIO interfaces are not available in all OMAP54xx devices.

For details, see Section 1.5, *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

24.1 MMC/SDIO Overview

The multimedia card high-speed/SDIO (MMC/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD® memory cards, or SDIO cards and handles MMC/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the level 3 (L3_MAIN) interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration. These controllers are embedded MMC/SD (eMMC/SD) controllers.

The application interface manages transaction semantics. The MMC/SDIO host controller deals with MMC/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SDIO host controller also supports two DMA channels.

There are five MMC/SDIO host controllers inside the device:

Figure 24-1 gives an overview of the MMC/SDIO1 controller instance MMC1 (SD card).

Figure 24-2 gives an overview of the MMC/SDIO2 controller instance MMC2 (eMMC).

Figure 24-3 gives an overview of the MMC/SDIO3 controller instance MMC3 (WLAN SDIO).

Figure 24-4 gives an overview of the MMC/SDIO4 and MMC/SDIO5 controller instances (generic SDIO controllers).

Figure 24-1. MMC/SDIO1 Overview

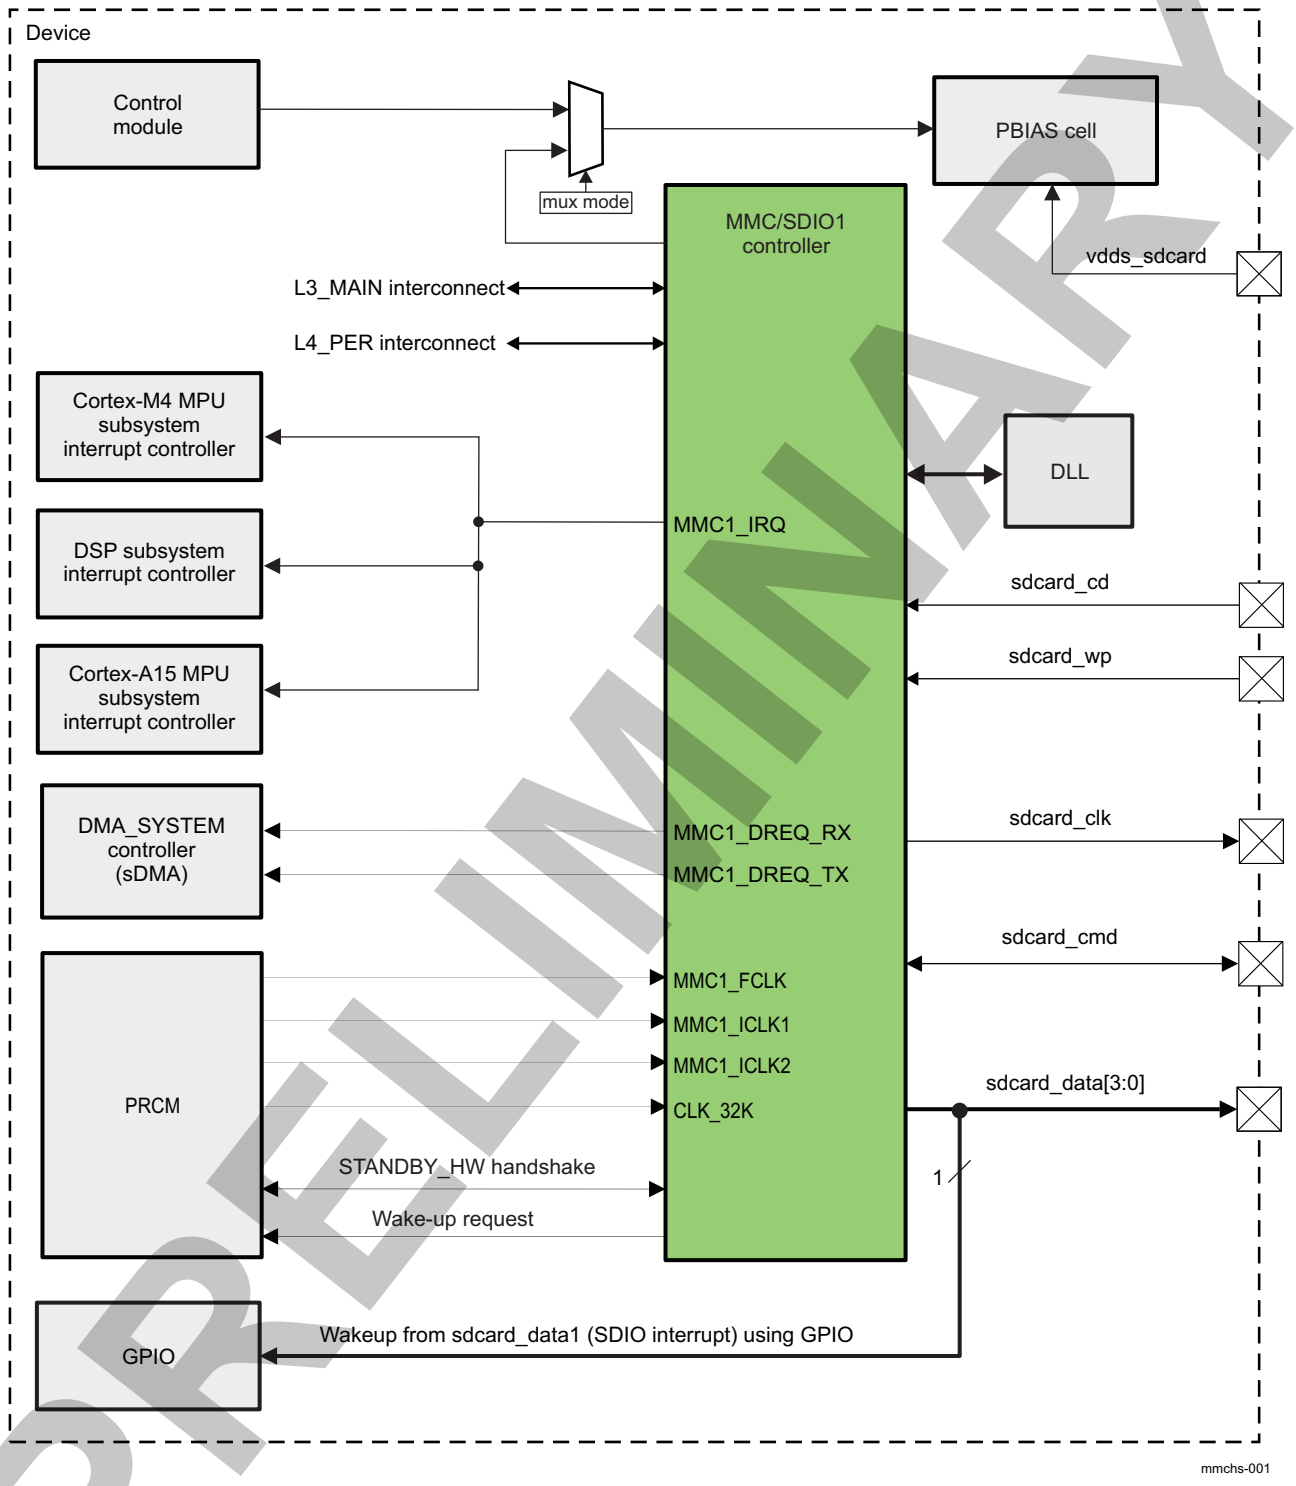

Figure 24-2. MMC/SDIO2 Overview

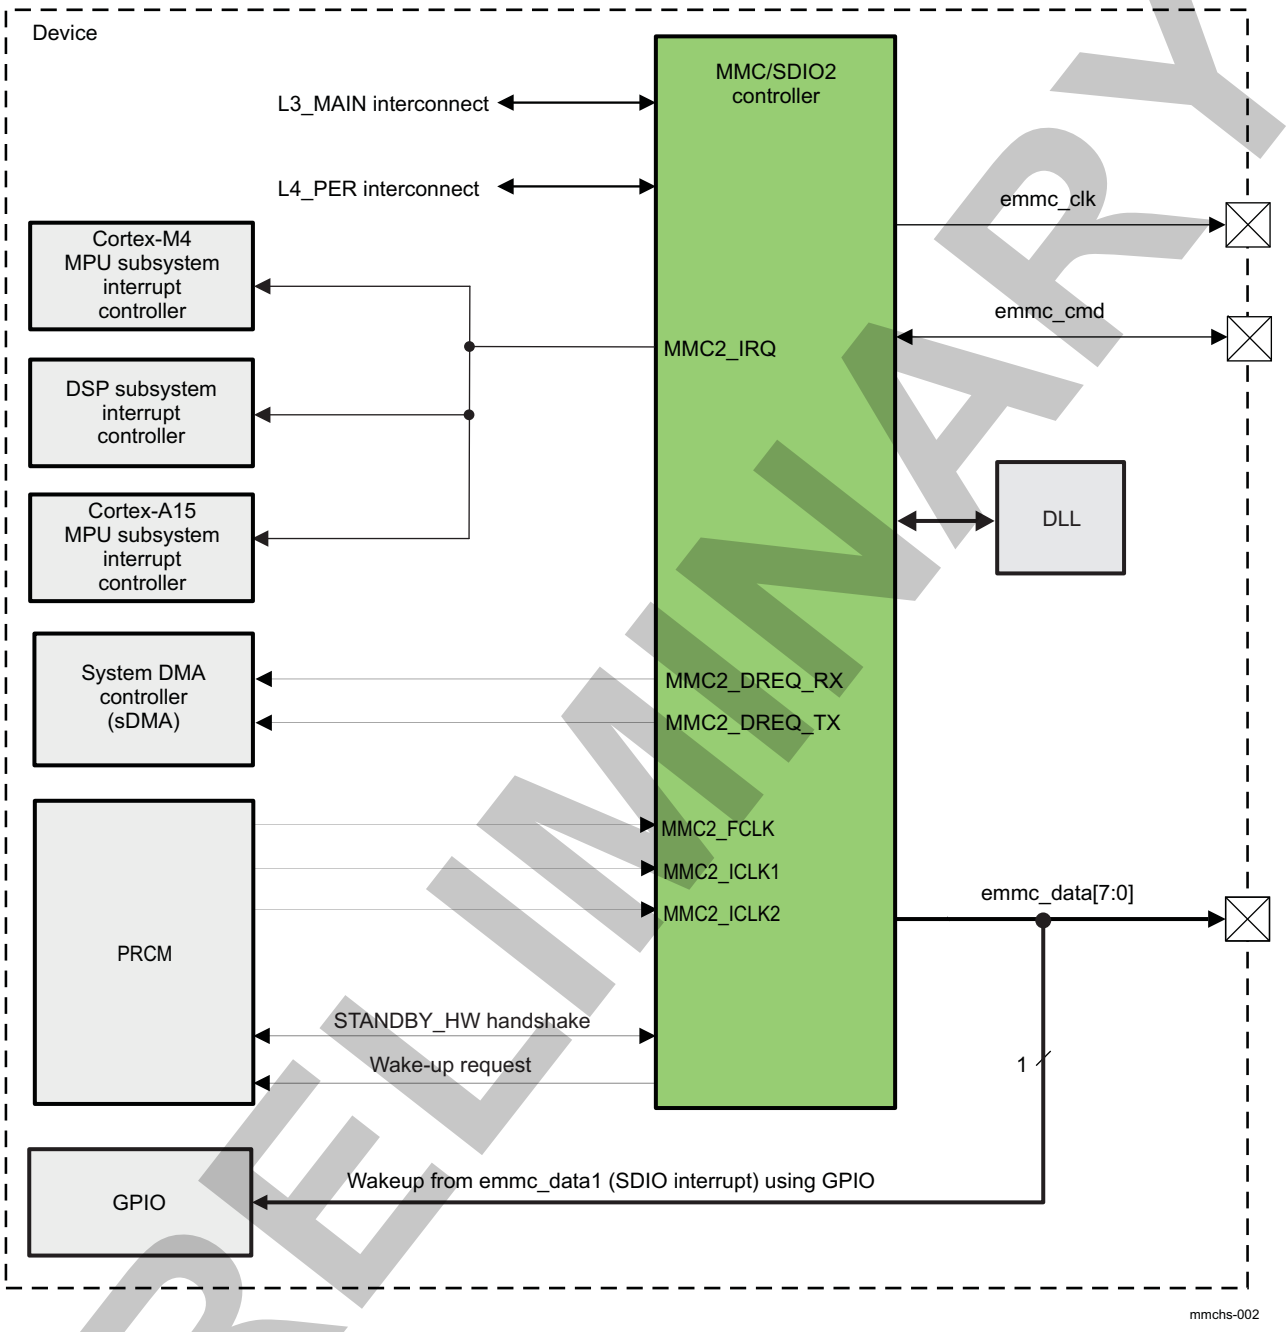

Figure 24-3. MMC/SDIO3 Overview

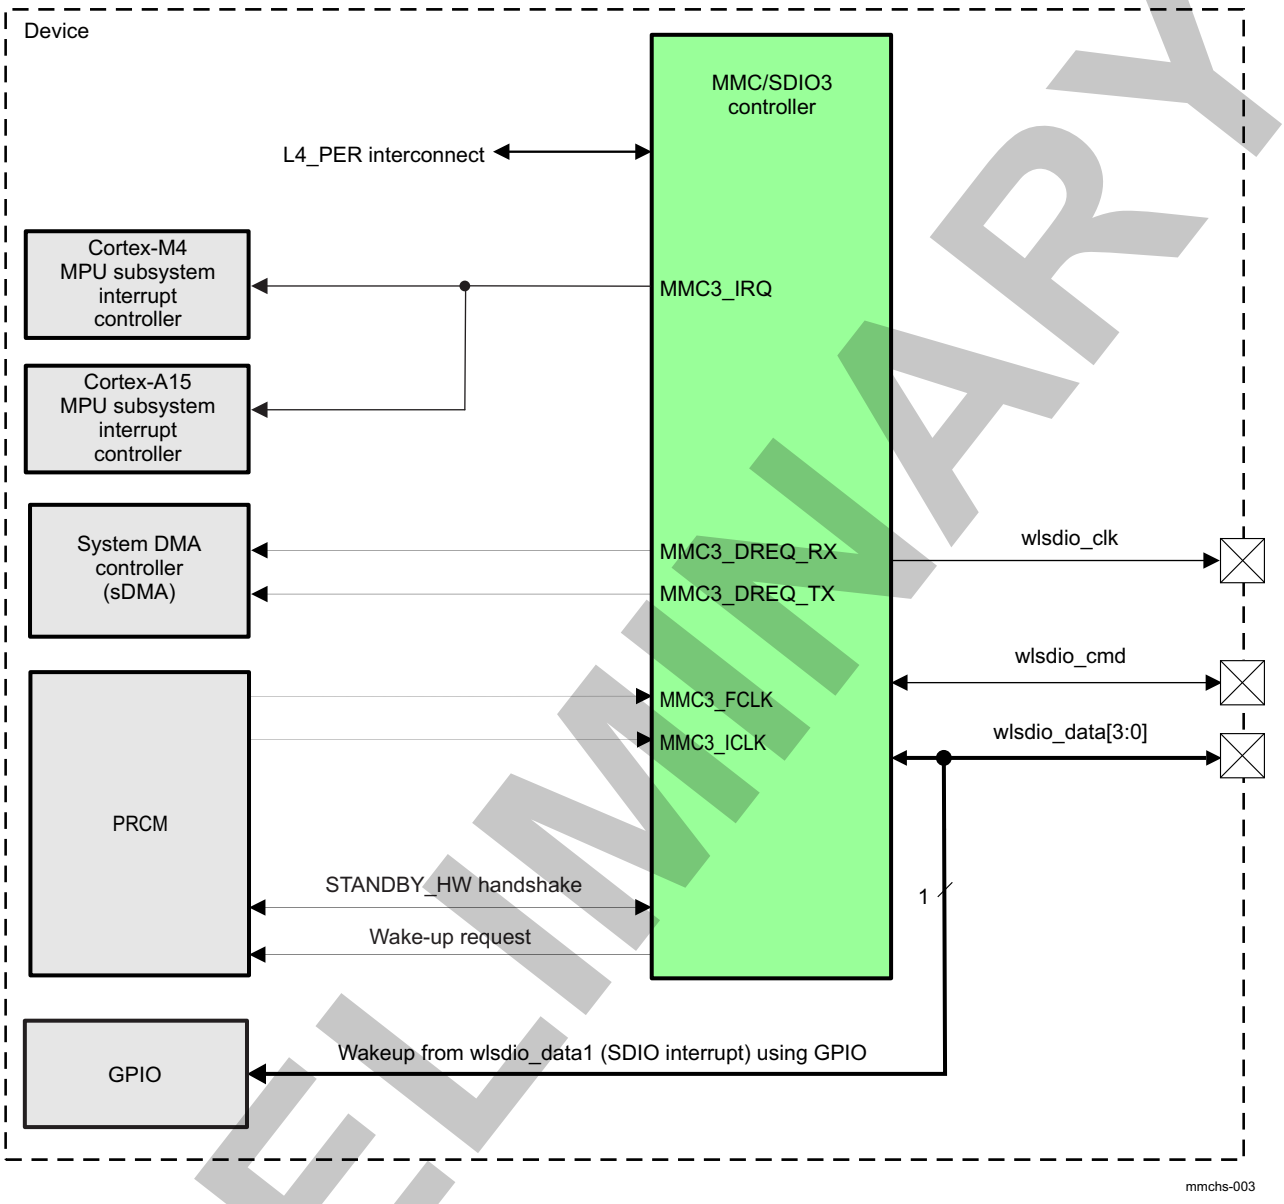

Figure 24-4. MMC/SDIOi Overview (where i = 4 or 5)

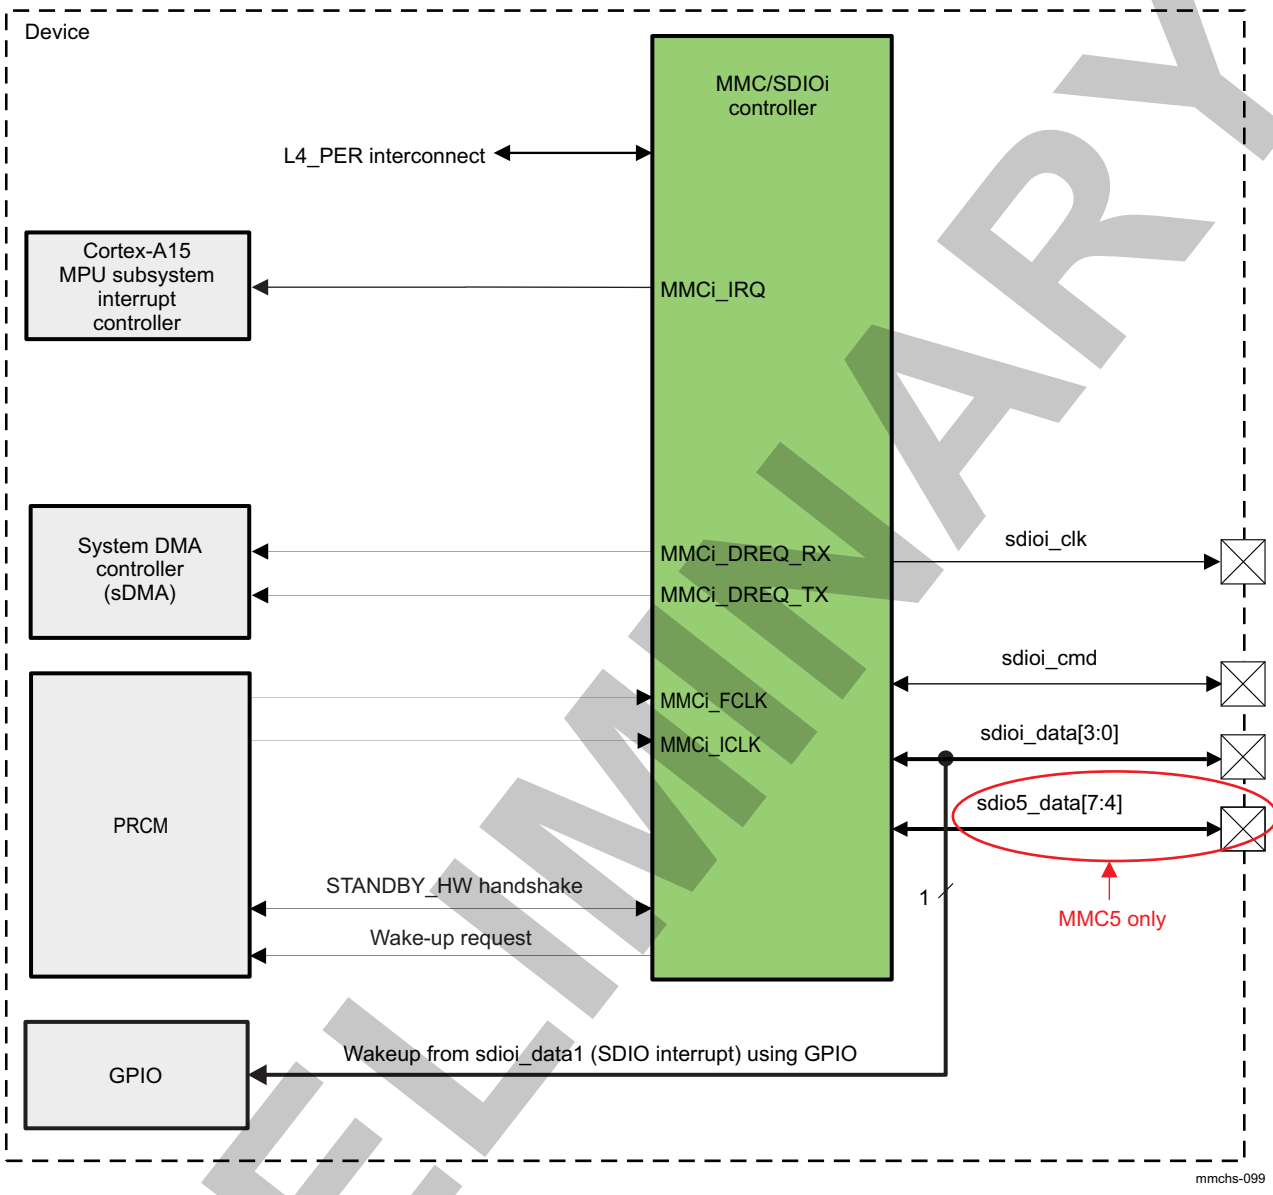

24.1.1 MMC/SDIO Features

This section describes the features supplied by the MMC/SDIO modules.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the JC64 MMC/eMMC standard specification, v4.5.
- Full compliance with SD command/response sets as defined in the SD Physical Layer specification v3.01
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00

Main features of the MMC/SDIO host controllers:

- Flexible architecture allowing support for new command structure

- 32-bit wide access bus to maximize bus throughput
- Designed for low power
- Programmable clock generation
- Support retention mode
- Dedicated DLL to support SDR104 mode (MMC1 only)
- Dedicated DLL to support HS200 mode (MMC2 only)
- Card insertion/removal detection and write protect detection (MMC1 only)
- L4 slave interface supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width
  - Streaming burst supported only with burst length up to 7
  - WNP supported
- L3 initiator interface Supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
- Built-in 1024-byte buffer for read or write
- Two DMA_SYSTEM channels, one interrupt line
- Support JC 64 v4.4.1 boot mode operations
- Support SDA 3.00 Part A2 programming model
- Support SDA 3.00 Part A2 DMA feature (ADMA2)
- Supported data transfer rates:
  - MMC1 supports the following SD v3.0 data transfer rates:
    - DS mode (3.3V IOs): up to 12 MBps (24 MHz clock)
    - HS mode (3.3V IOs): up to 24 MBps (48 MHz clock)
    - SDR12 (1.8V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (1.8V IOs): up to 24 MBps (48 MHz clock)
    - SDR50 (1.8V IOs): up to 48 MBps (96 MHz clock, due to IO frequency limitation)
    - DDR50 (1.8V IOs): up to 48 MBps (48 MHz clock)
    - SDR104 (1.8V IOs) cards can be supported up to 192 MHz clock (96 MBps max)
  - MMC1 supports the Default SD mode 1-bit data transfer up to 24Mbps (3MBps)
  - MMC2 supports the following JC64 v4.5 data transfer rates:
    - Up to 192 MBps in eMMC mode, 8-bit SDR mode (192 MHz clock frequency)
    - Up to 96 MBps in eMMC mode, 8-bit DDR mode (48 MHz clock frequency)
  - MMC2 supports JC64 v4.5

The differences between the MMC/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v3.00 are:

- The clock divider in the MMC/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v3.0. The MMC/SDIO host controller supports odd and even clock ratio.
- The MMC/SDIO host controller supports configurable busy time-out.
- DMA_SYSTEM and ADMA2 64-bit modes are not supported.
- There is no external LED control.

NOTE: Only even ratios are supported in DDR mode.

Table 24-1 lists the features supported in the 4.5 standard.

Table 24-1. Standard 4.5 Supported Features

Feature	Support	Limitation	Comment
Bus width	1-bit mode		x 1, 4, 8 bits
	4-bit mode		
	8-bit mode		
Support density	No hardware limitation for density support	Limitation can come from file system (32 GiB).	
Simple boot (CMD, alternate boot)	Yes		OMAP5 ROM code supports the following boot modes: 1. Alternate Boot 2. Raw (UDA) Boot 3. File System For more information about boot modes, see Section 28.3.7, *Memory Booting*. in Chapter 28, *Initialization.*
Sleep mode	Yes		
Reliable write	Yes		
Secure write protection	Yes		
Hardware reset	No		Use the reset command instead of GPIO if hardware reset is needed.
Secure memory block (RPMB)	Yes		
Partition feature	Yes		
Secure erase	Yes		
1.2 V	Yes		
DDR interface (bandwidth)	Up to 96 MBps in DDR mode – 8-bit		
High-priority interrupt (read while write)	Yes		
Background operation	Yes		
Enhanced reliable write	Yes		

24.2 MMC/SDIO Environment

One MMC/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC, and one SD card) are not supported through a single controller.

- The MMC/SDIO1 controller integrates an internal transceiver that allows a direct connection to the MMC/SDIO card (1.8 V and 3 V), without external transceiver. It is connected to the L3_MAIN interconnect (internal DMA enabled) and supports 1- and 4-bit data transfers.
- The MMC/SDIO2 controller allows connecting MMC/SDIO cards (only 1.8-V cards) or an external device that uses the MMC/SDIO interface (JC64, for example). The module is connected to the L3_MAIN interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers.
- The MMC/SDIO3, MMC/SDIO4, and MMC/SDIO5 controllers allow connecting MMC/SDIO cards (only 1.8-V cards) or an external device that uses the MMC/SDIO interface (wireless LAN, for example). The modules are connected to the level 4 (L4) interconnect. MMC3 and MMC4 instances support 1- and 4-bit data transfers. MMC5 instance supports 1-, 4-, and 8-bit data transfers, but 8-bit data transfer is supported only with embedded devices.

24.2.1 MMC/SDIO Functional Modes

24.2.1.1 MMC/SDIO Connected to an MMC, SD, or SDIO Card

Figure 24-5 shows the MMC/SDIOi host controller (where i = 1, 3, and 4) connected to an MMC, SD, or SDIO card and its related external connections.

Figure 24-5. MMC/SDIOi Controller Connected to an MMC, SD, or SDIO Card (where i = 1, 3, and 4)

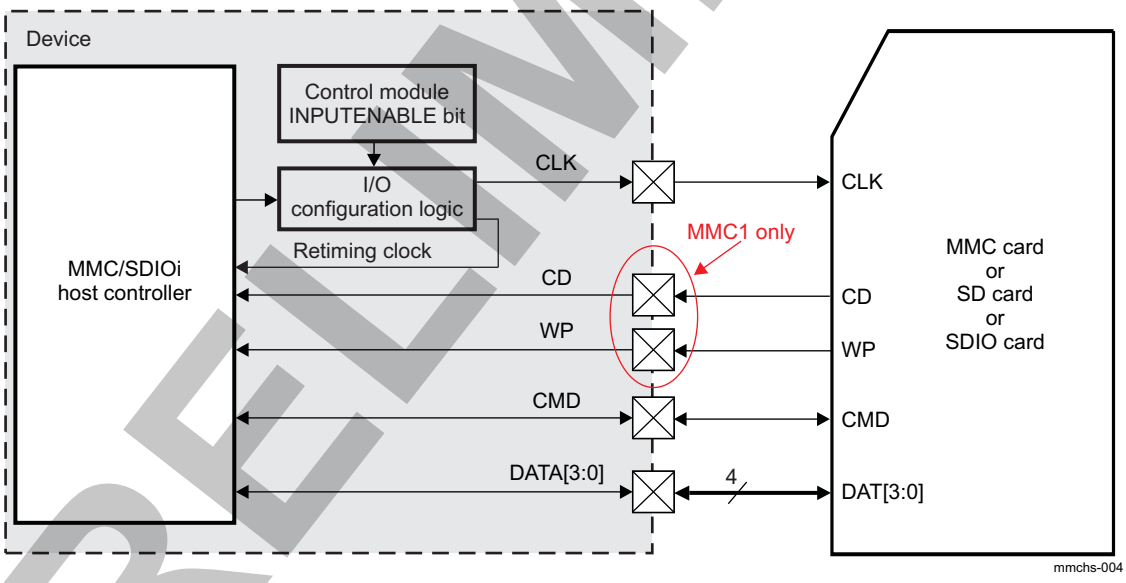

Table 24-2 describes the MMC/SDIOi host controller I/O's (where i = 1, 3, and 4).

Table 24-2. Description of MMC/SDIOi host controller I/O's (where i = 1, 3, and 4)

Instance	Signal/Pad name	Generic Signal Name	I/O[1]	Description	Reset Value[2]
MMC1	sdcard_clk	CLK	O	External clock for MMC/SD/SDIO card[3]	0
	sdcard_cmd	CMD	I/O	Command signal	Hi-Z[4]
	sdcard_data[3:0]	DATA[3:0]	I/O	Data signals	Hi-Z[4]
	sdcard_cd	CD	I	Card insertion/removal detection signal	Hi-Z
	sdcard_wp	WP	I	Wriwe protect detection signal	Hi-Z
MMC3	wlsdio_clk	CLK	O	External clock for MMC/SD/SDIO card[3]	0
	wlsdio_cmd	CMD	I/O	Command signal	Hi-Z[4]
	wlsdio_data[3:0]	DATA[3:0]	I/O	Data signals	Hi-Z[4]
MMC4	sdio4_clk	CLK	O	External clock for MMC/SD/SDIO card[3]	0
	sdio4_cmd	CMD	I/O	Command signal	Hi-Z[4]
	sdio4_data[3:0]	DATA[3:0]	I/O	Data signals	Hi-Z[4]

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).
(4) Initialized as input upon reset

Figure 24-6 shows the MMC/SDIOi host controller (where i = 2 and 5) connected to an MMC, SD or SDIO card and its related external connections.

Figure 24-6. MMC/SDIOi Controller Connected to an MMC, SD, or SDIO Card (where i = 2 and 5)

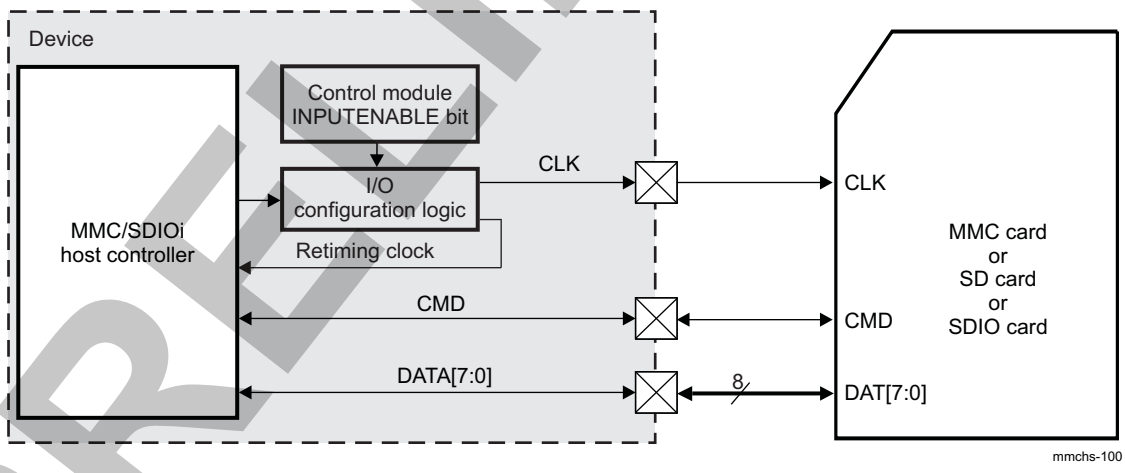

Table 24-3 describes the MMC/SDIOi host controller I/O's (where i = 2 and 5).

Table 24-3. Description of MMC/SDIOi host controller I/O's (where i = 2 and 5)

Instance	Signal/pad name	Generic signal name	I/O[1]	Description	Reset value[2]
MMC2	emmc_clk	CLK	O	External clock for MMC/SD/SDIO card[3]	0
	emmc_cmd	CMD	I/O	Command signal	Hi-Z[4]
	emmc_data[7:0]	DATA[7:0]	I/O	Data signals	Hi-Z[4]
MMC5	sdio5_clk	CLK	O	External clock for MMC/SD/SDIO card[3]	0
	sdio5_cmd	CMD	I/O	Command signal	Hi-Z[4]
	sdio5_data[7:0]	DATA[7:0]	I/O	Data signals	Hi-Z[4]

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).
(4) Initialized as input upon reset

24.2.2 Protocol and Data Format

The bus protocol between the MMC/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

- Command: A command starts an operation. The command is transferred serially from the MMC/SDIO host controller to the card on the CMD line.
- Response: A response is an answer to a command. The response is sent from the card to the MMC/SDIO host controller. It is transferred serially on the CMD line.
- Data: Data are transferred from the MMC/SDIO host controller to the card or from a card to the MMC/SDIO host controller using the data lines.
- Busy: The DATA[0] signal is maintained low by the card as far as it is programming the data received.
- CRC status: The CRC result is sent by the card through the DATA[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DATA[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DATA[0] and starts the data programming procedure.

24.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 24-7 and Figure 24-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the sdmmci_cmd line.

NOTE: Stream commands are supported only by MMC cards.

Figure 24-7. Sequential Read Operation (MMC Cards Only)

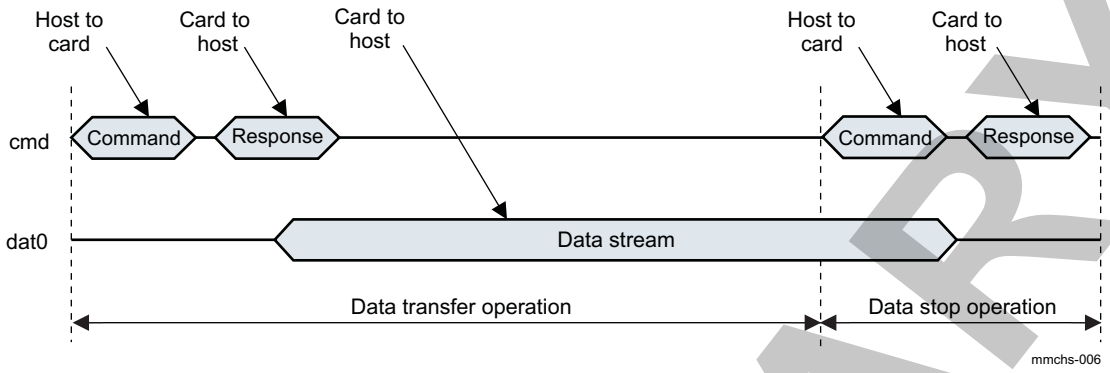

Figure 24-8. Sequential Write Operation (MMC Cards Only)

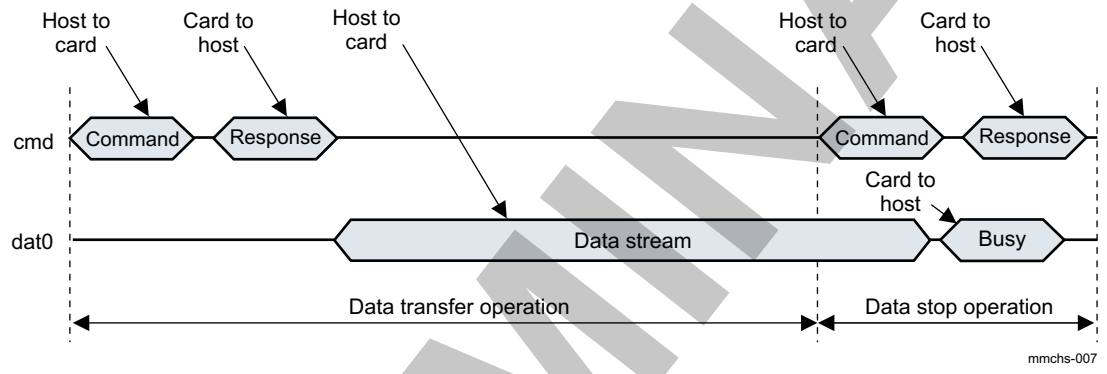

Figure 24-9 and Figure 24-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the sdmmci_cmd line. These operations are available for all kinds of cards.

Figure 24-9. Multiple Block Read Operation

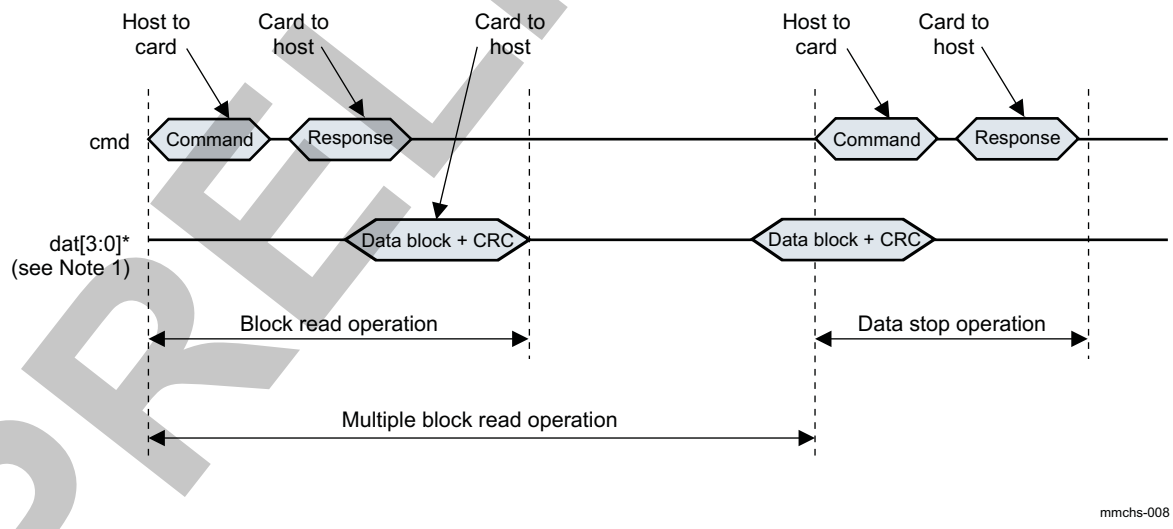

Figure 24-10. Multiple Block Write Operation With Card Busy Signal

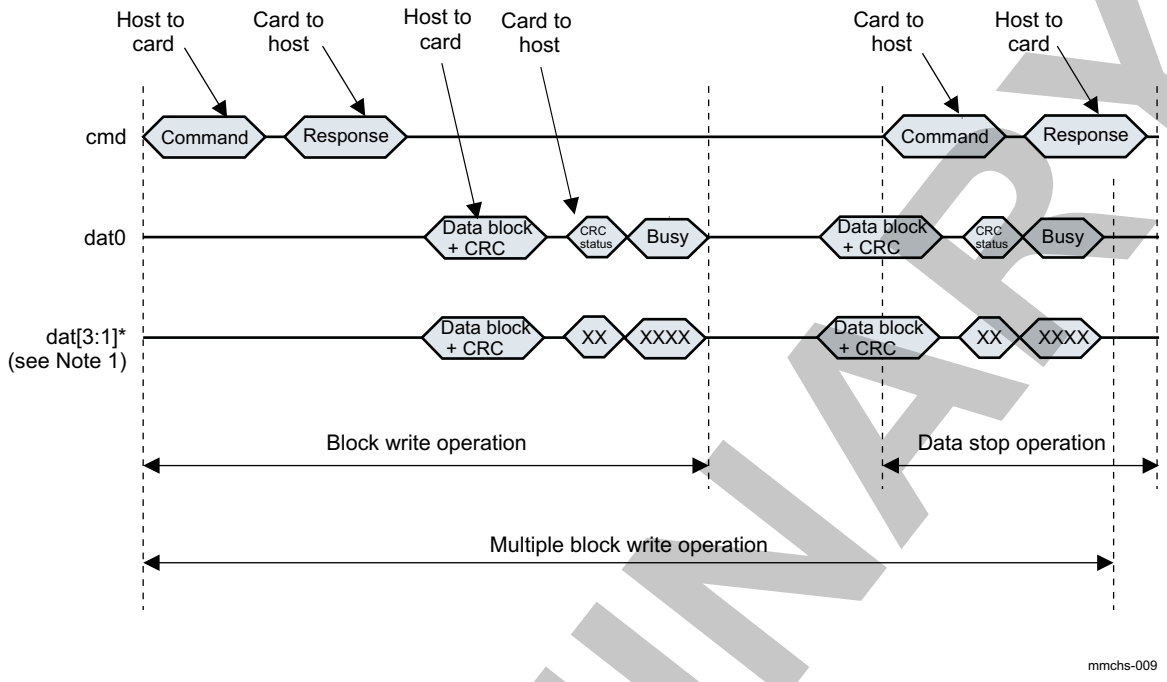


NOTE:

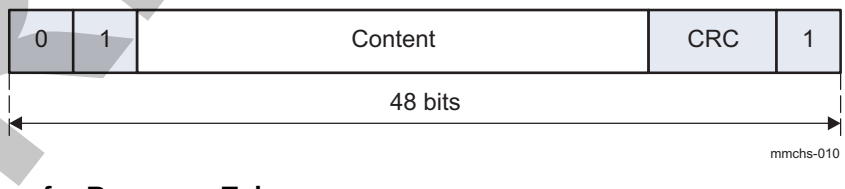
- The card busy signal is not always generated by the card; refer to Figure 24-9 and Figure 24-10, that show a particular case.
- Software must perform a software reset (set the MMCi.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure that CLK is stopped.
- For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

24.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 24-11).

Figure 24-11. Command Token Format



Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see Figure 24-12 and Figure 24-13). Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 24-4). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 24-12. Response Token Format (R1, R3, R4, R5, R6, R7)

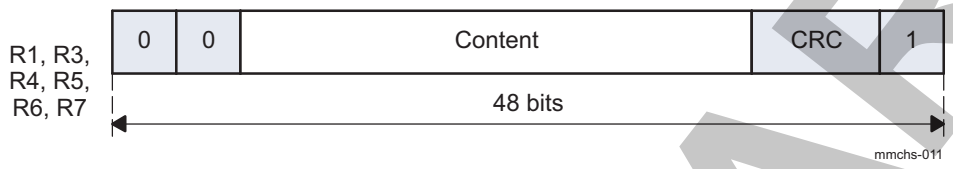


Figure 24-13. Response Token Format (R2)

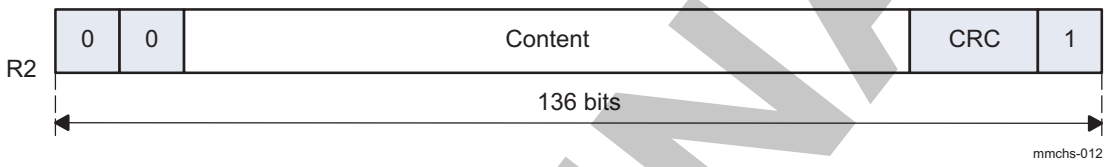

Table 24-4. Relationship Between Configuration and Name of Response Type

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, (R7 for SD cards)
11	1	1	R1b, R5b

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 24-14 through Figure 24-16).

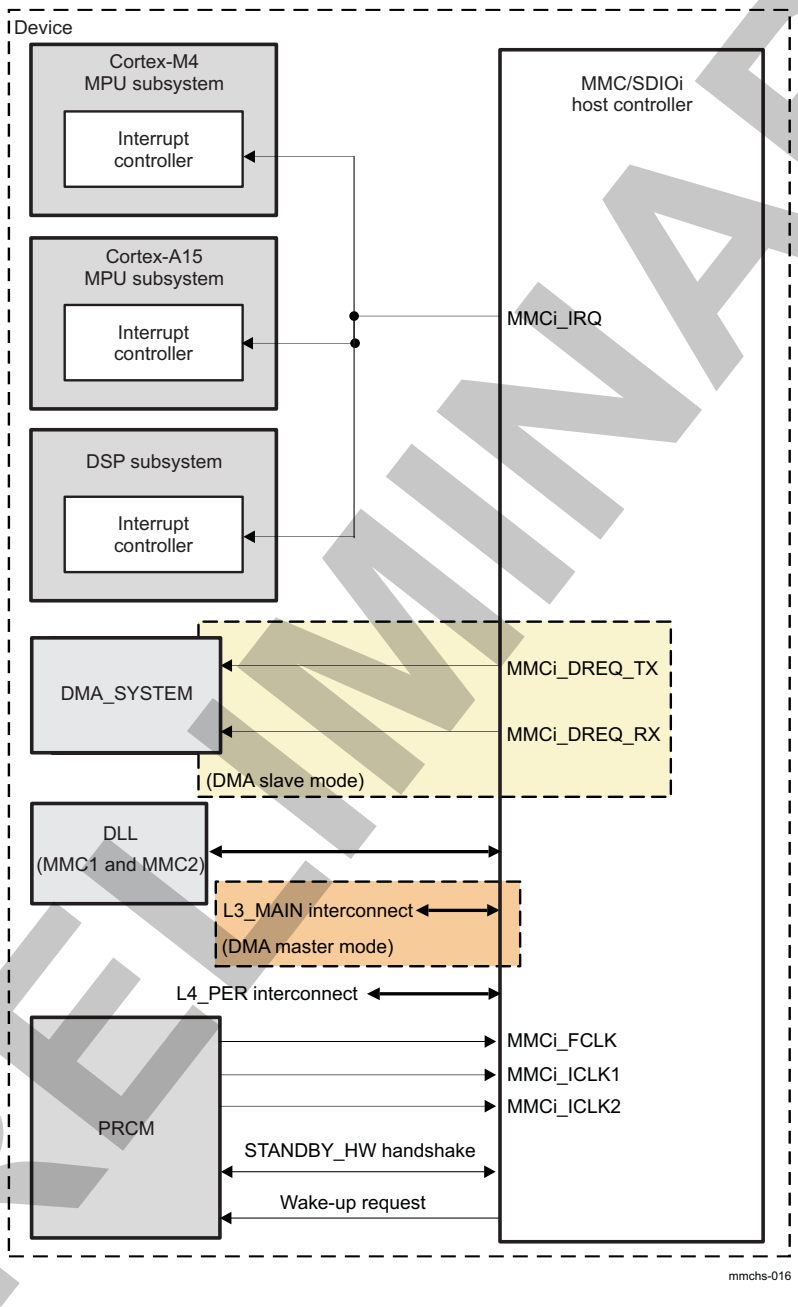
24.3 MMC/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-17 shows the MMC/SDIO integration.

Figure 24-17. MMC/SDIO Controllers Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1, *Device Power-Management Architecture Building Blocks*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-5 through Table 24-7 summarize the integration of the module in the device.

Table 24-5. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
MMC1	PD_L3INIT	L3 L4_PER
MMC2	PD_L3INIT	L3 L4_PER
MMC3	PD_CORE	L4_PER
MMC4	PD_CORE	L4_PER
MMC5	PD_CORE	L4_PER

	MMC5_DREQ_RX	DMA_SYSTEM_DREQ_59	DMA_SYSTEM	MMC5 DMA RX

NOTE:

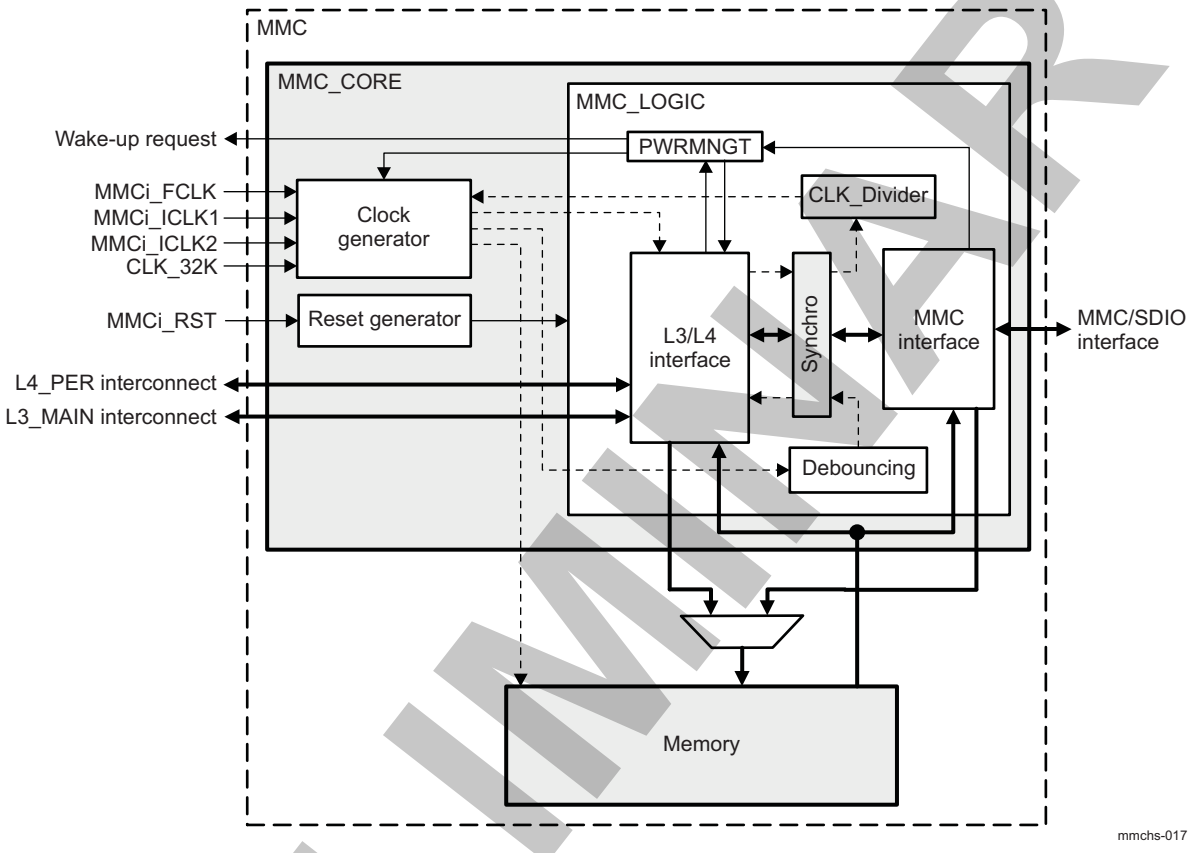
- For a description of the interrupt source, see Section 24.4.4, *Interrupt Requests*.
- For a description of the DMA source, see Section 24.4.5, *DMA Modes*.

24.4 MMC/SDIO Functional Description

24.4.1 Block Diagram

Figure 24-18 is a block diagram of the MMC/SDIOi host controller.

Figure 24-18. MMC/SDIO Diagram



NOTE: The SD card detect feature is available only if the PD_L3INIT is ON.

24.4.2 Resets

24.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 24-6 for more information about reset signals).

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (MMCi_FCLK) and interface clock (MMCi_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

24.4.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same effect on the module logic as the hardware signal (MMCi_RST), with the following exceptions:

- Debounce logic
- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD
- MMCi.MMCHS_SYSCTL[25] SRC

These 2 reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

24.4.3 Power Management

The MMC/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SDIO host controller is compliant with the handshake protocol of the power, reset, and clock management (PRCM) module.

When the MMC/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SDIOi clocks is to monitor the state of the DATA[1] input pin through a different GPIO line for each MMC/SDIO interface (for more information, see Section 25.1, *GPIO Overview*, in Chapter 25, *GPIO*).

NOTE: The wakeup feature on the sdcard_clk line is not supported, although the CONTROL_CORE_PAD0_USBB3_HSIC_DATA_PAD1_SDCARD_CLK register is configured.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (card insertion, card removal, an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

When a card removal event is detected the MMC/SDIO host controller automatically clears MMCHS_HCTL[8] SDBP and MMCHS_SYSCTL[2] CEN bits. Then it enters into low power state with auto gated interface clock even if MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to the MMC/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SDIO host controller complies with the handshaking protocol of the PRCM module:

- IDLE request from the system power manager
- Idle acknowledgment from the MMC/SDIO host controller
- Wake-up request from the MMC/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The MMC/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when it is in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

The debounce clock is used to debounce the signals related to the card insertion and the card removal that are also sources of wake-up in idle mode. The debounce clock must never be switched off by the system power manager in order to detect card removal in functional mode, and detect wake-up in idle mode.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The MMC/SDIOi host controller goes into idle mode when the PRCM issues an IDLE request, according to its internal activity.

The MMC/SDIO host controller acknowledges the IDLE request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the DATA[1] signal.

As long as the MMC/SDIOi controller does not acknowledge the IDLE request, if an event occurs, the MMC/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the IDLE request from the PRCM module.

As soon as the MMC/SDIOi controller acknowledges the IDLE request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when both the MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit and one of the three bits MMCi.MMCHS_HCTL[26] REM, MMCi.MMCHS_HCTL[25] INS, MMCi.MMCHS_HCTL[24] IWE are set to 0x1.

The corresponding interrupt status enable bits must also be set before going in idle mode. Setting one of the following bits:

- MMCi.MMCHS_IE[8] CIRQ_ENABLE

- MMCi.MMCHS_IE[7] CREM_ENABLE
- MMCi.MMCHS_IE[6] CINS_ENABLE

to 0x1 enables the wakeup event detection. The source of wakeup can be identified after idle mode exiting by reading one of the corresponding MMCHS_STAT bits.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 24-8 lists the supported cases in smart-idle mode.

Table 24-8. Smart-Idle Mode and Wake-Up Capabilities

Mode	MMCi_ICLK Clock	MMCi_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when a card interrupt on the DATA[1] signal is detected.
Card insertion	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card insertion is detected.
Card removal	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card removal is detected.

(1) The MMC/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The MMC/SDIO host controller detects the end of the idle period when the PRCM module deasserts the IDLE request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The MMC/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

One of the bits MMCHS_STAT[8] CIRQ, MMCHS_STAT[7] CREM, MMCHS_STAT[6] CINS in the interrupt status register is updated with the event that caused the wake-up when one of the bits MMCHS_IE[8] CIRQ_ENABLE, MMCHS_IE[7] CREM_ENABLE, MMCHS_IE[6] CINS_ENABLE is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the IDLE request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the MMC/SDIOi host controller responds unconditionally to the IDLE request from the PRCM module. Moreover, in this mode, the MMC/SDIOi host controller unconditionally deasserts interrupts and DMA request lines if they are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an IDLE request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the IDLE request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Standby Mode

The MMC/SDIO host controller also provides standby information to the system power manager if the generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is set to 1.

The MMC/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Standby request from the MMC/SDIO host controller
- Wait acknowledgement from the PRCM module

The standby request varies according to the MMCi.MMCHS_SYSCONFIG[13:12] STANDBYMODE bit field:

- 0x0: Force-standby. The MMC/SDIO host controller sends the standby request to the system power manager unconditionally.
- 0x1: No-standby. The MMC/SDIO host controller does not generate any standby request to the system power manager and behaves normally
- 0x2: Smart-standby. The MMC/SDIO host controller sends the standby request to the system power manager according to the master L3 interface state.

Power Pad Control

The MMC/SDIO host controller has the ability to reduce the pad power leakage when no transfer is sent through the pad. According to the MMCHS_CON[15] PADEN there are two different pad power management modes: automatic and manual.

If MMCHS_CON[15] PADEN is set to 1, pads CLK, CMD, DATA[0] and DATA[i] (where i = 2 through 7) are always powerd on.

If MMCHS_CON[15] PADEN is set to 0, the power for pads CLK, CMD, DATA[0] and DATA[i] (where i = 2 through 7) is "ON" only when there is a transfer on going. This is automatically managed by an internal state machine of the MMC/SDIO host controller.

The DATA[1] pad active state is controlled through MMCHS_CON[11] CTPL in order to detect SDIO asynchronous interrupt when there is no transaction.

The delay between pad power "ON" and the command transmission is controlled through the MMCHS_PWCNT register which act as a programmable counter. It is also used to delay the pad power "OFF" after the end of transmission. By default this counter is reset which means that no additional delay is added. But there is approximately 6-7 clock cycles margin between pad power "ON" and real start of the command due to an internal state machine of the MMC/SDIO host controller.

NOTE: The MMCHS_PWCNT register is considered as static. No dynamic configuration during the transfer is supported. This results in an unpredictable behavior.

Local Power Management

Table 24-9 describes the power-management features available for the MMC/SDIOi modules.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-9. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMCi_ICLK clock upon the interface activity, or gating the MMCi_FCLK clock upon the internal activity.
Slave-idle modes	MMCHS_SYSCONFIG[3:4] SIDLEMODE	Force-idle, No-idle, Smart-idle and Smart-idle wake-up-capable modes are available.
Clock activity	MMCHS_SYSCONFIG[8:9] CLOCKACTIVITY	For configuration details, see Table 24-10.
Master standby modes	MMCHS_SYSCONFIG[12:13] STANDBYMODE	Force-standby, No-standby and Smart-standby modes are available.
Global wake-up enable	MMCHS_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

Table 24-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_ FCLK		
00	OFF	OFF	None	Card interrupt, Card insertion, Card removal
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the Clock activity feature, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

24.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable or disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi_IRQ (from the MMC/SDIOi host controller to the MPU subsystem INTC) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the MMC/SDIOi host controller does not transmit an interrupt request.

NOTE: If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 24-11 lists the event flags, and their mask, that can cause module interrupts.

Table 24-11. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE = 0).
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT[26] TE	MMCHS_IE[26] TE_ENABLE	MMCi_IRQ	Tuning Error. This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure. The Tuning Error is with higher priority than the other error interrupts generated during data transfer.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	Auto CMD12 error and Auto CMD23 error. This bit is set automatically when one of the bits MMCHS_AC12[4:0] changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.

Table 24-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	Data time-out error. This bit is set automatically according to the following conditions: • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[24:15]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[7] CREM	MMCHS_IE[7] CREM_ENABLE	MMCi_IRQ	Card removal. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.
MMCHS_STAT[6] CINS	MMCHS_IE[6] CINS_ENABLE	MMCi_IRQ	Card insertion. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 0 to 1.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMCi_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMCi_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.

Table 24-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMCi_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). • In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). • In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMCi_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

NOTE: To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.MMCHS_IE and MMCi.MMCHS_ISE registers.

The MMC/SDIOi host controller supports interrupt-driven operation and polling.

24.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the MMCi.MMCHS_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS_STATregister (bits 31 through 16) are cleared.

24.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning clearing of the CIRQ and ERRI bits.

24.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If MMCHS_CAPA[29] AIS is set to 0, writing to MMCHS_AC12[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If MMCHS_AC12[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

24.4.5 DMA Modes

Two DMA management modes can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode:

  DMA master mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3_MAIN master interface, which supports burst accesses to maximize throughput.

  NOTE: This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 24.1, *MMC/SDIO Overview*.

  This mode is available for modules MMC1 and MMC2.

- DMA slave mode:

  DMA slave mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMCi_DMA_RX).

  NOTE: This mode is the only mode supported by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 24.1, *MMC/SDIO Overview*.

  This mode is available for all MMC modules.

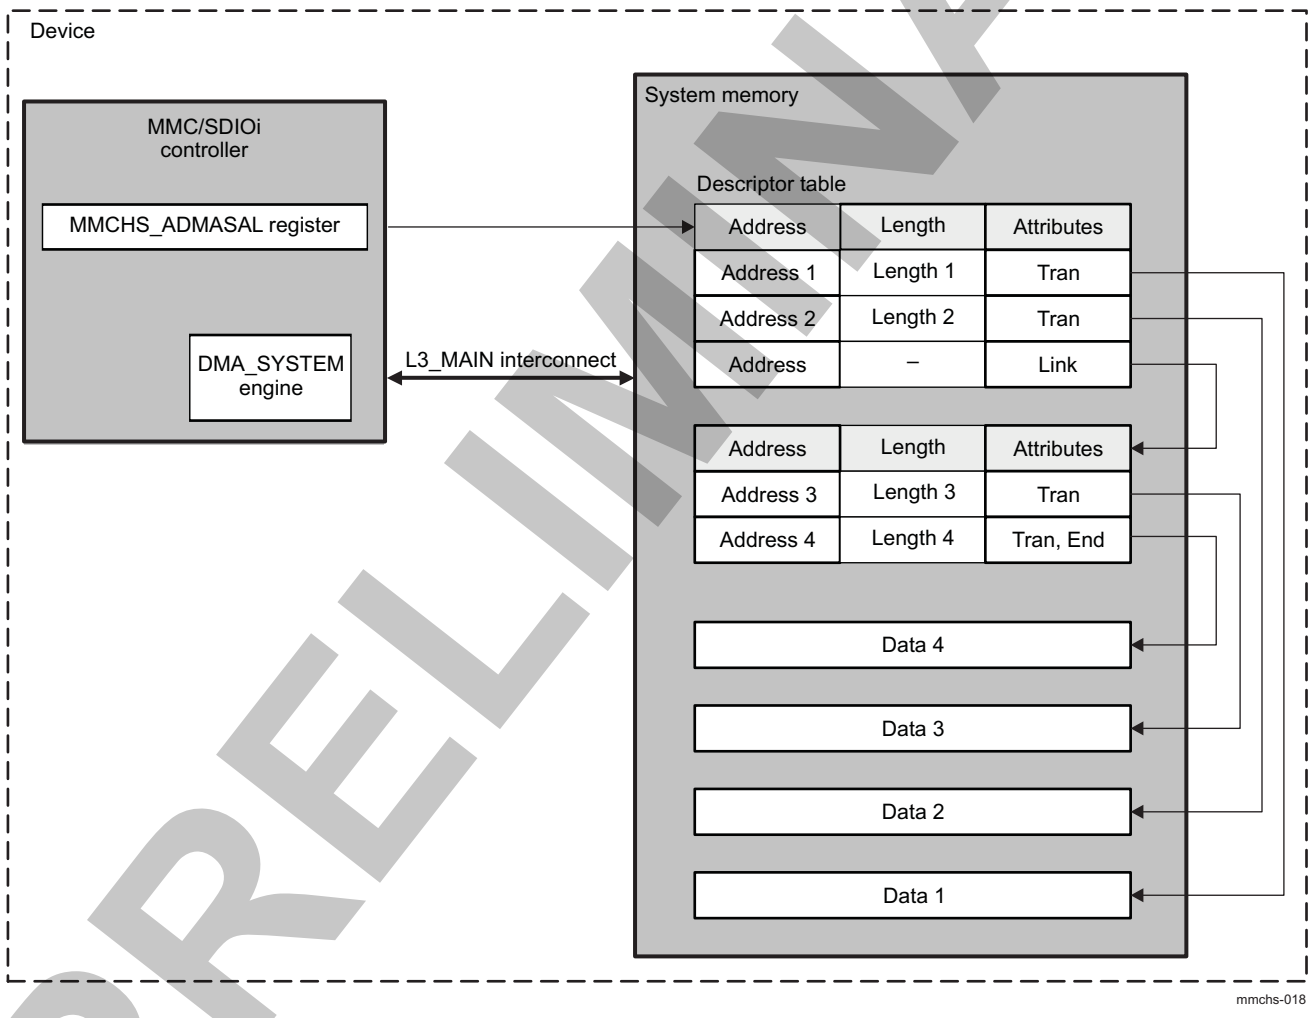
24.4.5.1 Master DMA Operations

The MMC/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the MMCHS_ADMASAL register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

NOTE: This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 24.1, *MMC/SDIO Overview*.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in Figure 24-19. In this case the MMCHS_ADMASAL register is used as the program address pointer

Figure 24-19. ADMA Block Diagram Overview



24.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3_MAIN master interface, and requires two 32-bit accesses to memory.

Table 24-12 shows the structure of a descriptor line.

Table 24-12. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit address		16-bit length		0x0		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 24-13 describes the available actions of a descriptor line.

Table 24-13. Available Actions of a Descriptor Line

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 24-14 describes the additional parameters of a descriptor line.

Table 24-14. Additional Parameters of a Descriptor Line

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

24.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

24.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KiB.
- Total length = $Length_1$ + $Length_2$+ $Length_3$ + ... + $Length_n$ must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the MMCHS_BLK[31:16] NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (MMCHS_CMD[1] BCE) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

NOTE: The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (MMCHS_PSTATE[9] RTA), write transfer active (MMCHS_PSTATE[8] WTA), and DAT line active (MMCHS_PSTATE[2] DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

24.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap request (the MMCHS_HCTL[16] SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the MMCHS_STAT[2] BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

24.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If the ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If the ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

24.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

NOTE: Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 24.4.5.1.1, *Descriptor Table Description*) and an FSM, as shown in Figure 24-20.

Figure 24-20. ADMA Finite State-Machine

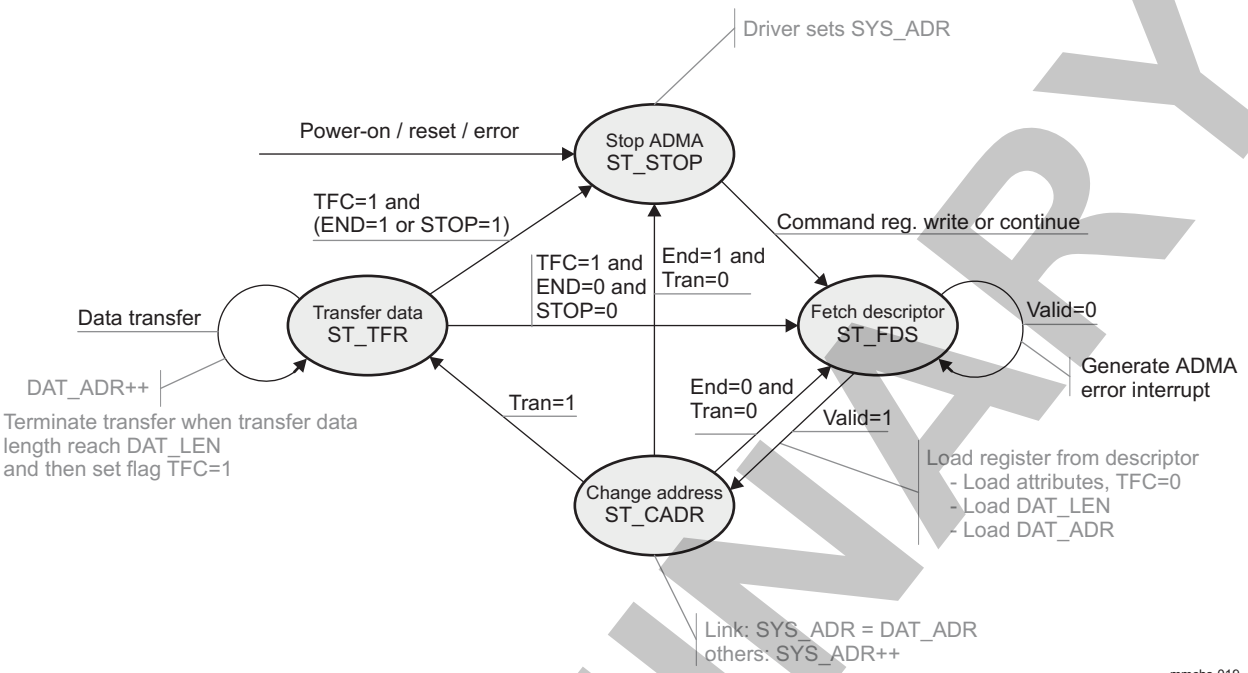


Table 24-15 describes each state of the ADMA FSM.

Table 24-15. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If End = 0, go to ST_FDS state. **NOTE**: ADMA2 does not stop at this state if some errors occur.
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: • If data transfer continues (End = 0), go to ST_FDS state. • If data transfer completes, go to ST_STOP state.
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: • After power-on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 24-16 gives the description of each symbol used in the ADMA FSM (see Figure 24-20).

Table 24-16. ADMA FSM Symbol Definition

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

24.4.5.2 Slave DMA Operations

The MMC/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (more than 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

NOTE: This mode is implied by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 24.4.5.1, *Master DMA Operations*.

The DMA request is issued if the following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the MMC/SDIOi host controller to write an entire block (BLEN writes).

24.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCi_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_RX is deasserted to its inactive level when the DMA_SYSTEM module reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA_SYSTEM has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA_SYSTEM reads is Integer(BLEN / 4) + 1.

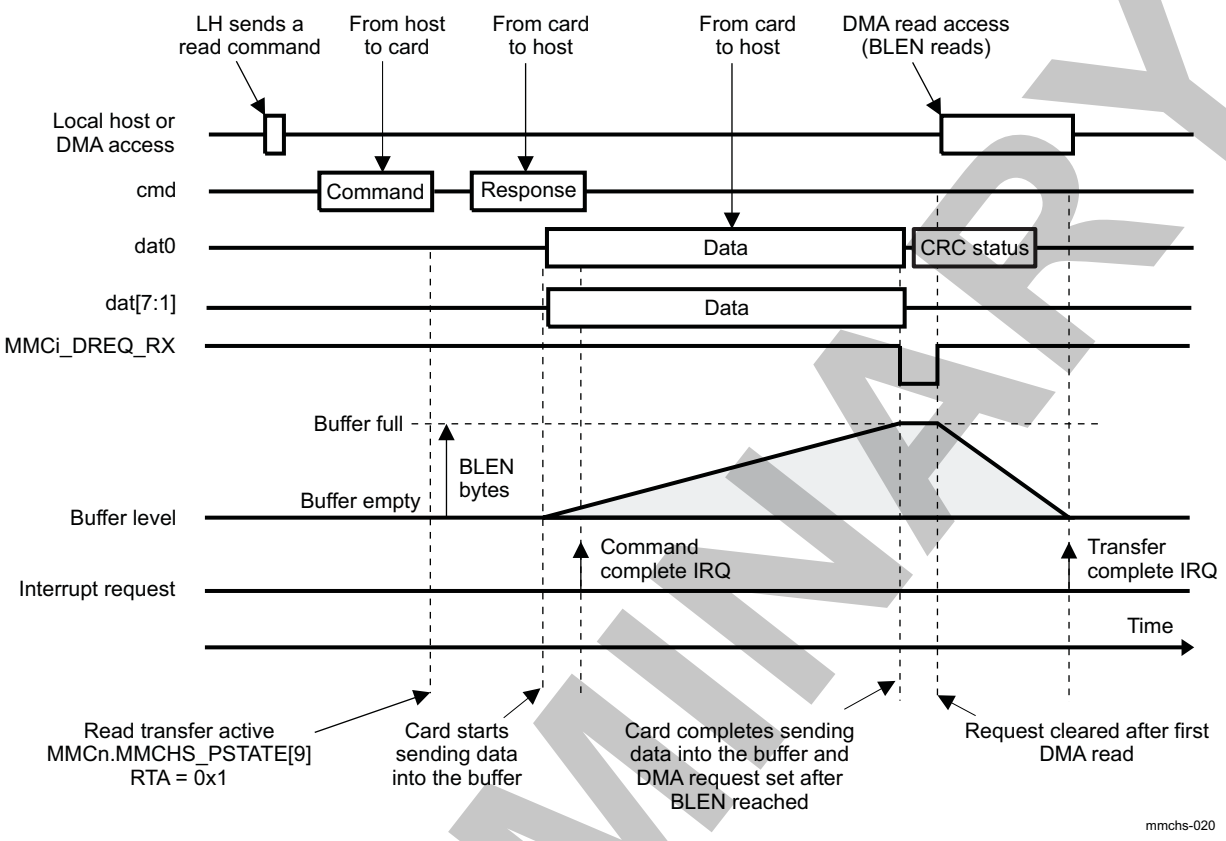
The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the sdmmci_clk clock signal (provided to the card) is momentarily stopped until the DMA_SYSTEM or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-21 shows DMA receive mode.

Figure 24-21. DMA Receive Mode



24.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_TX is deasserted to its inactive level when the DMA_SYSTEM writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

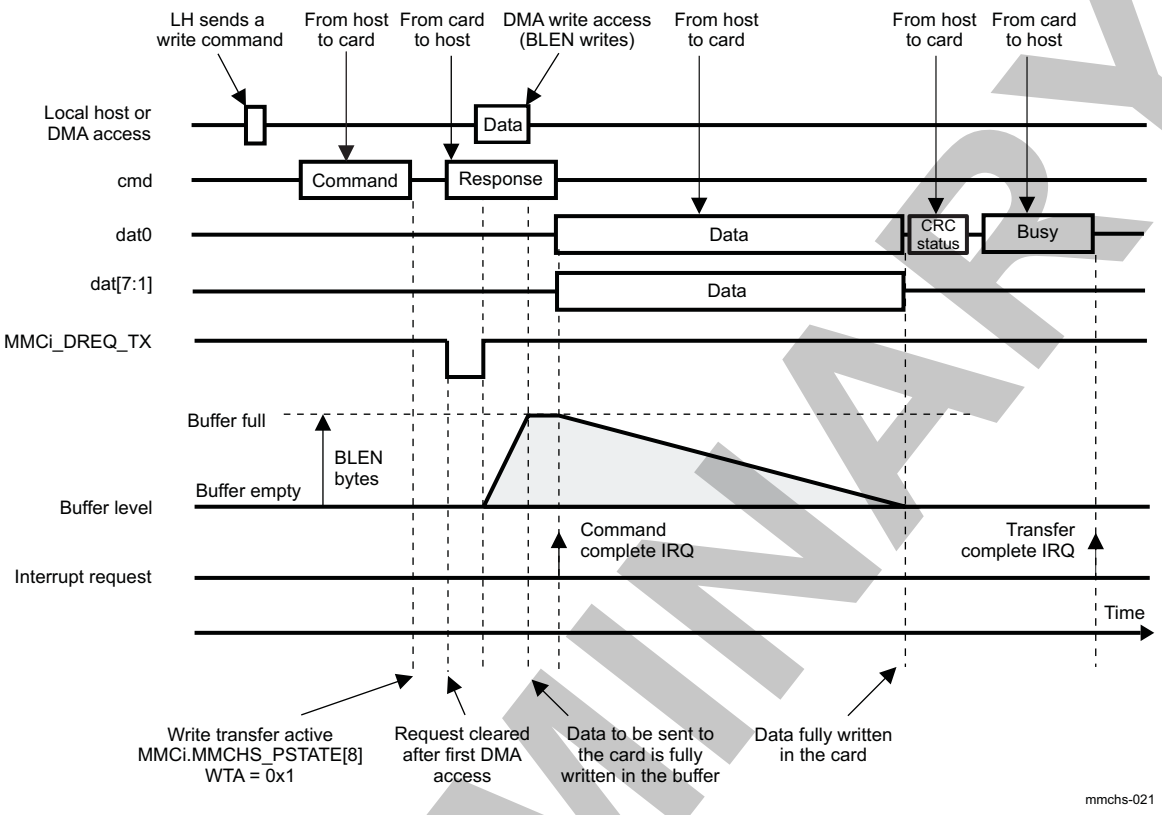
New DMA requests are internally masked if the DMA_SYSTEM has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA_SYSTEM reads is Integer(BLEN / 4) + 1) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-22 shows DMA transmit mode.

Figure 24-22. DMA Transmit Mode



24.4.6 Mode Selection

The MMC/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

24.4.7 Buffer Management

24.4.7.1 Data Buffer

The MMC/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[11:0] BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17:16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The MMC/SDIOi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 24-23 and Figure 24-24 show the buffer management for a write and a read, respectively.

Figure 24-23. Buffer Management for a Write

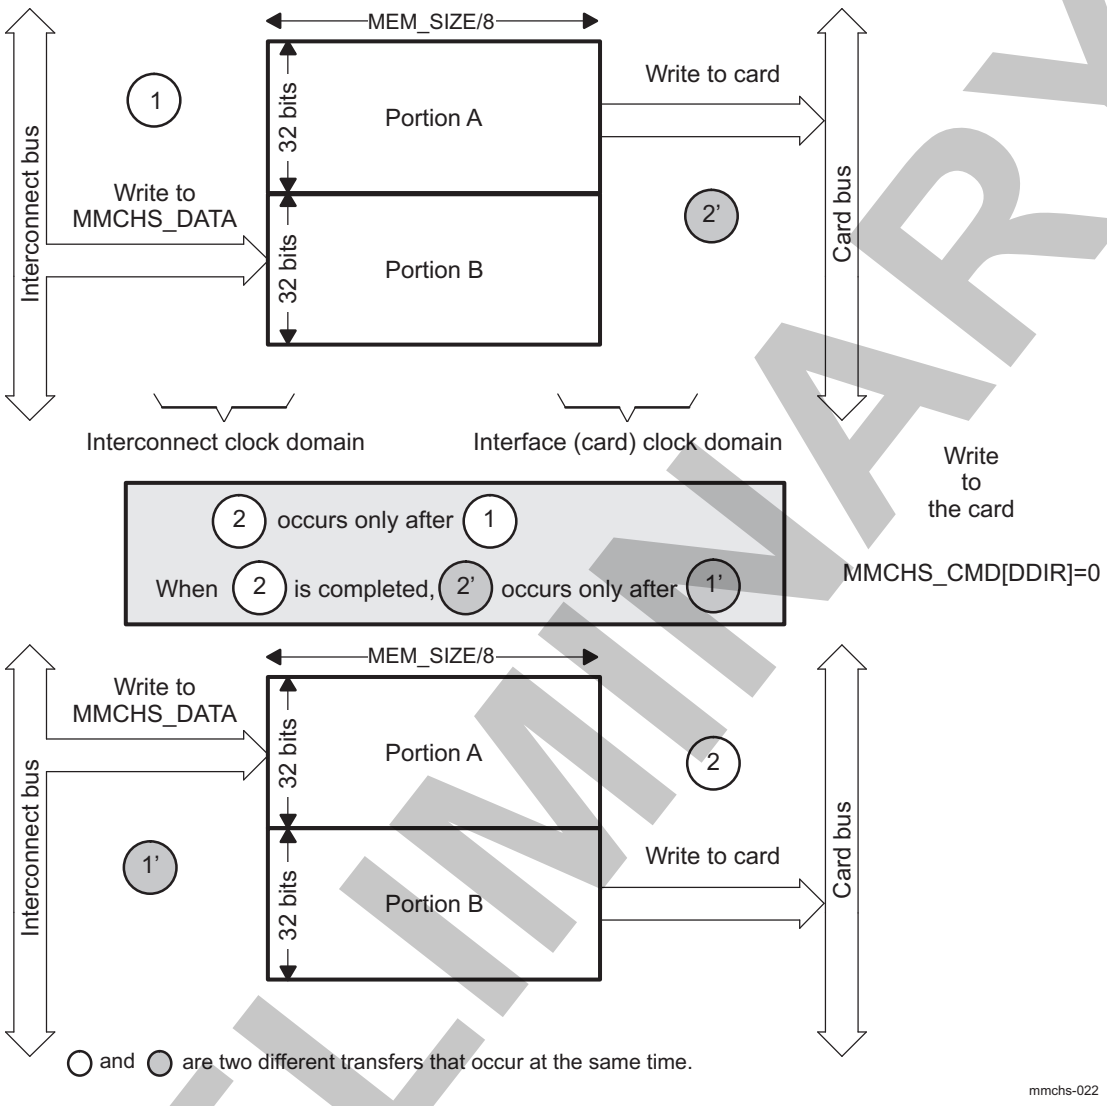


Figure 24-24. Buffer Management for a Read

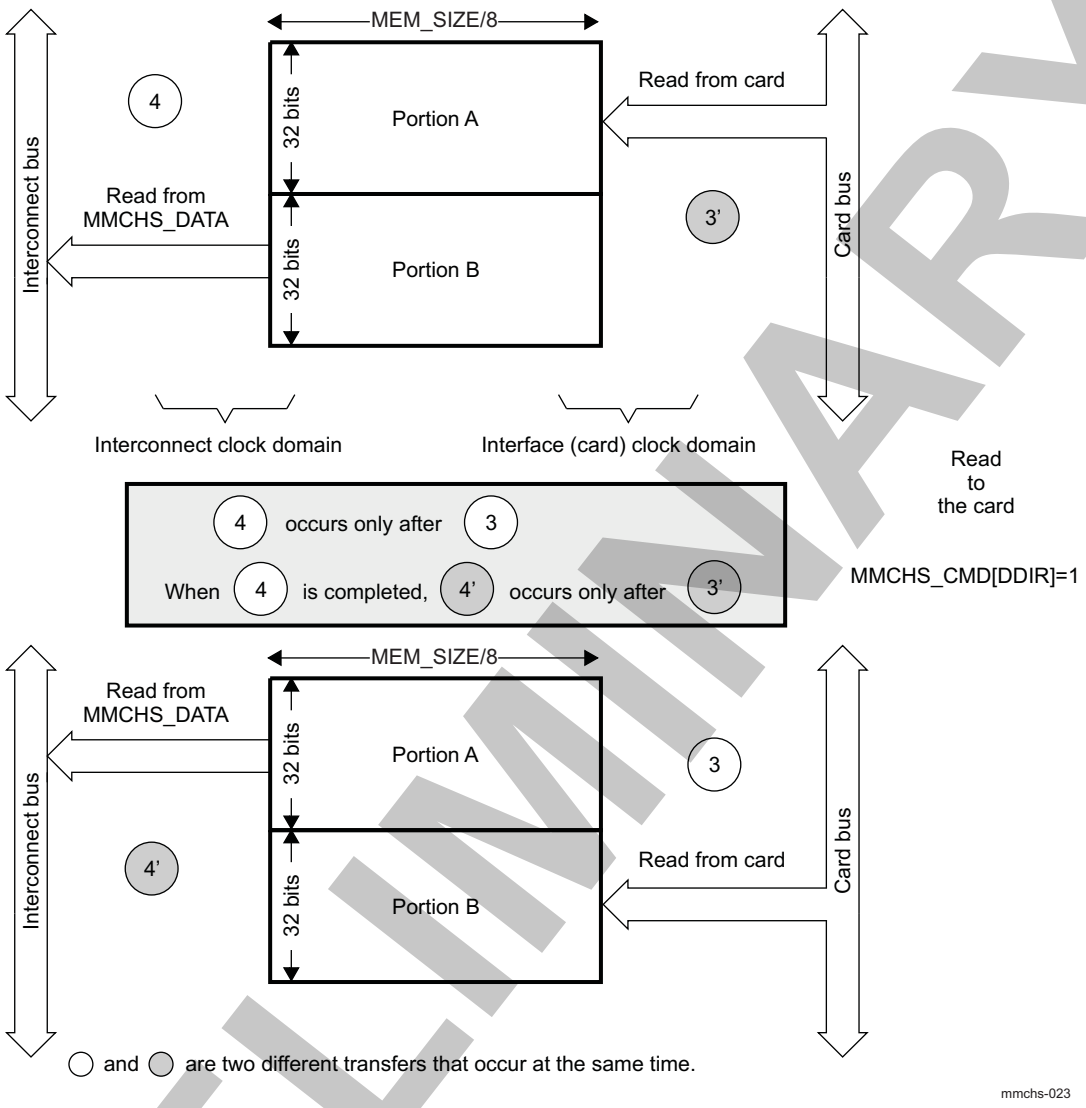


- When the size of the data block to transfer is larger than MEM_SIZE / 2, only one data transfer at a time can occur from one data bus to the other data bus. The MMC/SDIOi host controller uses the entire data buffer as a single portion.

  In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

24.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 24-17).

NOTE: Double-buffering is always the buffer management for large memory depth.

Table 24-17. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	**512**	**1024**
Maximum block length supported	512	1024

Table 24-17. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

NOTE: For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[4] DDIR bit is 1).

24.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

24.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

24.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*; or *the SD Card Specification, Part A2, SD Host Controller Standard Specification*.

24.4.8.2 Different Types of Responses

Different types of responses are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*; *SD Memory Card Specifications*; *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*.

Table 24-18 describes how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 24-18. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8](1)	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response), R1(Auto CMD23 response)	RESP[39:8](1)	MMCHS_RSP76[31:0]
R2	RESP[127:0](1)	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may execute multiple block data transfers on the DATA line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

While executing Auto CMD23 the response of CMD23 is saved in the MMCHS_RSP76[31:0] register and the response of multiple-block read and write command is saved in the MMCHS_RSP10 register. The response error of CMD23 is indicated in the MMCHS_AC12 register, bits [7:0].

24.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMC/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see Table 24-19 and the register description.

Table 24-19. CC and TC Values Upon Error Detected

Error Hold in MMCi.MMCHS_STAT		CC	TC	Comments
29	BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

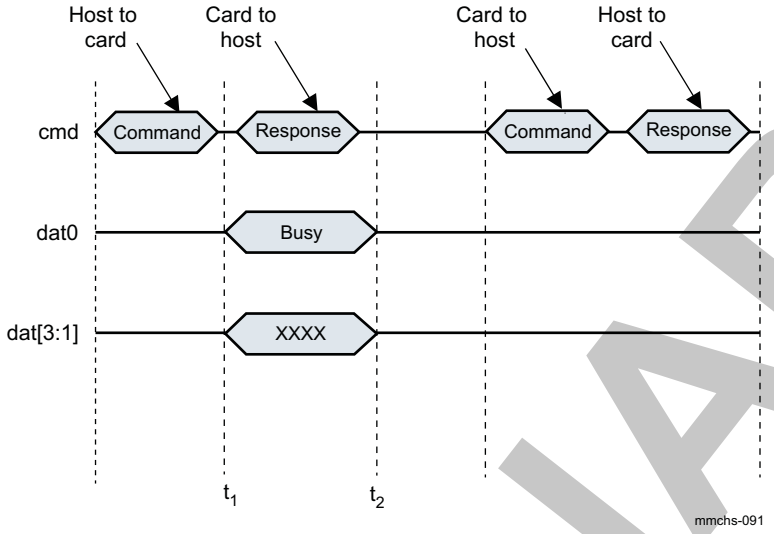
A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

24.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 24-25 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

Figure 24-25. Busy Time-Out for R1b, R5b Response Type



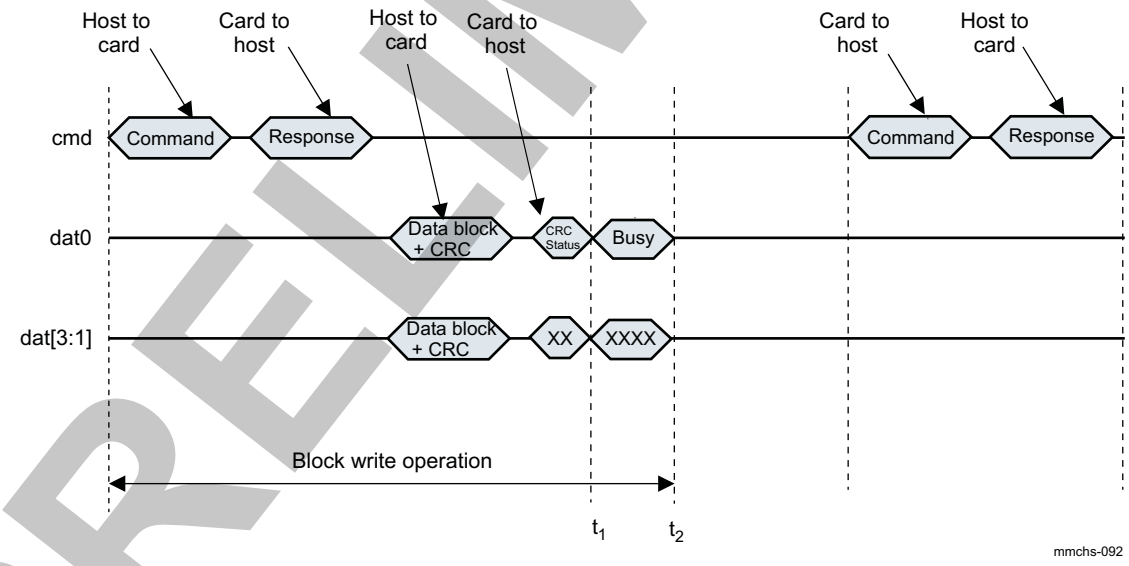
t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

24.4.9.2 Busy Time-Out After Write CRC Status

Figure 24-26 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

Figure 24-26. Busy Time-Out After Write CRC Status



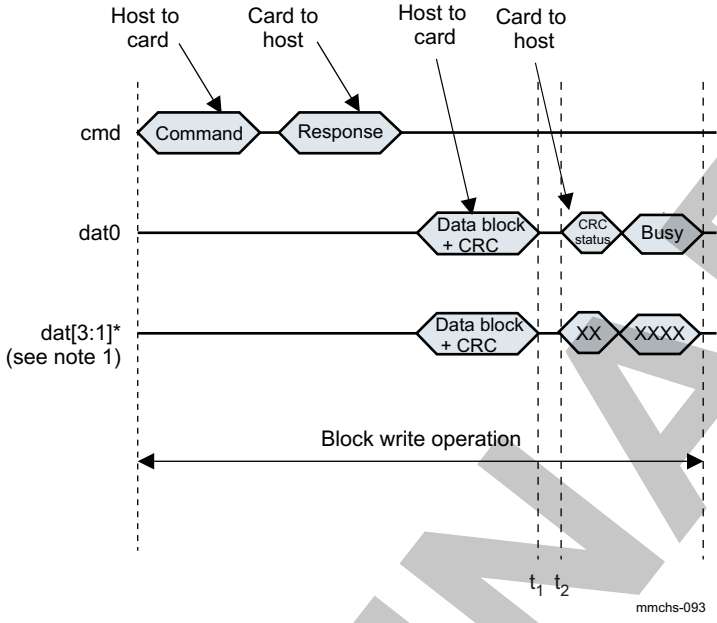
t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

24.4.9.3 Write CRC Status Time-Out

Figure 24-27 shows the DTO event condition asserted when there is a write CRC status time-out.

Figure 24-27. Write CRC Status Time-Out



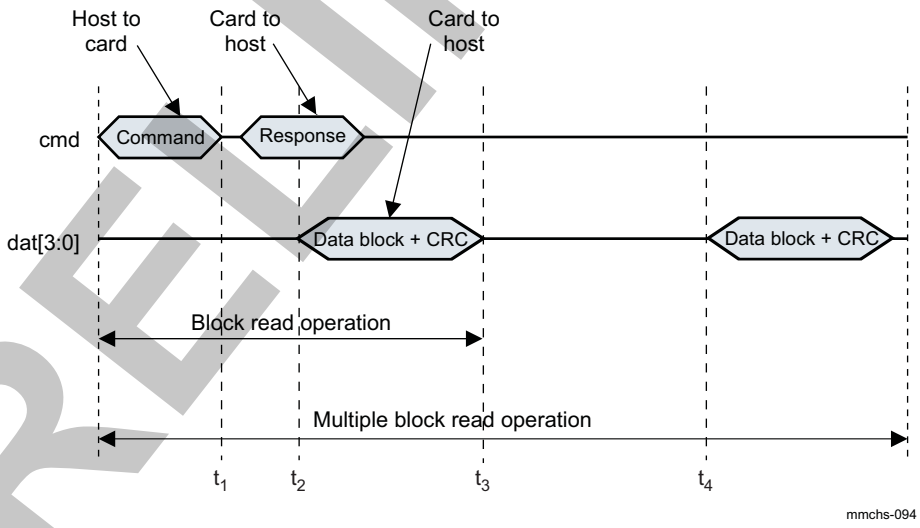
t_1 – Data time-out counter is loaded and starts after data block + CRC.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

24.4.9.4 Read Data Time-Out

Figure 24-28 shows the DTO event condition asserted when there is a read data time-out.

Figure 24-28. Read Data Time-Out



t_1 – Data time-out counter is loaded and starts after command transmission.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

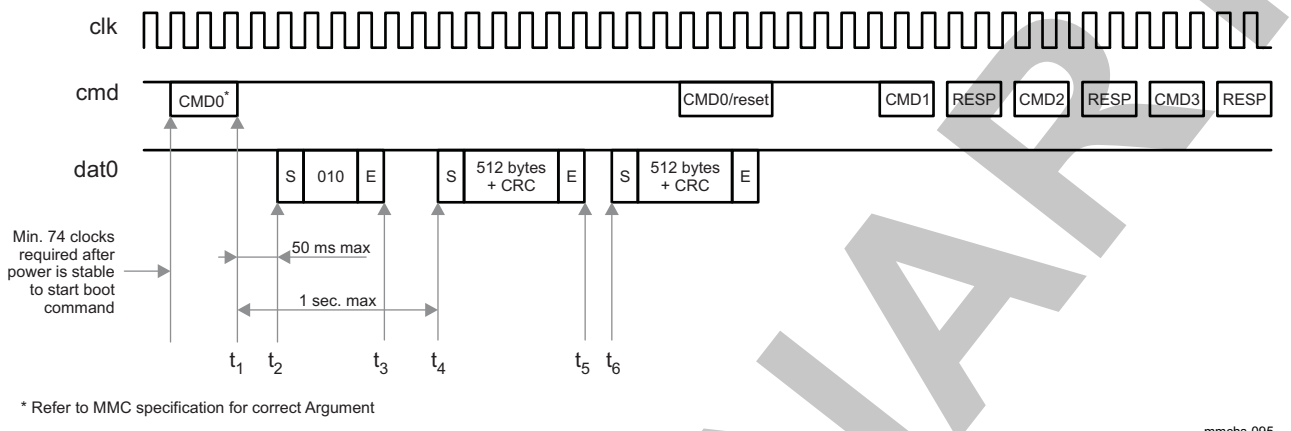
t_3 – Data time-out counter is loaded and starts after data block + CRC transmission.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

24.4.9.5 Boot Acknowledge Time-Out

Figure 24-29 shows the DTO event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

Figure 24-29. Boot Acknowledge Time-Out When Using CMD0



t_1 – Data time-out counter is loaded and starts after CMD0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

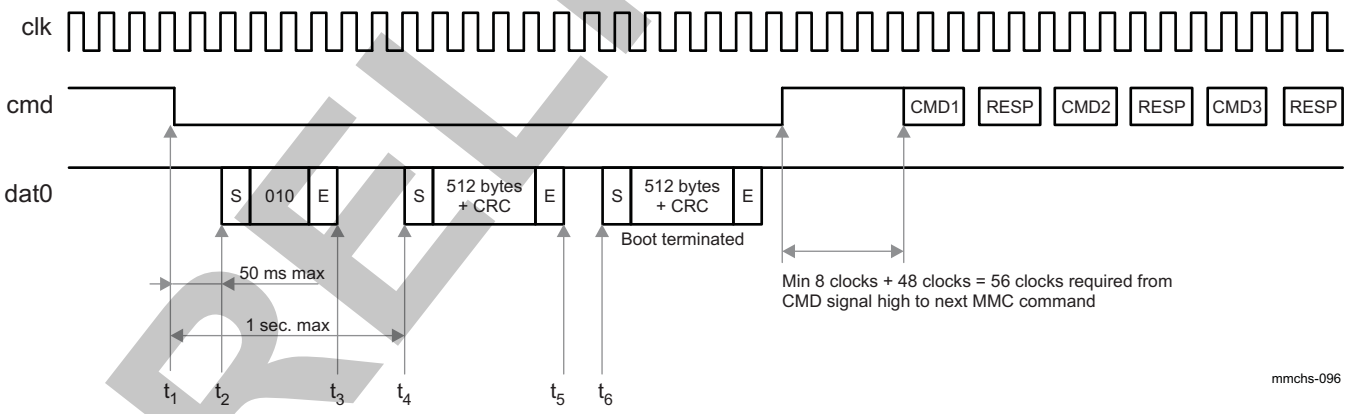
t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

Figure 24-30 shows the DTO event condition asserted when there is a boot acknowledge time-out when the CMD line is tied to 0.

Figure 24-30. Boot Acknowledge Time-Out When CMD Line Tied to 0



t_1 – Data time-out counter is loaded and starts after the CMD line is tied to 0.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_3 – Data time-out counter is loaded and starts.

t_4 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

t_5 – Data time-out counter is loaded and starts after data + CRC transmission.

t_6 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

24.4.10 Auto Command 12 Timings

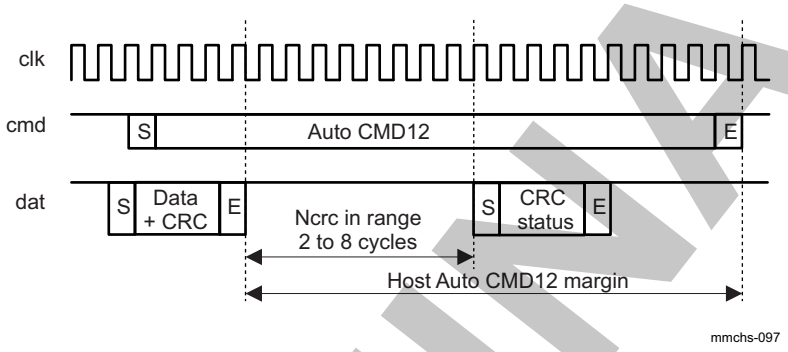
With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (Auto CMD12) end bit.

24.4.10.1 Auto CMD12 Timings During Write Transfer

A margin named Ncrc in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the Auto CMD12 end bit must arrive after the CRC status end bit.

Figure 24-31 shows the Auto CMD12 timings during write transfer.

Figure 24-31. Auto CMD12 Timings During Write Transfer



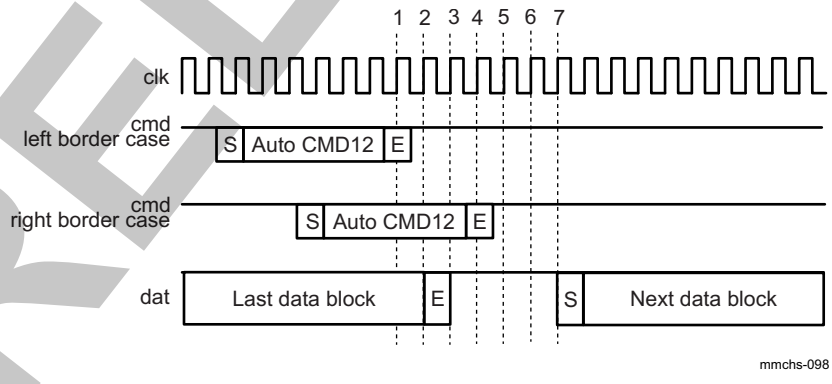
The host controller has a margin of 18 clock cycles to enure that the Auto CMD12 end bit arrives after the CRC status. This margin does not depend on the MMC/SD bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

24.4.10.2 Auto CMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards is extended from two cycles to four cycles. It provides more flexibility for the host Auto CMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 24-32 shows Auto CMD12 timings during read transfer.

Figure 24-32. Auto CMD12 Timings During Read Transfer



The Auto CMD12 arrival sent by the host controller is not sensitive to the MMC/SD bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

24.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)

- Continuous stream transfers (transfer has an infinite length)

NOTE: Because the MMC/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The MMC/SDIOi controller includes three features that make a transfer stop more convenient and easier to manage:

- Auto CMD12/Auto CMD23 (for eMMC and SD only):

  Auto CMD12/Auto CMD23 feature is enabled by setting the MMCi.MMCHS_CMD[3:2] ACEN bit field to 0x1 or to 0x2 respectively (this setting is relevant for an MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12/Auto CMD23 feature is enabled, the MMC/SDIOi controller automatically issues a CMD12/CMD23 command when the expected number of blocks is exchanged.
- Stop at block gap:

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- ADMA mode:

  For ADMA-capable modules (MMC1 and MMC2) (for more information, see Section 24.4.5, *DMA Modes*), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

NOTE: For MMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

NOTE: In SDR104 mode Auto CMD23 is used to stop multiple block read/write operation instead of Auto CMD12. In the other bus speed modes, if the card supports CMD23, Auto CMD23 is used instead of Auto CMD12.

Table 24-20 shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 24-20. MMC/SDIOi Controller Transfer Stop Command Summary

		Write Transfer		Read Transfer	
		SD/MMC	SDIO	SD/MMC	SDIO
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12/CMD23. Wait TC.	Send CMD52. Wait TC.	Send CMD12/CMD23. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	Set MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC.	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	**If READ_WAIT supported** Stop at block gap. Wait TC.
					If READ_WAIT not supported Send CMD52. Wait TC.

NOTE: The MMC/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

24.4.12 Retention Mode

This mode is enabled if the generic parameter bit MMCHS_HL_HWINFO[6] RETMODE is set to 1 during module integration. The controller can enter into retention mode when the module was previously set in idle mode. When the module goes into retention mode all clocks are left inactive at low level except for registers that are driven by a falling-edge clock, which are kept as free during retention mode. This also means that all divided functional clock subdomains are forced low when the module enters smart-idle mode. In force-idle mode, the system must ensure that all divided functional clocks are set inactive or are in bypass mode by configuring the MMCHS_SYSCTL register correctly before entering idle mode (under software responsibility).

24.4.13 Output Signals Generation

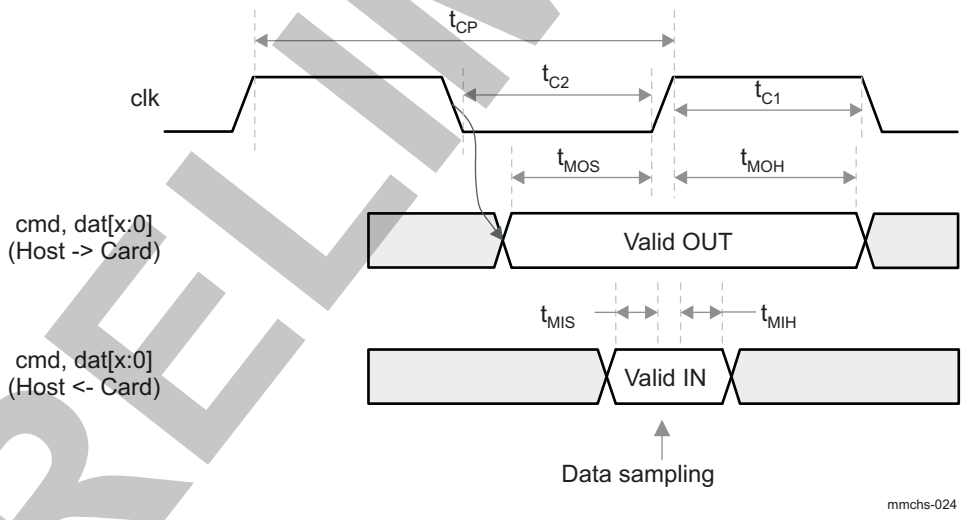
The MMC/SDIO output signals can be driven on the falling edge or rising edge, depending on the MMCHS_HCTL[2] HSPE bit. This feature allows achieving better timing performance, thus increasing data transfer frequency.

24.4.13.1 Generation on Falling Edge of MMC Clock

The controller defaults to this mode to maximize hold timings. In this case, the MMCHS_HCTL[2] HSPE bit is set to 0.

Figure 24-33 shows the output signals of the module when generating from the falling edge of the MMC clock.

Figure 24-33. Output Driven on Falling Edge



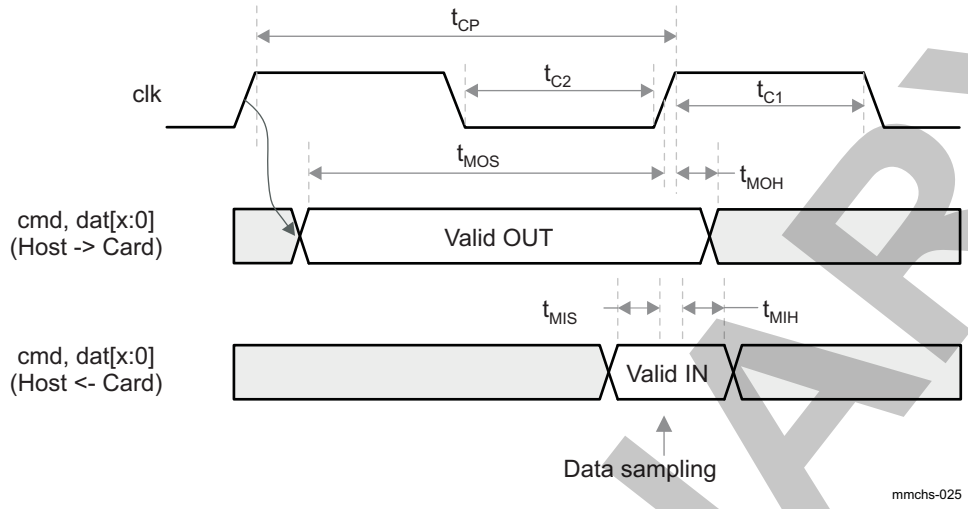
24.4.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting the MMCHS_HCTL[2] HSPE bit to 1. The controller must be set in this mode to support SDR transfers.

NOTE: Do not use this feature in DDR mode (when the MMCHS_CON[19] DDR bit is set to 1).

Figure 24-34 shows the output signals of the module when generating from the rising edge of the MMC clock.

Figure 24-34. Output Driven on Rising Edge



24.4.14 Sampling Clock Tuning

In UHS-I mode the SD bus operates in high clock frequency mode and the data window from the card on CMD and DAT lines get smaller. The position of the data window varies depending on the card and the host system. To adjust the sampling clock when SDR104/HS200 operation mode is used the MMC/SDIOi host controller supports a tuning circuit. This tuning circuit is a dedicated DLL which delays the clock signal used for data sampling. The DLL is not part of the MMC/SDIOi host controller. It is instantiated at top level between the IOs and the host controller. There are two DLLs. One for MMC1 when SDR104 mode is used and one for MMC2 when HS200 mode is used.

In the default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT lines. Before using the SDR104/HS200 or SDR50 (if MMCHS_CAPA2[13] TSDR50 = 0x1) modes software must execute the tuning procedure at the initialization sequence regardless of MMCHS_CAPA2[15:14] RTM value.

The software starts the tuning sequence by setting MMCHS_AC12[22] ET to 1. Then it issues CMD19 for a SD card or CMD21 for an eMMC device repeatedly until MMCHS_AC12[22] ET is set to 0. MMCHS_AC12[22] ET is reset when the tuning is complete or when the tuning is not complete within 40 tries. The software may abort this loop if the number of the loops reaches 40 or 150ms timeout occurs. In this case a fixed sampling clock is used and MMCHS_AC12[23] SCLK_SEL is set to 0. This indicates that the tuning procedure is failed. When MMCHS_AC12[23] SCLK_SEL is set to 1, this indicates that the tuning procedure is completed successfully. For more information about the DLL tuning procedure, see Section 24.5.1.2.4, *SDR104/HS200 DLL Tuning Procedure*.

24.4.15 Card Boot Mode Management

Boot operation mode lets the MMC/SDIOi host controller read boot data from the connected slave (MMC device) by keeping the CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

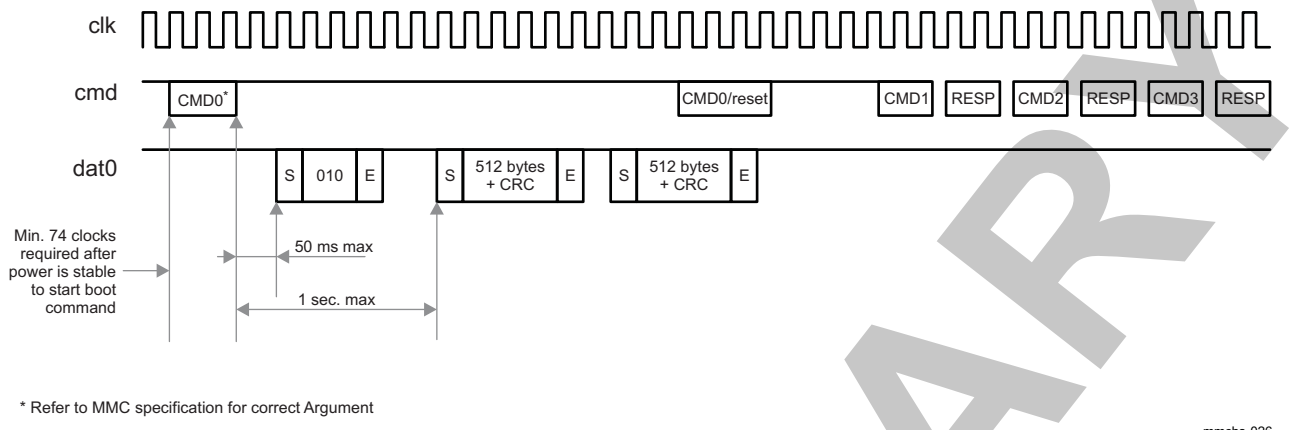
Power-on boot defines a way for the boot code to be accessed by the MMC/SDIOi host controller without an upper-level software driver, thus speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

24.4.15.1 Boot Mode Using CMD0

Figure 24-35 shows the timing diagram of a boot sequence using CMD0.

Figure 24-35. Boot Mode Using the CMD0 Timing Diagram



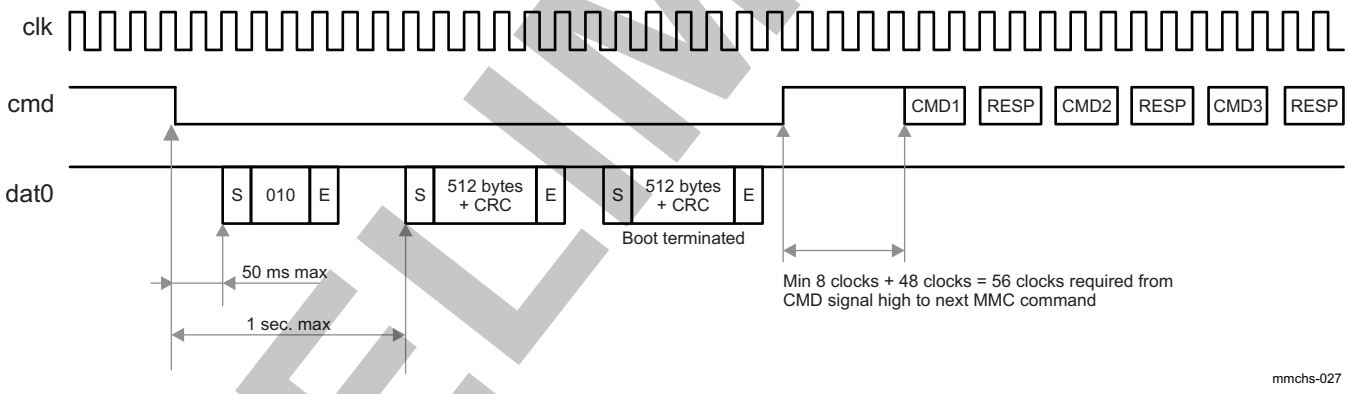
NOTE: Refer to MMC specification for correct Argument.

For more information about how to configure the MMC/SDIO host controller, see Section 24.5.1.2.3.1, *Boot Using the CMD0*.

24.4.15.2 Boot Mode With CMD Line Tied to 0

Figure 24-36 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 24-36. Boot Mode With CMD Line Tied to 0 Timing Diagram



For more information about how to configure the MMC/SDIO host controller, see Section 24.5.1.2.3.2, *Boot With CMD Line Tied to 0*.

24.4.16 MMC CE-ATA Command Completion Disable Management

The MMC/SDIOi host controller supports CE-ATA features, in particular the detection of the command completion token. When a command that requires a CCS (the MMCHS_CON[12] CEATA bit is set to 1 and the MMCHS_CMD[3:2] ACEN bit field is set to 0x1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- Set the MMCHS_CON[12] CEATA bit to 1.
- Set the MMCHS_CON[2] HR bit to 1.
- Clear the MMCHS_ARG register.
- Write into the MMCHS_CMD register with the value 0x00000000.

When a command completion disable token was emitted (that is, the MMCHS_STAT[0] CC bit is received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when CCSD is emitted during the last data block transfer, and the sequence on the command line is sent close to the CCS token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:

  An interrupt CIRQ is generated when CCS is detected, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

24.4.17 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register (MMCHS_FE) is used to control the error status and error interrupt status for Auto CMD12 and Auto CMD23.

The system test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the MMCHS_CON[4] MODE bit = 1) for boundary connectivity verification.

The MMCHS_HCTL[7] CDSS and MMCHS_HCTL[6] CDTL bits enable manual control of MMCHS_PSTATE[16] CINS and interrupt generating indicated in MMCHS_STAT[7] CREM and MMCHS_STAT[6] CINS.

24.4.18 MMC/SDIO Hardware Status Features

Table 24-21 describes the MMC/SDIO hardware status features.

Table 24-21. MMC/SDIO Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 24.4.4, *Interrupt Requests.*	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23:20] DLEV	Indicates the level of the data lines
Write protect switch pin level	Status	MMCHS_PSTATE[19] WP	Indicates whether the SD card is write protected or not.
Card detect pin level	Status	MMCHS_PSTATE[18] CDPL	Indicates the level of the sdcard_cd signal/pad
Card State Stable	Status	MMCHS_PSTATE[17] CSS	Used for testing. Indicates sdcard_cd stable state
Card inserted	Status	MMCHS_PSTATE[16] CINS	Indicates whether the SD card is inserted
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Re - Tuning Request	Status	MMCHS_PSTATE[3] RTR	Indicates whether the sampling clock needs re - tuning or not.
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active

Table 24-21. MMC/SDIO Hardware Status Features (continued)

Feature	Type	Register/Bit Field	Description
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

Table 24-22 describes the MMC/SDIO preset value features.

Table 24-22. MMC/SDIO Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 and SDR50 speed modes
Preset value register	Status	MMCHS_PVSDR104DDR50	Preset Values for SDR104 and DDR50 speed modes

24.5 MMC/SDIO Programming Guide

24.5.1 Low-Level Programming Models

24.5.1.1 Global Initialization

24.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SDIO modules. For more information, see Section 24.3, *MMC/SDIO Integration*, and Section 24.2, *MMC/SDIO Environment*.Table 24-23 shows the global initialization of surrounding modules.

Table 24-23. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Section 3.1.1, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, *Control Module* .
(optional) MPU INTC (or DSP INTC)	MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See Chapter 17, *Interrupt Controllers*.
(optional) DMA_SYSTEM (or DDMA)	DMA configuration must be done to enable the module DMA channel requests. See Chapter 16, *System DMA*.

NOTE: The MPU/DSP INTC and the DMA_SYSTEM/dDMA configurations are necessary if the interrupt and DMA-based communication modes are used.

24.5.1.1.2 MMC/SDIO Host Controller Initialization Flow

Table 24-24 shows the general boot process.

Table 24-24. MMC/SDIO Controller Meta Initialization Steps

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 24.5.1.1.2.1, *Enable Interface and Functional Clock for MMC Controller.*	
Software reset of the controller.		See Section 24.5.1.1.2.2, *MMCHS Soft Reset Flow*.	
Set module hardware capabilities.		See Section 24.5.1.1.2.3,*Set MMCHS Default Capabilities*.	
Set module idle and wake-up modes.		See Section 24.5.1.1.2.4, *Wake-Up Configuration*.	

24.5.1.1.2.1 Enable Interface and Functional Clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.

24.5.1.1.2.2 MMCHS Soft Reset Flow

Figure 24-37 shows the soft reset process of the MMCHS controller.

Figure 24-37. MMC/SDIO Controller Software Reset Flow

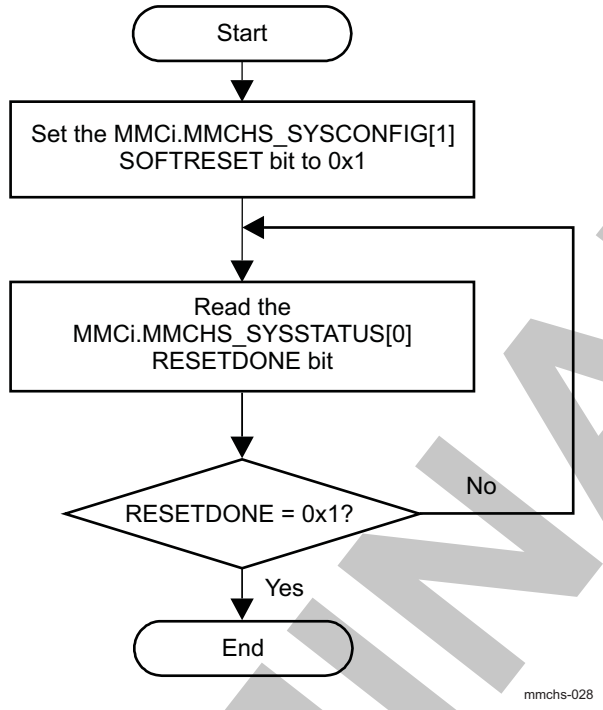


Table 24-25. Register Call Summary for Main Sequence – Software Reset Flow

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

24.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] bit fields before the MMC/SDIO host driver is started.

24.5.1.1.2.4 Wake-Up Configuration

Table 24-26 describes the MMCHS controller wake-up configuration.

Table 24-26. MMC/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCi.MMCHS_HCTL[24] IWE	0x1
SDIO card only: Enable card interrupt (if necessary).	W	MMCi.MMCHS_IE[8] CIRQ_ENABLE	0x1

24.5.1.1.2.5 MMC Host and Bus Configuration

Figure 24-38 shows the MMC bus configuration process.

Figure 24-38. MMC/SDIO Controller Bus Configuration

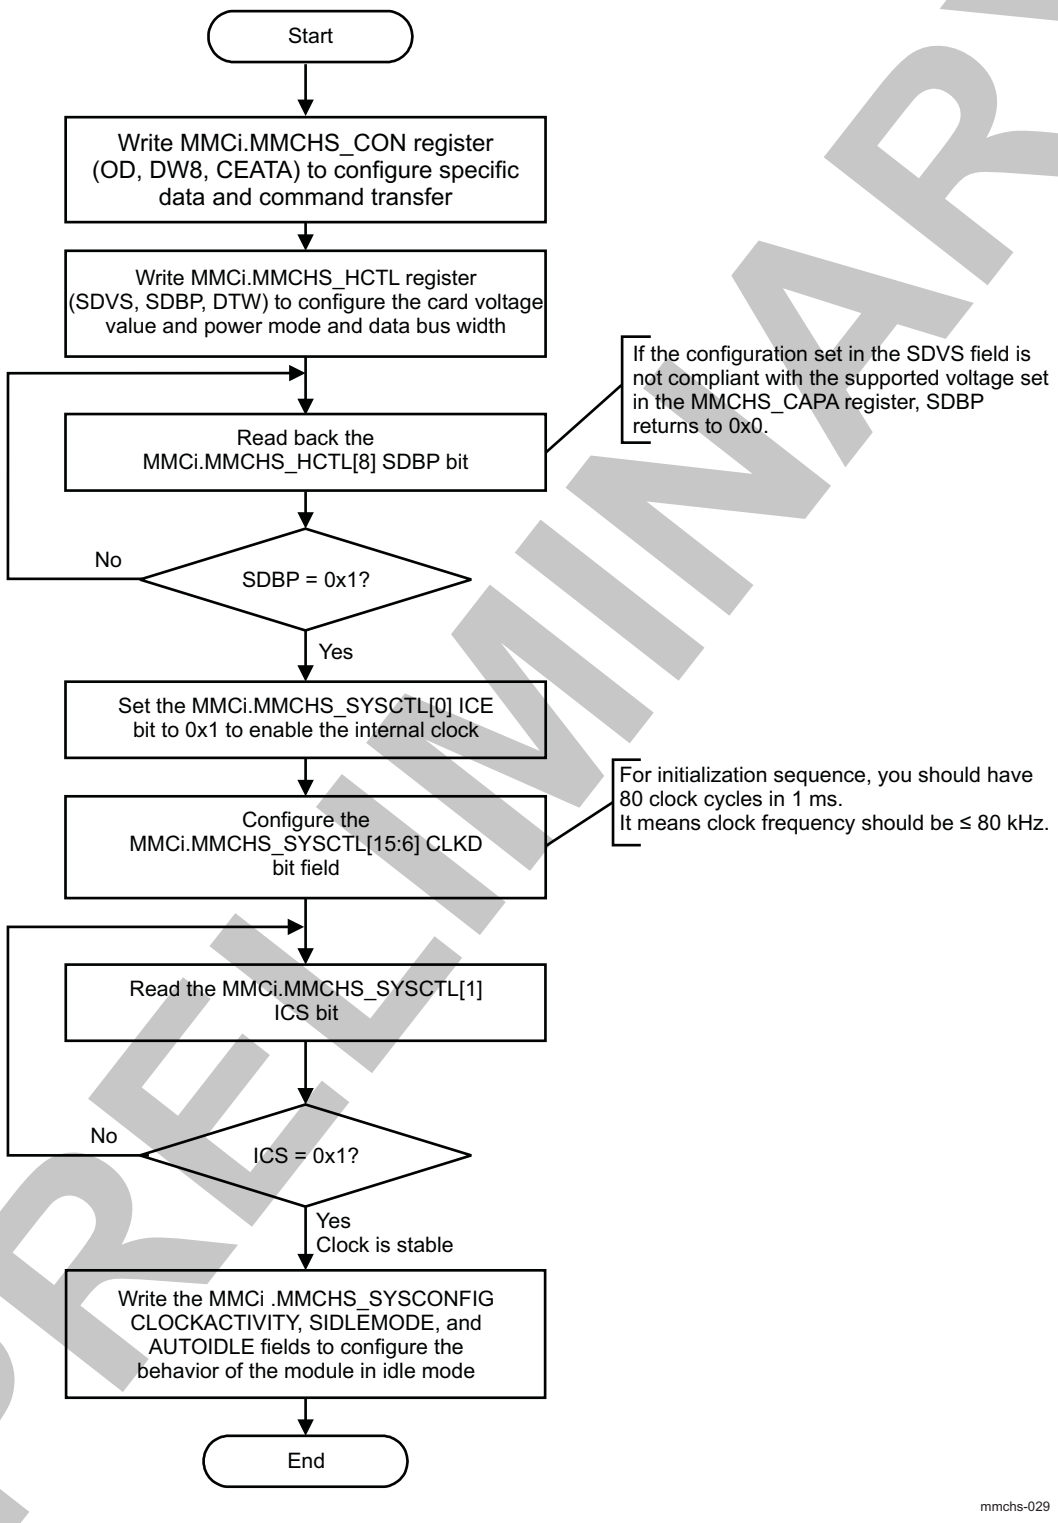

Table 24-27. Register Call Summary for Main Sequence – Bus Configuration

Register Name	Register Name
MMCHS_CON	MMCHS_HCTL
MMCHS_SYSCONFIG	MMCHS_SYSCTL

24.5.1.2 Operational Modes Configuration

24.5.1.2.1 Basic Operations for MMC/SDIO Host Controller

The MMC/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

24.5.1.2.1.1 Card Detection, Identification, and Selection

Figure 24-39 and Figure 24-40 show the card detection, identification and selection process.

Figure 24-39. MMC/SDIO Controller Card Identification and Selection – Part 1

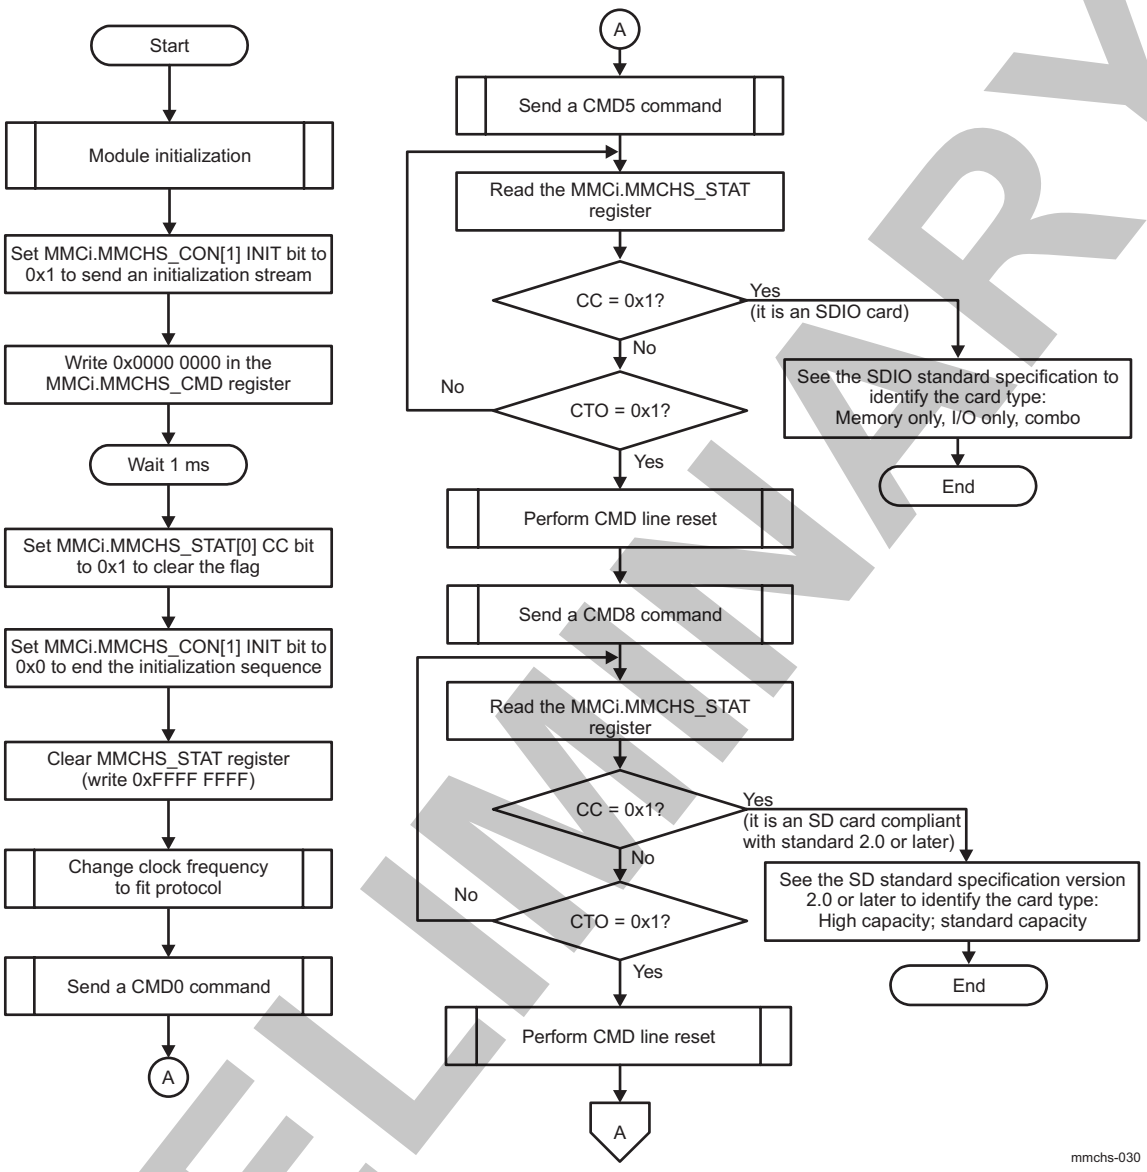

Figure 24-40. MMC/SDIO Controller Card Identification and Selection – Part 2

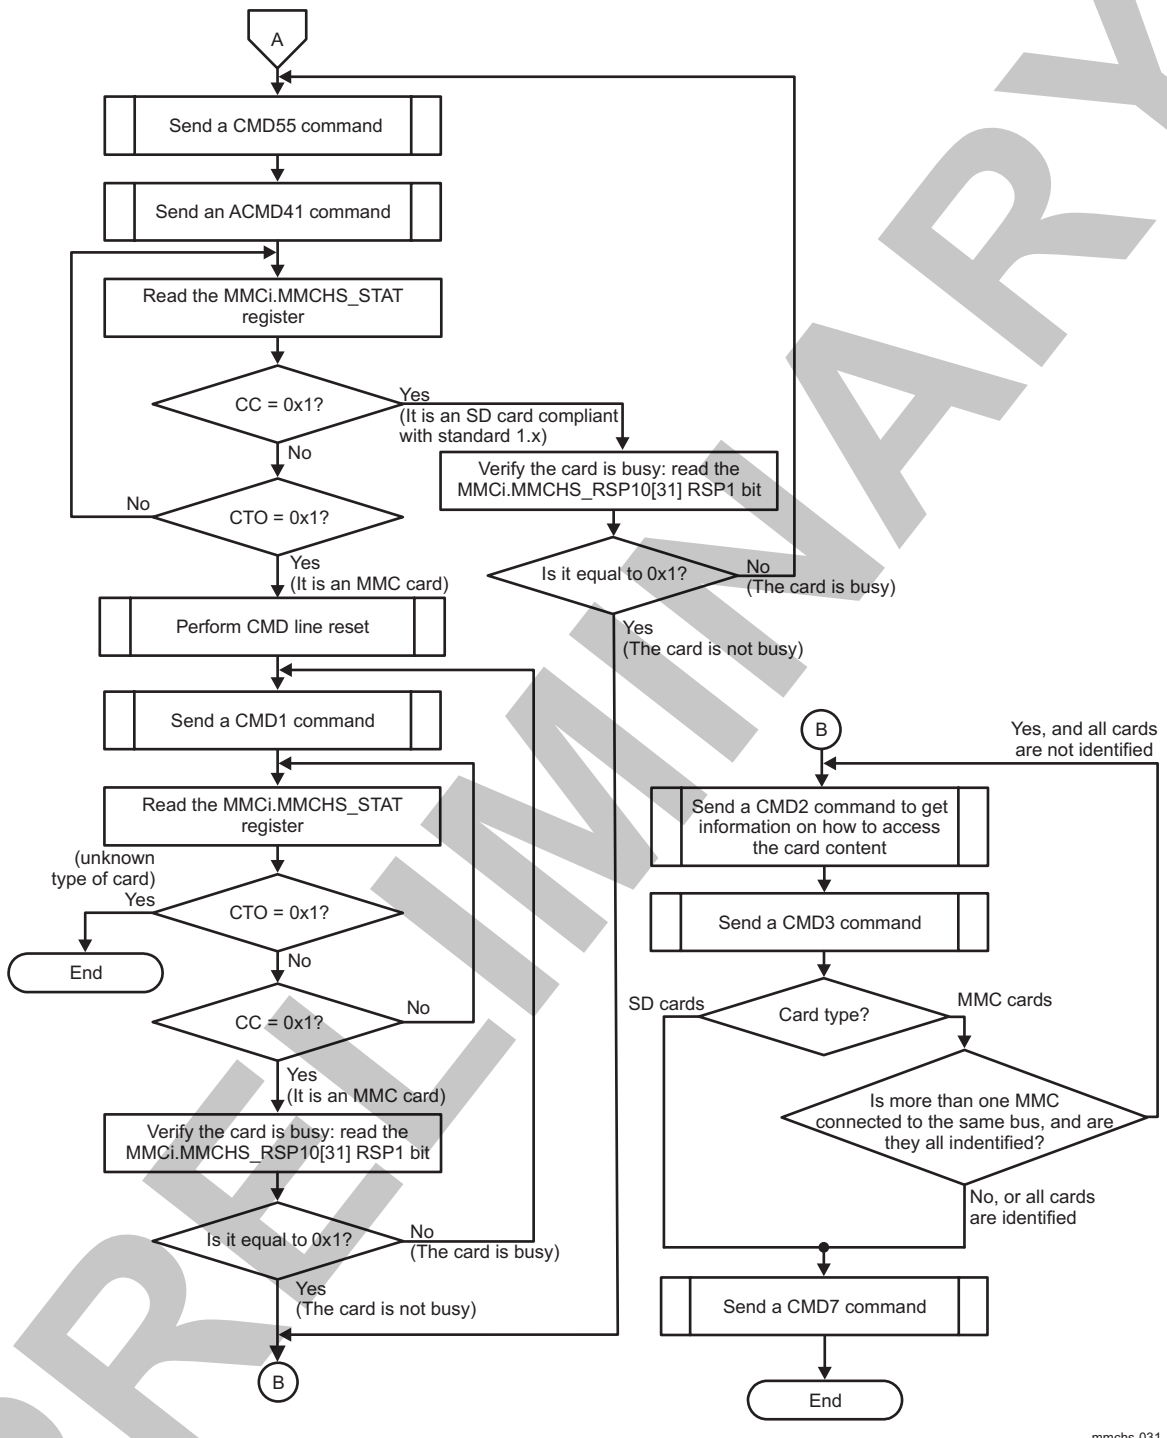

Table 24-28. Register Call Summary for Main Sequence – Card Identification and Selection

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_CMD	MMCHS_STAT
MMCHS_SYSCTL	MMCHS_RSP10	

Table 24-29 lists the subprocess call summary.

Table 24-29. Subprocess Call Summary for Main Sequence – Card Identification and Selection

Subprocess Name	Cross-Reference
Initialize module.	See Section 24.5.1.1.2 , *MMC/SDIO Host Controller Initialization Flow*.
Change clock frequency to fit protocol.	See Section 24.5.1.2.1.7.2, *MMCHS Clock Frequency Change*.
Send a command.	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.
Perform CMD line reset.	See Section 24.5.1.2.1.1.1, *CMD Line Reset Procedure*.

24.5.1.2.1.1.1 CMD Line Reset Procedure

Table 24-30lists the CML line reset.

Table 24-30. CMD Line Reset

Step	Access Type	Register/Bit Field/Programming Model	Value
Initiate CMD line reset.	W	MMCi.MMCHS_SYSCTL[25] SRC	0x1
Poll the SRC bit until it is set to 0x1.	R	MMCi.MMCHS_SYSCTL[25] SRC	= 0x1
Wait until the SRC bit returns to 0x0 (reset procedure is completed).	R	MMCi.MMCHS_SYSCTL[25] SRC	= 0x0

24.5.1.2.1.2 Read/Write Transfer Flow in DMA_SYSTEM Mode With Interrupt

Figure 24-41 shows the read and write protocol in DMA slave mode with interrupt signaling. For more information about the DMA settings, see Section 16.5, *DMA_SYSTEM Basic Programming Model*, in Chapter 16, *System DMA*.

Table 24-38. Register Call Summary for Main Sequence – Read/Write in CE-ATA Mode

Register Name	Register Name	Register Name
MMCHS_PSTATE	MMCHS_CON	MMCHS_IE
MMCHS_CMD	MMCHS_STAT	
MMCHS_ARG	MMCHS_SYSCTL	

Table 24-39. Subprocess Call Summary for Main Sequence – Read/Write in CE-ATA Mode

Subprocess Name	Cross-Reference
Perform CMD line reset.	See Section 24.5.1.2.1.1.1, *CMD Line Reset Procedure*.
Perform DATA lines reset.	See Section 24.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

24.5.1.2.1.6 Suspend-Resume Flow

The suspend-and-resume feature is supported only by SDIO cards.

24.5.1.2.1.6.1 Suspend Flow

Figure 24-45 shows the suspend flow for SDIO cards.

Figure 24-45. MMC/SDIO Controller Suspend Flow

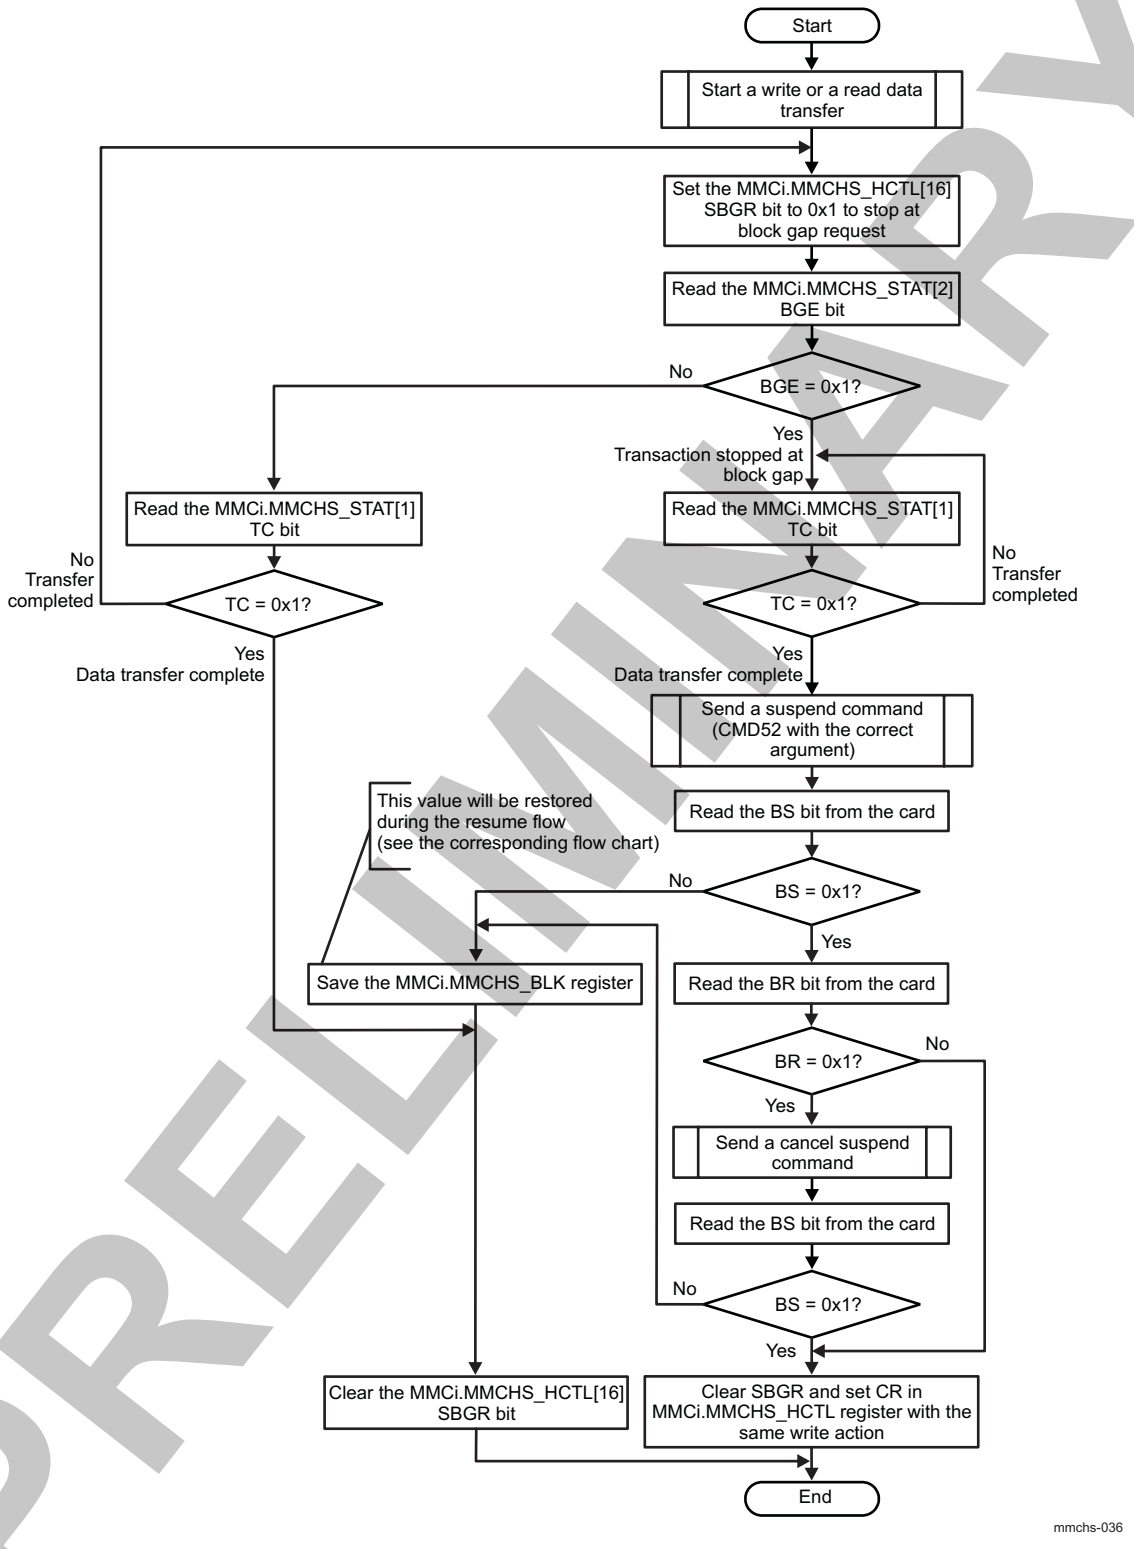

Table 24-40. Register Call Summary for Main Sequence – Suspend Flow

Register Name	Register Name	Register Name
MMCHS_HCTL	MMCHS_STAT	MMCHS_BLK

Table 24-41. Subprocess Call Summary for Main Sequence – Suspend Flow

Subprocess Name	Cross-Reference
Start a write or a read data transfer.	See Section 24.5.1.2.1, *Basic Operations for MMC/SDIO Host Controller*.
Send a suspend command (CMD52 with the correct argument).	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.
Send a cancel suspend command.	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.

24.5.1.2.1.6.2 Resume Flow

Figure 24-46 shows the resume flow for SDIO cards.

Figure 24-46. MMC/SDIO Controller Resume Flow

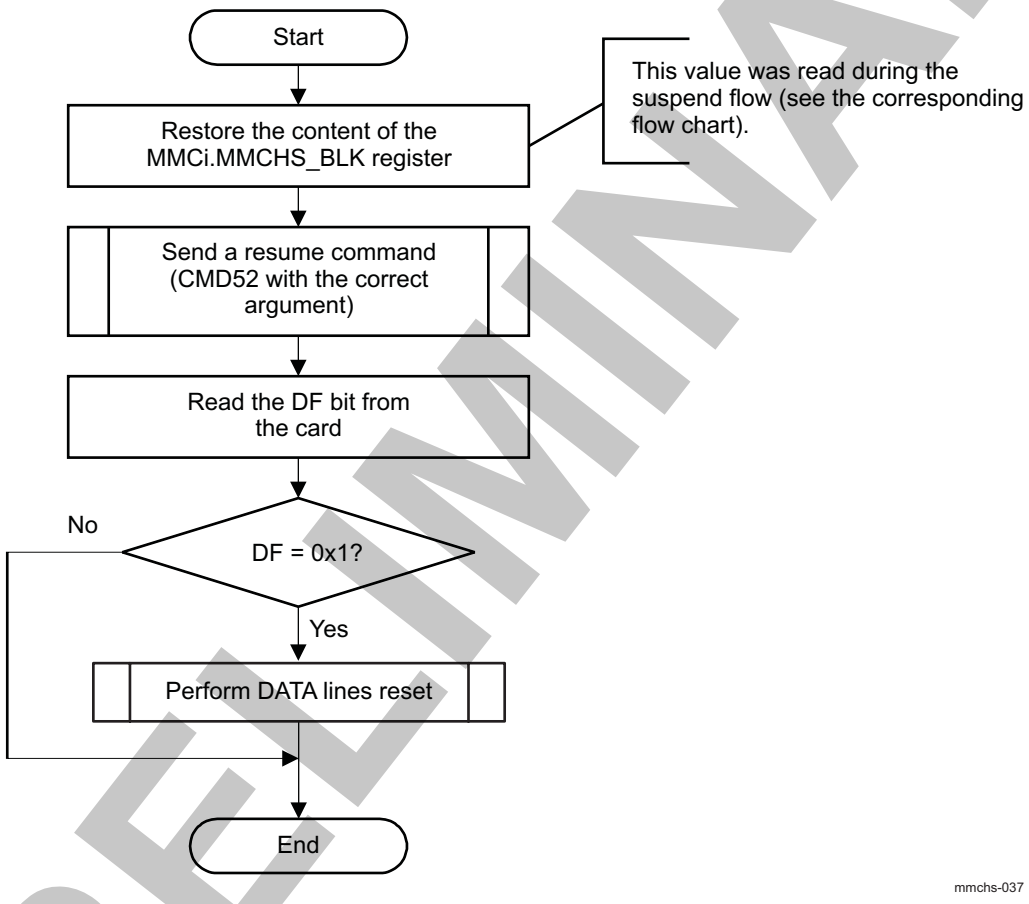

Table 24-42. Register Call Summary for Main Sequence - Resume Flow

Register Name	Register Name
MMCHS_BLK	MMCHS_SYSCTL

Table 24-43. Subprocess Call Summary for Main Sequence - Resume Flow

Subprocess Name	Cross-Reference
Send a resume command (CMD52 with the correct argument).	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.
Perform DATA lines reset.	See Section 24.5.1.2.1.2.1, *DATA Lines Reset Procedure*.

24.5.1.2.1.7 Basic Operations – Steps Detailed

24.5.1.2.1.7.1 Command Transfer Flow

Figure 24-47 shows how to send a command to the card using polling instead of interrupts for event signaling.

MMCHS_SYSCTL

24.5.1.2.1.7.3 Bus Width Selection

Figure 24-50 shows the different steps that allow changing the MMC/SDIO bus width.

Figure 24-50. MMC/SDIO Controller Bus Width Configuration Flow

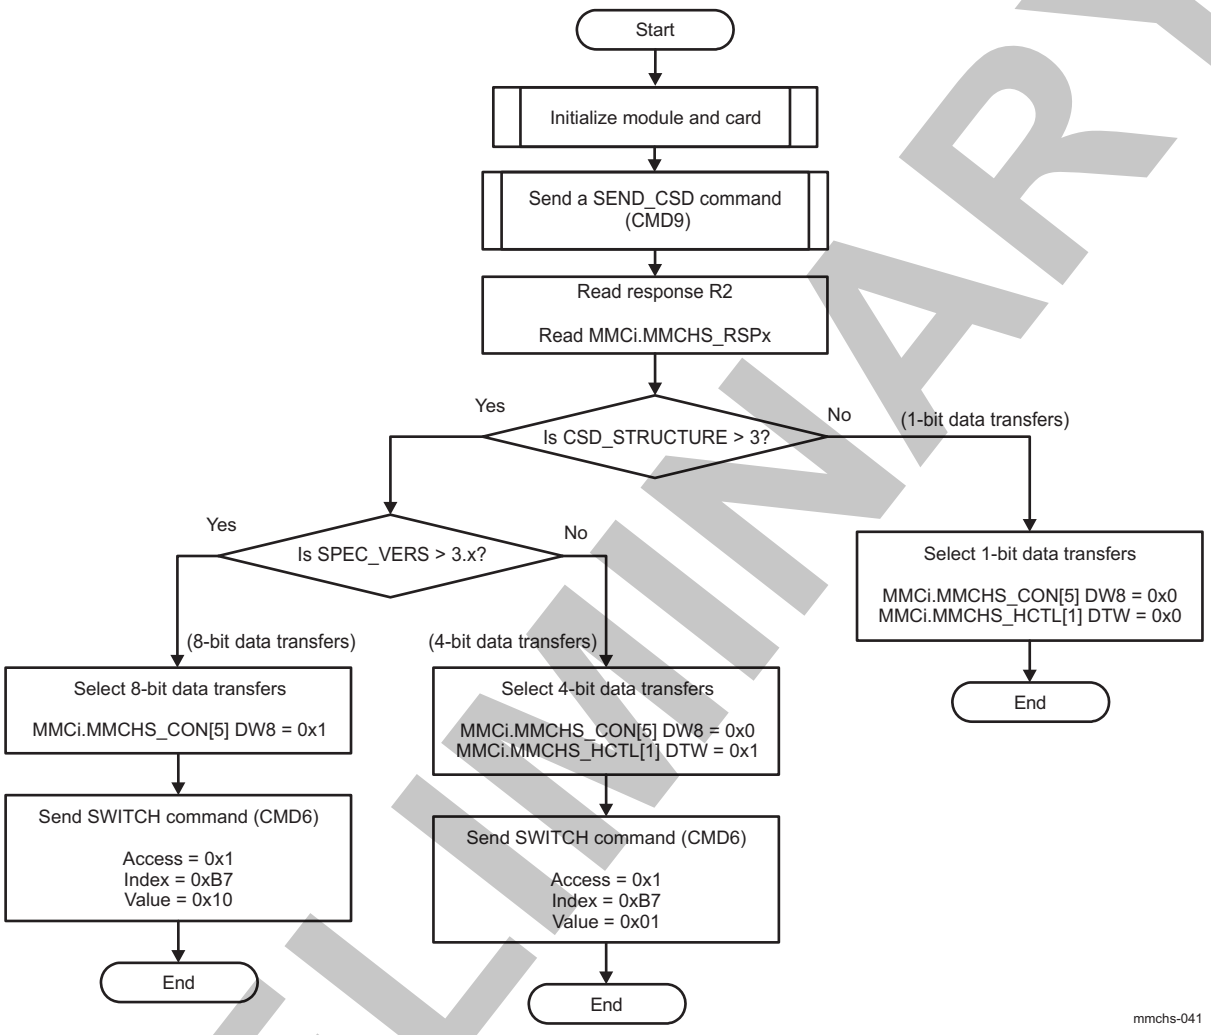

Table 24-49. Register Call Summary for Main Sequence – Bus Width Configuration Flow

Register Name	Register Name	Register Name
MMCHS_RSP10	MMCHS_RSP32	MMCHS_RSP54
MMCHS_RSP76	MMCHS_CON	MMCHS_HCTL

Table 24-50. Subprocess Call Summary for Main Sequence – Bus Width Configuration Flow

Subprocess Name	Cross-Reference
Initialize module and card.	See Section 24.5.1.1.2, *MMC/SDIO Host Controller Initialization Flow*. See Section 24.5.1.2.1.1, *Card Detection, Identification, and Selection*.
Send a SEND_CSD command (CMD9).	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.
Send SWITCH command (CMD6).	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.

24.5.1.2.2 Bus Voltage Selection

The MMC/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CTRL_MODULE_CORE_PAD.CONTROL_PBIAS register and the value of MMCHS_AC12[19] V1V8_SIGEN bit.

For more information about the PBIAS cell, see Section 18.4.9, *Extended-Drain I/O and PBIAS Cell*, in Chapter 18, *Control Module*.

CAUTION

The BIAS voltage must be set using the procedure described in *Section 18.5.1.2.1, Extended-Drain I/Os and PBIAS Cell Programming Guide*, in Chapter 18, *Control Module*. Failure to follow this procedure can damage the MMCHS interface.

Figure 24-51 shows how to configure the MMCHS controller to fit with power switching sequence.

Figure 24-51. MMC/SDIO Power Switching Procedure

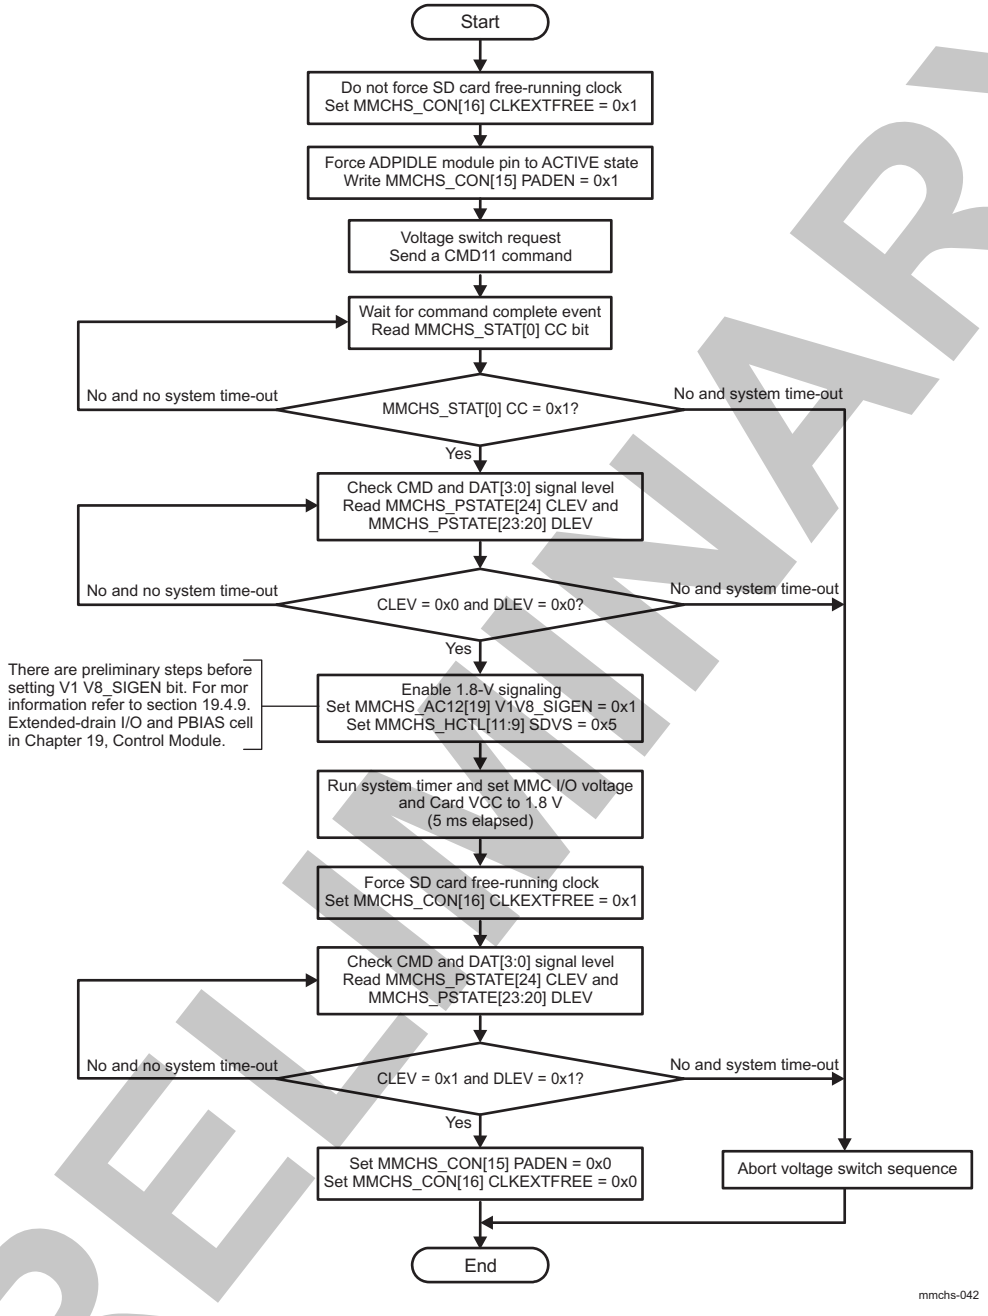

Table 24-51. Register Call Summary for Main Sequence – Power Switching Procedure

Register Name	Register Name
MMCHS_STAT	MMCHS_PSTATE
MMCHS_CMD	MMCHS_CON

Table 24-52. Subprocess Call Summary for Main Sequence – Power Switching Procedure

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.

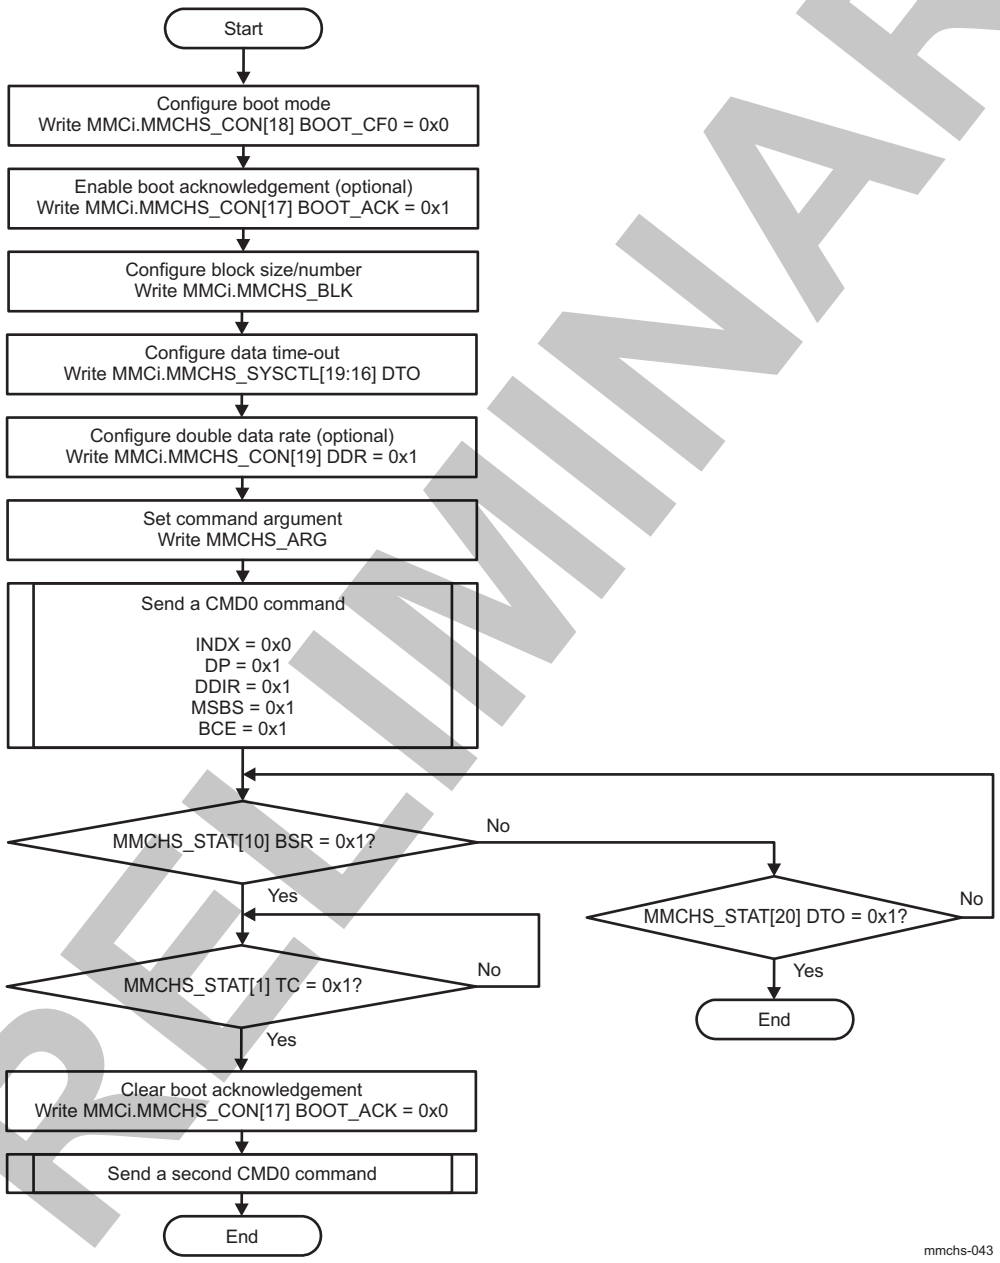
24.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

24.5.1.2.3.1 Boot Using CMD0

Figure 24-52 shows the necessary steps to configure the controller boot mode using CMD0.

Figure 24-52. MMC/SDIO Controller Boot Using CMD0



To abort a boot sequence, the system must issue a CMD0 with the MMCHS_CMD[23:22] CMD_TYPE bit field set to 0x3 (the MMCHS_CON[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 24-53. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	

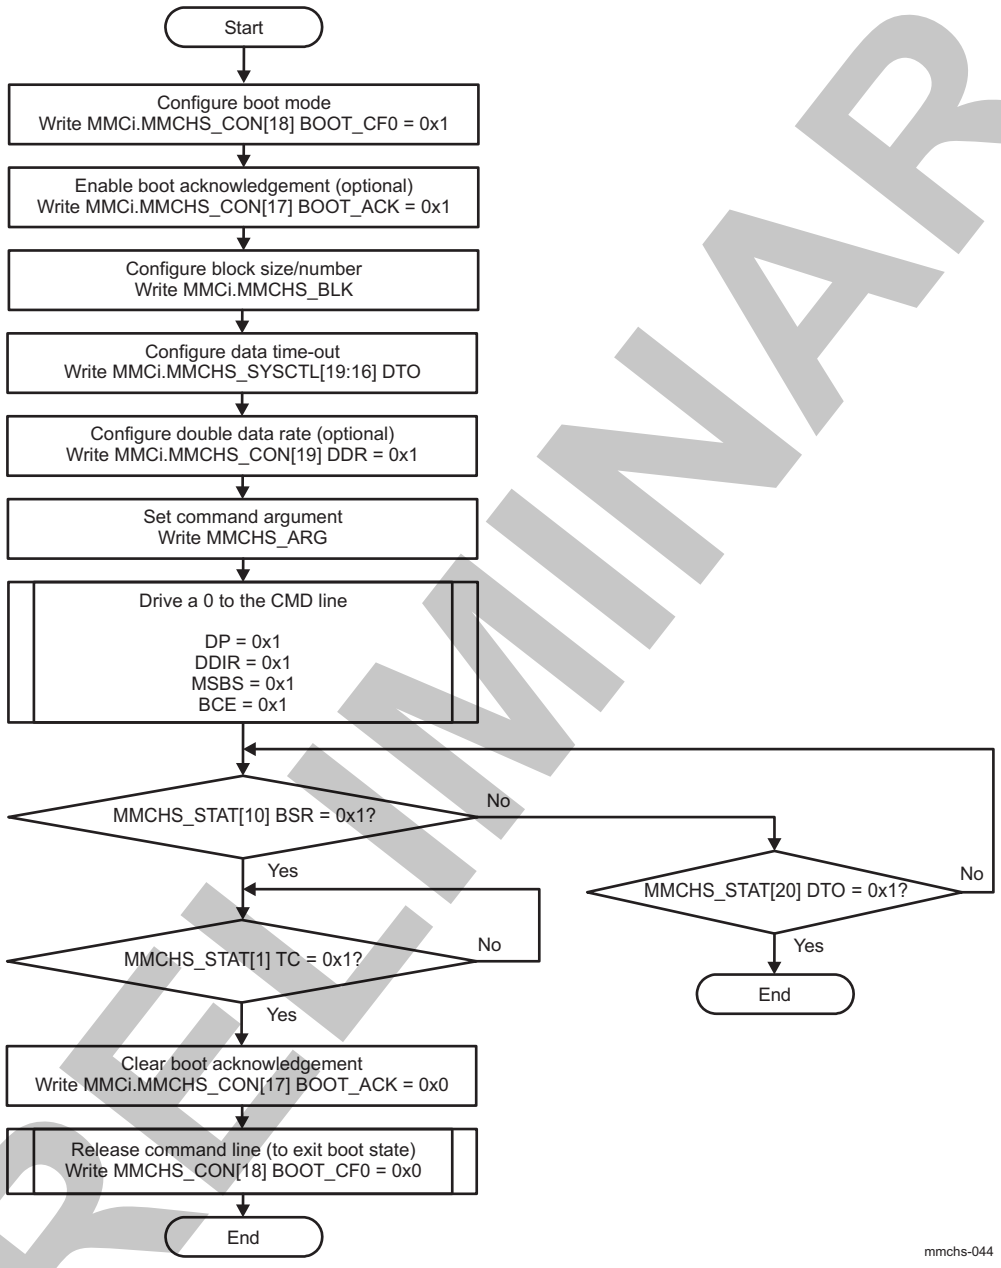
Table 24-54. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.

24.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 24-53 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

Figure 24-53. MMC/SDIO Controller Boot With CMD Line Tied to 0



To abort the boot sequence, the system must clear the MMCHS_CON[18] BOOT_CF0 bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

Table 24-55. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name
MMCHS_CON	MMCHS_BLK	MMCHS_SYSCTL
MMCHS_ARG	MMCHS_STAT	MMCHS_CMD

Table 24-56. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 24.5.1.2.1.7.1, *Command Transfer Flow*.

24.5.1.2.4 SDR104/HS200 DLL Tuning Procedure

Figure 24-54 shows the DLL tuning procedure when SDR104 and HS200 modes are used.

Figure 24-54. SDR104/HS200 DLL Tuning Procedure

Physical Address	0x4809 C010 0x480B 4010 0x480B 4010 0x480A D010 0x480D 1010 0x480D 1010 0x480D 5010 0x480D 5010
Description	Clock Management Configuration Register
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								STANDBYMODE		IDLEMODE		FREEEMU		SOFTRESET	

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x000 0000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state.Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state.Backup mode, for debug only. 0x3: Smart-Standby wakeup-capable mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module may generate (master-related) wakeup events when in standby state.Mode is only relevant if the appropriate IP module "mwakeup" output is implemented. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's IDLE requests unconditionally, i.e. regardless of the IP module's internal requirements.Backup mode, for debug only. 0x1: No-idle mode: local target never enters idle state.Backup mode, for debug only. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
1	FREEEMU	Sensitivity to emulation (debug) suspend input signal. Functionality NOT implemented in MMCHS. 0x0: IP module is sensitive to emulation suspend 0x1: IP module is not sensitive to emulation suspend	RW	0
0	SOFTRESET	Software reset. (Optional) Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action	RW	0

Description	System Configuration Register This register allows controlling various parameters of the Interconnect interface.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		STANDBYMODE		RESERVED		CLOCKACTIVITY		RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x0 0000
13:12	STANDBYMODE	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a '0'. 0x0: Force-standby. Mstandby is forced unconditionnaly. 0x1: No-standby. Mstandby is never asserted. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2
11:10	RESERVED		R	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock 0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x3: Interface and Functional clocks are maintained. 0x2: Functional clock is maintained. Interface clock may be switched-off.	RW	0x0
7:5	RESERVED	This bit is initialized to zero, and writes to it are ignored. Reads return 0.	R	0x0
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the MMCHS acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 0x1: If an IDLE request is detected, the request is ignored and the module keeps on behaving normally. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
2	ENAWAKEUP	Wakeup feature control 0x0: Wakeup capability is disabled 0x1: Wakeup capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. Write 0x0: No effect. Write 0x1: Trigger a module reset. Read 0x1: The module is reset. Read 0x0: Normal mode	RW	0
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity	RW	1

Address Offset	0x0000 0124
Physical Address	0x4809 C124 0x480B 4124 0x480B 4124 0x480A D124 0x480D 1124 0x480D 1124 0x480D 5124 0x480D 5124
Description	Card Status Response Error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP0[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP0). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RESP76) for possible card errors.

Address Offset	0x0000 0128
Physical Address	0x4809 C128 0x480B 4128 0x480B 4128 0x480A D128 0x480D 1128 0x480D 1128 0x480D 5128 0x480D 5128
Description	System Test Register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLEN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.

16	OBI	Out-Of-Band Interrupt (OBI) data value Read 0x1: The Out-of-Band Interrupt pin is driven high. Read 0x0: The Out-of-Band Interrupt pin is driven low.	R	0
15	SDCD	Card detect input signal (sdcard_cd) data value Read 0x1: The card detect pin is driven high. Read 0x0: The card detect pin is driven low.	R	0
14	SDWP	Write protect input signal (sdcard_wp) data value Read 0x1: The write protect pin sdcard_wp is driven high. Read 0x0: The write protect pin sdcard_wp is driven low.	R	0
13	WAKD	Wake request output signal data value Write 0x0: The pin SWAKEUP is driven low. Write 0x1: The pin SWAKEUP is driven high. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
12	SSB	Set status bit This bit must be cleared prior attempting to clear a status bit of the interrupt status register (MMCHS_STAT). Write 0x0: Clear this SSB bitfield. Writing 0 does not clear already set status bits; Write 0x1: Force to 1 all status bits of the interrupt status register (MMCHS_STAT) only if the corresponding bitfield in the Interrupt signal enable register (MMCHS_ISE) is set. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
11	D7D	DAT7 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT7 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT7 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT7 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT7 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
10	D6D	DAT6 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT6 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT6 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT6 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT6 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0

Bits	Field Name	Description	Type	Reset
9	D5D	DAT5 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT5 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT5 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT5 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT5 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
8	D4D	DAT4 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT4 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT4 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT4 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT4 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
7	D3D	DAT3 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT3 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT3 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT3 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT3 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
6	D2D	DAT2 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT2 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT2 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT2 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT2 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0

Bits	Field Name	Description	Type	Reset
5	D1D	DAT1 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT1 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT1 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT1 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT1 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
4	D0D	DAT0 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT0 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT0 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT0 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT0 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
3	DDIR	Control of the DAT[7:0] pins direction. Write 0x0: The DAT lines are outputs (host to card) Write 0x1: The DAT lines are inputs (card to host) Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
2	CDAT	CMD input/output signal data value Write 0x0: If SYSTEST[CDIR] = 0 (output mode direction), the CMD line is driven low. If SYSTEST[CDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[CDIR] = 0 (output mode direction), the CMD line is driven high. If SYSTEST[CDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[CDIR] = 1 (input mode direction), returns the value on the CMD line (high) If SYSTEST[CDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[CDIR] = 1 (input mode direction), returns the value on the CMD line (low). If SYSTEST[CDIR] = 0 (output mode direction), returns 0	RW	0
1	CDIR	Control of the CMD pin direction. Write 0x0: The CMD line is an output (host to card) Write 0x1: The CMD line is an input (card to host) Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
0	MCKD	MMC clock output signal data value Write 0x0: The output clock is driven low. Write 0x1: The output clock is driven high. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0

0x000										0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21	SDMA_LNE	Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion	RW	0
20	DMA_MNS	DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).This option is only available if generic parameter MADMA_EN is asserted to '1'. 0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.	RW	0

Bits	Field Name	Description	Type	Reset
19	DDR	Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting. 0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTRL[HSPE]. 0x1: Data Bytes and CRC are transmitted on both edge.	RW	0
18	BOOT_CF0	Boot status supported: This register is set when the CMD line need to be forced to '0' for a boot sequence. CMD line is driven to '0' after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction. Write 0x0: CMD line is released when it was previously forced to '0' by a boot sequence. Write 0x1: CMD line forced to '0' is enabled and will be active after writing into MMCHS_CMD Read 0x1: CMD line forced to '0' is enabled Read 0x0: CMD line not forced	RW	0
17	BOOT_ACK	Book acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.	RW	0
16	CLKEXTFREE	External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.	RW	0
15	PADEN	Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.	RW	0
14	OBIE	Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled	RW	0

Bits	Field Name	Description	Type	Reset
13	OBIP	Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Active high level 0x1: Active low level	RW	0
12	CEATA	CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.	RW	0
10:9	DVAL	Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (sdcard_cd). The usage of the card detect input signal (sdcard_cd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x3: 8,4 ms debounce period 0x2: 1 ms debounce period	RW	0x3
8	WPP	Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (sdcard_wp). The usage of the write protect input signal (sdcard_wp) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level 0x1: Active low level	RW	0
7	CDP	Card detect polarity All cards This bit selects the active level of the card detect input signal (sdcard_cd). The usage of the card detect input signal (sdcard_cd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active low level 0x1: Active high level	RW	0

Bits	Field Name	Description	Type	Reset
6	MIT	MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6). 0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)	RW	0
4	MODE	Mode select All cards This bit select between Functional mode and SYSTEST mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register. 0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer	RW	0
2	HR	Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCHS_CON[CEATA] is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token i.e. CMD line held to '0' during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.	RW	0

Bits	Field Name	Description	Type	Reset
1	INIT	Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification, or section 6.4 in the SD card specification). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0
0	OD	Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[HR]) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response	RW	0

Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDMA_ARG2																															

Bits	Field Name	Description	Type	Reset
31:0	SDMA_ARG2	SDMA System Address / Argument 2 This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23. (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.	RW	0x0000 0000

Description	Transfer Length Configuration Register MMCHS_BLK[BLEN] is the block size register. MMCHS_BLK[NBLK] is the block count register. This register shall be used for any card.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																RESERVED				BLEN											

Bits	Field Name	Description	Type	Reset
31:16	NBLK	Blocks count for current transfer This register is enabled when Block count Enable (MMCHS_CMD[BCE]) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0xFFFF: 65535 blocks 0x0: Stop count 0x1: 1 block 0x2: 2 blocks	RW	0x0000
15:12	RESERVED		R	0x0
11:0	BLEN	Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCHS_STAT[TC] set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. 0x1: 1 byte block length 0x7FF: 2047 bytes block length 0x0: No data transfer 0x1FF: 511 bytes block length 0x800: 2048 bytes block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x200: 512 bytes block length	RW	0x000

23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR	RW	0x0
21	DP	Data present select	RW	0

Bits	Field Name	Description	Type	Reset
		This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer		
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to1). **Note:** The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). **Note:** The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED		R	0
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response 0x1: Response Length 136 bits 0x3: Response Length 48 bits with busy after response 0x2: Response Length 48 bits	RW	0x0
15:6	RESERVED		R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK]. 0x1: Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write.	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Data Write (host to card) 0x1: Data Read (card to host)		
3:2	ACEN	Auto CMD Enable - SD card only. This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation 1. Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 2. Auto CMD23 Enable When this bit field is set to 10b, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. The Host Controller Version 3.00 and later shall support this function. The following conditions are required to use the Auto CMD23. – Auto CMD23 Supported (Host Controller Version is 3.00 or later) – A memory card that supports CMD23 (SCR[33]=1) – If DMA is used, it shall be ADMA. –Only when CMD18 or CMD25 is issued (**Note:** the Host Controller does not check command index.) Auto CMD23 can be used with or without ADMA. By writing the Command register, the Host Controller issues a CMD23 first and then issues a command specified by the Command Index in Command register. If response errors of CMD23 are detected, the second command is not issued. A CMD23 error is indicated in the Auto CMD Error Status register (MMCHS_AC12). 32-bit block count value for CMD23 is set to SDMA System Address / Argument 2 register (MMCHS_SDMASA). 0x0: Auto Command Disabled 0x1: Auto CMD12 enable or CCS detection enabled. 0x3: Reserved 0x2: Auto CMD23 Enable	RW	0x0
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer.	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Block count enabled for multiple block transfer with known number of blocks		
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Table 24-96. MMCHS_DATA

Address Offset	0x0000 0220
Physical Address	0x4809 C220 0x480B 4220 0x480B 4220 0x480A D220 0x480D 1220 0x480D 1220 0x480D 5220 0x480D 5220
Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

Description	Present State Register The Host can get status of the Host Controller from this 32-bit read only register.
Type	R

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED							CLEV	DLEV				WP	CDPL	CSS	CINS	RESERVED				BRE	BWE	RTA	WTA	RESERVED				RTR	DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	CLEV	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x1: The CMD line level is 1. Read 0x0: The CMD line level is 0.	R	-
23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-
19	WP	Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (sdcard_wp) level. The value of this register after reset depends on the protect input pin (sdcard_wp) level at that time. Read 0x1: If MMCHS_CON[WPP] is set to 0 (default), the card is not write protected, otherwise the card is protected. Read 0x0: If MMCHS_CON[WPP] is set to 0 (default), the card is write protected, otherwise the card is not protected.	R	-
18	CDPL	Card detect pin level This bit reflects the inverse value of the card detect input pin (sdcard_cd), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTAE[CSS]) is set to 1. Use of this bit is limited to testing since it must be debounced y software. The value of this register after reset depends on the card detect input pin (sdcard_cd) level at that time. Read 0x1: The value of the card detect input pin (sdcard_cd) is 0 Read 0x0: The value of the card detect input pin (sdcard_cd) is 1	R	-

Bits	Field Name	Description	Type	Reset
17	CSS	Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[CDPL]). Debouncing is performed on the card detect input pin (sdcard_cd) to detect card stability. This bit is not affected by a software reset. Read 0x1: No card or card inserted Read 0x0: Reset or Debouncing	R	0
16	CINS	Card inserted This bit is the debounced value of the card detect input pin (sdcard_cd). An inactive to active transition of the card detect input pin (sdcard_cd) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (sdcard_cd) will generate a card removal interrupt (MMCHS_STAT[REM]). This bit is not affected by a software reset. Read 0x1: If MMCHS_CON[CDP] is set to 1, the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 0, no card is detected. The card may have been removed from the card slot. Read 0x0: If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 0, the card has been inserted.	R	0
15:12	RESERVED		R	0x0
11	BRE	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer. Read 0x0: Read BLEN bytes disable	R	0
10	BWE	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data.	R	0
9	RTA	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x1: read data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0

Bits	Field Name	Description	Type	Reset
8	WTA	Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x1: Write data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
7:4	RESERVED		R	0x0
3	RTR	Re-Tuning Request Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting MMCHS_AC12[22] ET. This bit isn't set to 1 if MMCHS_AC12[23] SCLK_SEL is set to 0 (using fixed sampling clock). Refer to MMCHS_CAPA2[15:14] RTM for more detail. Read 0x1: Sampling clock needs re-tuning Read 0x0: Fixed or well tuned sampling clock	R	0
2	DLA	DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x1: DAT Line active Read 0x0: DAT Line inactive	R	0
1	DATI	Command inhibit(DAT) This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]). Read 0x1: Issuing of command using DAT lines is not allowed Read 0x0: Issuing of command using the DAT lines is allowed	R	0

Bits	Field Name	Description	Type	Reset
0	CMDI	Command inhibit(CMD) This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC] or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this register is not automatically cleared. Read 0x1: Issuing of command using CMD line is not allowed Read 0x0: Issuing of command using CMD line is allowed	R	0

Table 24-100. MMCHS_HCTL

Address Offset	0x0000 0228
Physical Address	0x4809 C228 0x480B 4228 0x480B 4228 0x480A D228 0x480D 1228 0x480D 1228 0x480D 5228 0x480D 5228
Description	Host Control Register This register defines the host controls to set power, wakeup and transfer parameters. MMCHS_HCTL[31:24] = Wakeup control MMCHS_HCTL[23:16] = Block gap control MMCHS_HCTL[15:8] = Power control MMCHS_HCTL[7:0] = Host control
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				OBWE	REM	INS	IWE	RESERVED				IBG	RWC	CR	SBGR	RESERVED				SDVS			SDBP	CDSS	CDTL	RESERVED	DMAS		HSPE	DTW	LED

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). The write to this register is ignored when MMCHS_CON[OBIE] is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt	RW	0
26	REM	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal	RW	0
25	INS	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion	RW	0
24	IWE	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	RESERVED		R	0x0
19	IBG	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0
17	CR	Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]). The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0

Bits	Field Name	Description	Type	Reset
16	SBGR	Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	RESERVED		R	0x0
11:9	SDVS	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer. 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) 0x5: 1.8V (Typical)	RW	0x0
8	SDBP	SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7	CDSS	Card Detect Signal Selection This bit selects source for the card detection.When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupts caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: sdcard_cd is selected (for normal use) 0x1: MMCHS_HCTL[6] CDTL is selected (for test purpose)	RW	0
6	CDTL	Card Detect Test Level: This bit is enabled while MMCHS_HCTL[7] CDSS is set to 1 and it indicates whether the card is inserted or not. 0x0: No Card 0x1: Card Inserted	RW	0
5	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
4:3	DMAS	DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register MMCHS_CAPA . Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x3: Reserved 0x2: 32-bit Address ADMA2 is selected	RW	0x0
2	HSPE	High Speed Enable: Before setting this bit, the Host Driver shall check the MMCHS_CAPA[21] HSS. If this bit is set to 0, the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock.This bit shall not be set when dual data rate mode is activated in MMCHS_CON[DDR]. 0x0: Normal speed mode 0x1: High speed mode	RW	0
1	DTW	Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[DW8] set to1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)	RW	0
0	LED	Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.	R	0

RESERVED					SRD	SRC	SRA	RESERVED				DTO				CLKD								CGS	RESERVED				CEN	ICS	ICE

Bits	Field Name	Description	Type	Reset
31:27	RESERVED		R	0x00
26	SRD	Software reset for DAT line This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see Section 24.5.1.2.1.2.1*DATA Lines Reset Procedure*. DAT finite state machine in both clock domain are also reset. Here below are the registers cleared by MMCHS_SYSCTL[SRD]: - MMCHS_DATA - MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line	RW	0
25	SRC	Software reset for CMD line For more information about SRC bit manipulation, see Section 24.5.1.2.1.1.1 *CMD Line Reset Procedure*. This bit is set to 1 for reset and released to 0 when completed. CMD finite state machine in both clock domain are also reset. Here below the registers cleared by MMCHS_SYSCTL[SRC]: - MMCHS_PSTATE: CMDI - MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line	RW	0

Bits	Field Name	Description	Type	Reset
24	SRA	Software reset for all This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the capabilities registers (MMCHS_CAPA and MMCHS_CUR_CAPA). 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	RESERVED		R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bitfield based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[TCF]). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STA[DTO]). The MMCHS_SYSCTL[DTO] register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0xF: Reserved 0x0: TCF x 2^13 0x1: TCF x 2^14 0xE: TCF x 2^27	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between MMCi_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCi_FCLK bypass 0x1: MMCi_FCLK bypass 0x2: MMCi_FCLK / 2 0x3: MMCi_FCLK / 3 0x3FF: MMCi_FCLK / 1023	RW	0x000
5	CGS	Clock Generator Select - For SD cards Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in MMCHS_SYSCTL[15:6] CLKD. If the Programmable Clock Mode is supported (non-zero value is set to MMCHS_CAPA2[23:16] CM), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read. This bit depends on the setting of MMCHS_AC12[31] PV_ENABLE. If PV_ENABLE = 0, this bit is set by Host Driver. If PV_ENABLE = 1, this bit is automatically set to a value specified in one of Preset Value registers, see, Table 24-22.	R	0
4:3	RESERVED		R	0x0
2	CEN	Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[ICS]).	RW	0

Bits	Field Name	Description	Type	Reset
1	ICS	Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[ICE]) or after changing the clock ratio (MMCHS_SYSCTL[CLKD]). Read 0x0: The internal clock is not stable.	R	0
0	ICE	Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) .	RW	0

Table 24-104. MMCHS_STAT

Address Offset	0x0000 0230
Physical Address	0x4809 C230 0x480B 4230 0x480B 4230 0x480A D230 0x480D 1230 0x480D 1230 0x480D 5230 0x480D 5230
Description	Interrupt Status Register The interrupt status regroups all the status of the module internal events that can generate an interrupt. MMCHS_STAT[31:16] = Error Interrupt Status MMCHS_STAT[15:0] = Normal Interrupt Status
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED		BADA	CERR	RESERVED	TE	ADMAE	ACE	RESERVED	DEB	DCRC	DTO	CIE	CEB	CCRC	CTO	ERRI	RESERVED				BSR	OBI	CIRQ	CREM	CINS	BRR	BWR	DMA	BGE	TC	CC

Bits	Field Name	Description	Type	Reset
31:30	RESERVED		R	0x0
29	BADA	Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[BRE] =0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[BWE] =0) Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Bad Access Read 0x0: No Interrupt.	RW	0
28	CERR	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card error Read 0x0: No Error	RW	0
27	RESERVED		R	0
26	TE	Tuning Error This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure (Occurrence of an error during tuning procedure is indicated by Sampling Select). By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning. To reset tuning circuit, Sampling Clock shall be set to 0 before executing tuning procedure. The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning Error, the Host Driver should discard data transferred by a current read/write command and retry data transfer after the Host Controller retrieved from tuning circuit error. The bit is set if the lock is lost (but not during the tuning process) or if the lock counter expires without the lock being asserted. If the latter happens, the SW can decide to ignore the interrupt and wait some more for the lock to be set. 0x0: No Error 0x1: Error	RW	0
25	ADMAE	ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register.In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: ADMA error Read 0x0: No Interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
24	ACE	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register (MMCHS_AC12) has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Auto CMD error Read 0x0: No Error.	RW	0
23	RESERVED		R	0
22	DEB	Data End Bit error This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data end bit error Read 0x0: No Error	RW	0
21	DCRC	Data CRC Error This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data CRC error Read 0x0: No Error.	RW	0
20	DTO	Data timeout error This bit is set automatically according to the following conditions: - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time out Read 0x0: No error.	RW	0
19	CIE	Command index error This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[CICE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command index error Read 0x0: No error.	RW	0
18	CEB	Command end bit error This bit is set automatically when detecting a 0 at the end bit position of a command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command end bit error Read 0x0: No error.	RW	0

Bits	Field Name	Description	Type	Reset
17	CCRC	Command CRC Error This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[CCCE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command CRC error Read 0x0: No Error.	RW	0
16	CTO	Command Timeout Error This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time Out Read 0x0: No error	RW	0
15	ERRI	Error Interrupt If any of the bits in the Error Interrupt Status register (MMCHS_STAT[24:15]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x1: Error interrupt event(s) occurred Read 0x0: No Interrupt.	R	0
14:11	RESERVED		R	0x0
10	BSR	Boot status received interrupt This bit is set automatically when MMCHS_CON[BOOT] is set 0x1 or 0x2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Boot status received interrupt. Read 0x0: No Interrupt.	RW	0
9	OBI	Out-Of-Band interrupt This bit is set automatically when MMCHS_CON[OBIE] is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[OBIP]. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Interrupt Out-Of-Band occurs Read 0x0: No Out-Of-Band interrupt.	RW	0

Bits	Field Name	Description	Type	Reset
8	CIRQ	Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end.All modes above are fully exclusive. The controller interrupt must be clear by setting MMCHS_IE[CIRQ] to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[CIRQ] is set to 1. Writes to this bit are ignored. Read 0x1: Generate card interrupt Read 0x0: No card interrupt	R	0
7	CREM	Card removal This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card removed Read 0x0: Card state stable or Debouncing	RW	0
6	CINS	Card insertion This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card inserted Read 0x0: Card state stable or debouncing	RW	0
5	BRR	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[BLEN] is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to read buffer Read 0x0: Not Ready to read buffer	RW	0

Bits	Field Name	Description	Type	Reset
4	BWR	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[BLEN]. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to write buffer Read 0x0: Not Ready to write buffer	RW	0
3	DMA	DMA interrupt : This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: No dma interrupt Read 0x0: Dma interrupt detected	RW	0
2	BGE	Block gap event When a stop at block gap is requested (MMCHS_HCTL[SBGR]), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[DLA]) between data blocks generates a Block gap event interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Transaction stopped at block gap Read 0x0: No block gap event	RW	0
1	TC	Transfer completed This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[SBGR]). In Read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[RTA]). In write mode: This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[DLA]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data transfer complete Read 0x0: No transfer complete	RW	0

Bits	Field Name	Description	Type	Reset
0	CC	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[CMDI]) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[CTO]) has higher priority than command complete (MMCHS_STAT[CC]). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command complete Read 0x0: No Command complete	RW	0

Address Offset	0x0000 023C
Physical Address	0x4809 C23C 0x480B 423C 0x480B 423C 0x480A D23C 0x480D 123C 0x480D 123C 0x480D 523C 0x480D 523C
Description	Host Control 2 Register and Auto CMD Error Status Register This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The Host driver can determine what kind of Auto CMD12 / CMD23 errors occur by this register. Auto CMD23 errors are indicated only in bits[4:1]. Bits[7:0] are valid only when the MMCHS_CMD[3:2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24]ACE) is set.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PV_ENABLE	AI_ENABLE	RESERVED						SCLK_SEL	ET	DS_SEL		V1V8_SIGEN	UHSMS			RESERVED								CNI	RESERVED		ACIE	ACEB	ACCE	ACTO	ACNE

Bits	Field Name	Description	Type	Reset
31	PV_ENABLE	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 24-22. If this bit is set to 0, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 24-22. 0x0: SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 0x1: Automatic Selection by Preset Value are Enabled.	RW	0
30	AI_ENABLE	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0x0: Disabled 0x1: Enabled	RW	0
29:24	RESERVED		R	0x00
23	SCLK_SEL	Sampling Clock Select Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when MMCHS_AC12[22] ET is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting MMCHS_AC12[22] ET. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block. 0x0: Fixed clock is used to sample data 0x1: Tuned clock is used to sample data	RW	0

Bits	Field Name	Description	Type	Reset
22	ET	Execute Tuning This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to MMCHS_AC12[23] SCLK_SEL. Tuning procedure is aborted by writing 0. This is Read-Write with automatic clear register 0x0: Not Tuned or Tuning Completed 0x1: Execute Tuning	RW	0
21:20	DS_SEL	Driver Strength Select Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register. This bit depends on setting of Preset Value Enable. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 24-22. 0x0: Driver Type B is selected (Default) 0x1: Driver Type A is selected 0x3: Driver Type D is selected 0x2: Driver Type C is selected	RW	0x0
19	V1V8_SIGEN	1.8V Signaling Enable This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V. 1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails. Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V. 3.3V regulator output shall be stable within 5ms. Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x) see also Section 24.5.1.2.2 *Bus Voltage Selection* in Chapter 24 *MMC/SDIO*. 0x0: 3.3V Signaling 0x1: 1.8V Signaling	RW	0

Bits	Field Name	Description	Type	Reset
18:16	UHSMS	UHS Mode Select This field is used to select one of UHS-I modes and effective when 1.8V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL according to Preset Value registers, see, Table 24-22. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again. When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. 0x6: Reserved 0x1: SDR25 0x7: Reserved 0x0: SDR12 0x2: SDR50 0x4: DDR50 0x5: Reserved 0x3: SDR104	RW	0x0
15:8	RESERVED		R	0x00
7	CNI	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Command not issued Read 0x0: No error	R	0
6:5	RESERVED		R	0x0
4	ACIE	Auto CMD Index Error - For Auto CMD12 and Auto CMD23 This bit is set if the Command Index error occurs in response to a command. Read 0x1: Error Read 0x0: No error	R	0
3	ACEB	Auto CMD End Bit Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting that the end bit of command response is 0. Read 0x1: End bit Error Generated Read 0x0: No error	R	0
2	ACCE	Auto CMD CRC Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting a CRC error in the command response. Read 0x1: CRC Error Generated Read 0x0: No error	R	0
1	ACTO	Auto CMD Timeout Error - For Auto CMD12 and Auto CMD23 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to1, the other error status bits (D04-D02) are meaningless. Read 0x1: Auto CMD Time Out Read 0x0: No error	R	0

Bits	Field Name	Description	Type	Reset
0	ACNE	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Auto CMD12 Not Executed Read 0x0: Auto CMD12 Executed	R	0

Bits	Field Name	Description	Type	Reset
28	BIT64	64 Bit System Bus Support Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. Read 0x1: 64 bit System bus address Read 0x0: 32 bit System bus address	R	0
27	RESERVED		R	0
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8V Not supported Write 0x1: 1.8V Supported Read 0x1: 1.8V Supported Read 0x0: 1.8V Not Supported	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.0V Not supported Write 0x1: 3.0V Supported Read 0x1: 3.0V Supported Read 0x0: 3.0V Not Supported	RW	0
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 3.3V Not supported Write 0x1: 3.3V Supported Read 0x1: 3.3V Supported Read 0x0: 3.3V Not Supported	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality.	R	1
22	DS	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x1: DMA Supported Read 0x0: DMA Not Supported	R	1
21	HSS	High speed support This bit indicates that the host controller supports high speed operations and can supply an up-to maximum card frequency. Read 0x1: High Speed Supported Read 0x0: High Speed Not Supported	R	1
20	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
19	AD2S	ADMA2 Support This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN Read 0x1: ADMA2 Supported Read 0x0: ADMA2 not Supported	R	0
18	RESERVED		R	0
17:16	MBL	Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x2: 2048 bytes Read 0x1: 1024 bytes Read 0x0: 512 bytes	R	0x1
15:8	BCF	Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1MHz. The supported clock range is 10MHz to 255MHz. FFh : 255MHz .... : ..... 02h : 2MHz 01h : 1MHz 00h : Get information via another method If the real frequency is 16.5MHz, the lager value shall be set 0001 0001b (17MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15:6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.	R	0x00
7	TCU	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x1: MHz Read 0x0: KHz	R	1
6	RESERVED		R	0
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

FFh : Clock Multiplier M = 256	R	0x00

Bits	Field Name	Description	Type	Reset
15:14	RTM	Re-Tuning Modes This field selects re-tuning method and limits the maximum data length. Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers. (1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MiB. (2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MiB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. (3) Re-Tuning Mode 3 The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. Re-Tuning Timer Control Example for Re-Tuning Mode 1 The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this register. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared. Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3 The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode. Read 0x3: Reserved Read 0x2: Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request Read 0x1: Timer and Re-Tuning Request - Max data length 4 MiB Read 0x0: Timer - Max data length 4 MiB	R	0x0

Bits	Field Name	Description	Type	Reset
13	TSDR50	Use Tuning for SDR50 If this bit is set to 1, this Host Controller requires tuning to operate SDR50. (Tuning is always required to operate SDR104.) Read 0x1: SDR50 requires tuning. Read 0x0: SDR50 does not require tuning.	R	0
12	RESERVED		R	0
11:8	TCRT	Timer Count for Re-Tuning This field indicates an initial value of the Re-Tuning Timer for Re-Tuning Mode 1 to 3. Setting to 0 disables Re-Tuning Timer. Read 0x3: 4 seconds Read 0xE: Reserved Read 0xC: Reserved Read 0x4: 8 seconds Read 0xB: 1024 seconds Read 0xF: Get information from other source Read 0x2: 2 seconds Read 0x0: Re-Tuning Timer disabled Read 0xA: 512 seconds Read 0x6: 32 seconds Read 0x1: 1 second Read 0x8: 128 seconds Read 0x7: 64 seconds Read 0x9: 256 seconds Read 0xD: Reserved Read 0x5: 16 seconds	R	0xF

Physical Address	0x4809 C248 0x480B 4248 0x480B 4248 0x480A D248 0x480D 1248 0x480D 1248 0x480D 5248 0x480D 5248
Description	Maximum Current Capabilities Register This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (MMCHS_CAPA). Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initilaization. This register is only reinitialized by a hard reset (via RESETN signal)

Address Offset	0x0000 0250
Physical Address	0x4809 C250 0x480B 4250 0x480B 4250 0x480A D250 0x480D 1250 0x480D 1250 0x480D 5250 0x480D 5250
Description	Force Event Register for Auto CMD Error Status and Error Interrupt status The Force Event Register is not a physically implemented register. Rather, it is an address at which the Auto CMD Error Status Register (MMCHS_AC12) can be written. Writing 1 : set each bit of the Auto CMD Error Status Register Writing 0 : no effect Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register if the corresponding bit of the Error Interrupt Status Enable Register is set. Writing 1 : set each bit of the Error Interrupt Status Register Writing 0 : no effect Note: By setting this register, the Error Interrupt can be set in the Error Interrupt Status register. In order to generate interrupt signal, both the Error Interrupt Status Enable and Error Interrupt Signal Enable shall be set.

Address Offset	0x0000 0254
Physical Address	0x4809 C254 0x480B 4254 0x480B 4254 0x480A D254 0x480D 1254 0x480D 1254 0x480D 5254 0x480D 5254
Description	ADMA Error Status Register When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address ST_FDS: Current location set in the ADMA System Address register is the error descriptor address ST_CADR: This sate is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

General-Purpose Interface

This chapter describes the general-purpose interface on the device.

NOTE: Some of the GPIO channels are not available in all OMAP54xx devices.

For details, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

25.1 General-Purpose Interface Overview

The general-purpose interface combines eight general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 256 (8 × 32) pins.

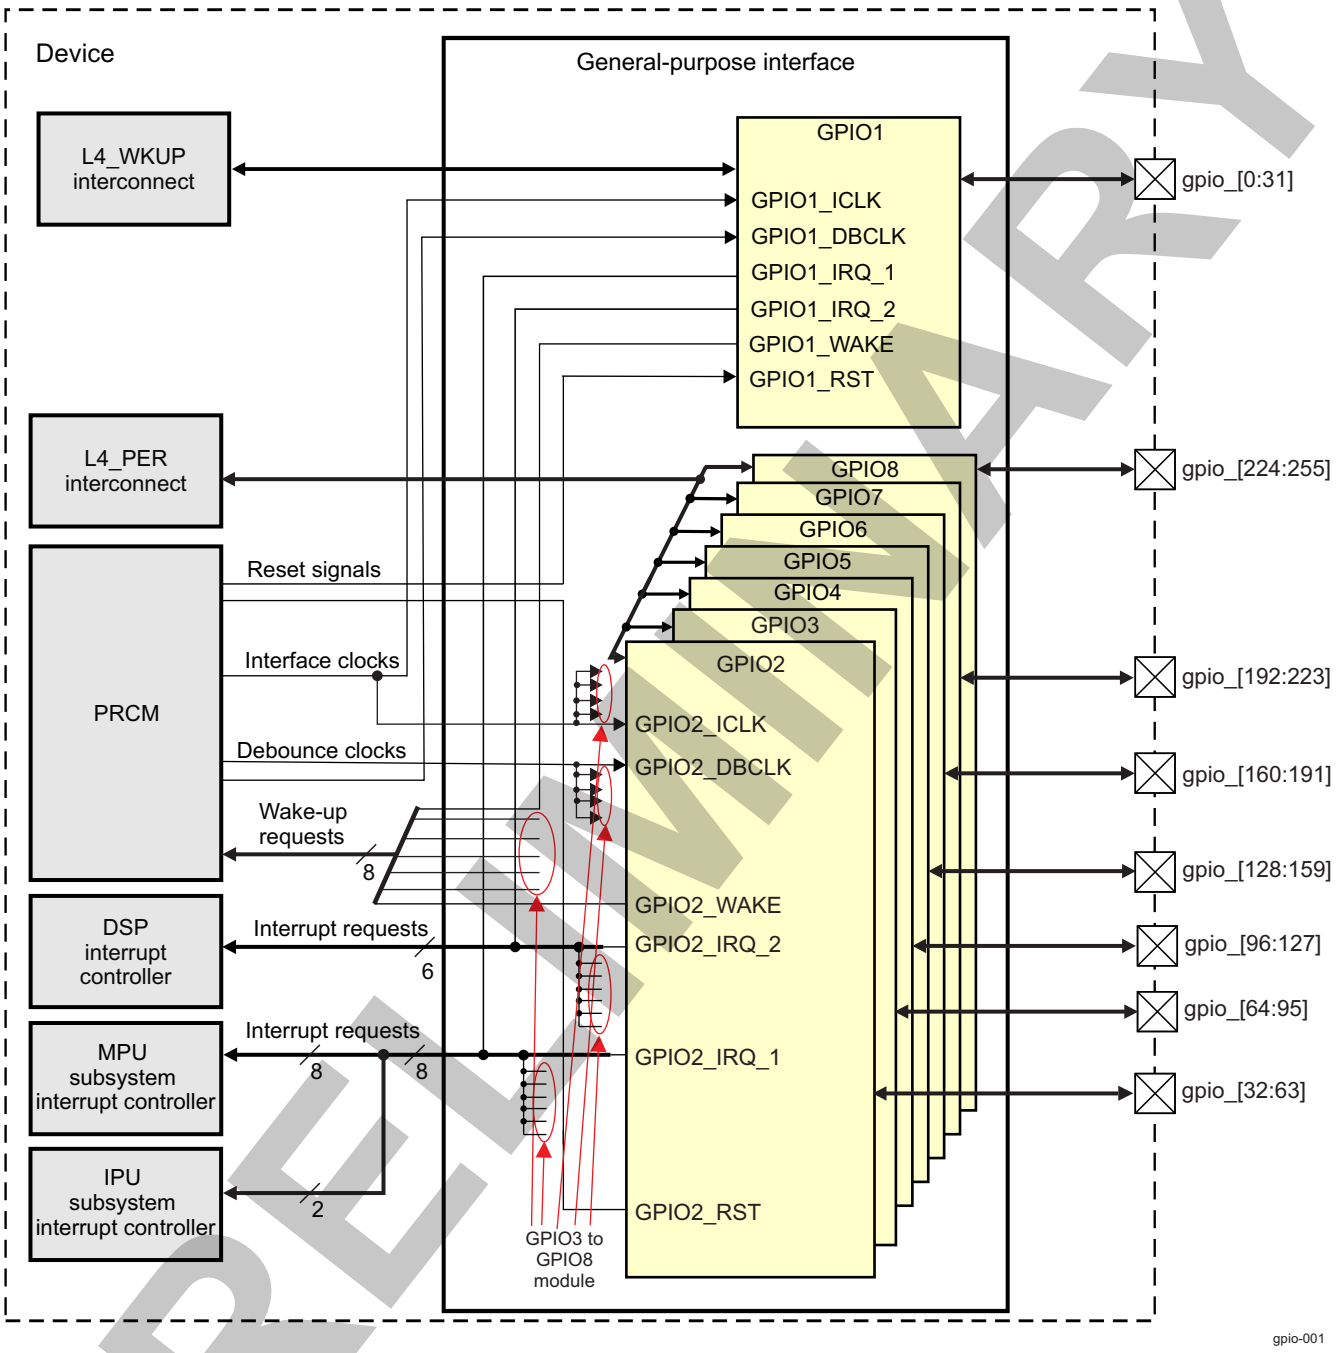
These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see Section 18.4.8, *Pad Functional Multiplexing and Configuration,* in Chapter 18, *Control Module*.

Figure 25-1 is an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview



The GPIO modules include the following global features:

- Two identical submodules can process synchronous interrupt requests from each channel to be used independently in a biprocessor environment. Each submodule controls its own synchronous interrupt request line. Each submodule also has its own interrupt-enable and interrupt status registers. The interrupt-enable register (GPIO_IRQSTATUS_SET_x [where x = 0 or 1]) selects the channel considered for the interrupt request generation. The interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel has activated the interrupt request. Event detection on GPIO channels is reflected into GPIO_IRQSTATUS_RAW independently from the content of the interrupt-enable registers.
- Wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.

- Data input (capture)/output (drive)
- Power-management support

The general-purpose interface has 14 interrupt lines (two interrupt lines per GPIO1 through GPIO6 modules and one interrupt line per GPIO7 and GPIO8).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4) interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO module, up to five different debouncing time values are possible.)
- The value of the input line is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the data-output register (GPIO_DATAOUT). For this register, the module implements the set-and-clear protocol register update (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

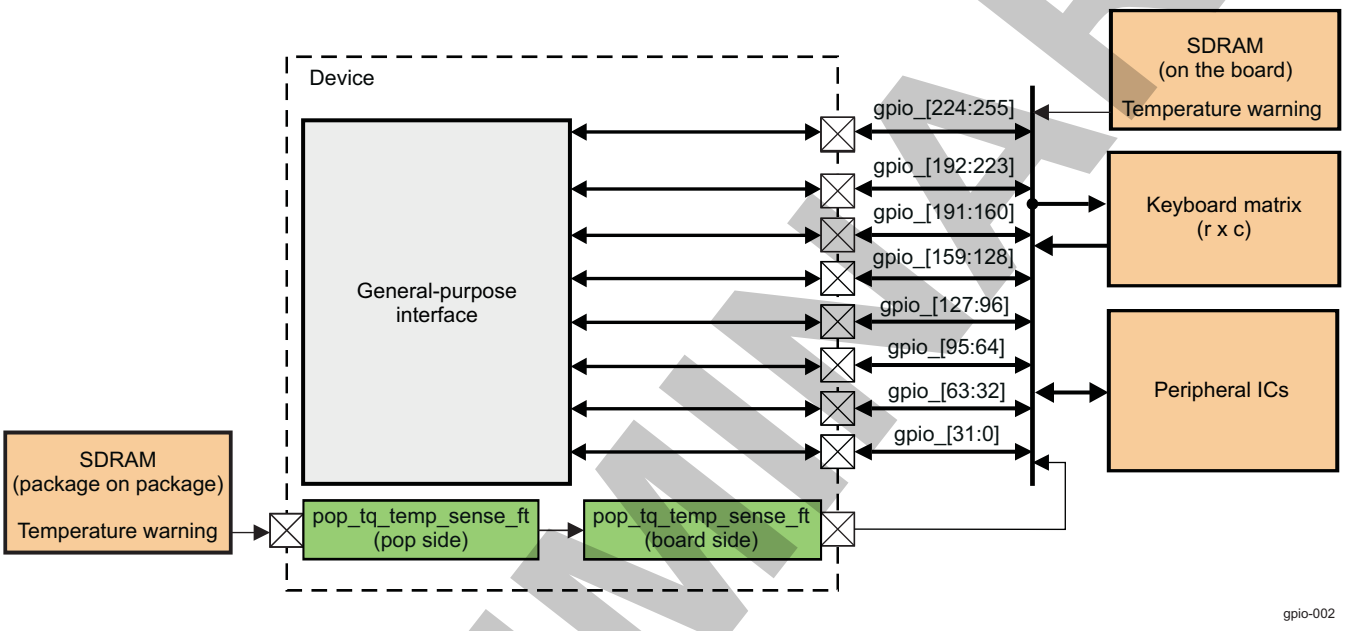
All module registers are 8-, 16-, or 32-bit accessible through the OCP-compatible interface (little-endian encoding)

25.2 General-Purpose Interface Environment

The general-purpose interface combines eight GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

Figure 25-2. General-Purpose Interface Typical Application



NOTE: Temperature Sensing

Most memories provide a temperature sensor to control the autorefresh duty cycle. The device monitors the temperature of the external memory using the pop_tq_temp_sense_ft ball and a GPIO input. To do this, pop_tq_temp_sense_ft is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

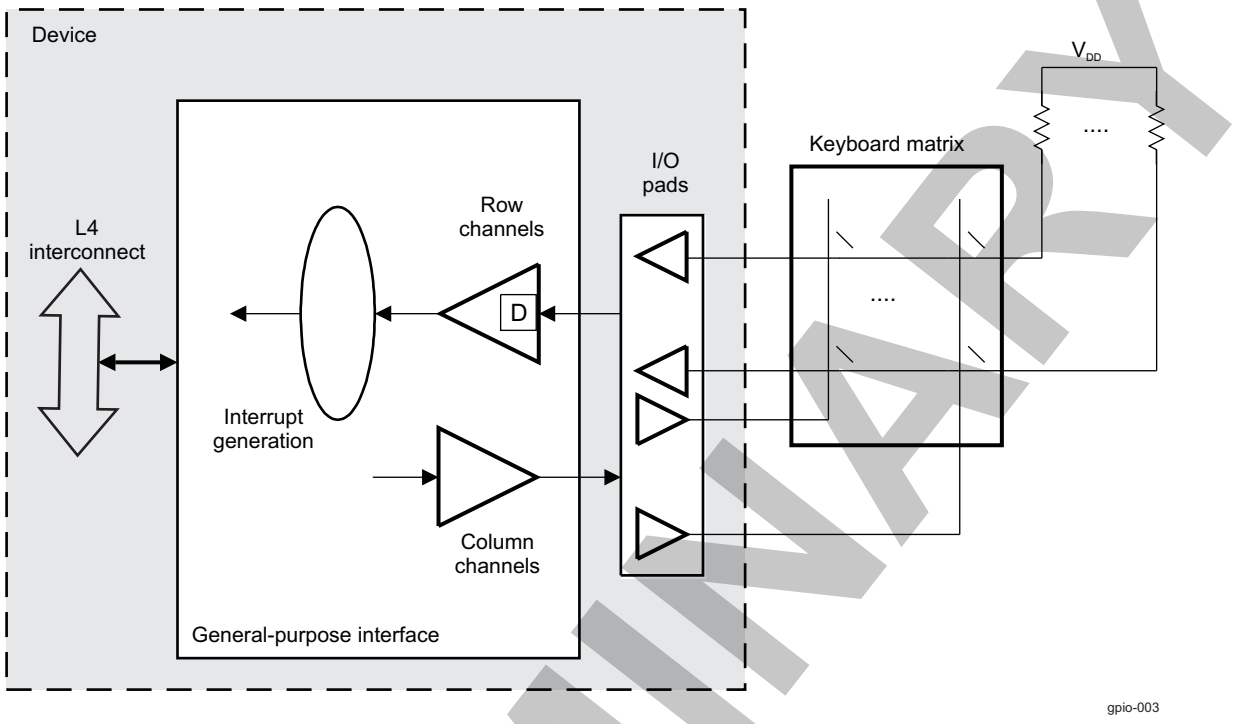
Because of buffer strength, an external serial resistor must be connected to the balls where gpio_46 through gpio_55 are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

25.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix (r × c). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface



When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 25.4.6, *Interrupt and Wake-up Requests*).

When the keyboard interrupt is received, the processor (microprocessor unit [MPU] and/or digital signal processor [DSP] subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

25.2.2 General-Purpose Interface Signals

Table 25-1 describes the module signals.

Table 25-1. I/O Description

Signal	I/O[1]	Description	Reset Value[2]
gpio1_wkout[0:5]	O	GPIO (direct wake-up path)	Hi-Z
gpio1_wk[6:31]	I/O	GPIO (direct wake-up path)	Hi-Z
gpio2_[32:63]	I/O	GPIO	Hi-Z
gpio3_[64:95]	I/O	GPIO	Hi-Z
gpio4_[96:127]	I/O	GPIO	Hi-Z
gpio5_[128:156]	I/O	GPIO	Hi-Z
gpio5_in157	I	GPIO (inputs only)	Hi-Z
gpio5_[158:159]	I/O	GPIO	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance

Table 25-1. I/O Description (continued)

Signal	I/O[1]	Description	Reset Value[2]
gpio6_[160:191]	I/O	GPIO	Hi-Z
gpio7_[192:223]	I/O	GPIO	Hi-Z
gpio8_[224:235]	I/O	GPIO	Hi-Z
gpio8_in[236:255]	I	GPIO (inputs only)	Hi-Z

Figure 25-4 shows the signal connections of GPIO1.

Figure 25-4. GPIO1 Signal Connections

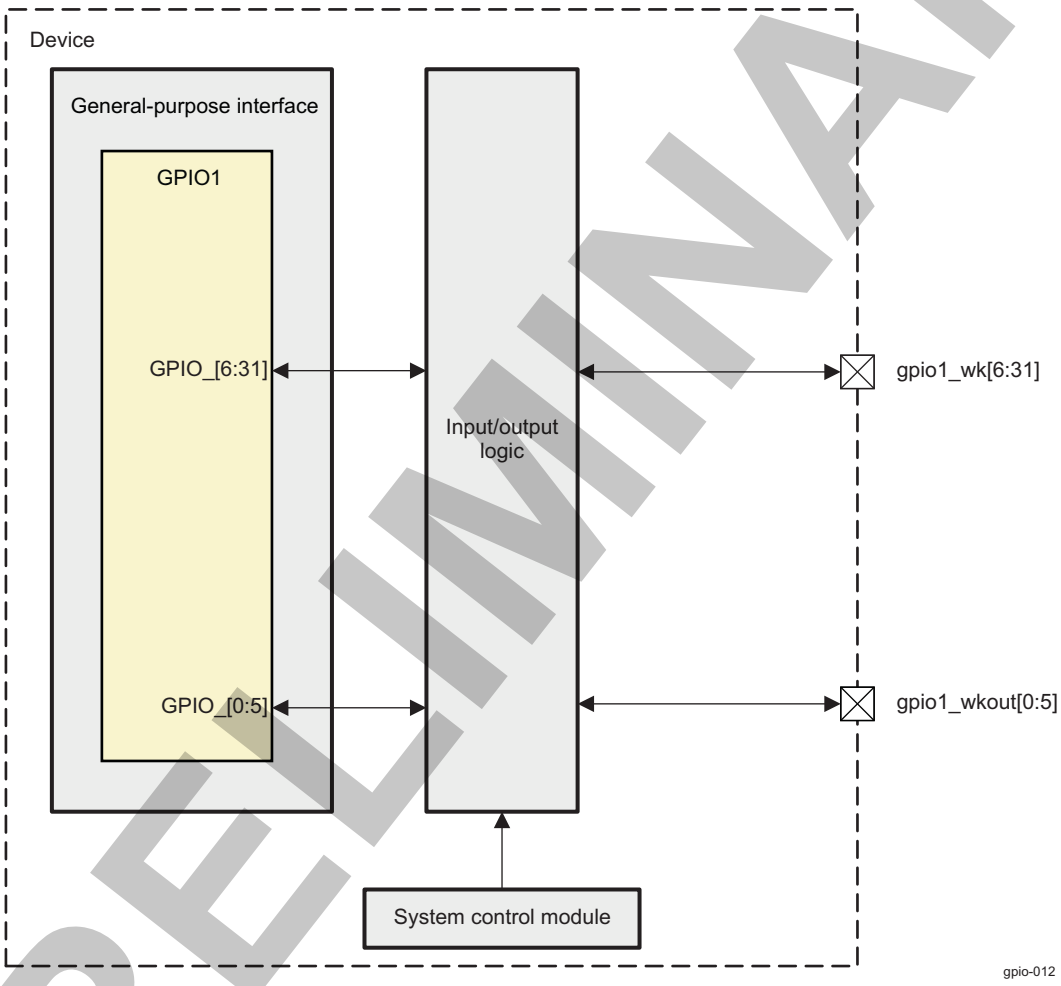


Figure 25-5 shows the signal connections of GPIO2 through GPIO8.

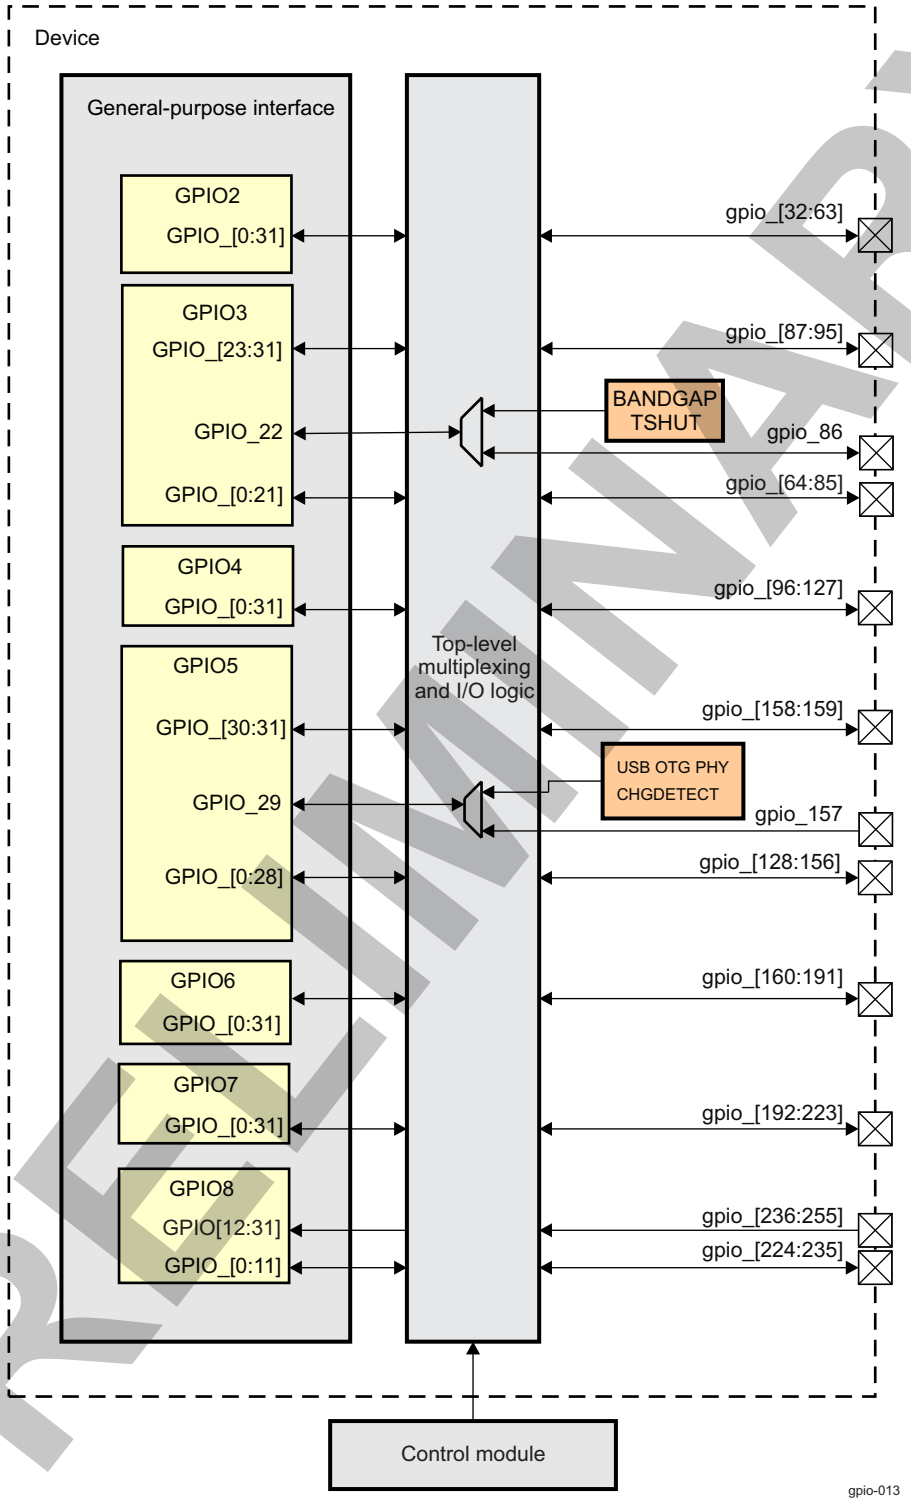
Figure 25-5. GPIO2 Through GPIO8 Signal Connections



NOTE: For more information about the GPIO1 through GPIO8 signals and channel description, see Section 25.4.7, *General-Purpose Interface Channels Description.*

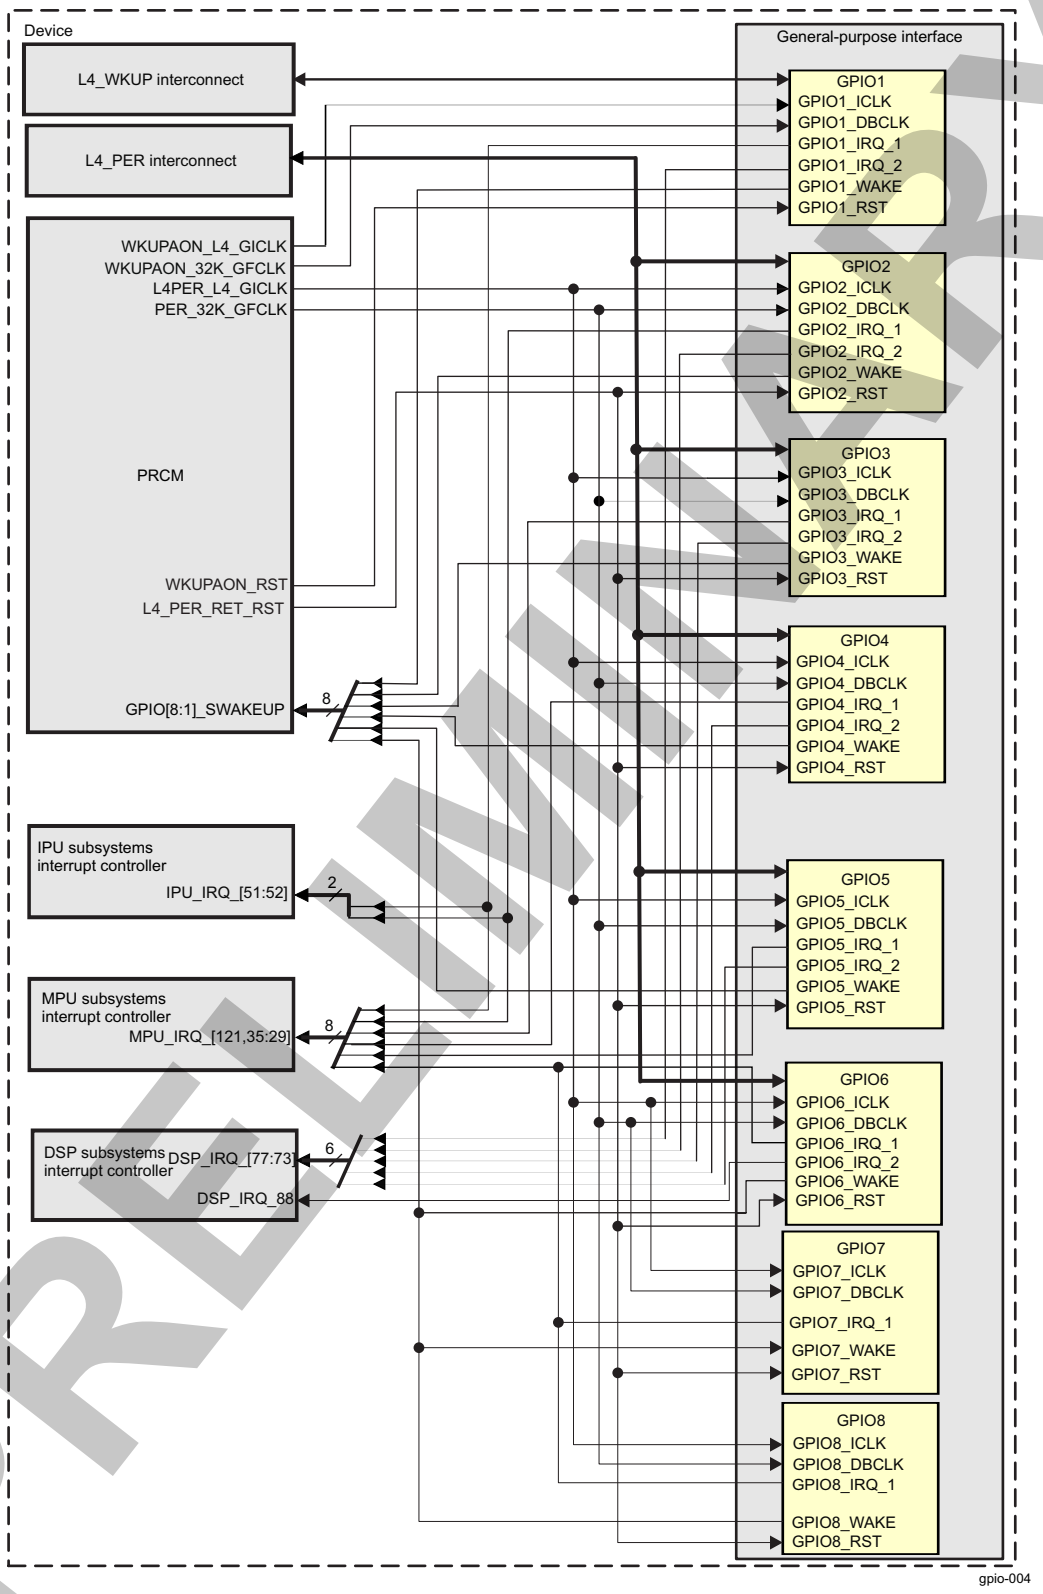
NOTE: For more information about GPIO signal multiplexing, see Section 18.4.8, *Pad Functional Multiplexing and Configuration, and Section 18.4.12.7.5 Device Interfaces Signal Group Controls Mapping* in Chapter 18, *Control Module*.

25.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 25-6 shows this module integration.

Figure 25-6. GPIO Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 25-2 through Table 25-4 summarize the integration of the module in the device.

Table 25-2. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
GPIO1	PD_WKUPAON	L4_WKUP
GPIOi (where i = 2 to 8)	PD_L4_PER	L4_PER

Table 25-3. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
GPIO1	GPIO1_ICLK	WKUPAON_GICLK	PRCM	GPIO interface clock
GPIO1	GPIO1_DBCLK	WKUPAON_32K_GFCLK	PRCM	GPIO debounce clock

GPIO8	GPIO_IRQ_1	MPU_IRQ_121	MPU	An interrupt to MPU subsystem INTC (first interrupt)

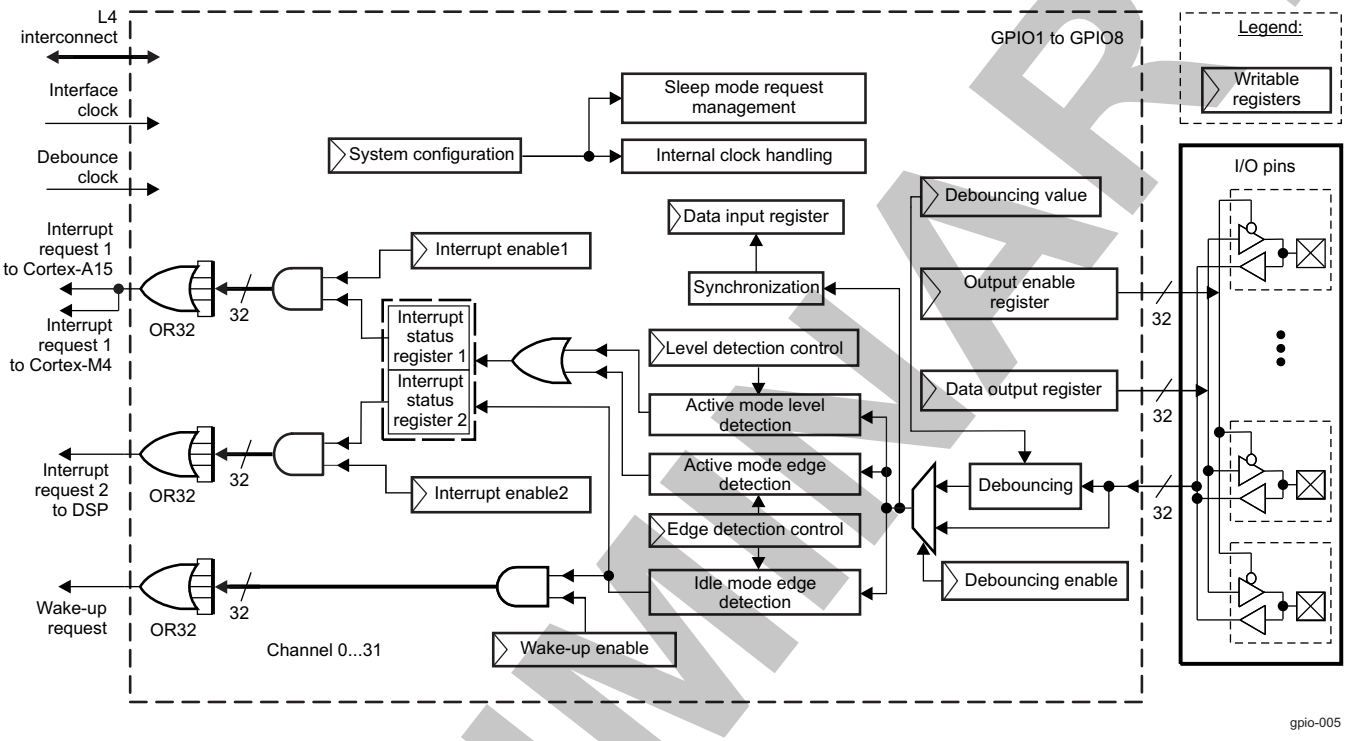
NOTE: For the description of the interrupt source, see Section 25.4.6, *Interrupt and Wake-Up Requests*.

25.4 General-Purpose Interface Functional Description

25.4.1 General-Purpose Interface Block Diagram

Figure 25-7 shows the general-purpose interface block diagram.

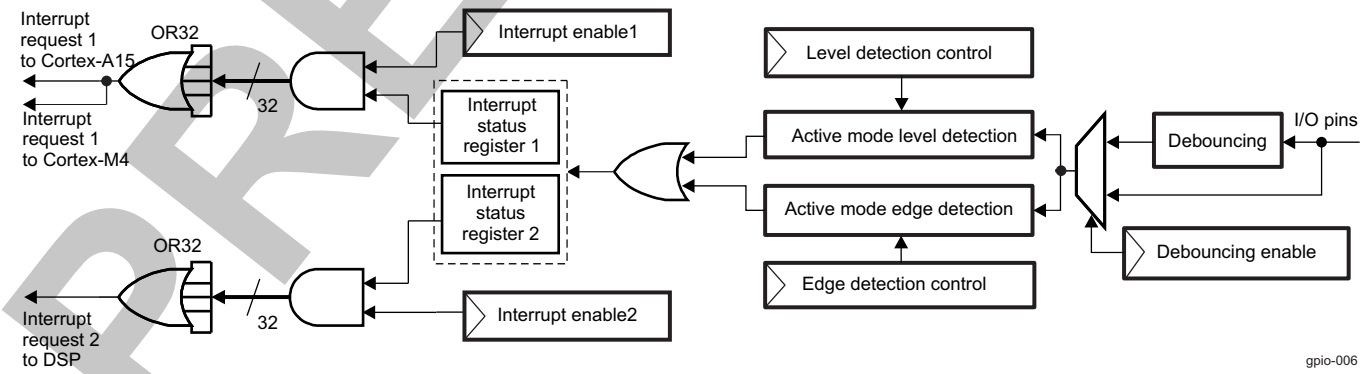
Figure 25-7. General-Purpose Interface Block Diagram



shows the details of the GPIO modules in the general-purpose interface block diagram, including their configuration registers and main functional paths:

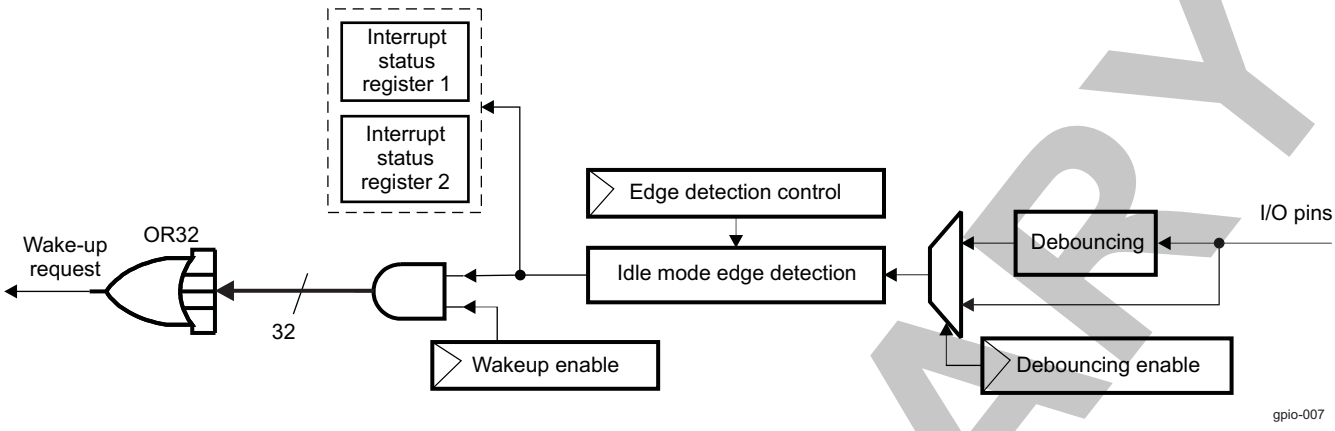
- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 25-8.

Figure 25-8. Synchronous Path



- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 25-9.

Figure 25-9. Asynchronous Path



- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

25.4.2 General-Purpose Interface Interrupt and Wake-Up Features

25.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 14 interrupt lines (two interrupt lines per GPIO module instance for biprocessor operation for GPIO1 through GPIO6 and one interrupt line for GPIO7 and GPIO8 module instance). The 14 interrupt signals are GPIOi_IRQ_1 (used by the MPU, IPU subsystems) and GPIOi_IRQ_2 (used by the DSP subsystem), where i = 1 to 7, and 8 (for interrupt line 2 [where i = 1 to 6]).

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the DSP subsystem on one side and by the MPU, IPU subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1) and interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 25.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 25.4.5.2.4, *Module Power Saving*). When an event matches the programmed settings (see Section 25.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), the corresponding bit in the interrupt status register (GPIO_IRQSTATUS_RAW_x [where x = 0 or 1]) is set to 1, and on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers GPIO_IRQSTATUS_SET_x [where x = 0 or 1]).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (that is, *N* times the interface clock period; see Section 25.4.5.2.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed three internally gated interface clock cycles plus two interface clock cycles when the debounce feature is not used.

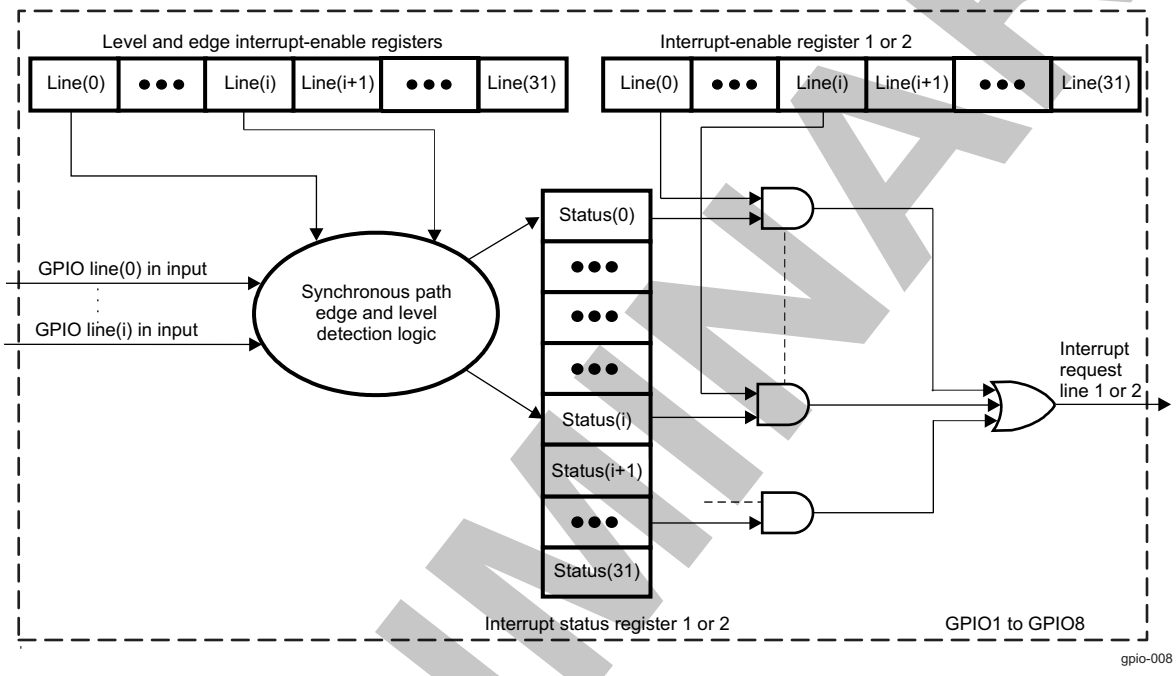
When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see Section 25.4.3, *General-Purpose Interface Clock Configuration*) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU, IPU subsystems.

Synchronous interrupt request line 2 is mapped on the DSP INTC.

Figure 25-10 is an overview of the interrupt request generation.

Figure 25-10. Interrupt Request Generation



25.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has eight wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 25.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP [where i = 1 to 8), if the wake-up-enable register is set.

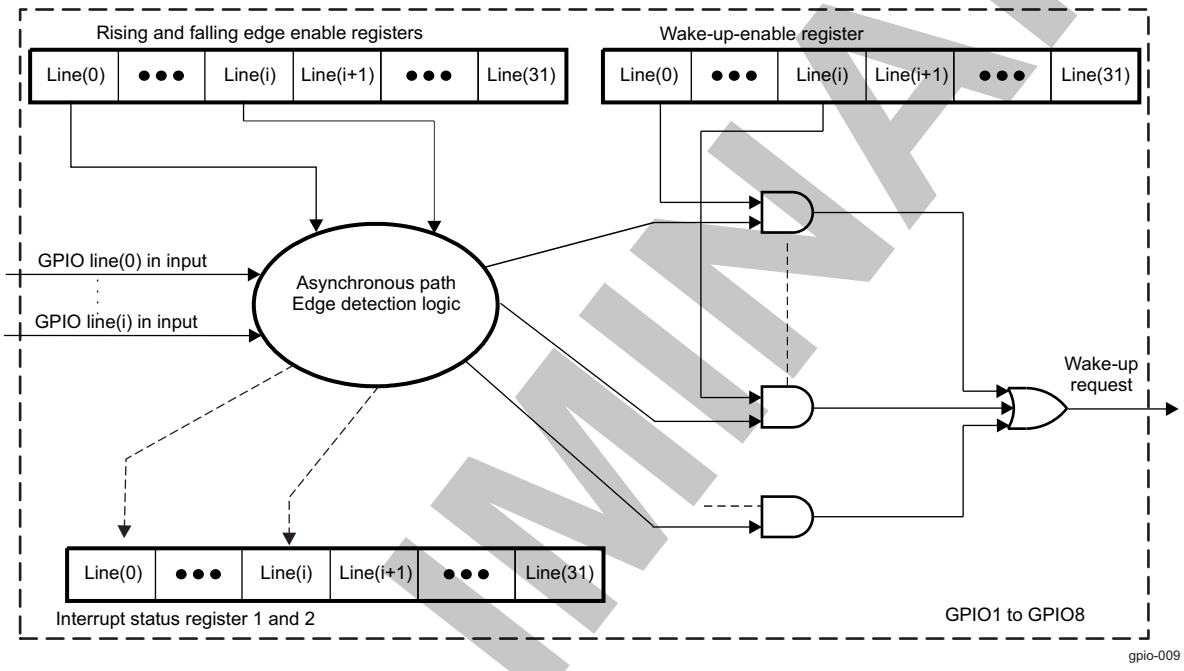
When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active high) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

NOTE:

- If the debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request, because there is no sampling operation.
- If the debouncing is used, the minimum pulse width is set by the debouncing specified time.
- The ENAWAKEUP bit of the GPIO_SYSCONFIG register allows the enabling or disabling of the GPIO wake-up feature globally: if this bit is set to 0, GPIO_IRQWAKEN_x has no effect

Figure 25-11 is an overview of the wake-up request generation.

Figure 25-11. Wake-Up Request Generation



25.4.2.3 Wake-Up Event Conditions During Transition To/From IDLE State

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see Section 25.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of SLEEPTRANS state. During this period a synchronous interrupt request (see Section 25.4.2.1, *Synchronous Path: Interrupt Request Generation*) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

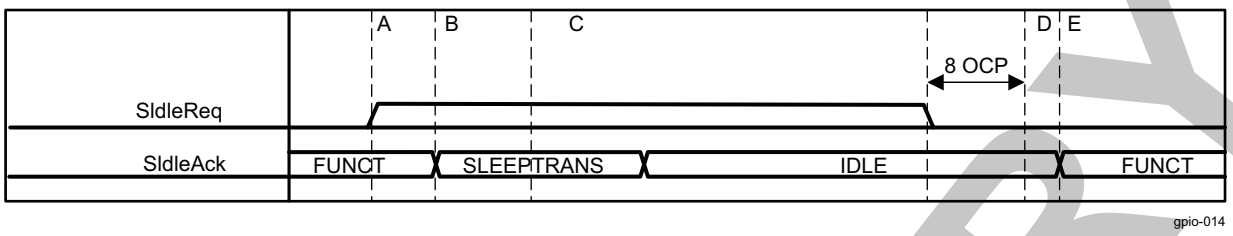
In phase C, only the asynchronous path is enabled. A wake-up request (see Section 25.4.2.2, *Asynchronous Path: Wake-Up Request Generation*) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight open-core protocol (OCP) clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see Section 25.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see Section 25.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

Figure 25-12 shows the wake-up event conditions.

Figure 25-12. Wake-Up Event Conditions



25.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

25.4.3 General-Purpose Interface Clock Configuration

25.4.3.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1 to 8 with one debounce clock per module), comes from the PRCM module and is used to debounce the submodule logic (without the corresponding configuration registers). This module can sample the input line and filter the input level using a programmed delay.

  The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. Because the value is global for all the ports of one GPIO module, up to eight different debouncing values are possible. The debounce cell runs with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used.

  The following formula describes the required input stable time to be propagated to the debounced output:

  Required input line stable = (the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field + 1) × 31,

  where the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field is from 0 to 255.

  For more information, see Section 3.6.8, *CD_L4_PER_Clock Domain*, and Section 3.6.4, *CD_WKUPAON Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

- Interface clock: The interface clock, GPIOi_ICLK (where i = 1 to 8), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

  For more information, see Section 3.6.8, *CD_L4_PER_Clock Domain*, and Section 3.6.4, *CD_WKUPAON Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 25-3 describes the clocks in the GPIO modules.

Table 25-5 summarizes the functional clock configuration.

Table 25-5. Functional Clock Configuration

Interface Clock	GPIO_CTRL[2:1]GATINGRATIO	Functional Clock
GPIOi_ICLK (where i = 1 to 8)	00	GPIOi_ICLK /1 (where i = 1 to 8)
GPIOi_ICLK (where i = 1 to 8)	01	GPIOi_ICLK /2 (where i = 1 to 8)
GPIOi_ICLK (where i = 1 to 8)	10	GPIOi_ICLK /4 (where i = 1 to 8)
GPIOi_ICLK (where i = 1 to 8)	11	GPIOi_ICLK /8 (where i = 1 to 8)

25.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO8 modules are attached to the L4_PER_RET_RST reset domain. GPIO1 is attached to the WKUPAON_RST reset domain.

  The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit. The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

  Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1 resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the

GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. RESETDONE is set to 1 when the software reset completes.

25.4.5 General-Purpose Interface Power Management

25.4.5.1 Power Domain

GPIO1 is attached to the WKUPAON power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUPAON power domain is continuously active. The GPIO2 to GPIO8 modules are attached to the L4PER power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*). The L4PER power domain is not active continuously.

25.4.5.2 Power Management

25.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- Efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP) are sideband signals between the PRCM module and the general-purpose interface (see Section 25.4.6.2, *Wake-Up Requests Generation*).

25.4.5.2.2 Operating Modes

Three operating modes are defined for the module:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

  If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle mode is configured within the module and activated on request by the host processor through sideband signals (see Section 25.4.5.2.3, *System Power Management and Wakeup*).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the system interface. When setting the GPIO_CTRL[0] DISABLEMODULE bit (enabling or disabling the GPIO module), it is important to switch the debouncing clock on or off in the following order:

- The GPIO optional debouncing clock must be enabled before the GPIO module is set (GPIO_CTRL[0]DISABLEMODULE = 0x0).
- The GPIO optional debouncing clock must be disabled after the GPIO module is disabled (GPIO_CTRL[0]DISABLEMODULE = 0x1).

25.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIO modules to be idled for power-saving purposes.

The general-purpose interface has eight identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see Section 25.4.6.2, *Wake-Up Requests Generation*): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode

  When the GPIO module is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no write access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

  Idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

  In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.

- Smart-idle wake-up mode

  If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to have the interface clock switched off. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO_DEBOUNCINGTIME register pending to be synchronized), the idle acknowledge is asserted and the GPIO enters into Idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see). When the system is awake, the IDLE request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the wake-up in the system) signals are immediately deasserted, and the asynchronous wake-up request (if it exists) is reflected into the synchronous interrupt status registers.

- Force-idle mode

  When the GPIO module is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x0) and receives an IDLE request from the PRCM module, the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

  When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

  When the GPIO module is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x1) and receives an IDLE request from the PRCM module, the GPIO module does not go into idle mode and the idle acknowledge is never sent.

NOTE: For more information about the idle modes, see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*.

25.4.5.2.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the system interface logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.

- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no detection, the corresponding clock is gated off.

  All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field and can take the values 1, 2, 4, and 8. The interface clock is enabled for this logic one cycle every N cycles. When N is 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at the equivalent frequency of interface clock frequency divided by N.
- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. Setting this bit to 1 forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Table 25-6 describes the power-management features available for the general-purpose interface module.

NOTE: For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 25-6. Local Power-Management Features

Feature	Register Bits/Bit Fields	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE	It sets the clock-gating strategy for the OCP interface block.
Slave-idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 25-7 describes the clock activity settings.

Table 25-7. Clock Activity Settings

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO module goes into inactive mode independently of the internal module state, and the IDLE acknowledge is never sent.	No
01	No-idle	The GPIO module does not go into Idle mode and the IDLE acknowledge is never sent.	No

Table 25-7. Clock Activity Settings (continued)

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
10	Smart-idle	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	No
11	Smart-idle wake-up	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	Yes

25.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

25.4.6.1 Interrupt Requests Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 16 interrupt lines (two interrupt lines per GPIO module instance).

- Synchronous interrupt request line 1 is mapped on the MPU and IPU INTCs.
- Synchronous interrupt request line 2 is mapped on the DSP INTC.

Table 25-8 lists the event flags, and their mask, that can cause module interrupts.

Table 25-8. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/ level	MPU_IRQ_n IPU_IRQ_n(1)	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/ level	DSP_IRQ_n(2)	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/ level	MPU_IRQ_n IPU_IRQ_n(1)	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/ level	DSP_IRQ_n(2)	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	Yes	Edge/ level	MPU_IRQ_n IPU_IRQ_n(1)	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	Yes	Edge/ level	DSP_IRQ_n(2)	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_0 [31:0] INTLINE	No	Edge/ level	MPU_IRQ_n IPU_IRQ_n(1)	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_1 [31:0] INTLINE	No	Edge/ level	DSP_IRQ_n(2)	Corresponding to the second line of interrupt

(1) For GPIO1 and GPIO2 only
(2) For GPIO1 to GPIO6 only

Synchronous interrupt request line 1 and line 2 are active depending on their respective interrupt-enable1 and enable 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

- interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)

  The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input

GPIO to prevent the generation of an interrupt request on line 1 (or line 2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or by using the alternate set-and-clear protocol feature for register update. This feature allows setting or clearing explicit bits of these registers with a single write access (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)

  The interrupt status 1 (or interrupt status 2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line 2) request (or the wake-up line).

  When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, set the appropriate bit to 1. However, an interrupt cannot be generated by writing 1 to the interrupt status 1 (or interrupt status 2) register.

  If 0 is written to a bit in this register, the value in the corresponding bit in the interrupt status 1 and remains unchanged. The interrupt status 1 (or interrupt status 2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and interrupt status 2 registers are set when the GPIO module is awaken.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1) the corresponding status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

25.4.6.2 Wake-Up Requests Generation

The GPIO1 module of the general-purpose interface is attached to the WKUPAON power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*, and can wake up the system.

NOTE: The GPIO2 to GPIO8 modules belong to the L4PER power domain and thus their wake-up capabilities are operational only when the L4PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio_wkx[10:0] and gpio_wkx[31:29] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1 to 8).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations.

NOTE: There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future IDLE request.

Table 25-9 lists the mapping of the wake-up signals.

Table 25-9. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1 to 8. The destination is the PRCM module.

25.4.7 General-Purpose Interface Channels Description

Table 25-10 describes the GPIO channels.

Table 25-10. GPIO Channels Description

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
GPIO1 Module				
[5:0]	O	gpio1_wkout[5:0]	Yes	Wake-up path
[31:6]	I/O	gpio1_wk[31:6]	Yes	Wake-up path
GPIO2 Module				
[31:0]	I/O	gpio2_[63:32]	Yes [2]	GPIO
GPIO3 Module				
[21:0]	I/O	gpio3_[85:64]	Yes [2]	GPIO
[22] [3]	I/O	gpio3_86	Yes [2]	GPIO
	I	thermal shutdown comparator output signal (TSHUT)	Yes [2]	Bandgap internal TSHUT
[31:23]	I/O	gpio3_[95:87]	Yes [2]	GPIO
GPIO4 Module				
[31:0]	I/O	gpio4_[127:96]	Yes [2]	GPIO
GPIO5 Module				
[28:0]	I/O	gpio5_[156:128]	Yes [2]	GPIO
[29] [3]	I	gpio5_in157	Yes [2]	GPIO (inputs only)
	I	CHGDETECT	Yes [2]	USB charge detect
[31:30]	I/O	gpio5_[159:158]	Yes [2]	GPIO
GPIO6 Module				
[31:0]	I/O	gpio6_[191:160]	Yes [2]	GPIO
GPIO7 Module				

(1) I = Input; O = Output; I/O = bidirectional

(2) Only when the L4_PER power domain is active

(3) The GPIO channel provides additional internal functionality (see the Comments column), besides its general-purpose I/O capabilities, when it is not connected to a pad of the device. For more information about pad configuration and multiplexing, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*.

Table 25-10. GPIO Channels Description (continued)

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
[31:0]	I/O	gpio7_[223:192]	Yes [2]	GPIO
GPIO8 Module				
[11:0]	I/O	gpio8_[235:224]	Yes [2]	GPIO
[31:12]	I	gpio8_in[255:236]		GPIO (inputs only)

NOTE: TSHUT is an output from the bandgap module. This signal is high during normal operation and goes low during a thermal shutdown event. When channel 22 of GPIO3 is not connected to a ball of the device (the corresponding pin is configured in a mode different from configuration mode 4; see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*, for more information about pin configuration), TSHUT is connected to channel 22 of GPIO3. The channel must be configured correctly so that it can generate an interrupt when a high-to-low transition occurs on TSHUT.

NOTE: Channel 29 in GPIO5 is internally connected inside the device to the charger detection (CHGDETECT) output of the USB OTG PHY module. This allows interrupt generation on the corresponding GPIO channel, if the mentioned event occurs.

NOTE: For more information about pin configuration, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*.

25.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the I/O capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_ WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_0) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see Section 25.4.9, *General-Purpose Interface Set-and-Clear Protocol.*

25.4.9 General-Purpose Interface Set-and-Clear Protocol

25.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

25.4.9.2 Clear Instruction

25.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

  A write operation in the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear interrupt enable0 (or enable1) register returns the value of the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register.
- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).

  A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear data-output register returns the value of the data-output register.

25.4.9.2.2 Clear Instruction Example

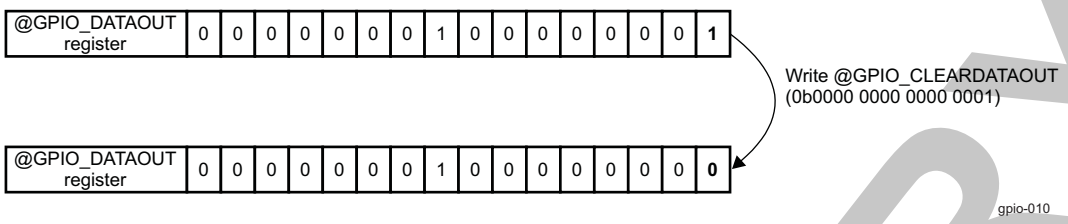
Assume the data-output register (or one of the interrupt or wake-up-enable registers) contains the binary value 0b0000 0001 0000 0001 and bit 0 is to be cleared.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt or wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt or wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 least-significant bits (LSBs) are represented in this example.

Figure 25-13 is an example of a clear instruction.

Figure 25-13. GPIO_CLEARDATAOUT Register Example



25.4.9.3 Set Instruction

25.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

  A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the set interrupt-enable 0 (or enable1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.

- Set data-output register (GPIOi.GPIO_SETDATAOUT).

  A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

  A read of the set data-output register returns the value of the data-output register.

25.4.9.3.2 Set Instruction Example

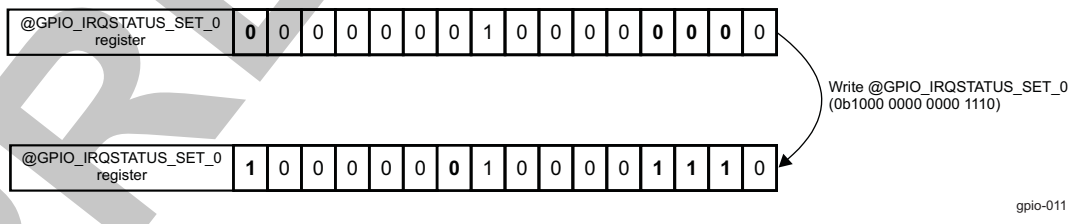
Assume the interrupt enable1 (or enable2) register (or the data-output register) contains the binary value 0b0000 0001 0000 0000 and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, the user has only to write 0b1000 0000 0000 1110 at the address of the GPIO_SETDATAOUT register. After this write operation, a reading of the GPIO_SETDATAOUT register returns 0b1000 0001 0000 1110: bits 15, 3, 2, and 1 have been set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 LSBs are represented in this example.

Figure 25-14 is an example of a set instruction.

Figure 25-14. Write in GPIO_IRQSTATUS_SET_0 Register Example



The set wake-up-enable register offers the same feature with the wake-up-enable register.

25.5 General-Purpose Interface Programming Guide

25.5.1 General-Purpose Interface Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see Section 25.2, *General-Purpose Interface Environment*, and Section 25.3, *General-Purpose Interface Integration*.

Table 25-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1, *Clock Management*, in Chapter 3 *Power, Reset, and Clock Management*.
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18 *Control Module*.
MPU INTC	MPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Section 17.4.1, *INTC_MPU Functional Description*, in Chapter 17, *Interrupt Controllers* .
DSP INTC	DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Section 5.3.2.6, *DSP INTC* , in Chapter 5, *DSP Subsystem*.

25.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

Table 25-12. General-Purpose Interface Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	xx
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	x
Set clock-gating power saving.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and GPIO_LEVELDETECT1[31:0} LEVELDETECT1 and GPIO_RISINGDETECT[31:0] RISINGDETECT and GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x0000 00FF
Set clock-gating ratio.	GPIO_CTRL [2:1] GATINGRATIO	xx
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	xxx
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCINGTIME	xxx
Enable/disable debouncing for desired input line.	GPIO_DEBOUNCENABLE[31:0] DEBOUNCENABLE	xxx
Interrupt and wake-up requests configuration		

Table 25-12. General-Purpose Interface Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Configure detection events.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and/or GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and/or GPIO_RISINGDETECT[31:0] RISINGDETECT and/or GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x1
Enable/disable interrupts.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	xxx
Enable/disable wake-up for GPIO channels.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	xxx
Enable/disable wake-up generation.	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1

25.5.1.2 General-Purpose Interface Operational Modes Configuration

25.5.1.2.1 General-Purpose Interface Read Input Register

Table 25-13. General-Purpose Interface Read Input Register

Step	Register/Bit Field/Programming Model	Value
Read input register value.	GPIO_DATAIN[31:0] DATAIN	xxxx

25.5.1.2.2 General-Purpose Interface Write Output Register

Table 25-14. General-Purpose Interface Write Output Register

Step	Register/Bit Field/Programming Model	Value
Write value to output register.	GPIO_DATAOUT[31:0] DATAOUT	xxx

25.5.1.2.3 General-Purpose Interface Set Bit Function

Table 25-15. General-Purpose Interface Set Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to set desired bit(s) in register.	GPIO_SETDATAOUT [31:0] INTLINE GPIO_IRQSTATUS_SET_0 [31:0] INTLINE GPIO_IRQSTATUS_SET_1 [31:0] INTLINE	0x-

25.5.1.2.4 General-Purpose Interface Clear Bit Function

Table 25-16. General-Purpose Interface Clear Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to clear desired bit(s) in register.	GPIO_CLEARDATAOUT [31:0] INTLINE GPIO_IRQSTATUS_CLR_0 [31:0] INTLINE GPIO_IRQSTATUS_CLR_1 [31:0] INTLINE	0x1

25.6 General-Purpose Interface Register Manual

25.6.1 General-Purpose Interface Instance Summary

Table 25-17 summarizes the general-purpose interface instance.

Table 25-17. Instance Summary

Module Name	Base Address	Size
GPIO1	0x4AE1 0000	4 KiB
GPIO2	0x4805 5000	4 KiB
GPIO3	0x4805 7000	4 KiB
GPIO4	0x4805 9000	4 KiB
GPIO5	0x4805 B000	4 KiB
GPIO6	0x4805 D000	4 KiB

Description	System configuration register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x0000000
4:3	IDLEMODE	0x0: Force-idle: An IDLE request is acknowledged unconditionally. 0x1: No-idle: An IDLE request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an IDLE request is given based on the internal activity (see Section 25.4.5.2.3, *System Power Management and Wakeup*). 0x3: Smart-idle wakeup	RW	0x0
2	ENAWAKEUP	Wake-up control. 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	OCP clock gating control. 0x0: Internal interface OCP clock is free-running. 0x1: Automatic internal OCP clock gating, based on the OCP interface activity	RW	0

Keyboard Controller

This chapter describes the keyboard module (KBD) of the device.

Topic **Page**

26.1 Keyboard Controller Overview

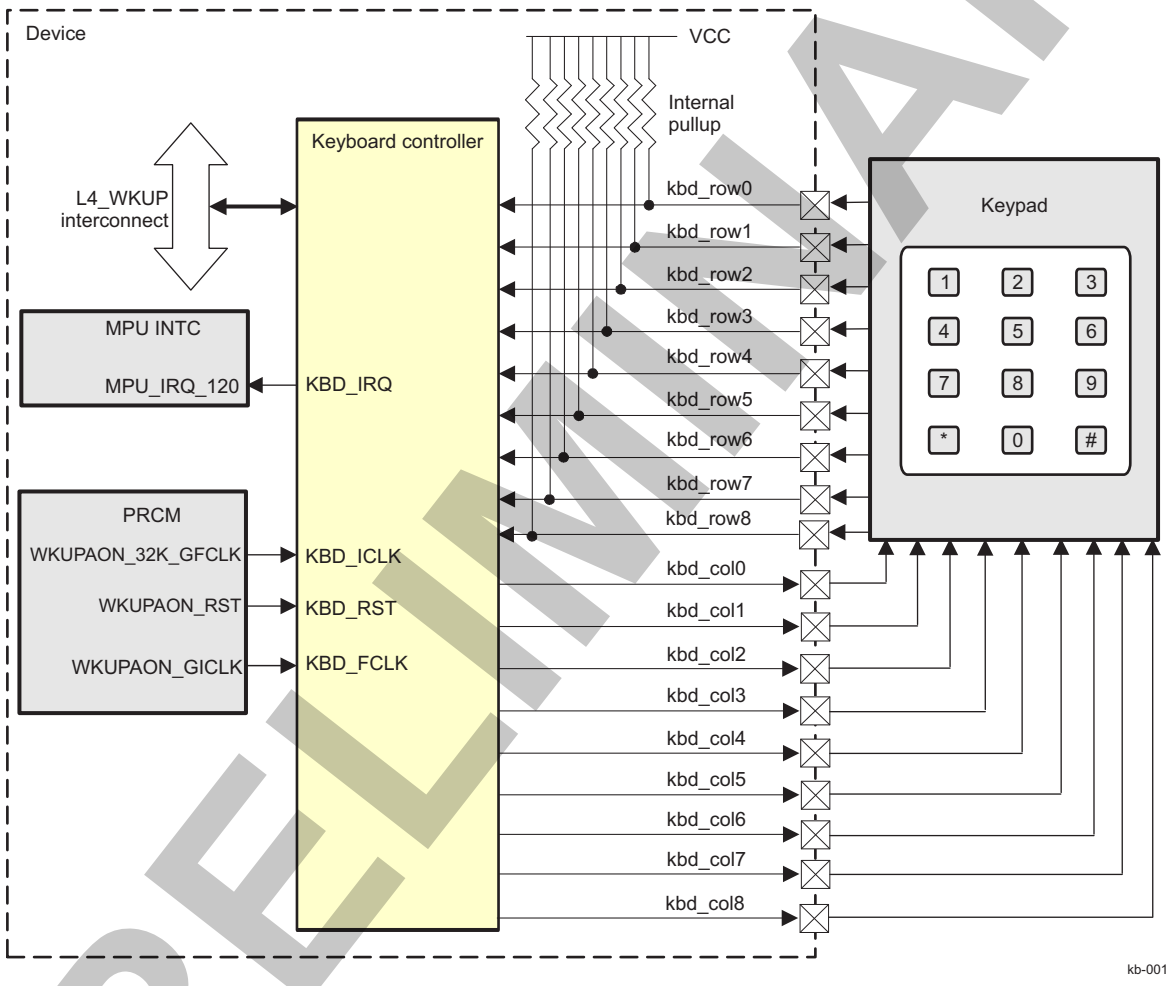
The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 26-1 shows the keyboard controller.

Figure 26-1. Keyboard Controller Overview



The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events

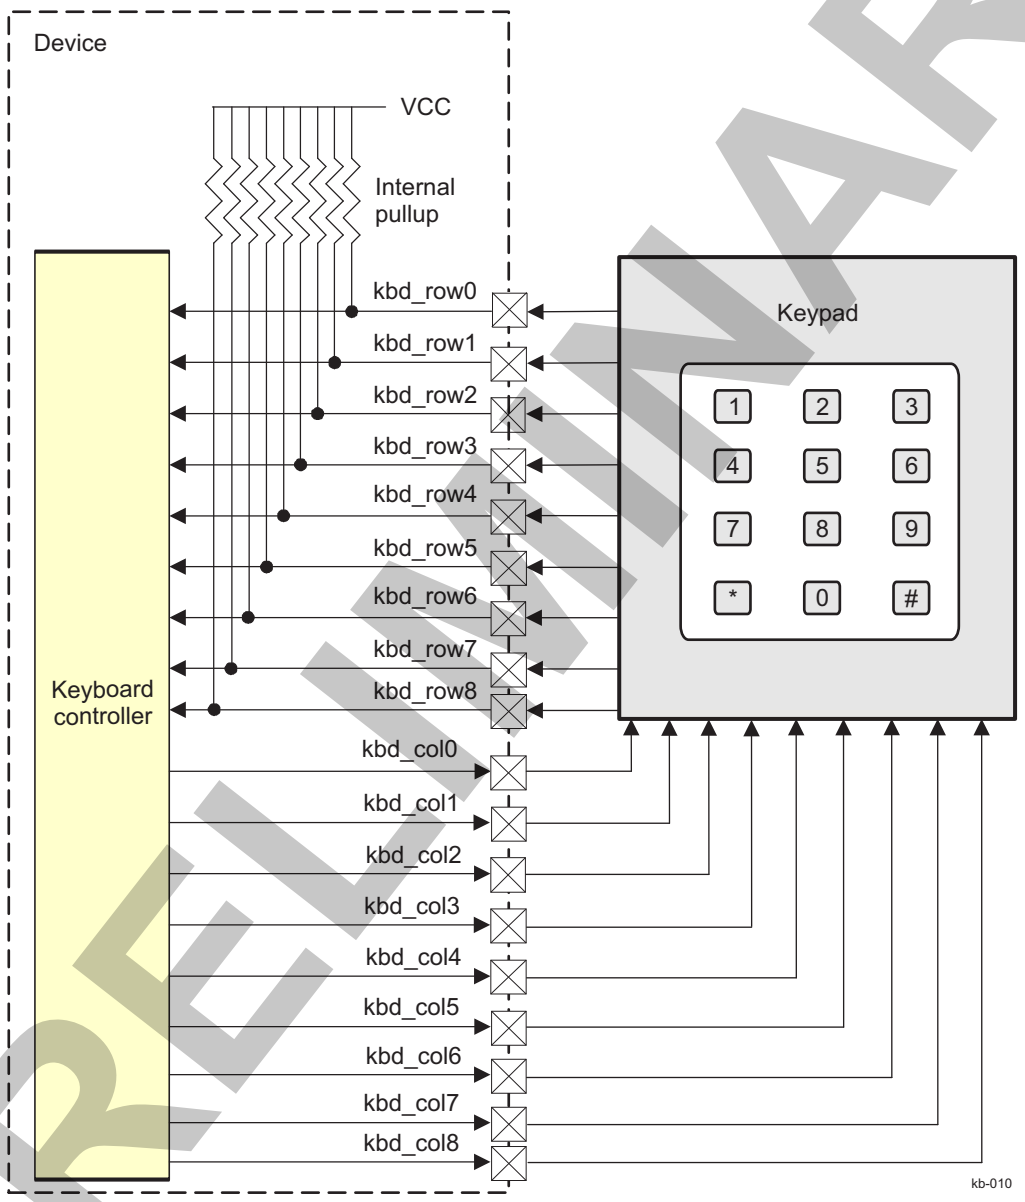
- Software reset capability
- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus

26.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device IO cells are configured and multiplexed for the keypad function by the control module. For more information, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and Section 25.2.1, *General-Purpose Interface as a Keyboard interface*.

The external keypad typically connects directly to the keyboard controller of the device (see Figure 26-2).

Figure 26-2. Typical Keyboard Environment



26.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Keypad scanning and decoding for input of the external key presses. For more information, see Section 26.4.5, *Keyboard Controller Software Mode*, and Section 26.4.6, *Keyboard Controller Hardware Decoding Modes*.
- Device wakeup by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see Section 26.4.6.4, *Keyboard Controller Interrupt Generation*.

26.2.2 Keyboard Controller Signals

Table 26-1 describes the module signals and specifies their links to functions.

Table 26-1. I/O External Keyboard Signals

Signal	I/O[1]	Description	Reset Value	Function	Wake-Up Capability
kbd_row0	I	Keypad row 0 feed	HiZ (pulled up)	Key reading	Yes
kbd_row1	I	Keypad row 1 feed	HiZ (pulled up)	Key reading	Yes
kbd_row2	I	Keypad row 2 feed	HiZ (pulled up)	Key reading	Yes
kbd_row3	I	Keypad row 3 feed	HiZ (pulled up)	Key reading	Yes
kbd_row4	I	Keypad row 4 feed	HiZ (pulled up)	Key reading	Yes
kbd_row5	I	Keypad row 5 feed	HiZ (pulled up)	Key reading	Yes
kbd_row6	I	Keypad row 6 feed	HiZ (pulled up)	Key reading	Yes
kbd_row7	I	Keypad row 7 feed	HiZ (pulled up)	Key reading	Yes
kbd_row8	I	Keypad row 8 feed	HiZ (pulled up)	Key reading	Yes
kbd_col0	O	Keypad column 0 feed, active low	HiZ	Key reading	No
kbd_col1	O	Keypad column 1 feed, active low	HiZ	Key reading	No
kbd_col2	O	Keypad column 2 feed, active low	HiZ	Key reading	No
kbd_col3	O	Keypad column 3 feed, active low	HiZ	Key reading	No
kbd_col4	O	Keypad column 4 feed, active low	HiZ	Key reading	No
kbd_col5	O	Keypad column 5 feed, active low	HiZ	Key reading	No
kbd_col6	O	Keypad column 6 feed, active low	HiZ	Key reading	No
kbd_col7	O	Keypad column 7 feed, active low	HiZ	Key reading	No
kbd_col8	O	Keypad column 8 feed, active low	HiZ	Key reading	No

(1) I = Input; O = Output

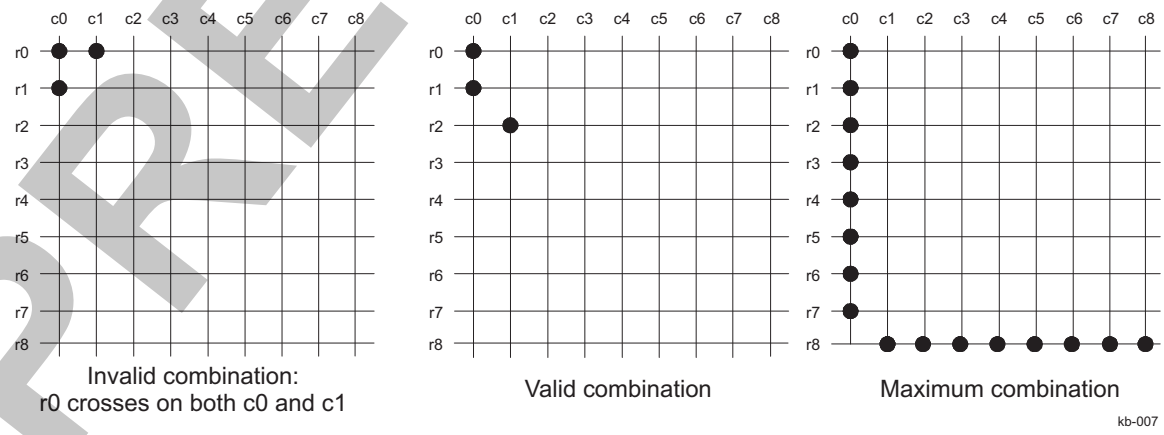
26.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 26-3 shows an example of multikey limitation.

Figure 26-3. Multikey Limitation Example

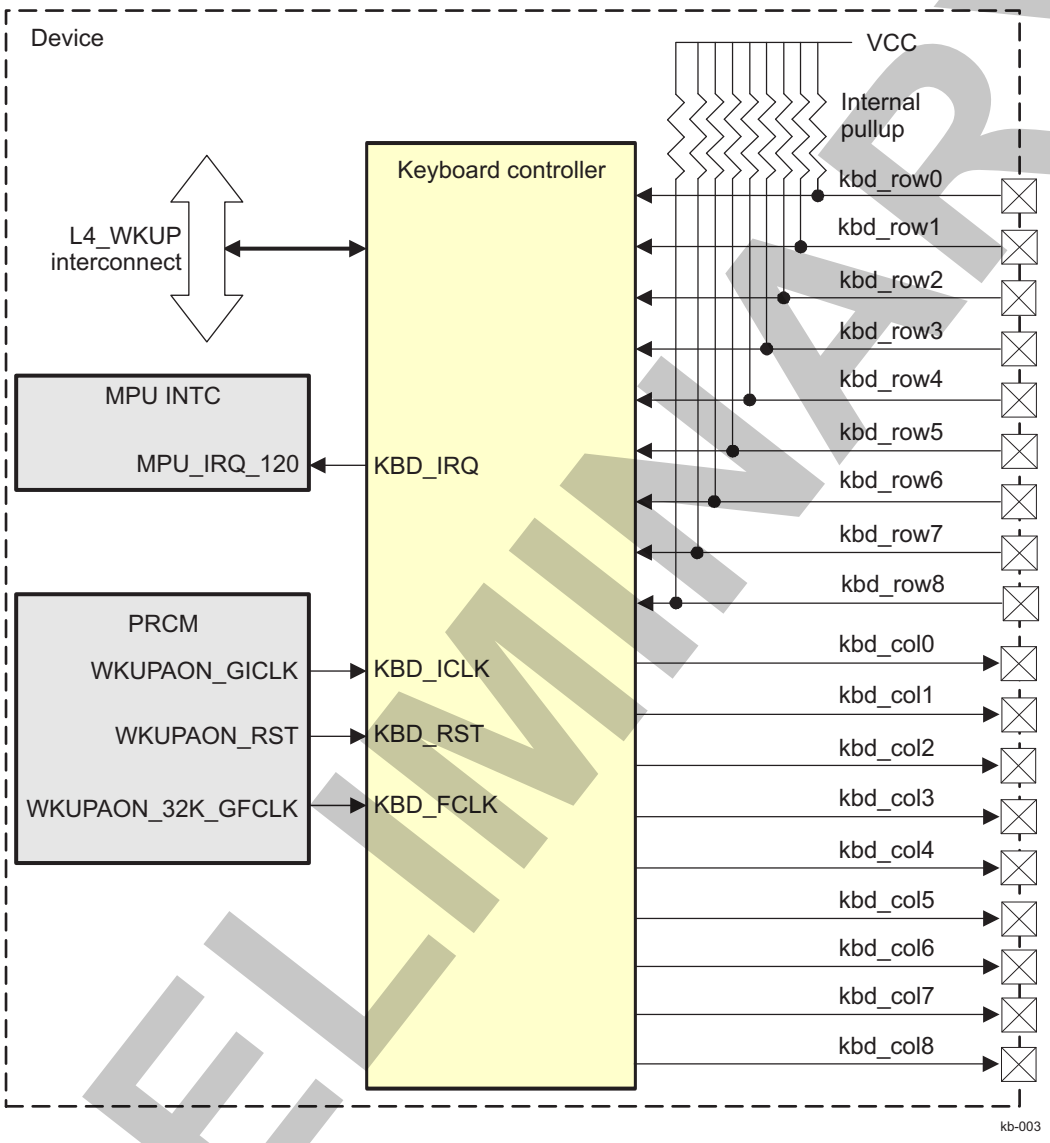


NOTE: When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

26.3 Keyboard Controller Integration

Figure 26-4 shows keyboard controller integration.

Figure 26-4. Keyboard Controller Integration



The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about the configuration, see Chapter 18, *Control Module*).

Table 26-2 through Table 26-4 summarize the integration of the module in the device.

Table 26-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect

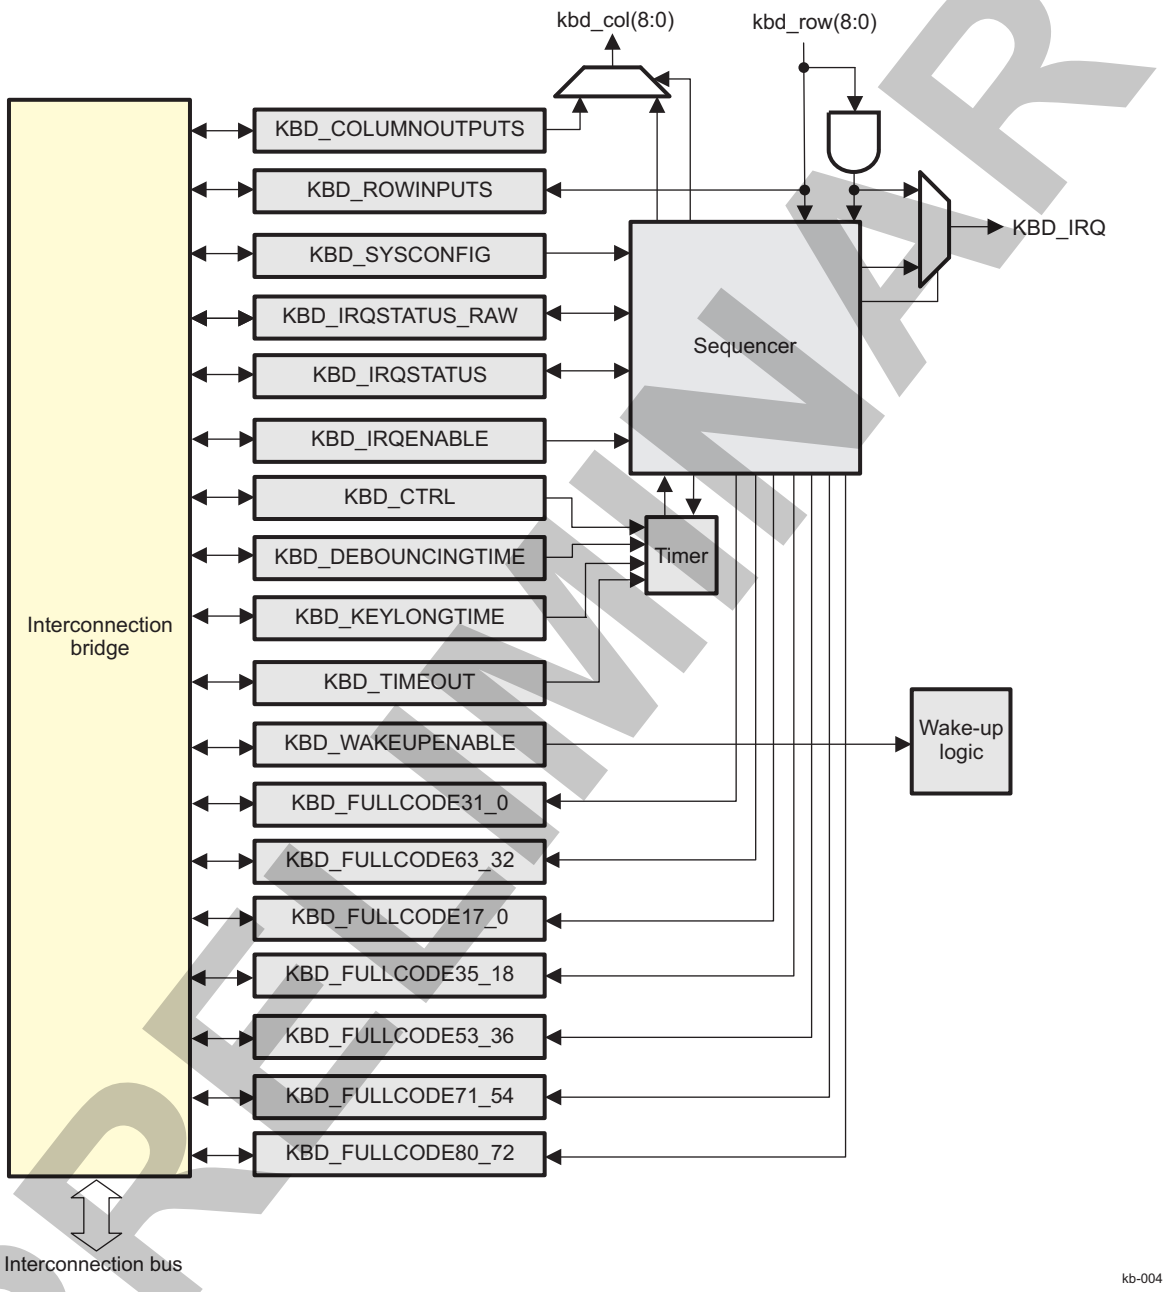
NOTE: For the description of the interrupt source, see Section 26.4.4, *Interrupt Requests*.

26.4 Keyboard Controller Functional Description

26.4.1 Keyboard Controller Block Diagram

Figure 26-5 shows the functional specification block diagram of the keyboard controller.

Figure 26-5. Keyboard Controller Block Diagram



The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the KBD_COLUMNOUTPUTS[8:0] KBC_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control and data paths).

26.4.2 Keyboard Controller Software Reset

To perform a software reset, set the KBD_SYSCONFIG[1] SOFTRESET bit to 1. When the software reset completes, the KBD_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

26.4.3 Keyboard Controller Power Management

Table 26-5 describes the power-management features available for the keyboard controller.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 26-5. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	KBD_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Master standby modes	N/A	N/A
Wake-up sources enable	KBD_IRQWAKEEN	This register holds one active-high enable bit per event source able to generate a wake-up signal.

26.4.4 Keyboard Controller Interrupt Requests

Table 26-6 lists the event flags, and their mask, that can cause module interrupts.

Table 26-6. Events

Event Flag	Event Mask	Description
KBD_IRQSTATUS[3] MISS_EVENT	–	A miss event occurs.
KBD_IRQSTATUS[2] IT_TIMEOUT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR[2] IT_TIMEOUT_EN	A time-out event is detected.
KBD_IRQSTATUS[1] IT_LONG_KEY	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR[1] IT_LONG_KEY_EN	A long-key event is detected.
KBD_IRQSTATUS[0] IT_EVENT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR[0] IT_EVENT_EN	An event is detected.

26.4.5 Keyboard Controller Software Mode

The KBD_CTRL[1] NSOFTWARE_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register (KBD_COLUMNOUTPUTS) and the keyboard controller row inputs register (KBD_ROWINPUTS). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the KBD_ROWINPUTS register.

For more information about the software scan, see Section 26.5.1, *Keyboard Controller Low-Level Programming Model*.

26.4.6 Keyboard Controller Hardware Decoding Modes

26.4.6.1 Functional Modes

When running in hardware (default) decoding mode (the KBD_CTRL[1] NSOFTWARE_ MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in Table 26-7. The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register (KBD_IRQENABLE_SET). If the event is enabled (bit 0 is set to 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register (KBD_IRQSTATUS) is updated.

Table 26-7. Keyboard Controller Functional Modes

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Keyboard event	Event interrupt	Debouncing value	Occurs when a key is pressed or released Always enabled	KBD_CTRL[8:5] bits must be set to 0 to disable all the other features.
Long key	Long-key interrupt	Long-key value	Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode	KBD_CTRL[5] LONG_KEY
Repeat key	Long-key interrupt	Long-key value	Generates an interrupt every long-key delay No time-out can be associated.	KBD_CTRL[8] REPEAT_MODE
Empty time-out	Time-out interrupt	Empty time-out value	Interrupt generated if no key is pressed during an empty time-out period.	KBD_CTRL[6] TIMEOUT_EMPTY
Long-key time-out	Time-out interrupt	Long-key time-out value	Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period	KBD_CTRL[7] TIMEOUT_LONG_KEY

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the KBD_CTRL register with the appropriate values (for more information, see Section 26.6, *Keyboard Controller Register Manual*).

26.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- KBD_DEBOUNCINGTIME
- KBD_KEYLONGTIME
- KBD_TIMEOUT

Table 26-8 summarizes the values of the keyboard controller timer.

Table 26-8. Keyboard Controller Timer Values

Timer Value	Associated Register Field	Description
Debouncing time	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay.

Table 26-8. Keyboard Controller Timer Values (continued)

Timer Value	Associated Register Field	Description
Long-key time	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated. In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again.
Long-key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode.
Empty key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state.

The timer countdown period depends on three factors:

- The loaded value as set in:
  - KBD_DEBOUNCINGTIME
  - KBD_KEYLONGTIME
  - KBD_TIMEOUT
- The value of the prescale clock timer as set in the KBD_CTRL[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz)

The period is calculated as follows:

$T_{period} = (T_{value} + 1) \times 2^{PTV + 1} \times T_{clk}$

Where:

T_{value} is the value stored in the KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, or KBD_TIMEOUT register.

PTV is the value of the KBD_CTRL[4:2] PTV bit field.

T_{clk} is the period of the 32-kHz functional clock; that is, 31.25 µs.

The KBD_CTRL[4:2] PTV bit field determines the division factor of the timer clock. Table 26-9 lists the divider rates.

Table 26-9. Timer Prescale Values

KBD_CTRL[4:2] PTV Value	Divisor
0	2
1	4
2	8
3	16
4	32
5	64
6	128
7	256

NOTE: The timer minimum period is 62.5 µs; its maximum period is 524.288 seconds.

CAUTION

To prevent undefined results, the KBD_CTRL[4:2] PTV bit field must not be changed when the timer is running.

The timer value registers (KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, and KBD_TIMEOUT) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The KBD_KEYLONGTIME register is updated; the new value stored in the KBD_KEYLONGTIME register is loaded into the timer when the register is written. If the timer is already counting down when KBD_KEYLONGTIME is updated, it counts down from the new value loaded in KBD_KEYLONGTIME.
- The KBD_DEBOUNCINGTIME or KBD_TIMEOUT register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

26.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. Table 26-10 lists the corresponding codes.

Table 26-10. State-Machine Values

KBD_STATEMACHINE[3:0] Value	Description
0x0	Idle
0x1	Scanning
0x2	Load timer debouncing
0x3	Test timer debouncing
0x4	Generated interrupt event
0x6	Load timer long key
0x7	Test timer long key
0x8	Generated interrupt long key
0x9	Load timer time-out
0xA	Test timer time-out
0xB	Generated interrupt time-out
0xF	Other

26.4.6.4 Keyboard Controller Interrupt Generation

26.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates the KBD_IRQ interrupt signal to external INTC. Each functional mode generates dedicated interrupt events (logged in the KBD_IRQSTATUS register) that can be masked using the KBD_IRQENABLE_CLR register, or unmasked using the KBD_IRQENABLE_SET register.

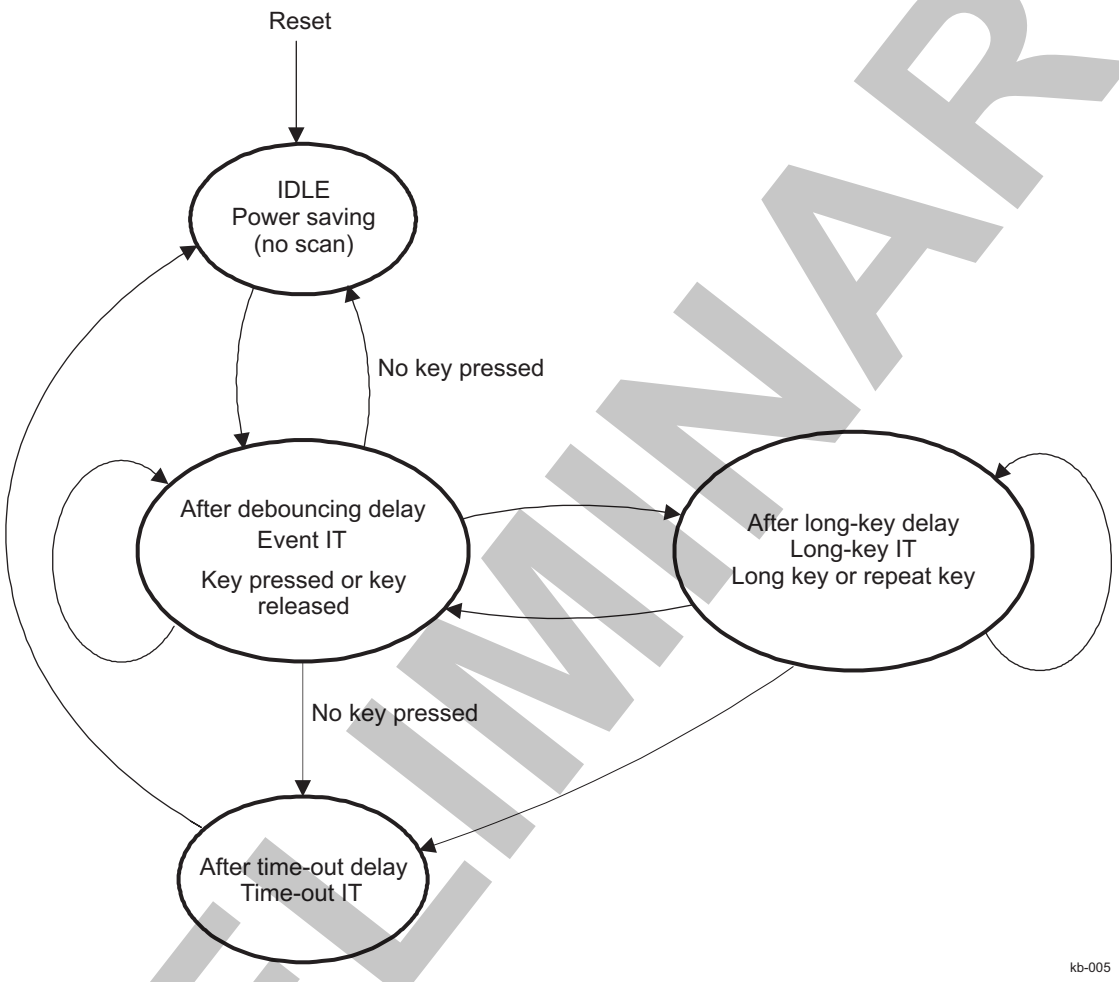
The KBD_IRQSTATUS register is updated when the selected functional mode generates an interrupt event. However, the KBD_IRQ signal is asserted on the related event only if the corresponding bit is set to 0x1 in the KBD_IRQENABLE_SET register.

NOTE: To reset the interrupt status bit, 1 must be written to the appropriate bit of the KBD_IRQSTATUS read/write register.

Figure 26-6 shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

NOTE: Depending on the selected mode, some interrupt events cannot be generated.

Figure 26-6. Functional Modes and Related Interrupt Events



While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the KBD_IRQSTATUS[0] IT_EVENT bit) is set after the timer counts down the debouncing delay. An IT_EVENT is generated when a key is pressed or released.

NOTE: An IT_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the KBD_IRQSTATUS[1] IT_LONG_KEY bit) is generated. If the repeat mode is set, the IT_LONG_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the KBD_IRQSTATUS[2] IT_TIMEOUT bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

NOTE: No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

26.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the KBD_IRQSTATUS[3] MISS_EVENT bit) is generated to report the lost event.

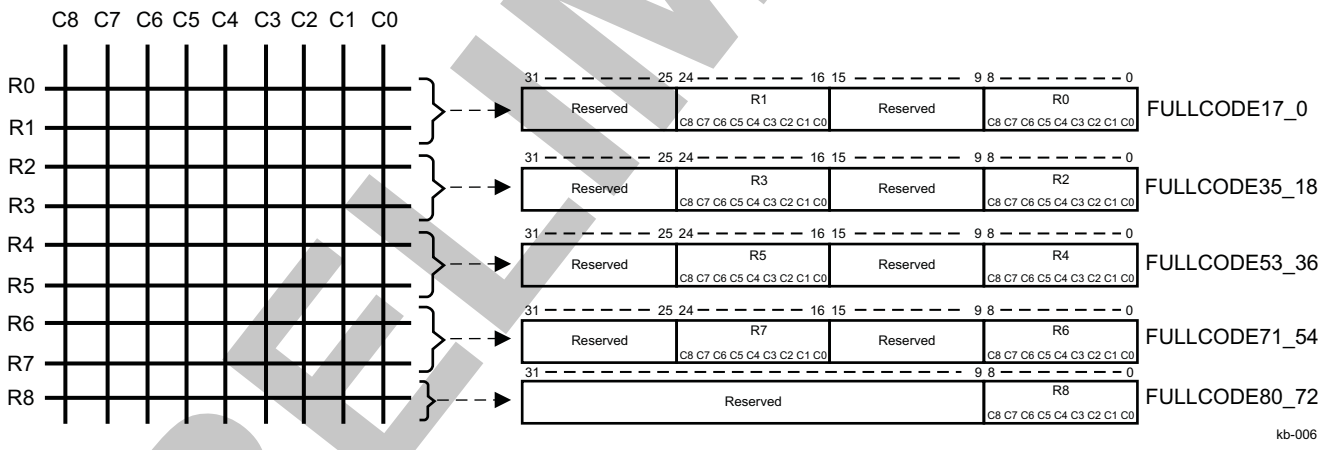
NOTE: The MISS_EVENT interrupt is not routed to the KBD_IRQ signal; software must check the KBD_IRQSTATUS[3] MISS_EVENT bit to detect any missed events.

26.4.7 Keyboard Controller Key Coding Registers

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers, as shown in Figure 26-7. These registers are updated only when interrupt event status is inactive to prevent a lost event.

NOTE: The KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers, which are limited to supporting keyboards of a maximum 8 × 8 array size, can be used for back-to-back software compatibility.

Figure 26-7. Key Coding Registers



Each of the 9 × 9 keyboard size supporting registers (KBD_FULLCODE17_0 to KBD_FULLCODE71_54) stores the state of two keyboard rows. The KBD_FULLCODE80_72 register stores the state of the last row, R8:

- The KBD_FULLCODE17_0 register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The KBD_FULLCODE35_18 register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The KBD_FULLCODE53_36 register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The KBD_FULLCODE71_54 register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The KBD_FULLCODE80_72 register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding KBD_FULLCODE80_72):

- Bit 0 corresponds to column(0) – row (i) key, … , bit 8 corresponds to column(8) – row (i) key.
- Bits from 9 to 15 are reserved.
- Bit 16 corresponds to column(0) – row (i + 1) key, … , bit 24 corresponds to column (8) – row (i + 1) key.
- Bits 31 to 25 are reserved, where i = 0, 2, 4, 6.

In the KBD_FULLCODE80_72 register, bit 0 corresponds to column (0) – row (8) key, …, the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8 × 8-keyboard size supporting registers (KBD_FULLCODE31_0 and KBD_FULLCODE63_32) stores the state of four keyboard rows:

- The KBD_FULLCODE31_0 register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The KBD_FULLCODE63_32 register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- KBD_FULLCODE31_0[0] corresponds to column (0) – row (0) key,…, KBD_FULLCODE31_0[7] corresponds to column (7) – row (0).
- KBD_FULLCODE31_0[8] corresponds to column (0) – row (1) key,..., KBD_FULLCODE31_0[15] corresponds to column (7) – row (1).
- KBD_FULLCODE31_0[16] corresponds to column (0) – row (2) key,..., KBD_FULLCODE31_0[23] corresponds to column (7) – row (2).
- KBD_FULLCODE31_0[24] corresponds to column (0) – row (3) key,..., KBD_FULLCODE31_0[31] corresponds to column (7) – row (3).
- KBD_FULLCODE63_32[0] corresponds to column (0) – row (4) key,..., KBD_FULLCODE63_32[7] corresponds to column (7) – row (4).
- KBD_FULLCODE63_32[8] corresponds to column (0) – row (5) key,..., KBD_FULLCODE63_32[15] corresponds to column (7) – row (5).
- KBD_FULLCODE63_32[16] corresponds to column (0) – row (6) key,..., KBD_FULLCODE63_32[23] corresponds to column (7) – row (6).
- KBD_FULLCODE63_32[24] corresponds to column (0) – row (7) key,..., KBD_FULLCODE63_32[31] corresponds to column (7) – row (7).

NOTE: The keyboard fullcode registers are not updated in software mode.

NOTE: When using a smaller keyboard (for example, 5 × 5 or 4 × 4), the bits of the unused columns/rows are not used.

26.4.8 Keyboard Controller Register Access

26.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register (KBD_PENDING).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the KBD_PENDING register, and can be quantified:

T (reset posted bit maximum) = 3 × Ticlk + 3 × Tfuncclk

The time it takes to accomplish the writing is:

T (write accomplish maximum) = 1 × Ticlk + 3 × Tfuncclk

where:

Ticlk is the L4 interface clock period, and Tfuncclk is the functional clock period.

26.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if Freq(KBD_FCLK) < Freq(KBD_ICLK)/4.

26.5 Keyboard Controller Programming Guide

26.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

26.5.1.1 Global Initialization

26.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see Section 26.2, *Keyboard Controller Environment,* and Section 26.3, *Keyboard Controller Integration*.

Table 26-11 describes the global initialization of surrounding modules.

Table 26-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
Cortex-A15 MPU INTC	Interrupt request KBD_IRQ from the keyboard must be unmasked. For more information, see Section 17.1, *Interrupt Controllers Overview*.
Control module	The pad configuration registers must be configured to map the keyboard interface signals to the device pads to determine the signal directions and, for all keyboard rows, to enable the internal pull-ups of the associated IO cells. For more information about this configuration, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*.

26.5.1.1.2 Keyboard Controller Global Initialization

26.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see Table 26-12).

Table 26-12. Keyboard Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row).	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0x–
Perform the functional configuration of the keyboard module and the prescale clock timer value.	KBD_CTRL	0x00000–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request.	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR[2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

26.5.1.2 Operational Modes Configuration

26.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

26.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. Table 26-13 describes the keyboard controller hardware mode.

Table 26-13. Keyboard Controller Hardware Mode

Step	Register/Bit Field/Programming Model	Value
Activate the internal keyboard controller sequencer by setting the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b1
Select the functional mode by setting its corresponding bit to 1.	KBD_CTRL[8:5]	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR[2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–
Wait for the KBD_IRQ interrupt signal assertion.		
Read the interrupt-status register to determine which event caused the interrupt.	KBD_IRQSTATUS	
Read the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers (or 8 × 8 keyboard-size-supporting KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers) to determine which key matrix combination was pressed.	KBD_FULLCODE17_0 [ROWi bits] (where i = 0 or 1) up to KBD_FULLCODE71_54 [ROWi bits] (where i = 6 or 7); KBD_FULLCODE80_72 [ROWi bits] (where i = 8); (or KBD_FULLCODE31_0[j] FULL_CODE_31_0 and KBD_FULLCODE63_32[k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63)	
Clear the corresponding bit(s) in the interrupt-status register by writing logical 1.	KBD_IRQSTATUS	0x1

NOTE: The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

NOTE: All interrupts are disabled on reset.

NOTE: When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the KBD_IRQSTATUS[3] MISS_EVENT bit is set. Software must check this bit, which is not reflected on the KBD_IRQ line.

NOTE: The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see Section 26.4.8.1, *Write Registers Access*.

26.5.1.2.2 Keyboard Controller Software Scanning Mode

26.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

Table 26-14 describes the keyboard controller software mode.

Table 26-14. Keyboard Controller Software Mode

Step	Register/Bit Field/Programming Model	Value D
Deactivate the internal keyboard controller sequencer by clearing the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b0
Enable the interrupt event by setting the bit.	KBD_IRQENABLE_SET[0] IT_EVENT_EN	0b1
Wait for the KBD_CTL_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted:		
1) Disable all columns to drive a logical 0 on the kbd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row)	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0xFF
2) Drive kbd_col(i) output, (where i = 0 to 8), to 0 to capture a pressed-key-event, at the corresponding row input.	KBD_COLUMNOUTPUTS[i] KBC_REG (where i = 0 to 8)	0b0
3) Read the KBR_LATCH bit field of the KBD_ROWINPUTS register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled.	KBD_ROWINPUTS[8:0] KBR_LATCH	
END IF		
Repeat step 2) and step 3) for all existing columns.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

NOTE: In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

26.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see Section 26.4.6.2, *Keyboard Controller Timer*.

26.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see Section 26.4.6.3, *State-Machine Status*.

26.5.1.3 Keyboard Controller Events Servicing

Table 26-15 lists the keyboard controller event servicing.

Table 26-15. Keyboard Controller Event Servicing

Step	Register/ Bit Field / Programming Model	Value
Read the status register.	KBD_IRQSTATUS	
IF:	KBD_IRQSTATUS[2] IT_TIMEOUT	=1
Handle the timeout event.		

Table 26-15. Keyboard Controller Event Servicing (continued)

Step	Register/ Bit Field / Programming Model	Value
Clear the corresponding status flag.	KBD_IRQSTATUS[2] IT_TIMEOUT	0x1
ELSE IF:	KBD_IRQSTATUS[1] IT_LONG_KEY	=1
Handle the long pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[1] IT_LONG_KEY	0x1
ELSE IF:	KBD_IRQSTATUS[0] IT_EVENT	=1
Handle the pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[0] IT_EVENT	0x1
ENDIF		
Disable the interrupts if needed.	KBD_IRQENABLE_CLR[2:0]	0x1

26.6 Keyboard Controller Register Manual

Shared PHY Component Subsystems

This chapter describes the shared PHY component subsystems of the device.

NOTE: The following naming rule is applied across the chapter:

- RXP/ RXN and TXP/ TXN naming is used at SATA PHY and USB3 PHY module level
- rx/ry and tx/ty naming is used at device level

where:

RXP corresponds to sata_rx / usbd0_ss_rx.
RXN corresponds to sata_ry / usbd0_ss_ry.
TXP corresponds to sata_tx / usbd0_ss_tx.
TXN corresponds to sata_ty / usbd0_ss_ty.

Topic **Page**

27.1 SATA PHY Subsystem

This chapter describes the features and functions of the serial advanced technology attachment (SATA) PHY subsystem of the device.

27.1.1 SATA PHY Subsystem Overview

The physical layer (PHY) is responsible for transmitting and receiving the parallel 8b/10b encoded information as a serial data stream on the wire.

The SATA host controller subsystem instantiates a single serializer (transmitter), SATA_PHY_TX, and a single deserializer (receiver), SATA_PHY_RX. Together the transmitter and receiver are also signified as SATA_PHY throughout this chapter. The role of the TX and RX components is to adapt SATA Link parallel 10-bit input/output (I/O) data stream for a serialized differential transmission and reception over SATA electrical interface, respectively.

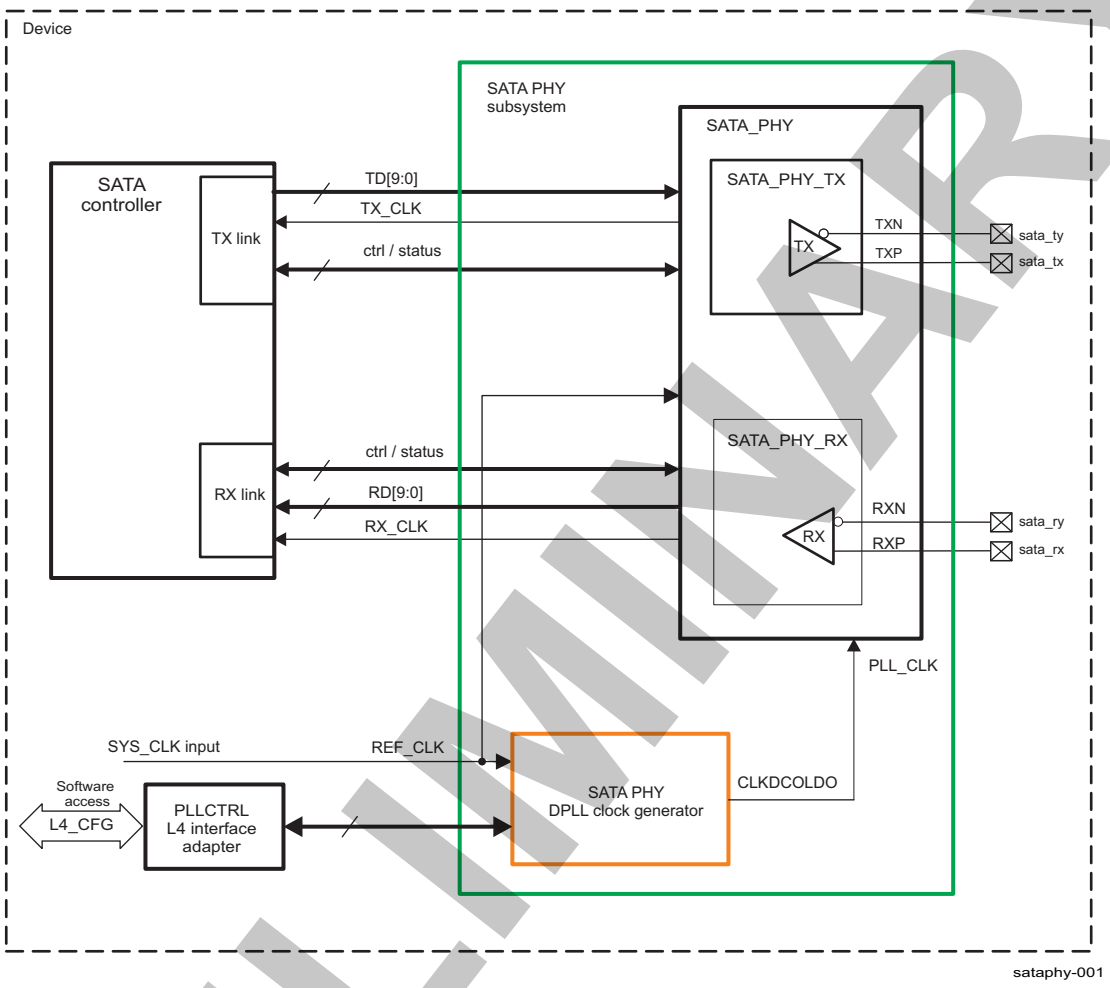
The high speed transmission clock is generated by and integrated into the SATA host subsystem dpll (DPLL_SATA).

The DPLL_SATA is configured and controlled through a SATA dedicated PLL controller (PLLCTRL_SATA) with associated registers, accessible over a L4_CFG interface adapter.

The components (SATA_PHY_RX, SATA_PHY_TX, DPLL_SATA, PLLCTRL_SATA, and PLLCTRL_SATA L4-interface adapter) build the SATA PHY subsystem. This subsystem is responsible for PHY components clock generation and physical layer transmission/reception within the device SATA subsystem.

Figure 27-1 gives an overview of the SATA PHY subsystem. As shown in Figure 27-1, at one side the SATA_PHY components directly interface the attached to host controller SATA mass storage device (over TXP/TXN transmission and RXP/RXN reception interface I/Os) and on the other side they interface the SATA controller, described in detail in Section 23.12, *SATA Controller*.

Figure 27-1. SATA PHY Subsystem Overview



27.1.2 SATA PHY Subsystem Environment

27.1.2.1 SATA PHY I/O Signals

Table 27-1 lists the module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 27-1. SATA PHY I/O Signals

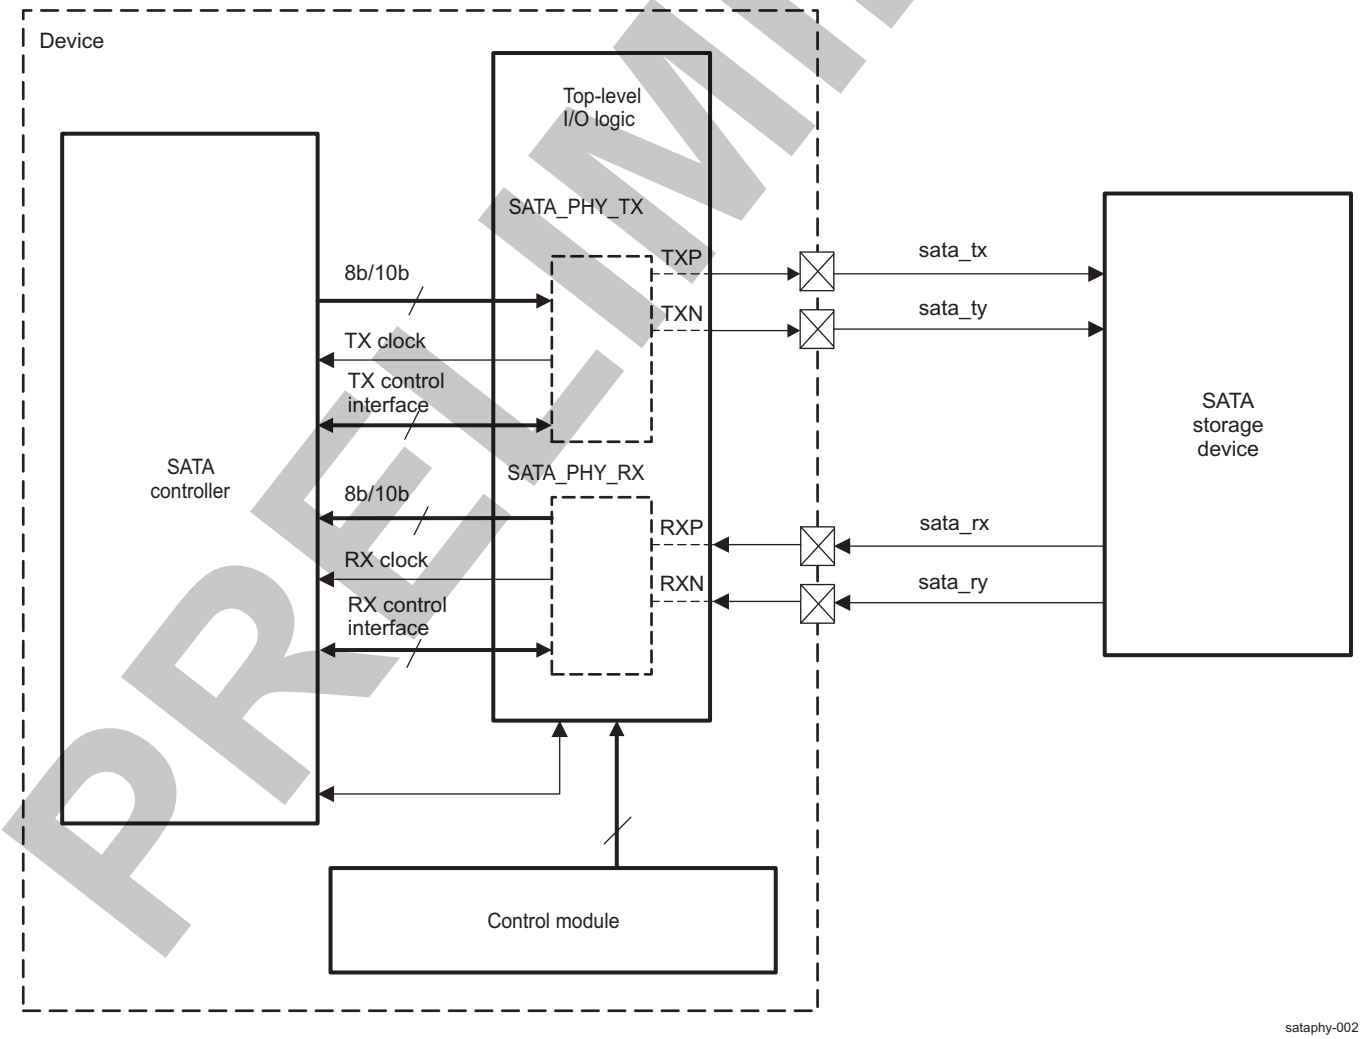
Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
TXP[2]	sata_tx	O	TX output of the SATA PHY differential transmission line	0
TXN[2]	sata_ty	O	TY output of the SATA PHY differential transmission line	0
RXP[2]	sata_rx	I	RX input of the SATA PHY differential reception line	HiZ
RXN[2]	sata_ry	I	RY input of the SATA PHY differential reception line	HiZ

(1) I = Input; O = Output

(2) The SATA PHY subsystem signals that implement the physical interface with an external SATA storage device.

Figure 27-2 shows module pin signals mapping to SATA PHY I/O signals visible at device pad level.

Figure 27-2. SATA PHY I/O Signals



NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers. See Section 18.4.8, *Pad Functional Multiplexing and Configuration* and Section 18.4.12.7.5, *Device Interfaces Signal Group Controls Mapping* in Chapter 18, *Control Module*, for more information.

27.1.3 SATA PHY Subsystem Integration

This section describes the SATA PHY subsystem-related components (SATA_PHY, DPLL_SATA, PLLCTRL_SATA, OCP2SPC3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 27-3 shows the SATA_PHY integration.

The SATA_PHY module integration features are:

- A low-power nonretention reset, L3INIT_RST
- A DPLL reference input clock, PLL_CLK
- Parallel 10-bit TD[9:0] (SATA_PHY_TX) and 10-bit RD[9:0] (SATA_PHY_RX) data interfaces to SATA controller
- TX_CLK output clock for the parallel TX data interface between SATA_PHY.SATA_PHY_TX and SATA controller
- RX_CLK output clock for the parallel RX data interface between SATA_PHY.SATA_PHY_RX and SATA controller
-
- REF_CLK clock input (SATA_REF_GFCLK)
- A device core control module command port to the SATA_PHY integrated power sequencer

The DPLL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- A power, reset, and clock management (PRCM) gated version of SYS_CLK (SATA_REF_GFCLK) supplying the DPLL_SATA.CLKINP pin
- A single high-frequency clock output (DPLL_SATA.CLKDCOLDO to the SATA_PHY TX/RX components)
- No high-speed (HS) divider integration
- Idle signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK locked status indication output to SATA_PHY and the SATA controller

The PLLCTRL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC3) Interconnect adapter target interface
- Configuration/control programming interface to the DPLL_SATA
- No direct gate control for DPLL_SATA.CLKINP and CLKDCOLDO

Figure 27-3. SATA PHY Subsystem Integration

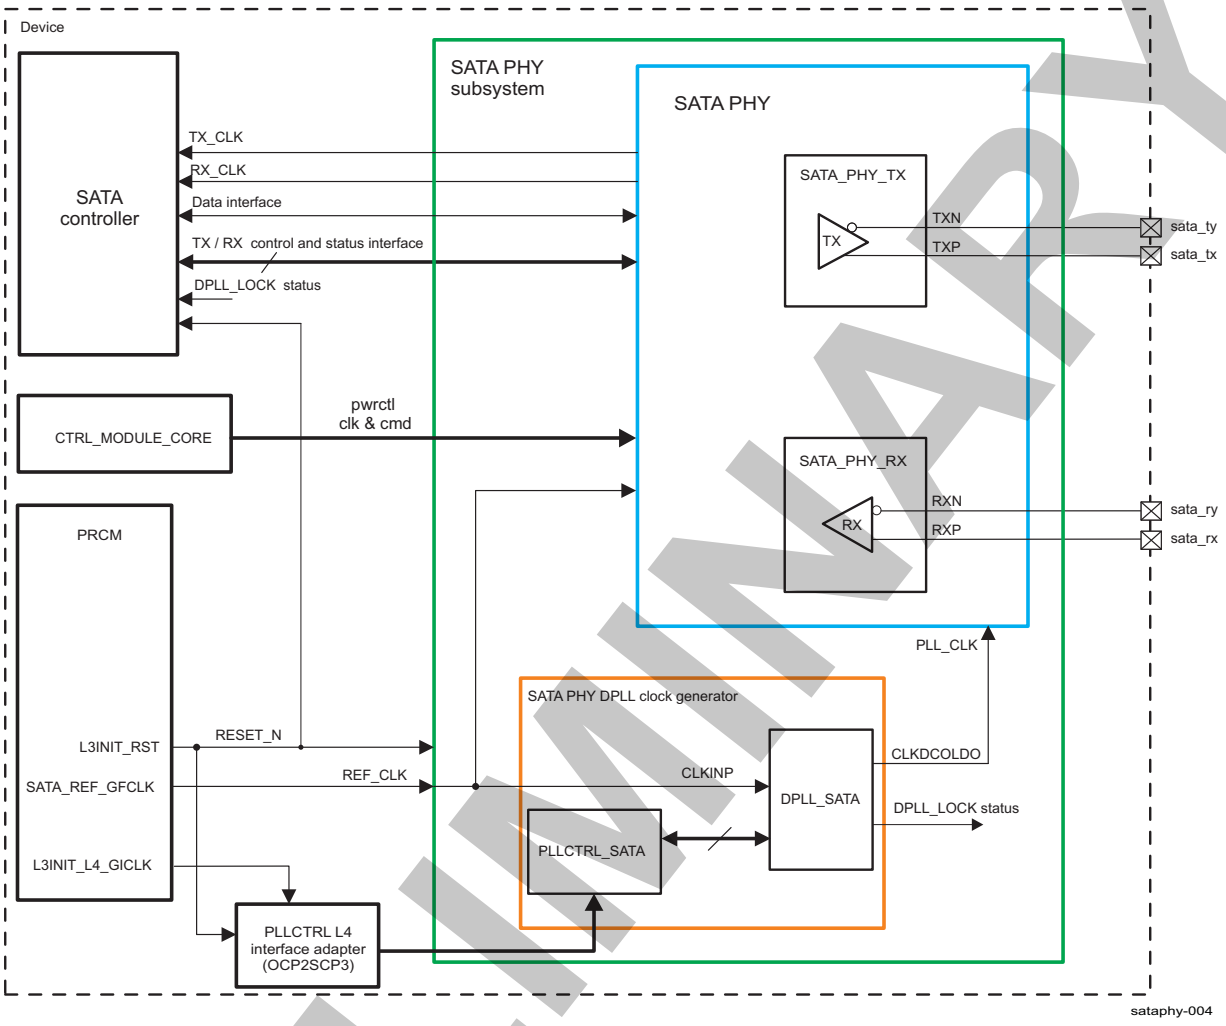


Table 27-2 through Table 27-4 summarize the integration of the module in the device.

Table 27-2. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PLLCTRL_SATA	PD_L3INIT	OCP2SCP3 adapter SCP interconnects
DPLL_SATA		
OCP2SCP3		L4_CFG

Table 27-3. Clocks

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DPLL_SATA / SATA_PHY	REF_CLK	SATA_REF_GFCLK	PRCM	SATA DPLL and SATA PHY reference functional clock (SYS_CLK)
OCP2SCP3	L4CFG_ADAPTER_CLKIN	L3INIT_L4_GICLK	PRCM	PHY / DPLL L4_CFG adapter interface clock

Table 27-4. Resets

Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SATA_PHY subsystem	RESET_N	L3INIT_RST	PRCM	A nonretention reset to all SATA_PHY subsystem components

NOTE: The SATA_PHY, DPLL_SATA, and PLLCTRL_SATA modules do not generate DMA, interrupt, or wakeup hardware requests to the surrounding modules integrated in the device.

27.1.4 SATA PHY Subsystem Functional Description

27.1.4.1 SATA PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP3), allows user software to configure the PLLCTRL_SATA registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the PLLCTRL_SATA.

Before initiating any software reset to this adapter, a value >= 0x6 should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP3. The smart-idle mode supported by OCP2SCP3 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP3 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the PLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

27.1.4.2 SATA PHY Serializer and Deserializer Functional Descriptions

27.1.4.2.1 SATA PHY Reset

No software reset is applicable to SATA_PHY. L3INIT reset assertion is automatically managed by hardware.

27.1.4.2.2 SATA_PHY Clocking

27.1.4.2.2.1 SATA_PHY Input Clocks

A standard high-speed 1.5 GHz input clock of SATA_PHY is provided by the DPLL_SATA.CLKDCOLDO output. PRCM. SATA_REF_GFCLK (derived from the SYS_CLK) should be enabled, to provide the necessary DPLL_SATA and SATA_PHY clocking within the SATA subsystem.

Depending on the SATA_REF_GFCLK (SYS_CLK derived) frequency, following settings should be made in the CTRL_MODULE_CORE.CONTROL_PHY_POWER_SATA[31:22] SATA_PWRCTL_CLK_FREQ bitfield for proper operation:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

27.1.4.2.2.2 SATA_PHY Output Clocks

The 10-bit data parallelly transmitted data between SATA_PHY_TX and SATA controller link logic is sampled with respect to the TX_CLK. Frequency of this clock is obtained as the SATA_PHY.PLL_CLK clock frequency:

- Divided by 10 if a 1.5-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x1
- Divided by 5 if a 3-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x0 or 0x2

The actually negotiated between host and the attached SATA device speed is indicated in the read-only SATA controller.SATA_PxSSTS[7:4] SPD bit field. For more information, see Section 23.12.6, *SATA Controller Register Manual*, in Section 23.12, *SATA Controller*.

RX_CLK: The SATA_PHY_RX output RX_CLK is a clock that is recovered from the serial data received over the RXP/RXN lines serial data. The RX_CLK clock supplies the SATA controller link parallel 10-bit data reception logic.

27.1.4.2.3 SATA_PHY Power Management

The SATA_PHY power sequencer receives a power-up/power-down command input from the device general core control module. The power sequencer takes care to execute different stages of the SATA_PHY_TX and SATA_PHY_RX power-up/-down processes. Besides a power-up/-down functionality, the SATA PHY accepts power transition commands/states (Ready state, Partial or Slumber states) from the SATA controller link power management port .

27.1.4.2.3.1 SATA_PHY Power-Up/-Down Sequences

Powering up/down the SATA_PHY_TX and SATA_PHY_RX modules is triggered by software writing corresponding power-up/-down commands in the CTRL_MODULE_CORE. CONTROL_PHY_POWER_SATA register of the device core control module, as follows:

- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x0 (default value), commands both SATA_PHY_TX and SATA_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x1, powers up the SATA_PHY_RX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x2, powers up the SATA_PHY_TX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x3, simultaneously powers up the SATA_PHY_RX and the SATA_PHY_TX.

For more information, see Chapter 18, *Control Module*.

27.1.4.2.3.2 SATA_PHY Low-Power Modes

Setting the DWC_ahsata.SATA_PxSCTL[3:0] DET bit field to 0x4 automatically puts the SATA_PHY_RX deserializer in offline mode. This software operation has no impact over the SATA_PHY_TX serializer.

NOTE: The SATA controller transition to partial or slumber mode has no impact over the SATA_PHY_RX deserializer.

NOTE: The SATA_PHY_TX.TX_CLK output clock is a free-running clock and cannot be gated, even when the transmitter is disabled by a SATA controller.

27.1.4.2.4 SATA_PHY Hardware Requests

No DMA, interrupt or wake-up requests are generated by the SATA_PHY to the surrounding SATA controller subsystem components.

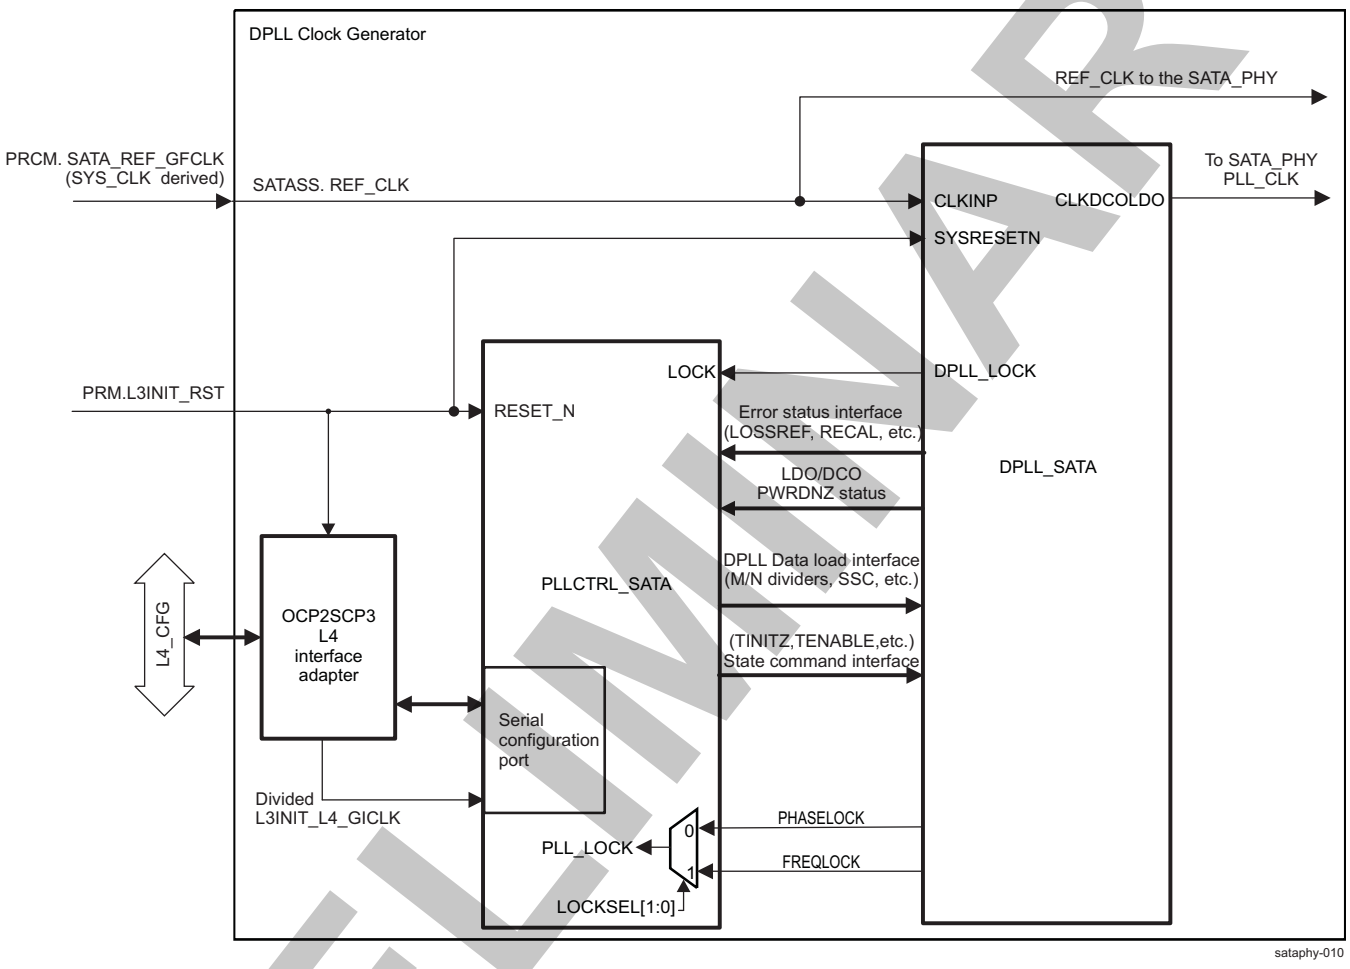
27.1.4.3 SATA Clock Generator Subsystem Functional Description

The DPLL_SATA, which is located outside the PRCM boundaries and is part of the SATA host controller subsystem, directly injects a high-speed clock into the SATA_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, PLLCTRL_SATA.

27.1.4.3.1 SATA DPLL Clock Generator Overview

The SCP interface of the SATA PLL controller (the PLLCTRL_SATA instance) is used to set the configuration of the digital phase-locked loop (DPLL) modules, primarily the various counter values. Figure 27-4 is an overview of the DPLL clock generator embedded into the SATA host controller subsystem.

Figure 27-4. SATA DPLL Clock Generator Overview



NOTE: The PLLCTRL_SATA module is user accessible on the L4_CFG interconnect. However, to make access possible, the user must configure the OCP2SCP3 instance prior to accessing the PLLCTRL_SATA registers.

The DPLL_SATA features are:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock spread spectrum clocking (SSC) support
- No retention capabilities
- No idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode

- Relock from standby

The PLLCTRL_SATA components features are:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation

27.1.4.3.2 SATA DPLL Clock Generator Reset

The SATA PLL controller and SATA DPLL clock generator share a common hardware nonretention reset (L3INIT_RST) which comes from the device power and reset manager. When the DPLL_SATA hardware reset completes, the PLLCTRL_SATA.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

The PLLCTRL_SATA itself has no software reset capabilities.

The PLLCTRL_SATA performs a software reset sequence on the DPLL_SATA in hardware (through the TINITZ signal activation).

27.1.4.3.3 SATA DPLL Low-Power Modes

The power-management port (PMP) is not integrated for PLLCTRL_SATA. The DPLL_SATA has no retention capabilities. This means the DPLL digital power supply remains switched on during all modes of operation.

The low-power (LP) modes supported by DPLL_SATA are idle-bypass low power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter idle-bypass and MN-bypass low-power modes, see Section 27.1.4.3.6.4, *SATA DPLL Idle-Bypass Low-Power Mode*, and Section 27.1.4.3.6.5, *SATA DPLL MN-Bypass Mode*.

DPLL_SATA is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after POR, before the first PLL_GO command has been software-triggered on the PLL controller. See Section 27.1.4.3.6.1, *SATA Clock Generator Power Up*.

27.1.4.3.4 SATA DPLL Clocks Configuration

27.1.4.3.4.1 SATA DPLL Input Clock Control

The DPLL_SATA accepts the functional clock (SATA_REF_GFCLK) on its CLKINP pin (REF_CLK input at SATA SS level) directly from the device SCRM, without involving any PLLCTRL_SATA interractions. The SATA_REF_GFCLK is derived from SCRM.SYS_CLK, and can be optionally software-gated by setting the PRCM.CM_L3INIT_SATA_CLKCTRL[8] OPTFCLKEN_REF_CLK bit. The status of the SATA_REF_GFCLK clock can be monitored in the PRCM.CM_L3INIT_CLKSTCTRL[19] CLKACTIVITY_SATA_REF_GFCLK bit. See Section 3.6.4.5, *Clock Domain Module Attributes* in Chapter 3, *Power, Reset, and Clock Management*.

If CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to PLLCTRL_SATA, is asserted high. When CLKINP resumes, the LOSSREF signal goes low (LOSSREF inactive state). The LOSSREF status signal can be monitored by software in the PLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit.

NOTE: PLLCTRL_SATA has no software or hardware mechanisms to control DPLL_SATA input clock, CLKINP.

27.1.4.3.4.2 SATA DPLL Output Clock Configuration

Only the DPLL_SATA output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the SATA_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done by programming the PLLCTRL_SATA.PLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM, PLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN, and PLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The SATA DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

NOTE: At the DPLL/PLLCTRL integration level, the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are tied-off by hardware to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 27.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*.

27.1.4.3.4.2.1 SATA DPLL Output Clock Gating

There is no direct software gate control for the DPLL_SATA.CLKDCOLDO output.

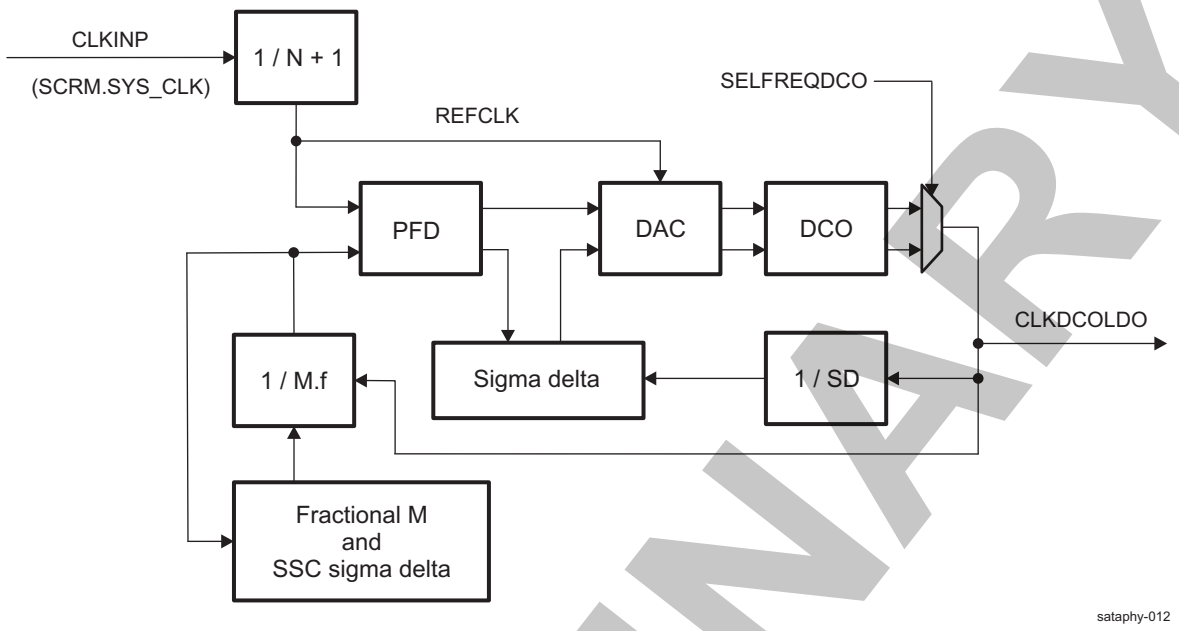
The DPLL_SATA.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on the power-up sequence, see Section 27.1.4.3.6.1, *SATA Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on the relocking sequence, see Section 27.1.4.3.6.2, *SATA DPLL Sequences*.
- DPLL entering idle-bypass low-power mode. For more information on idle-bypass mode, see Section 27.1.4.3.6.4, *SATA DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 27.1.4.3.6.5, *SATA DPLL MN Bypass Mode*.

27.1.4.3.5 SATA DPLL Subsystem Architecture

Figure 27-5 is a simplified block diagram of the DPLL_SATA instance integration in the SATA clock generator subsystem.

Figure 27-5. DPLL_SATA Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the PLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_SATA input clock (CLKINP) and the DPLL internal reference clock (REFCLK = CLKINP / N + 1) are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP × M / (N + 1). For that purpose the feedback multiplier M must be configured through the PLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_SATA module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the PLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division Fractional M should be set to 000…0.

NOTE: Fractional synthesis is not supported for M > 4093.

The module also supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm); that is, {10 × log10(df/fm)} dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df); that is, dM/M = df/Fout.

Because this is in-band modulation for the DPLL_SATA, the modulation frequency must be within the loop bandwidth of the DPLL. A higher modulation frequency would result in lesser spreading in the output clock.

The SSC can be enabled and disabled by asserting the PLLCTRL_SATA.PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the PLLCTRL_SATA.PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value programmed in the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK/(4*fm).The ModFreqDivider is split into Mantissa and $2^{Exponent}$ (ModFreqDivider = ModFreqDividerMantissa × $2^{ModFreqDividerExponent}$).

- The Mantissa is controlled by bits [29:23] of the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), dM must be controlled as previously explained. To define dM, the step size of M for each REFCLK during the triangular pattern must be programmed. This is defined as follows:

- dM = ($2^{ModFreqDividerExponent}$) × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent <= 3
- dM = 8 × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent > 3

the DeltaMStep value is split into integer part and fractional part, as follows:

- The MSB of 3-bit integer part, DeltaMStepInteger is controlled by the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2 [30] DELTAM2 bit and the remaining LSBs by bits [19:18] of the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.
- The 18-bit fractional part, DeltaMStepFraction, is controlled by bits [17:0] of the PLLCTRL_SATA.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.

If the PLLCTRL_SATA.PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for 20 percent overshot).

27.1.4.3.6 SATA DPLL Clock Generator Modes and State Transitions

The DPLL_SATA can be set in different modes during operation. PLLCTRL triggers DPLL_SATA state transitions to different static modes by means of TINITZ and TENABLE hardware control signals.

27.1.4.3.6.1 SATA Clock Generator Power Up

After power up, the DPLL_SATA.SYSRESETN input is automatically pulled low by PRM, together with PLLCTRL_SATA.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_SATA input clock (DPLL_SATA.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence on the CLKINP clock. If CLKINP is present upon reset assertion, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completion. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After POR, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

27.1.4.3.6.2 SATA DPLL Sequences

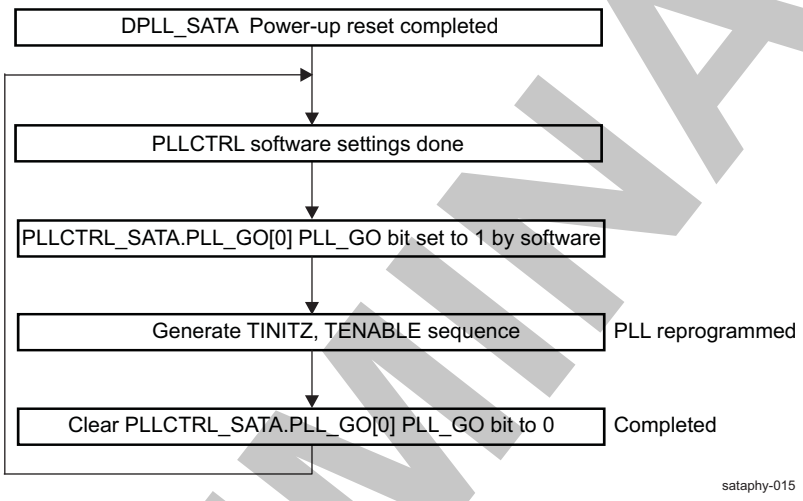
Once all the configuration values have been initially programmed into the PLLCTRL_SATA registers (see Section 27.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*), the PLLCTRL_SATA.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After PLLCTRL_SATA.PLL_GO[0] PLL_GO bit is set high in software, the PLLCTRL_SATA state-machine takes the following action:

1. Sets TINITZ signal to 0. TINITZ acts as a soft reset to DPLL_SATA. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_SATA initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by the PLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the PLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 27-6 summarizes the software and hardware sequences flow of DPLL_SATA.

Figure 27-6. SATA PLL GO Sequence



NOTE: All thick-outlined blocks in Figure 27-6 show operations performed by software. Other blocks show operations performed by hardware.

DPLL_SATA Relock Sequence: When DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting PLLCTRL_SATA.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_SATA enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The PLLCTRL_SATA.PLL_GO[0] PLL_GO bit can be used by software to monitor if PLLCTRL locking process is still pending (PLL_GO = 0b1).

27.1.4.3.6.3 SATA DPLL Locked Mode

When DPLL_SATA finishes calibration and lock sequences it enters the LOCKED state. During the LOCKED state, LOSSREF is deasserted, BYPASSACK is deasserted, and the FREQLOCK or PHASELOCK signals are asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software selectable through the PLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL indicates it is in the LOCKED state to the PLLCTRL_SATA, SATA controller core controller, and SATA_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the PLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit, which is active high.

27.1.4.3.6.4 SATA DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_SATA.

DPLL_SATA supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the PLLCTRL_SATA.PLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low, respectively. Also, the internal reference clock REFCLK = CLKINP / N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, DPLL_SATA.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0 → 1 to module initialization. The DCO oscillator exits power down (TICOPWDN goes low) whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_SATA.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON/OFF states are reflected within the read-only PLLCTRL_SATA.PLL_STATUS[16] PLL_TICOPWDN and PLLCTRL_SATA.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should set PLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal and DPLL_SATA automatically enters a relock sequence. The CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on selected locking criteria.

27.1.4.3.6.5 SATA DPLL MN-Bypass Mode

The MN-Bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-Bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down the internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

NOTE: When the PLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO output clock is gated.

27.1.4.3.6.6 SATA DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss of lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The PLLCTRL_SATA.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_SATA must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The PLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit gives the SATA PLL LOCKED state.
- The PLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit informs whether the PLLCTRL_SATA has lost the reference clock.
- The PLLCTRL_SATA.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

27.1.4.3.7 SATA PLL Controller Functions

27.1.4.3.7.1 SATA PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP3 L4 adapter register space using the SCP interface of the PLLCTRL_SATA. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

NOTE: Because the SATA_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the SATA controller, the PLLCTRL_SATA and DPLL_SATA must be configured before any data transfer between the SATA controller and an external SATA storage device.

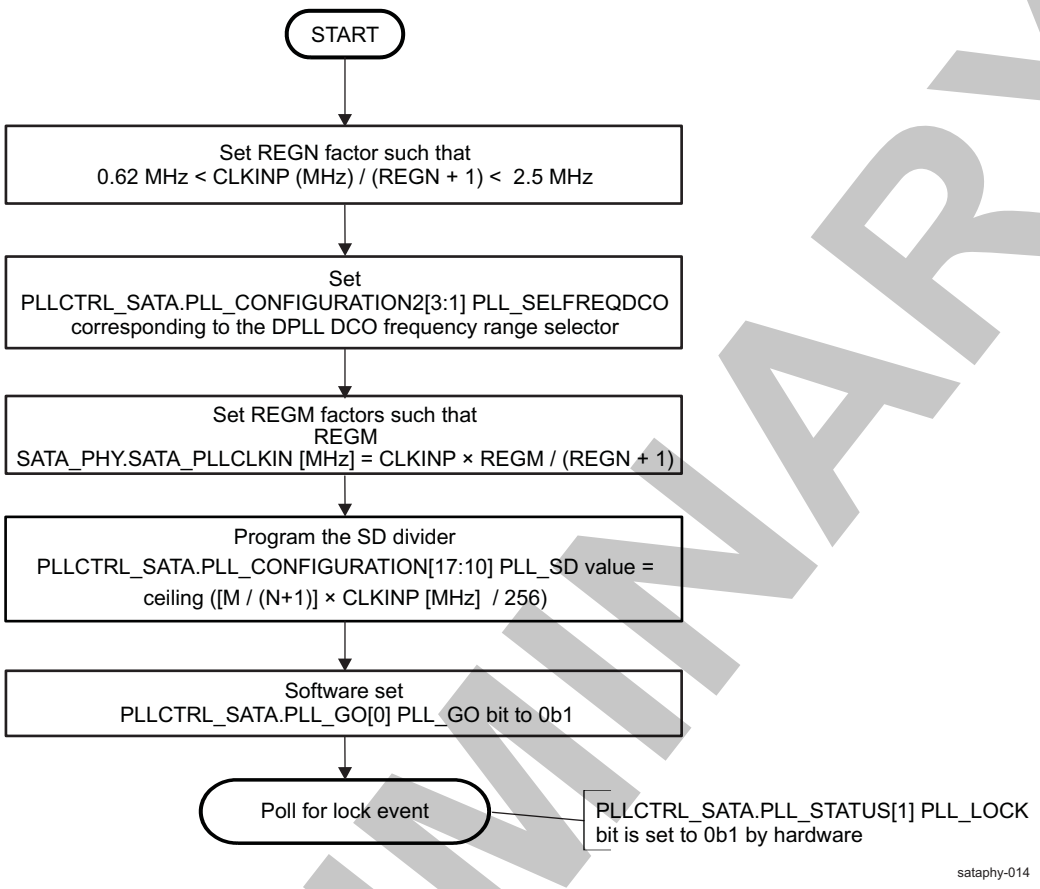
27.1.4.3.7.2 SATA DPLL Clock Programming Sequence

The DPLL_SATA factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- The REGM factor is programmed in the PLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- The fractional part of REGM factor is programmed in the PLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- The REGN factor is programmed in the PLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- The DCO frequency range is set in the PLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2, if 500 MHz < CLKDCOLDO [MHz] < 1000 MHz
  - PLL_SELFREQDCO should be set to 0x4, if 1000 MHz < CLKDCOLDO [MHz] < 2000 MHz
- The SD divider is programmed in the PLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The PLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M / (N + 1). The formulas are shown in Figure 27-7.

Figure 27-7 shows the programming sequence.

Figure 27-7. SATA PLL Programming Sequence



NOTE:

- The equation for SATA_PHY_TX/SATA_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_SATA.
- For normal operation CLKDCOLDO output frequency of the DPLL_SATA should be either 750 MHz (SATA-1 mode) or 1500 MHz (SATA-2 mode).

Table 27-5 summarizes the registers for the PLLCTRL_SATA programming sequence.

Table 27-5. Register Call Summary for SATA PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
PLLCTRL_SATA.PLL_CONFIGURATION2	PLLCTRL_SATA.PLL_GO	PLLCTRL_SATA.PLL_STATUS	PLLCTRL_SATA.PLL_CONFIGURATION3

27.1.4.3.7.3 SATA DPLL Recommended Values

Table 27-6 lists the DPLL_SATA recommended values.

Table 27-6. Recommended Programming Values

Field Name	Value	Description
PLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider

(1) The value of the bit field must be set according to the desired clock frequencies – 750 MHz for SATA-1 and 1.5 GHz for SATA-2 speeds.

Table 27-6. Recommended Programming Values (continued)

Field Name	Value	Description
PLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
PLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
PLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
PLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
PLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM / (PLL_REGN + 1)] × CLKINP(MHz) / 256 }
PLLCTRL_SATA.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

27.1.5 SATA PHY Subsystem Low-Level Programming Model

Table 27-7 summarizes the low-level programming sequence to set up the SATA PHY subsystem for SATA I/O operations.

Table 27-7. SATA PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low-performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.SATA_REF_GFCLK.	See Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK clock to enable the OCP2SCP3 interface adapter operation.	See Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP3 and poll until soft reset completion is indicated in status.	See Section 27.1.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the PLLCTRL_SATA.	See Section 27.1.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	. See Section 27.1.4.1.After this step user is ready to access PLLCTRL_SATA .
7.	Configure DPLL_SATA to generate frequency (CLKDCOLDO) = 1.5 GHz.	See Section 27.1.4.3.7.2 and Table 27-8.
8.	Soft assert bit PLLCTRL_SATA.PLL_GO[0] PLL_GO to 0x1.	Start the DPLL lock with desired parameters.
9.	Poll PLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit until it is seen 1.	DPLL locked event
10.	Perform a SATA_PHY tuning required for SATA i/f operation	Follow steps described in Table 27-9, *SATA PHY Tuning Table*.
11.	Software trigger the SATA_PHY_TX power-up sequence.	For more details, see Section 27.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.
12.	Software trigger the SATA_PHY_RX power-up sequence.	For more details, see Section 27.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.

Table 27-8. DPLL CLKDCOLDO Recommended Settings

Parameter	Setting				
F(CLKDCOLDO) MHz	1500				
SYS_CLK (MHz)	12	16.8	19.2	26	38.4
N	4	6	7	12	15
SELFREQDCO[2:0]	100	100	100	100	100
M	625	625	625	750	625
Frac	0	0	0	0	0
SD	6	7	6	6	6

Table 27-9. SATA PHY Tuning Table

Physical address[1] [bits to modify]	Preferred value setting[2]
0x4A09 600C [31:27]	**0b01000** for SATA 1.5 Gbps mode **0b00100** for SATA 3 Gbps mode
0x4A09 600C [17:14]	**0b1010** for SATA-Gen1x and SATA-Gen2x **0b0101** for SATA-Gen1m and SATA-Gen2m
0x4A09 6028 [23:19]	**0b11100** if spread-spectrum is ON. **0b00001** if spread-spectrum is OFF.
0x4A09 6028 [18:11]	**0b01100110**(regardless of spread-spectrum being ON or OFF)
0x4A09 6028 [28:26]	**0b011** for 1.5 Gbps with 1.5GHz PLL clock (PLL_CLK) **0b001** for 3 Gbps with 1.5GHz PLL clock (PLL_CLK)
0x4A09 600C [6:5]	**0b00**, for **3Gbps** @ PLL_CLK = 1.5GHz by DPLL_SATA output with 0x4A09 6028 [28:26] being set to **'0b001'**. **0b00** applies also for **1.5Gbps** @PLL_CLK=1.5GHz by DPLL_SATA output with 0x4A09 6028 [28:26] being set to **'0b011'**.
0x4A09 601C [31:30]	**0b01**
0x4A09 6024 [31:30]	**0b10**, assuming PLL_CLK=1.5GHz in both SATA 1.5Gbps and SATA 3Gbps speed modes
0x4A09 6038 [31:16]	**0x0000**
0x4A09 6038 [15:7]	**0b111110000**
0x4A09 6038 [2:1]	**0b11**
0x4A09 6044 [10:9]	**0b00**

(1) Accesses to these locations have to be done in 32-bits only. User must NOT modify SATA PHY bits different than those described in Table 27-9.

(2) These are the preferred settings of SATA_PHY, in case that SATA PHY PLL_CLK=1.5 GHz.

27.2 USB3 PHY Subsystem

This chapter describes the features and functions of the USB3 PHY subsystem of the device.

27.2.1 USB3 PHY Subsystem Overview

The USB3.0 physical layer (PHY) is responsible for transmitting the USB_OTG_SS controller media access layer (MAC) 32-bit parallel data output as a serial data stream over a differential pair (TXP/TXN) and converting the differentially received serial data (RXP/RXN) to 32-bit parallel input data demanded by the MAC receiver logic.

The USB3 PHY component operates with a 2.5 GHz-source clock, to achieve the USB 3.0 super-speed throughput of 5 Gbps. The USB3 PHY serializer/deserializer source clock is generated by a DPLL clock generator (DPLL_USB_OTG_SS) which isintegrated into the USB_OTG_SS host subsystem.

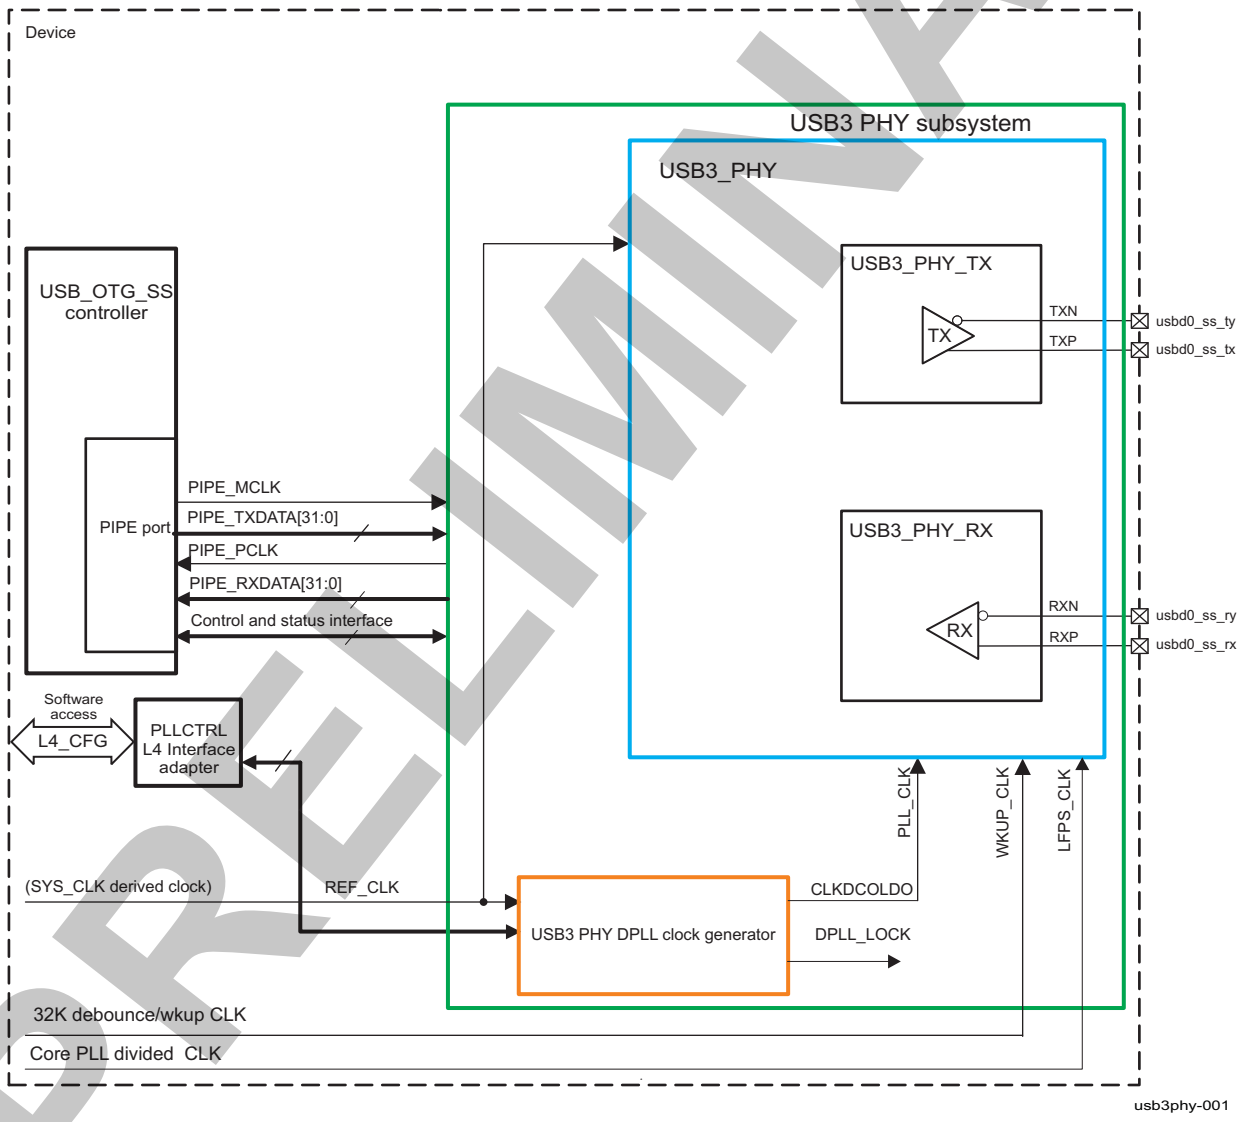
The DPLL_USB_OTG_SS is configured and controlled through the USB3 PHY dedicated PLL controller (PLLCTRL_USB_OTG_SS) with associated serial configuration port (SCP) accessible registers.

A common interconnect adapter component, OCP2SCP1, lets the user program the PLLCTRL_USB_OTG_SS component through the L4_CFG interconnect.

NOTE: The system of components (USB3_PHY_RX, USB3_PHY_TX, DPLL_USB_OTG_SS, PLLCTRL_USB_OTG_SS, and OCP2SCP1) is signified as the USB3 PHY subsystem throughout this chapter. This subsystem is responsible for PHY components clock generation and physical layer transmission/reception within the device USB3 PHY subsystem.

Figure 27-8 gives an overview of the USB3 PHY subsystem. Figure 27-8 shows that the USB3 PHY serializer and deserializer directly interract with the attached to USB OTG SS controller USB3.0 compatible device (over TXP/TXN transmission and RXP/RXN reception interface I/Os). The PIPE port interracts with the USB_OTG_SS MAC port, described in details in Section 23.11, *Super-Speed USB OTG Subsystem*.

Figure 27-8. USB3 PHY Subsystem Overview



27.2.2 USB3 PHY Subsystem Environment

27.2.2.1 USB3 PHY I/O Signals

Table 27-10 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

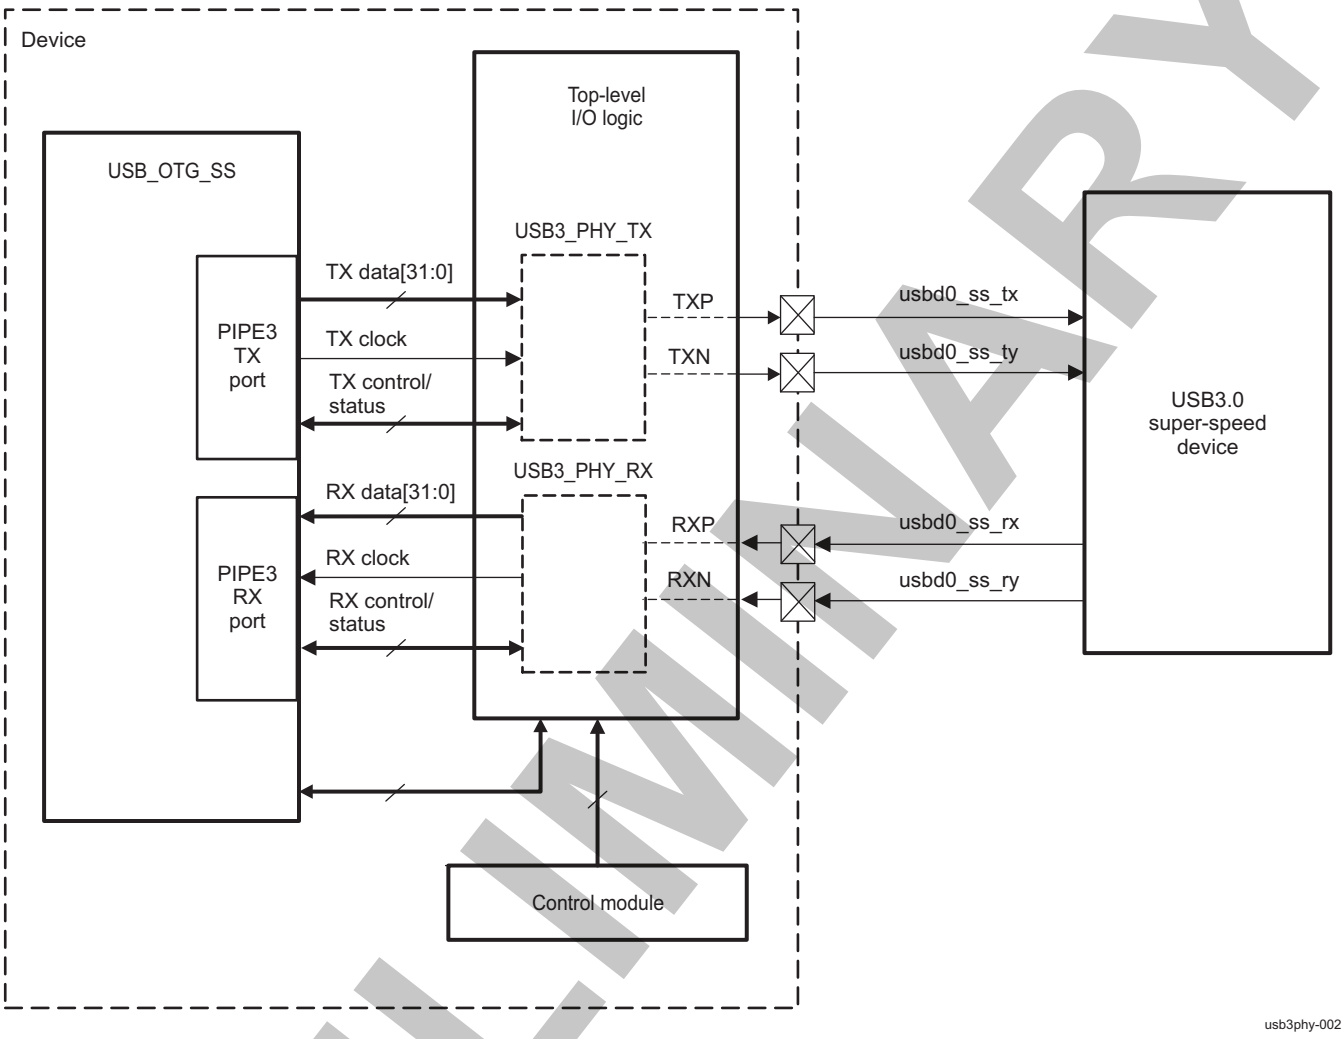
Table 27-10. USB3 PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O[1]	Description	Module Pin Reset Value[2]
TXP[3]	usbd0_ss_tx	O	TX output of the USB3 PHY differential transmission line	0
TXN[3]	usbd0_ss_ty	O	TY output of the USB3 PHY differential transmission line	0
RXP[3]	usbd0_ss_rx	I	RX input of the USB3 PHY differential reception line	HiZ
RXN[3]	usbd0_ss_ry	I	RY input of the USB3 PHY differential reception line	HiZ

(1) I = Input; O = Output
(2) HiZ = High impedance
(3) The USB3 PHY signals that implement the physical interface with an external USB3 storage device

Figure 27-9 shows module pin signals mapping to USB3 PHY signals visible at the device pad level.

Figure 27-9. USB3 PHY I/O Signals



NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and can be programmed in the control module registers. For more information, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, and *Section 18.4.12.7.5, Device Interfaces Signal Group Controls Mapping*, in Chapter 18, *Control Module*.

27.2.3 USB3 PHY Subsystem Integration

This section describes the USB3 PHY subsystem-related components (USB3_PHY module, DPLL_USB_OTG_SS, PLLCTRL_USB_OTG_SS, and OCP2SPC1) integration in the device, including information about clocks, resets, and hardware requests.

Figure 27-10 shows the USB3 PHY integration.

The USB3 PHY module integration features:

- A low-power nonretention reset, L3INIT_RST
- A high-frequency input clock (PLL_CLK) tied to the DPLL_USB_OTG_SS.CLKDCOLDO output
- A local port connected to the USB_OTG_SS MAC PIPE3 port
- A clock output (PIPE_PCLK) to the USB_OTG_SS PIPE port
- A clock output (PIPE_MCLK) from the USB_OTG_SS PIPE port
- A common clock from PRCM - REF_CLK, to supply DPLL and PHY RX / TX logic
- PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock tied to the USB3_PHY_TX
- A device CORE CONTROL MODULE command port to the power sequencer

The DPLL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- A PRCM gated version of the device SYS_CLK (USB_OTG_SS_REF_CLK) supplying DPLL_USB_OTG_SS.CLKINP pin
- A single high-frequency clock output, DPLL_USB_OTG_SS.CLKDCOLDO, to the PLL_CLK input of the USB3 PHY TX/RX components.
- No HS divider integration
- IDLE signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK LOCKED status indication

The PLLCTRL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface also providing the input SCP clock to the PLLCTRL_USB_OTG_SS
- Configuration/control programming interface to the DPLL_USB_OTG_SS
- No direct gate control for DPLL_USB_OTG_SS.CLKINP and CLKDCOLDO

Figure 27-10. USB3 PHY Subsystem Integration

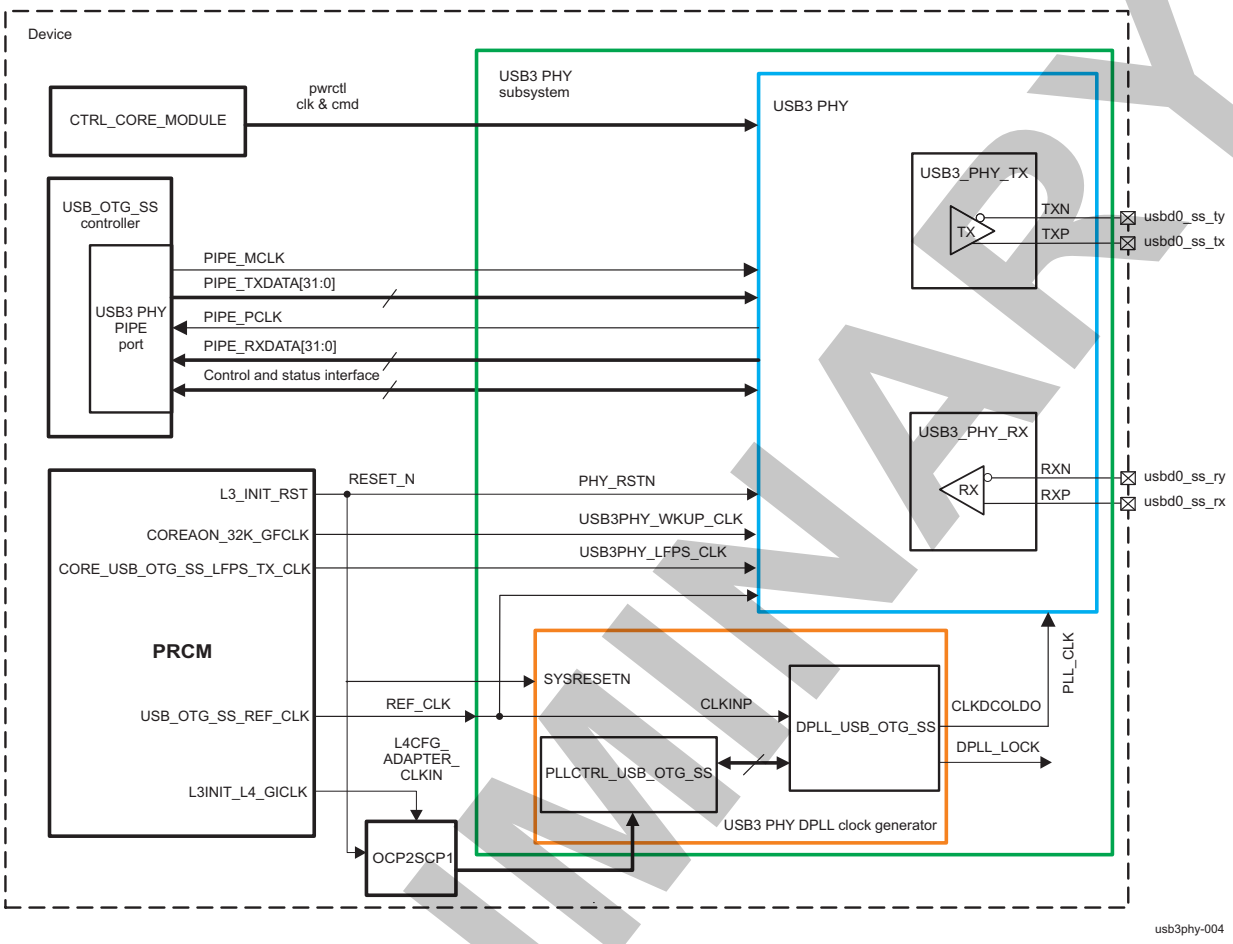


Table 27-11 through Table 27-13 summarize the integration of the module in the device.

Table 27-11. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PLLCTRL_USB_OTG_SS DPLL_USB_OTG_SS	PD_L3INIT	OCP2SCP1 adapter SCP interconnect
OCP2SCP1		L4_CFG

27.2.4 USB3 PHY Subsystem Functional Description

27.2.4.1 USB3 PHY Subsystem Block Diagram

27.2.4.2 Super-Speed USB PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP1), allows user software to configure the PLLCTRL_USB_OTG_SS registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the PLLCTRL_USB_OTG_SS.

Before initiating any software reset to this adapter, a value >= 0x6 should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP1. The smart-idle mode supported by OCP2SCP1 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP1 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the PLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

27.2.4.3 USB3 PHY Serializer and Deserializer Functional Descriptions

27.2.4.3.1 USB3 PHY Module Resets

27.2.4.3.1.1 Hardware Reset

The USB3 PHY active low reset which is sourced from PRCM module. L3INIT_RST is hardware-asserted upon power up. For more information on the hardware reset source , see Section 3.5.4, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

27.2.4.3.1.2 Software Reset

The USB3 PHY PIPE i/f logic is software reset from USB_OTG_SS over PIPE port by software assertion of the USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST bit to 0x1. The user must set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1 before triggering the serializer and deserializer power-up sequence in the CTRL_MODULE_CORE.CONTROL_PHY_POWER_USB register. For more information on power-up sequence, see Section 27.2.4.3.3.1, *USB3 PHY Power-Up/Down Sequences*.

The user should deassert USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0, after the serializer and deserializer power-up sequence completes. For more information, see Section 27.2.4.3.3.1, *USB3 PHY Power-Up/Down Sequences*.

27.2.4.3.2 USB3 PHY Subsystem Clocking

27.2.4.3.2.1 USB3 PHY Subsystem Input Clocks

The USB3 PHY component receives a feedback clock, PIPE_MCLK, which is the reflected version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the USB3 PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The USB3_PHY.PLL_CLK high-speed transmission (2.5 GHz) clock input pin is connected to the DPLL_USB_OTG_SS clock output, CLKDCOLDO. For more information on the DPLL_USB_OTG_SS.CLKDCOLDO output clock settings, see Section 27.2.4.4.4.2, *USB3 PHY DPLL Output Clock Configuration*.

As shown in Figure 27-11, the same PRCM-sourced clock (USB_OTG_SS_REF_CLK), tied at the USB3 PHY subsystem REF_CLK input, supplies the USB3 PHY RX/TX components and the DPLL_USB_OTG_SS.CLKINP inputs.

The PHY associated power sequencer receives PRCM.USB_OTG_SS_REF_CLK as a functional clock. Software must notify the PHY logic about which REF_CLK frequency is selected by writing the CTRL_MODULE_CORE.CONTROL_PHY_POWER_USB[31:22] USB_PWRCTL_CLK_FREQ bit field, as follows:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

The USB3PHY_LFPS_CLK clock input is used to support different USB3_PHY functions, such as the low-frequency periodic signaling (LFPS) generator. This USB3_PHY_TX clock input is tied to the PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK functional clock.

The USB3_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.COREAON_32K_GFCLK clock (SCRM.SYS_32K based), applied at the USB3PHY_WKUP_CLK input.

27.2.4.3.2.2 USB3 PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the USB3_PHY component, used to synchronize USB_OTG_SS PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the USB_OTG_SS MAC layer is synchronous to this clock.

The PIPE_PCLK clock which drives the PIPE3 logic is sourced by the on-chip USB3_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize USB_OTG_SS PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the USB3_PHY power control port. For more details, see Section 27.2.4.3.3, *USB3 PHY Power Management*.

27.2.4.3.3 USB3 PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a power sequencer module tightly integrated with the the USB3_PHY physical layer TX/RX components.

27.2.4.3.3.1 USB3 PHY Power-Up/-Down Sequences

Powering-up/-down the USB3_PHY_TX and USB3_PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_MODULE_CORE. CONTROL_PHY_POWER_USB register of the device core control module, as follows:

- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x0 (default value) commands both USB3_PHY_TX and USB3_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x1 powers up the USB3_PHY_RX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x2 powers up the USB3_PHY_TX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x3 simultaneously powers up the USB3_PHY_RX and the USB3_PHY_TX

For more information, see Chapter 18, *Control Module*.

27.2.4.3.3.2 USB3 PHY Low-Power Modes

An implemented powerdown control port allows USB3_PHY to support four low-power states:

- 0b00: P0, normal operation (used for all Polling, Configuration, Recovery, Loopback, and Hot_Reset states, and U0 state),
- 0b01: P1, low recovery time latency, power saving state (used for U1 state)
- 0b10: P2, longer recovery time latency, lower power state (used for U2, Rx.Detect and SS.Inactive states)
- 0b11: P2, lowest power state (used for SS.disabled and U3)

The USB3_PHY transitions from P0-active mode to low-power P1, or either of the two P2 states, is synchronized with USB_OTG_SS transitions from U0 active state to U1, U2, and U3 low-power states through the input PIPE_POWERDOWN[1:0]. The PIPE port low-power behavior is configured from various bit fields inside the USB_OTG_SS.USBOTGSS_GUSB3PIPECTL register. For more information on PIPE port low-power (LP) configuration, see Section 23.11.5.2.2, *DWC_USB3 Register Description* in Section 23.11, *Super-Speed USB OTG Subsystem*.

27.2.4.3.3.3 Clock Gating

The USB3_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P1 low-power state.

27.2.4.3.4 USB3 PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the USB3_PHY_RX I/Os (RXP, RXN). When the wake-up request is acknowledged, the DPLL_USB_OTG_SS and PIPE_PCLK are restarted.

Neither interrupt nor DMA requests are generated.

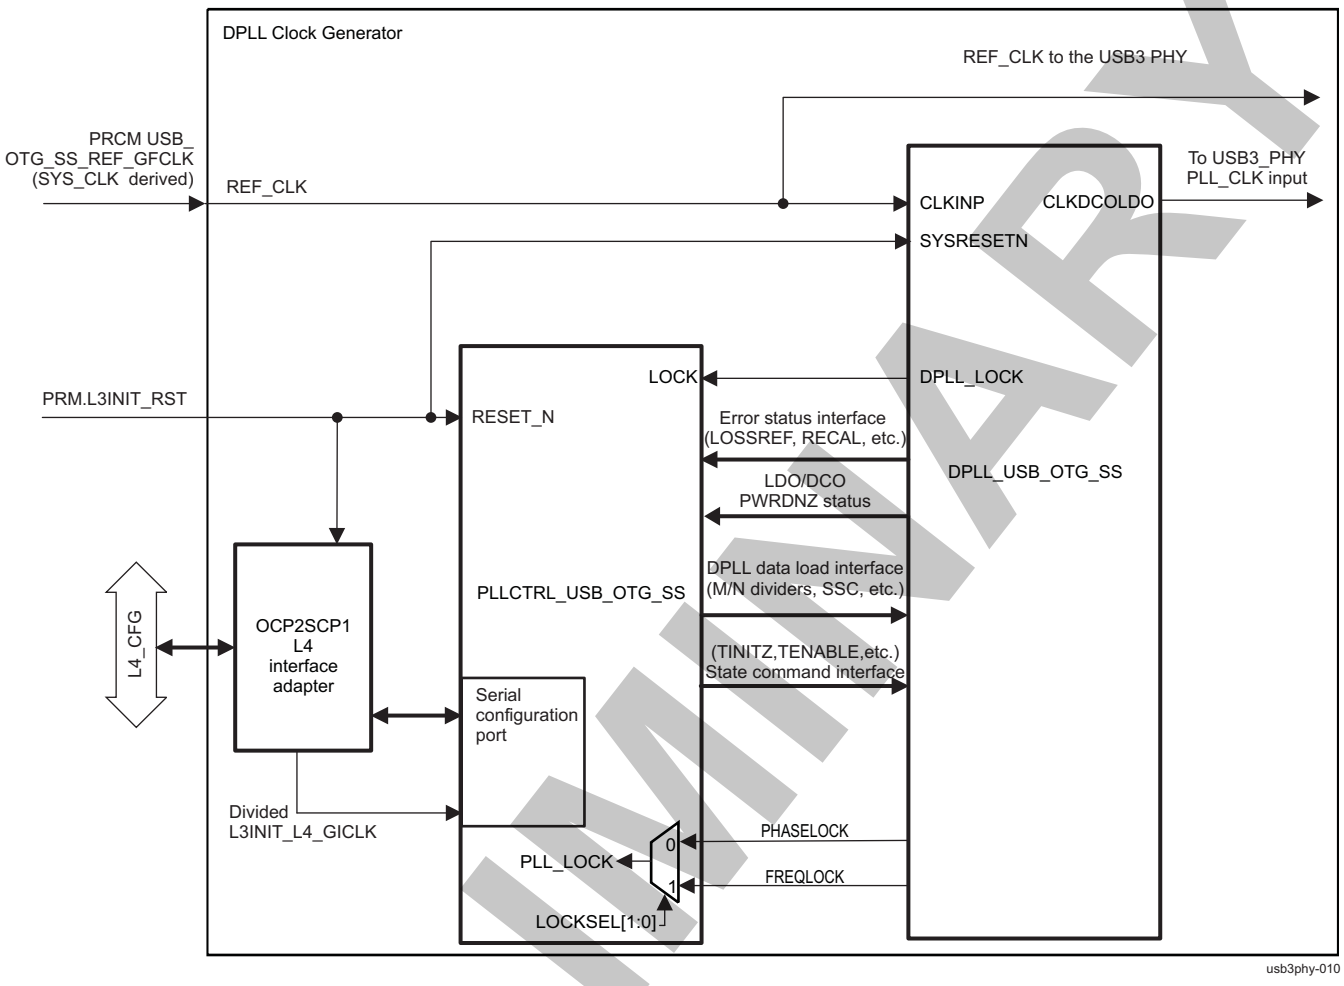
27.2.4.4 USB3 PHY Clock Generator Subsystem Functional Description

The DPLL_USB_OTG_SS, which is located outside the PRCM boundaries and is part of the USB_OTG_SS controller subsystem, directly injects a high-speed clock into the USB3_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, PLLCTRL_USB_OTG_SS.

27.2.4.4.1 USB3 PHY DPLL Clock Generator Overview

The SCP interface of the USB3 PHY PLL controller (PLLCTRL_USB_OTG_SS instance) is used to set the configuration of the DPLL modules, primarily the various counter values. Figure 27-11 is an overview of the DPLL clock generator embedded into the USB_OTG_SS controller subsystem.

Figure 27-11. USB3 PHY DPLL Clock Generator Overview



NOTE: The PLLCTRL_USB_OTG_SS module is user accessible on the L4_CFG interconnect. However, to make access possible, the user should take care to configure the OCP2SCP1 instance before accessing the PLLCTRL_USB_OTG_SS registers.

The DPLL_USB_OTG_SS features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock SSC (spread spectrum clocking) support
- No retention capabilities
- No Idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The PLLCTRL_USB_OTG_SS components features:

- DPLL error and status notification
- DPLL initialization and configuration

- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation
- Automatic enable/disable control, synchronized with USB_OTG_SS controller PIPE port commands to set USB3_PHY to P1, P2, and P3 low-power states

27.2.4.4.2 USB3 PHY DPLL Clock Generator Reset

The USB3 PHY PLL controller and USB3 PHY DPLL clock generator share a common hardware nonretention reset, L3INIT_RST, which comes from the device power and reset manager. Upon DPLL_USB_OTG_SS hardware reset completion, the PLLCTRL_USB_OTG_SS.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see Section 3.5.4, *Reset Domains* in Chapter 3, *Power, Reset, and Clock Management*.

The PLLCTRL_USB_OTG_SS itself has no software reset capabilities.

PLLCTRL_USB_OTG_SS performs a software reset sequence on the DPLL_USB_OTG_SS in hardware (through the TINITZ signal activation).

27.2.4.4.3 USB3 PHY DPLL Low-Power Modes

The power-management port (PMP) is not integrated for PLLCTRL_USB_OTG_SS. The DPLL_USB_OTG_SS has no retention capabilities. This means, the DPLL digital power supply remains switched on during all modes of operation.

The low-power modes supported by DPLL_USB_OTG_SS are Idle-bypass low-power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter Idle-bypass and MN-bypass low-power modes, see Section 27.2.4.4.6.4, *USB3 PHY DPLL Idle-bypass low-power Mode* , and Section 27.2.4.4.6.5, *USB3 PHY DPLL MN-Bypass Mode*.

DPLL_USB_OTG_SS is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after Power-up Reset, before first PLL_GO command has been software triggered on the PLL controller. See Section 27.2.4.4.6.1, *USB3 PHY Clock Generator Power Up*.

27.2.4.4.4 USB3 PHY DPLL Clocks Configuration

27.2.4.4.4.1 USB3 PHY DPLL Input Clock Control

The DPLL_USB_OTG_SS accepts the functional clock, USB_OTG_SS_REF_CLK, on its CLKINP pin (REF_CLK input at USB3 PHY subsystem level) directly from the device SCRM, without involving any PLLCTRL_USB_OTG_SS interractions. The USB_OTG_SS_REF_CLK is derived from SCRM.SYS_CLK. See Section 3.6.4.5, *Clock Domain Module Attributes* in Chapter 3, *Power, Reset, and Clock Management*.

If the CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to PLLCTRL_USB_OTG_SS, is asserted high. When CLKINP resumes, LOSSREF goes low (LOSSREF inactive state). The LOSSREF status signal can be software-monitored in the PLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit.

NOTE: PLLCTRL_USB_OTG_SS has no software or hardware mechanisms to control DPLL_USB_OTG_SS input clock (CLKINP).

27.2.4.4.4.2 USB3 PHY DPLL Output Clock Configuration

Only the DPLL_USB_OTG_SS output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the USB3 PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done through programming the PLLCTRL_USB_OTG_SS.PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9], PLL_REGM, PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1], PLL_REGN, and PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The USB3 PHY DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

NOTE: At DPLL/PLLCTRL integration level the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are hardware tie-off to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 27.2.4.4.7.2, *USB3 PHY DPLL Clock Programming Sequence*.

27.2.4.4.4.2.1 USB3 PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_USB_OTG_SS.CLKDCOLDO output.

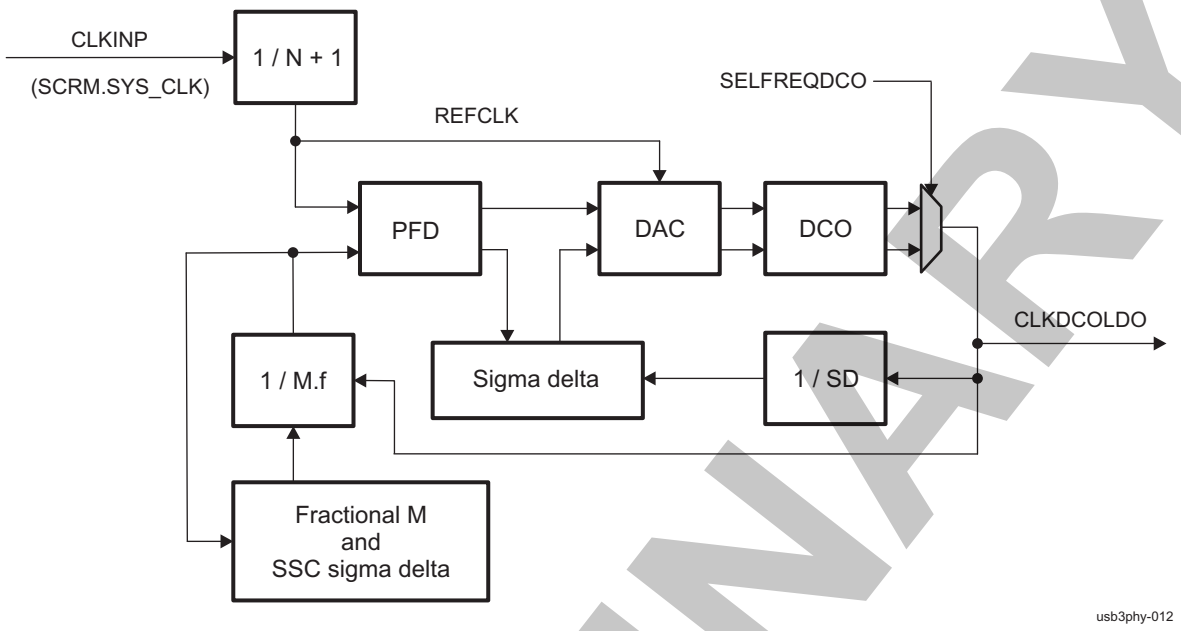
DPLL_USB_OTG_SS.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

- DPLL power-up sequence. For more information on power-up sequence, see Section 27.2.4.4.6.1, *USB3 PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 27.2.4.4.6.2, *USB3 PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 27.2.4.4.6.4, *USB3 PHY DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 27.2.4.4.6.5, *USB3 PHY DPLL MN-Bypass Mode*.

27.2.4.4.5 USB3 PHY DPLL Subsystem Architecture

Figure 27-12 is a simplified block diagram of the DPLL_USB_OTG_SS instance integration in the USB3 PHY clock generator subsystem.

Figure 27-12. DPLL_USB_OTG_SS Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_USB_OTG_SS input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP / N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP×M / (N + 1). For that purpose the feedback multiplier M must be configured through the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_USB_OTG_SS module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported, thus enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division, Fractional M should be set to 000…0.

NOTE: Fractional synthesis is not supported for M>4093.

The module also supports SSC on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm); that is, {10×log10(df/fm)} dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df); that is, $dM/M = df/F_{OUT}$.

Because this is in-band modulation for the DPLL_USB_OTG_SS, the modulation frequency must be within the loop bandwidth of the DPLL. A higher modulation frequency would result in less spreading in the output clock.

The SSC can be enabled and disabled by asserting the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the PLLCTRL_USB_OTG_SS.PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value programmed in the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK/(4×fm).The ModFreqDivider is split into Mantissa and $2^{Exponent}$ (ModFreqDivider = ModFreqDividerMantissa × $2^{ModFreqDividerExponent}$).

- The Mantissa is controlled by bits [29:23] of the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), dM must be controlled as previously explained. To define dM, the step size of M for each REFCLK during the triangular pattern must be programmed.This is defined as follows:

- dM =($2^{ModFreqDividerExponent}$) × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent <= 3
- dM = 8 × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent > 3

DeltaMStep value is split into integer part and fractional part, as follows:

- The MSB of 3-bit integer part, DeltaMStepInteger, is controlled by the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[30] DELTAM2 bit and the remaining LSBs by bits [19:18] of the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.
- The 18-bit fractional part, DeltaMStepFraction, is controlled by bits [17:0] of the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.

If the PLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for 20 percent overshot).

27.2.4.4.6 USB3 PHY DPLL Clock Generator Modes and State Transitions

The DPLL_USB_OTG_SS can be set in different modes during operation. PLLCTRL triggers DPLL_USB_OTG_SS state transitions to different static modes by means of the TINITZ and TENABLE hardware control signals.

27.2.4.4.6.1 USB3 PHY Clock Generator Power Up

After power up, the DPLL_USB_OTG_SS.SYSRESETN input is automatically pulled low by the PRM, together with the PLLCTRL_USB_OTG_SS.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_USB_OTG_SS input clock (DPLL_USB_OTG_SS.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence of the CLKINP clock. If CLKINP is present when reset is asserted, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completes. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

27.2.4.4.6.2 USB3 PHY DPLL Sequences

Once all the configuration values have been initially programmed into the PLLCTRL_USB_OTG_SS registers (see Section 27.2.4.4.7.2) , the PLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

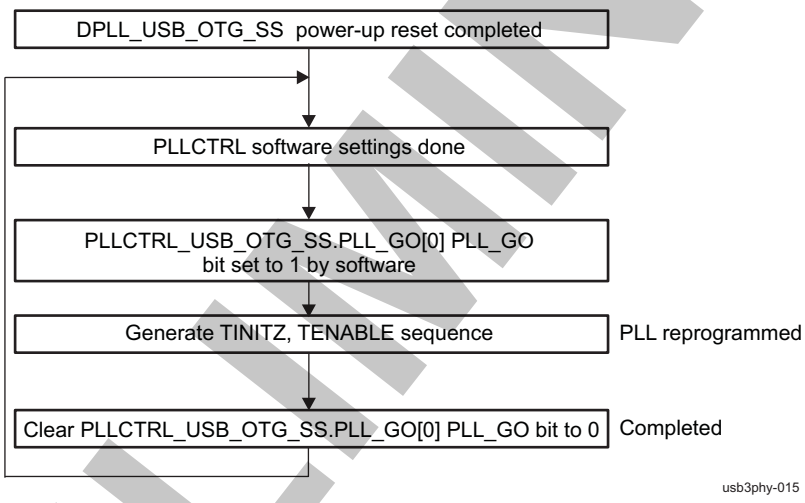
After the PLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit is set high in software, the PLLCTRL_USB_OTG_SS state-machine takes the following action:

1. Sets the TINITZ signal to 0, which acts as a soft reset to DPLL_USB_OTG_SS. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_USB_OTG_SS Initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by PLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the PLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 27-13 summarizes the software and hardware sequences flow of DPLL_USB_OTG_SS.

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

Figure 27-13. USB3 PHY PLL GO Sequence



DPLL_USB_OTG_SS relock sequence:

When the DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting the PLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_USB_OTG_SS enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The PLLCTRL_USB_OTG_SS.PLL_GOUSB3PHY_PLL_GO[0] PLL_GO bit can be used by software to monitor if PLLCTRL locking process is still pending (PLL_GO = 0b1).

27.2.4.4.6.3 USB3 PHY DPLL Locked Mode

When DPLL_USB_OTG_SS finishes calibration and lock sequences it enters a locked state. During the locked state, LOSSREF and BYPASSACK are deasserted, FREQLOCK or PHASELOCK is asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software-selectable through the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL signalizes the locked state to PLLCTRL_USB_OTG_SS, USB_OTG_SS core controller, and USB3 PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the PLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit, which is active high.

27.2.4.4.6.4 USB3 PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_USB_OTG_SS.

DPLL_USB_OTG_SS supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the PLLCTRL_USB_OTG_SS.PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low. Also, the internal reference clock REFCLK = CLKINP / N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, the DPLL_USB_OTG_SS.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0->1 to module initialization. The DCO oscillator exits power-down (TICOPWDN goes low) whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_USB_OTG_SS.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in the period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON and OFF states are reflected within the read-only PLLCTRL_USB_OTG_SS.PLL_STATUS[16] PLL_TICOPWDN and PLLCTRL_USB_OTG_SS.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should write PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal, and DPLL_USB_OTG_SS automatically enters a relock sequence. CLKDCOLDO output clock is activated after the FREQLOCK or the PHASELOCK signal goes high, depending on selected locking criteria.

27.2.4.4.6.5 USB3 PHY DPLL MN-Bypass Mode

The MN-bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

NOTE: When the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO is gated.

27.2.4.4.6.6 USB3 PHY DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss-of-lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The PLLCTRL_USB_OTG_SS.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_USB_OTG_SS must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The PLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit gives the USB3 PHY PLL lock state.
- The PLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit informs whether the

PLLCTRL_USB_OTG_SS has lost the reference clock.

- The PLLCTRL_USB_OTG_SS.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

27.2.4.4.7 USB3 PHY PLL Controller Functions

27.2.4.4.7.1 USB3 PHY PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP1 L4 adapter register space using the SCP interface of the PLLCTRL_USB_OTG_SS. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

NOTE: Because the USB3 PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the USB_OTG_SS MAC controller, the PLLCTRL_USB_OTG_SS and DPLL_USB_OTG_SS must be configured before any data transfer between the USB_OTG_SS controller MAC layer and an external USB3 device.

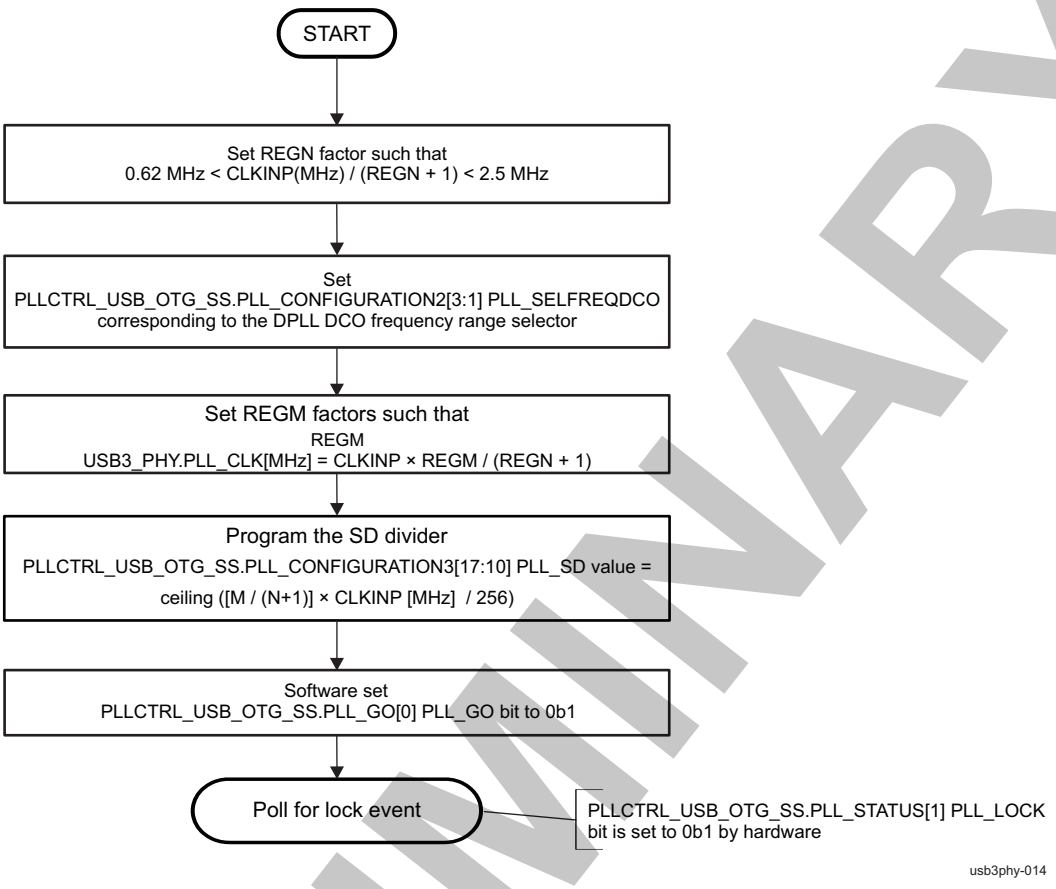
27.2.4.4.7.2 USB3 PHY DPLL Clock Programming Sequence

The DPLL_USB_OTG_SS factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- REGM factor is programmed in the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- Fractional part of REGM factor is programmed in the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- REGN factor is programmed in the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- DCO frequency range is set in the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2 if 500 MHz < CLKDCOLDO [MHz] < 1000 MHz.
  - PLL_SELFREQDCO should be set to 0x4 if 1000 MHz < CLKDCOLDO [MHz] < 2000 MHz.
- SD divider is programmed in the PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO register bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M / (N + 1).

Figure 27-14 shows the formulae and programming sequence.

Figure 27-14. USB3 PHY PLL Programming Sequence



NOTE:

- The equation for USB3_PHY_TX/USB3_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_USB_OTG_SS.
- CLKDCOLDO output frequency of the DPLL_USB_OTG_SS should be programmed to 2.5 GHz, for the super-speed USB (5 Gbps) mode.

Table 27-14 summarizes the registers for the PLLCTRL_USB_OTG_SS programming sequence.

Table 27-14. Register Call Summary for USB3 PHY PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2	PLLCTRL_USB_OTG_SS.PLL_GO	PLLCTRL_USB_OTG_SS.PLL_STATUS	PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3

27.2.4.4.7.3 USB3 PHY DPLL Recommended Values

Table 27-15 lists the DPLL_USB_OTG_SS recommended values.

Table 27-15. Recommended Programming Values

Field Name	Value	Description
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider

(1) The value of the bit field must be set according to the desired clock frequency.

Table 27-15. Recommended Programming Values (continued)

Field Name	Value	Description
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION 2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION 2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION 2[0] PLL_IDLE	0	PLL active
PLLCTRL_USB_OTG_SS.PLL_CONFIGURATION 3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM / (PLL_REGN+1)] × CLKINP(MHz) / 256 }
PLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

27.2.5 USB3 PHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the USB3 PHY subsystem for USB superspeed I/O operations is summarized in the Table 27-16

Table 27-16. USB3 PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.USB_OTG_SS_REF_CLK.	See Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK to enable the OCP2SCP1 interface adapter operation.	See Section 3.6.4.5, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP1 and poll until soft reset completion is indicated in status.	See Section 27.2.4.2.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the PLLCTRL_USB_OTG_SS .	See Section 27.2.4.2.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	See Section 27.2.4.2. After this step, the user is ready to access the PLLCTRL_USB_OTG_SS registers.
7.	Configure DPLL_USB_OTG_SS to generate frequency (CLKDCOLDO) = 2.5 GHz.	See Section 27.2.4.4.7.2.
8.	Software-assert the PLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0x1	Start the DPLL lock with desired parameters.
9.	Poll the PLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit until it reads 1.	DPLL locked event
10.	Perform a USB3_PHY tuning required for the Super-Speed OTG USB i/f operation	Follow steps described in Table 27-17, *USB3 PHY Tuning Table*.
11.	Set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1	Software reset the USB3 PHY over USB OTG SS controller PIPE port. Note that this reset does NOT impact settings made in step 10.
12.	Software-trigger the USB3_PHY_TX power-up sequence.	For more details, see Section 27.2.4.3.3.1.
13.	Software-trigger the USB3_PHY_RX power-up sequence.	For more details, see Section 27.2.4.3.3.1.

Table 27-16. USB3 PHY Subsystem Low-Level Programming Sequence (continued)

Step	Description	Comment
14.	Clear USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0	Deassert the software reset bit after power-up sequence completion is indicated

Table 27-17. USB3 PHY Tuning Table

Physical address[1] [bits to modify]	Preferred value setting[2]
0x4A08 440C [31:27]	**0b10000**
0x4A08 440C [17:14]	**0b1010**
0x4A08 4428 [23:11]	**0b1110001100110**
0x4A08 4428 [28:26]	**0b001**
0x4A08 440C [6:5]	**0b00**
0x4A08 441C [31:30]	**0b10**
0x4A08 4424 [31:30]	**0b11**
0x4A08 4438 [10:7]	**0b1001**
0x4A08 4438 [2]	**0b0**

(1) Accesses to these locations have to be done in 32-bits only. User must NOT modify USB3 PHY bits different than those described in Table 27-17.

(2) These are the preferred settings of USB3_PHY, in case that USB3 PHY PLL_CLK=2.5 GHz.

27.3 USB3 PHY and SATA PHY PLL Controllers Register Manual

This chapter summarizes the SATA and USB3 PHY Subsystems PLL Controller registers

27.3.1 USB3 PHY and SATA PHY PLL Controllers Instance Summary

Initialization

This chapter introduces the steps in the general-purpose (GP) device initialization.

NOTE: Some of the ROM code features, primarily those concerning the device I/O pads, are not available in all OMAP54xx devices.

For details, see Section 1.5, *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

28.1 Initialization Overview

This chapter provides an overview of the requirements to initialize the OMAP™ device from power on to operating system (OS) and application execution, the overall initialization process (including hardware- and software-related steps), the general ROM code operational requirements, and behavior expectations.

28.1.1 Terminology

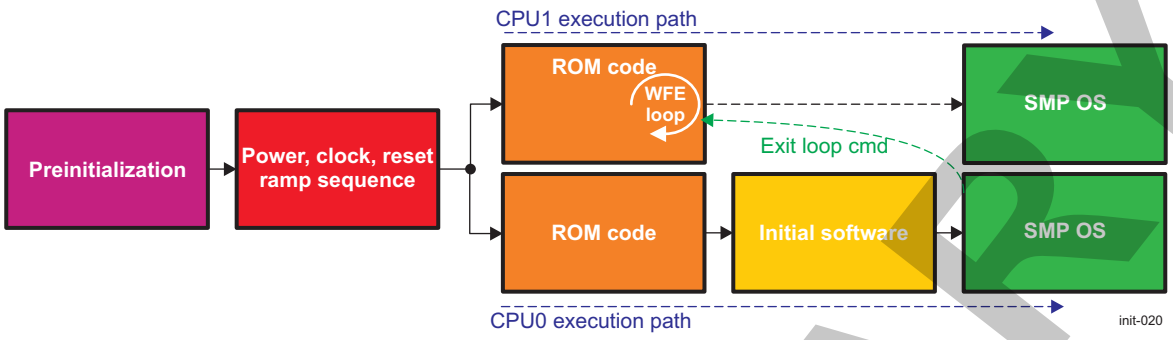
- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure that precedes the initial software and allows the redefinition of the ROM code default settings
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code during the preflashing stage. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The ARM® Cortex™-A15 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after a warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in OMAP ROM that implements booting
- **ROM Code-controlled Boot Phase:** This phase covers the sequence operations from the time the platform releases the reset to the time first user- or customer-owned software starts execution. This phase is fully controlled by the OMAP ROM code.
- **Save-And-Restore (SAR) RAM memory:** On-chip RAM memory that is not cleared after warm resets or wakeups from low-power modes
- **Slave CPU:** The ARM Cortex-A15 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.
- **Software booting configuration:** A logical structure stored in the SAR memory that allows the redefinition of the ROM code default settings when booting after a warm reset

28.1.2 Initialization Process

Figure 28-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding, for downloading, and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

Figure 28-1. Initialization Process



The first two steps in the initialization process are hardware-oriented; however, they require an understanding of the process of configuring these system interface pins (balls on the OMAP device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these system-interface pins and the associated configuration registers that are vital to the correct initialization of the device.

28.2 Preinitialization

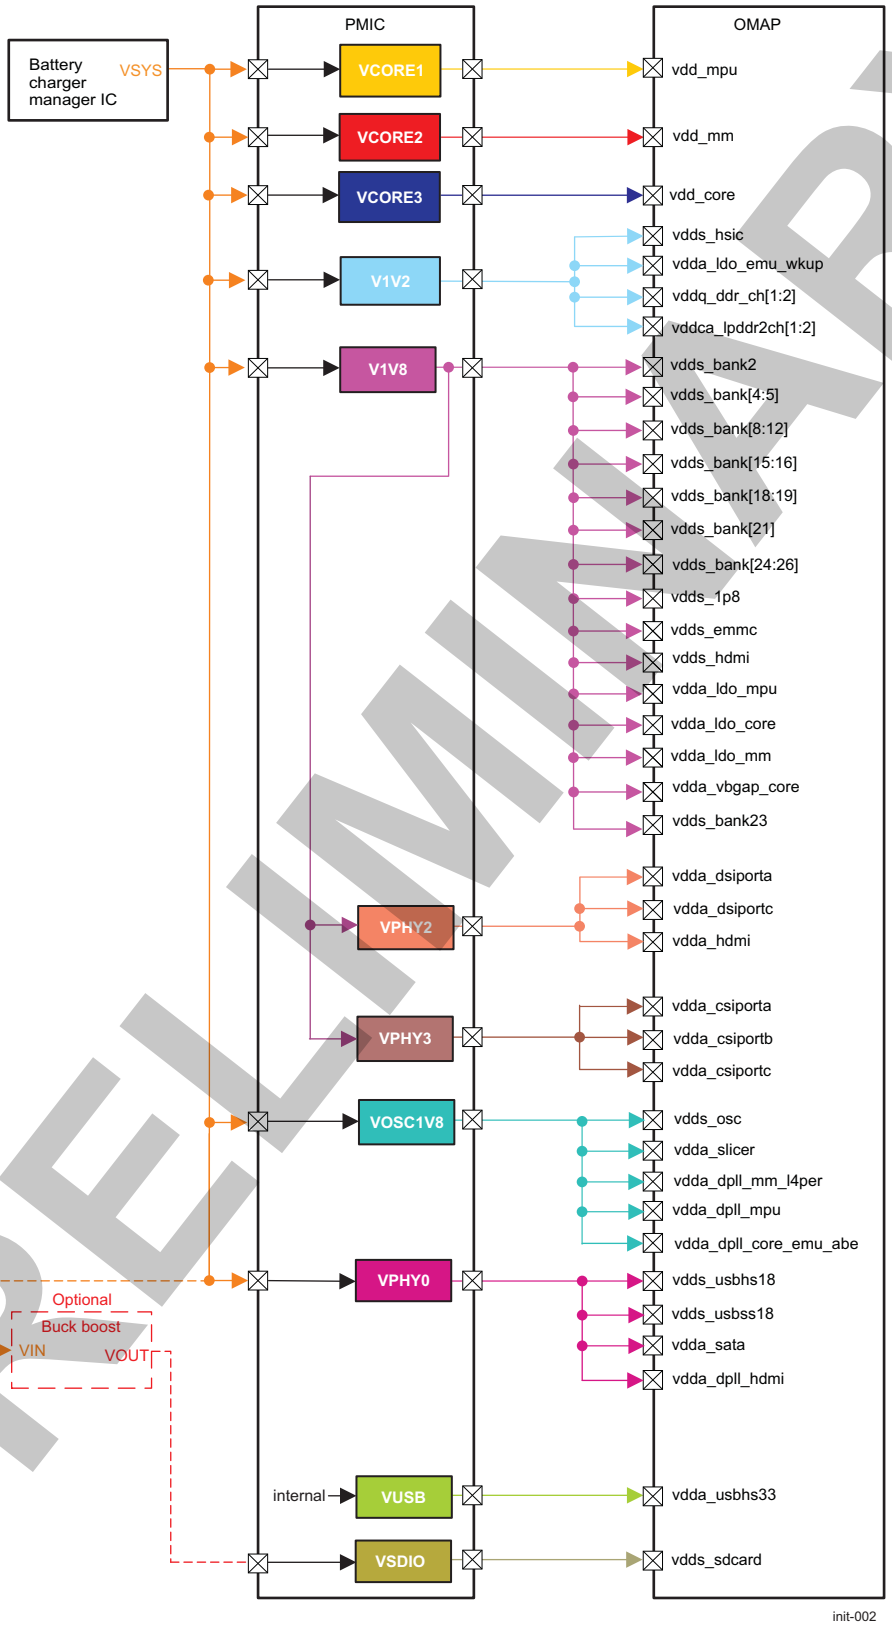
To accomplish a successful boot-up operation with an OMAP GP device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly to successfully initialize the device. The following sections describe the specific requirements for the preinitialization stage.

28.2.1 Power Requirements

The OMAP device can be supplied by an external power-management integrated circuit (PMIC). TI provides a global solution with the OMAP device connected to the power-management and audio-management IC companion chips.

Figure 28-2 shows the power connections between OMAP and the PMIC companion chip.

Figure 28-2. Power Supply Connections



NOTE: Figure 28-2 is an example of power connections between the OMAP device and the PMIC. These connections depend on the actual application.

Table 28-1 describes the device power balls.

Table 28-1. OMAP Power Balls (1)

Voltage Ball Name	Power Supplied OMAP Internal Modules and Peripherals
vdd_core	OMAP subsystems and modules supplied in CORE voltage domain
vdd_mpu	• MPU subsystem
vdd_mm	• IVA subsystem • DSP subsystem • GPU subsystem
vdda_ldo_emu_wkup	• Wakeup • Emulation subsystem
vddq_ddr_ch1	EMIF channel 1 DQ I/Os (OMAP side only)
vddq_ddr_ch2	EMIF channel 2 DQ I/Os (OMAP side only)
vddq_vref_ddrch1	Supplies VDDQ_VREF generator for EMIF channel 1
vddq_vref_ddrch2	Supplies VDDQ_VREF generator for EMIF channel 2
vddca_lpddr2ch1	EMIF channel 1 CA I/Os (OMAP side only)
vddca_lpddr2ch2	EMIF channel 2 CA I/Os (OMAP side only)
vddca_vref_lpddr2ch1	Supplies VDDCA_VREF generator for EMIF channel 1
vddca_vref_lpddr2ch2	Supplies VDDCA_VREF generator for EMIF channel 2
vdds_hsic	USBB1, USBB2, USBB3 HSIC I/Os
vdda_dsiporta	DSI Port A lanes (dual-votage I/Os)
vdda_dsiportc	DSI Port C lanes (dual-votage I/Os)
vdda_hdmi	HDMI dual-votage I/Os
vdda_csiporta	CSI Port A lanes (dual-votage I/Os)
vdda_csiportb	CSI Port B lanes (dual-votage I/Os)
vdda_csiportc	CSI Port C lanes (dual-votage I/Os)
vdda_dpll_mm_l4per	Analog power supply for the DPLL_IVA and DPLL_PER
vdda_dpll_mpu	Analog power supply or the DPLL_MPU
vdda_dpll_core_emu_abe	Analog power supply fot the DPLL_CORE, DPLL_DEBUGSS, and DPLL_ABE
vdda_dpll_hdmi	Analog power supply for the DPLL_HDMI
vdda_ldo_mpu	Analog power supply for the OMAP internal MPU LDOs
vdda_ldo_core	Analog power supply for the OMAP internal CORE LDOs
vdda_ldo_mm	Analog power supply for the OMAP internal MM LDOs
vdda_vbgap_core	Analog power supply for the OMAP BANDGAPTS_CORE
vdda_usbhs33	Analog power supplies for the high speed (HS) USB I/Os
vdda_usbhs18	
vdda_usbss18	Analog power supply for SuperSpeed (SS) USB I/Os
vdda_sata	Analog power supply for SATA I/Os
vdds_sdcard	MMC1 module I/Os (SD™ card I/Os)
vdds_bank2	Bank of I/Os: HSI1, UART1 (dual-votage)
vdds_bank4	Bank of I/Os: HSI2, UART2 (dual-votage)
vdds_bank5	Bank of I/Os: TIMER9, TIMER10, DSIPORT B, DSIPORT C I/Os (dual voltage)
vdds_bank8	Bank of I/Os: MCSPI2, I2C4 (dual voltage)
vdds_bank9	Bank of I/Os: RFBI, GPIO6 (dual voltage)

(1) The package-on-package (POP) OMAP device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. Based on memory requirements, the device must provide the correct power supply to the feedthroughs.

Table 28-1. OMAP Power Balls [(1)] (continued)

Voltage Ball Name	Power Supplied OMAP Internal Modules and Peripherals
vdds_bank10	Bank of I/Os: TCTRL, TIMER5, TIMER6, TIMER8, TIMER11, I2C3, GPIO8 (dual voltage)
vdds_bank11	Bank of I/Os: ABE clocks, MCBSP2, MCPDM (dual voltage)
vdds_bank12	Bank of I/Os: DMIC (dual voltage)
vdds_bank15	Bank of I/Os: MMC3 module I/Os -("WLSDIO" dual-votage I/Os)
vdds_bank16	Bank of I/Os: UART5, I2C2 (dual voltage)
vdds_bank18	Bank of I/Os: MCSPI1, I2C5 (dual voltage)
vdds_bank19	Bank of I/Os: GPIO5 (dual voltage)
vdds_bank21	Bank of I/Os: UART6, UART3 (dual voltage)
vdds_bank23	Bank of I/Os: JTAG®
vdds_bank24	Bank of I/Os: System interface
vdds_bank25	Bank of I/Os: System interface (dual voltage)
vdds_bank26	Bank of I/Os: System interface, SmartReflex™ PMIC I^2C, I2C1 PMIC interface (dual voltage)
vdds_osc	F_{REF} XTAL oscillator (system interface I/Os)
vdda_slicer	F_{REF} slicer oscillator (system interface I/Os)
vdds_emmc	MMC2 module I/Os (eMMC I/Os)

For a complete description of the power balls on the OMAP package, see the *Device Data Manual*. For more information about power management, see Section 3.6 *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: The OMAP device package restricts the physical connection to only one memory type: LPDDR2 or DDR3. See more details about OMAP device family and packaging in Section 1.1, *Overview*, in Chapter 1, *Introduction*.

28.2.2 Interraction With the PMIC Companion

The ROM code does not perform any I^2C transactions with the PMIC. The following system conditions must be met to perform OMAP device initialization:

- The USB transceivers (USB2.0 and USB3.0 PHYs), internal to OMAP, are powered on any cold and warm reset, as expected by the USB peripheral booting feature.
- The SD card cage must be appropriately powered before entering the SD card boot feature on any cold and warm reset.
- The attached external SATA drive must be appropriately powered before entering the SATA boot feature on any cold and warm reset.

NOTE: In the OMAP device, the ROM code does not interact with the PMIC companion chip over the I^2C interface.

28.2.3 Clock, Reset, and Control

28.2.3.1 Overview

Figure 28-3 shows the clock and reset environment where clocks and reset-related signals are gathered at the system level, the system-expansion signals, and the crystal oscillator connection scenario applicable to all OMAP devices.

Figure 28-3. Clock, Reset, and Control Environment

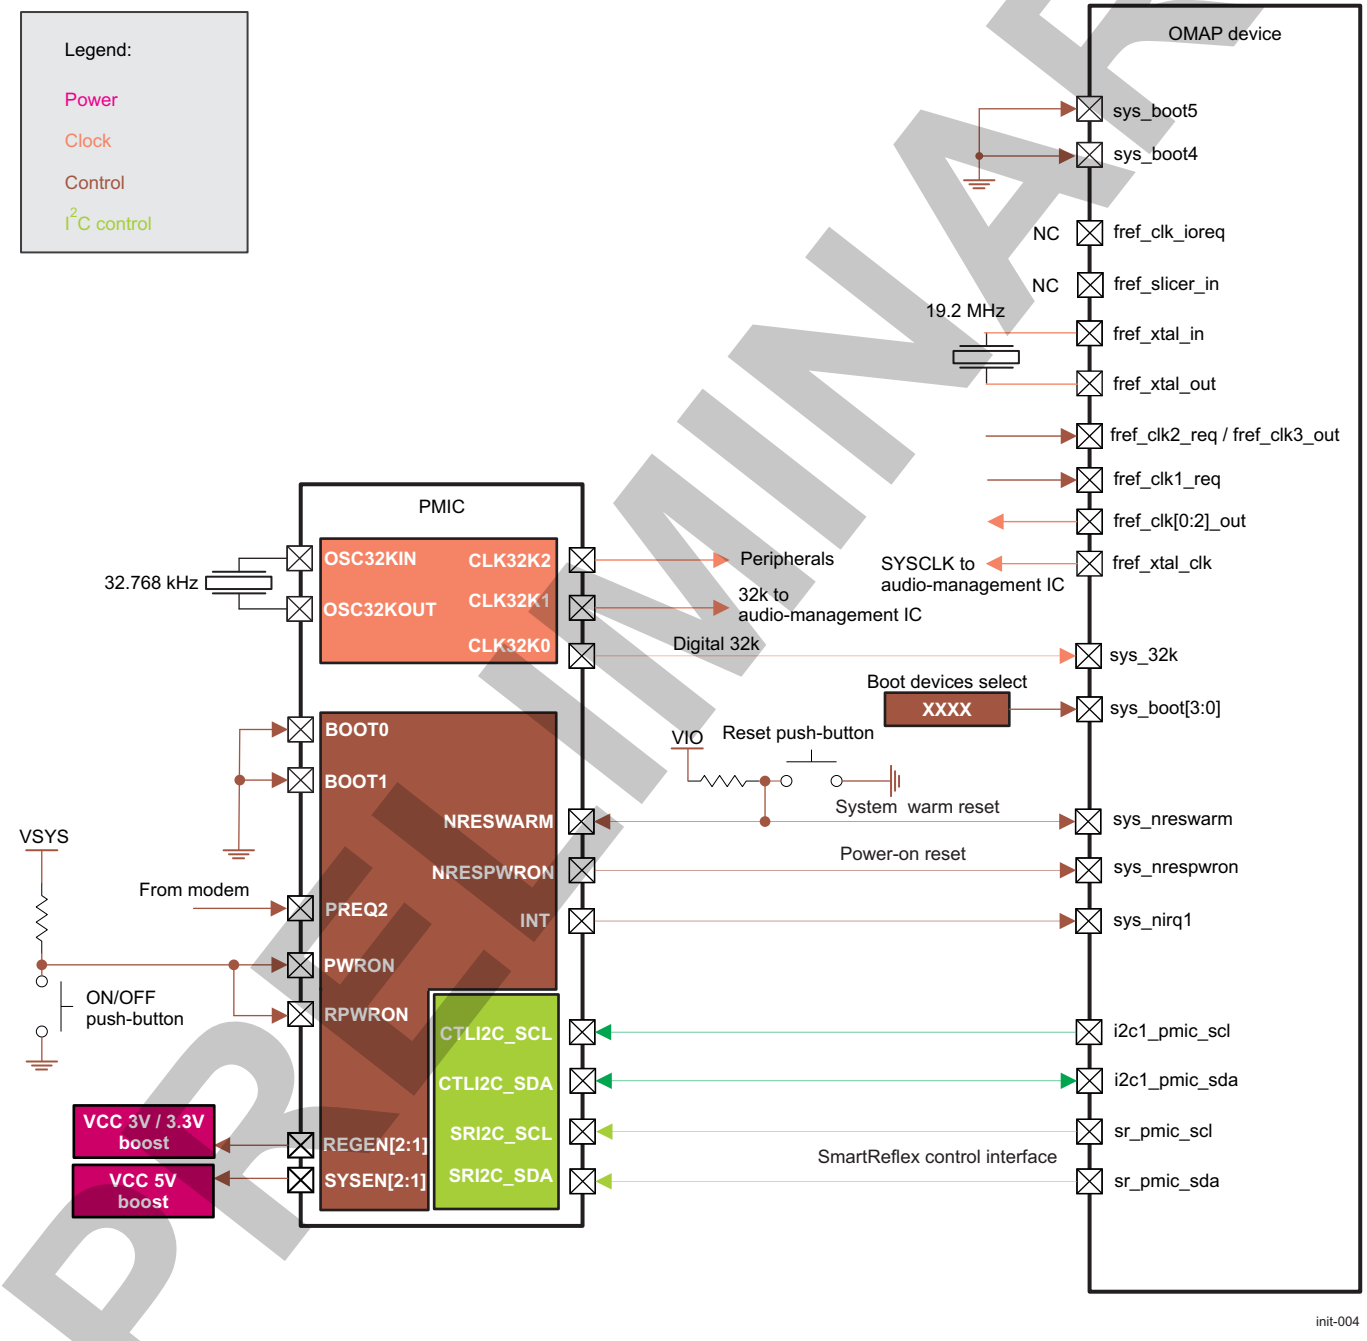


Figure 28-4 shows the device slicer-active mode connectivity scenario which applies only to the OMAP5430 device.

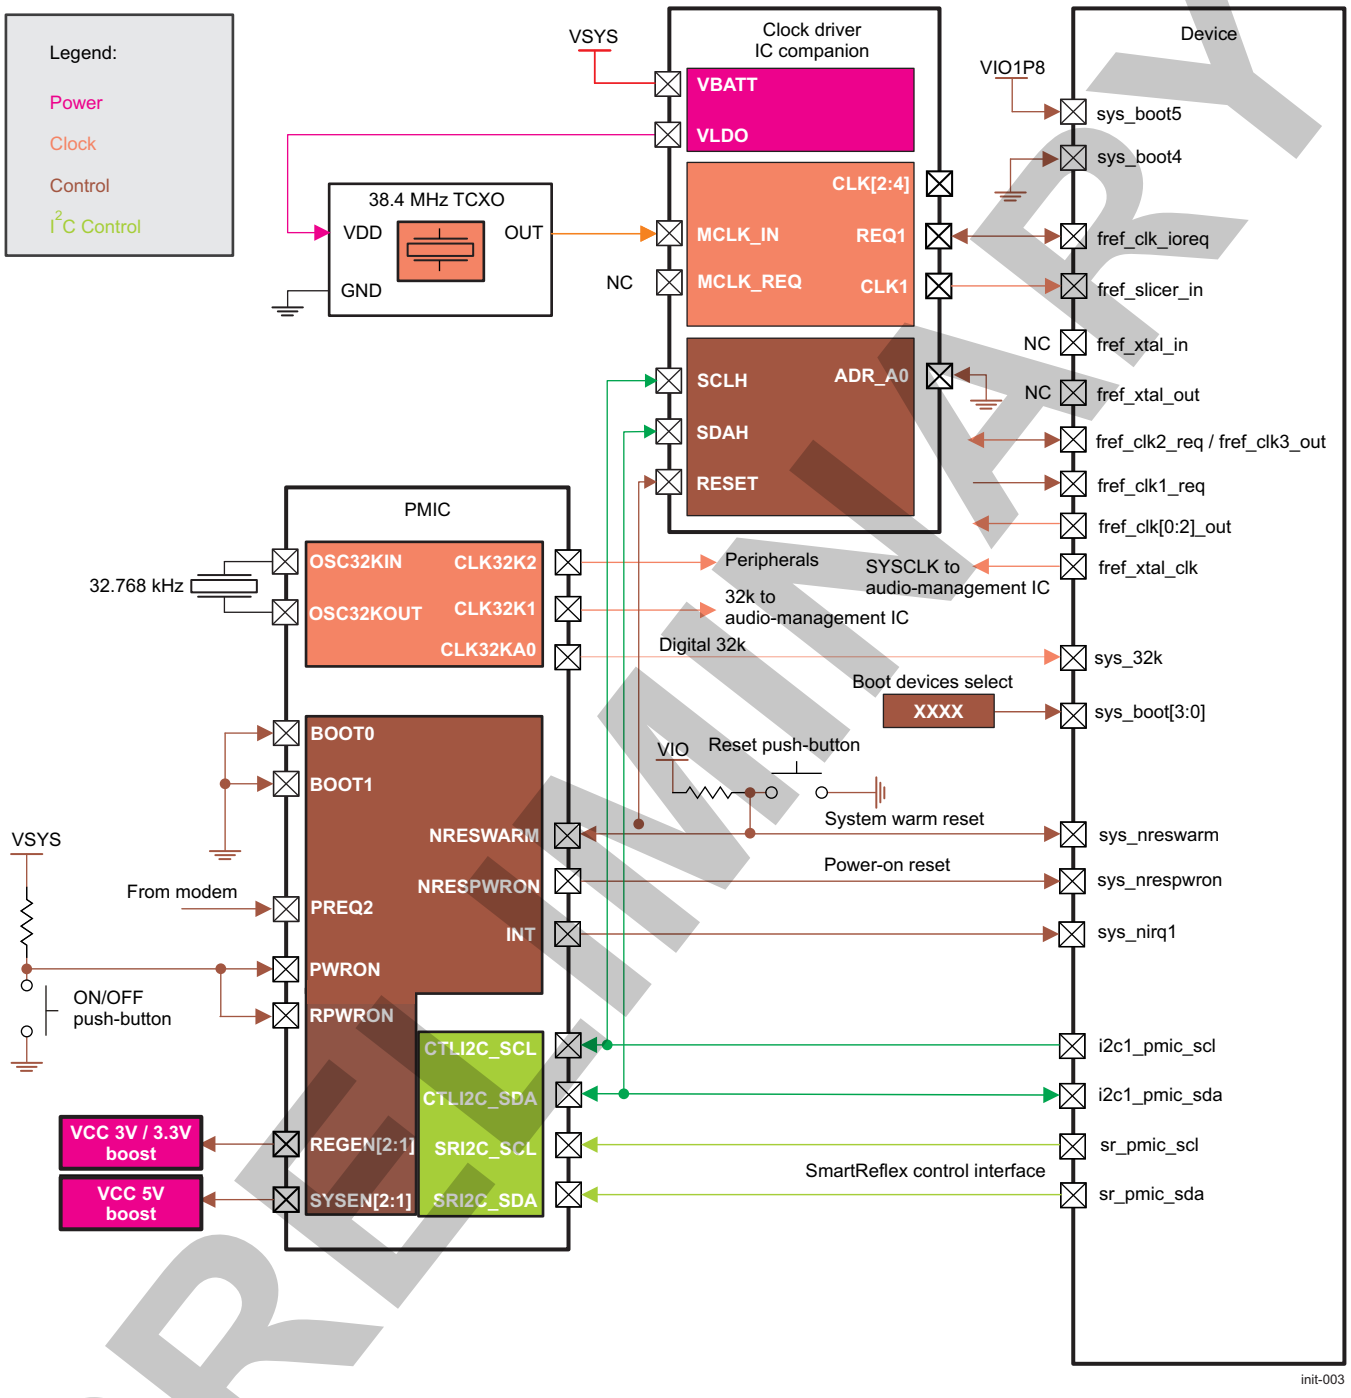
Figure 28-4. OMAP5430 Slicer-Active Mode Connectivity



The main features of the system interface are:

- Accepts external 12, 16.8, 19.2, 26, and 38.4 MHz reference square clocks at the crystal oscillator input (fref_xtal_in) or at the clock slicer input (fref_slicer_in)
- Accepts crystal working on fundamental frequency 12, 16.8, or 19.2 MHz connected between OMAP fref_xtal_in and fref_xtal_out pads
- An output (fref_xtal_clk) to deliver the oscillator cell (FREF_XTAL) generated system clock to a companion audio-manager IC.
- Accepts 12, 16.8, 19.2, 26, or 38.4 MHz reference sine wave clock on slicer input

- A 32-kHz CMOS clock input
- Four configurable clock outputs
- Two clock request inputs
- A bidirectional clock request (OMAP device to external clock source and vice versa)
- SYS_BOOT[3:0] input signals to define the boot mode
- SYS_BOOT[5:4] input signals to select clock configuration
- Two reset sources
  - Power-on reset (cold reset)
  - Bidirectional warm reset
- Two external interrupt lines
- Two external DMA requests
- Outputs for voltage control

NOTE: A mapping dependency table is implemented in the OMAP device that enables any clock output to be delivered upon any clock request input; the multiplexing nevertheless allows two options, as follows:

- Three clock outputs (out0, 1, 2) versus two clock request inputs (req1, 2)
- Four clock outputs (out0, 1, 2, 3) versus one clock request input (req1)

NOTE: The options to supply an external sine-wave clock or a square-wave clock (in the slicer-bypassed mode) through the fref_slicer_in pad are valid only for the OMAP5430 device. For more information on the slicer input restrictions in the OMAP5432 device, see Section A.11.2, *Clock and Reset* in Appendix A, *OMAP5432 Multimedia Device*.

28.2.3.2 Clocking Scheme

28.2.3.2.1 Required System Input Clocks

The OMAP device operation requires external input clocks, as follows:

- 32k clock: A 32.768-kHz crystal is connected to the PMIC companion chip that embeds the 32k-oscillator (a square CMOS clock can also be delivered on the 32k_xtalin pin of Power-management IC, if the 32k-crystal is connected on another device of the system). The resulting 32k-clock is delivered to the entire system on three outputs:
  - CLK32KAO is always on (meaning that when PMIC chip VIO pin is on; that is, it is in WAIT-ON or ACTIVE state). It is used to deliver a 32k clock to always-on domain of the OMAP device and, for example, a modem.
  - CLK32K1 is software-controlled and is delivered to the audio-management IC companion chip. (not shown in Figure 28-3) when requested by the OMAP device (this input is on by default at system boot).
  - CLK32K2 gated clock is software-controlled and is delivered when requested by the OMAP device (this input is on by default at system boot).
- The OMAP chip delivers digital clocks to other peripherals. The OMAP device supports different types of input clock sources at several frequencies:
  - Crystal source. An internal oscillator embedded in the OMAP device is used. The fref_clk_ioreq is then set as an input to be used by an external device to request the OMAP device to deliver the clock on fref_clk0_out.
  - External oscillator type source. The OMAP internal oscillator is disabled. In case of external oscillator, the fref_clk_ioreq is configured as output, to request the clock from the external source. There are two possibilities to apply an external clock, as follows:
    - The external source delivers a sine (slicer active) or square (slicer bypassed) single-ended clock on the fref_slicer_in pin.

- An external square-wave-only clock is injected into the fref_xtal_in pad, with the fref_xtal_out pad remaining unconnected.

- Audio clock: The audio-management IC builds its own clock, either from the 32k clock or the high-speed (HS) clock (depending on the audio scenario). This internal clock is delivered to the device ABE subsystem (abe_clks input) for audio flow synchronization.
- The audio-management IC companion can receive a buffered oscillator HS clock, generated by the OMAP device crystal oscillator cell (in either osciallator-bypassed or oscillator-active modes) from the OMAP output pad (fref_xtal_clk).

Clock input modes are selected by the sysboot signals (sys_boot[5:4] pads) to let the system wake up in the proper mode, even after a cold boot (selection of the relevant input signal [fref_slicer_in or fref_xtal_in/out] and slicer/oscillator mode setting [on or bypass]).

The OMAP device provides the HS clock to other devices on three fref_clk[0:2]_out pads. An additional clock output signal (fref_clk3_out) is multiplexed (MuxMode=0x1) on the OMAP device pad fref_clk2_req. For more information on multiplexing, see Chapter 18, *Control Module*.

The audio-management IC receives a HS clock when the audio scenario requires it (some low-power audio player scenarios can be performed only with the 32k clock).

Table 28-2 lists the mapping for the OMAP clock input sources. Table 28-3 lists the PMIC clock requirements.

Table 28-2. Mapping for Input Sources

Input Source	Mapping	Frequency Range/List	Type
Internal oscillator	fref_xtal_in and fref_xtal_out	12, 16.8, or 19.2 MHz	Crystal connection pins
External HS clock	fref_slicer_in	12, 16.8, 19.2, 26, or 38.4 MHz	Sine or square single ended
External 32k clock	sys_32k	32.768 kHz (nom.)	Square
Audio-management IC companion	abe_clks	<19.2 MHz	Square

Table 28-3. PMIC Clock Requirements

Input Source	Mapping	Frequencies Range/List	Type
Internal oscillator	OSC32KIN and OSC32KOUT	32.768 kHz (nom.)	Crystal connection pins

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not apply to production. For more information, see the *Device Data Manual*.

28.2.3.2.2 Optional System Output Clocks

The OMAP device can output four alternate clocks, fref_clk[0:3]_out. Each output clock, 0 through 3, can be gated or enabled by the activation of any associated clock-request signal, fref_clk[1:2]_req or fref_clk_ioreq (when configured as an input clock request). The mapping of an input clock request versus clock output as well as request polarity is programmable in the *System Clock and Reset Manager* registers. For more information, see Section 3.3, *PRCM Subsystem Environment*, in Chapter 3, *Power, Reset, and Clock Management*.

28.2.3.3 Reset Configuration

28.2.3.3.1 ON/OFF Interconnect and Power-On-Reset

The entire system is typically awakened by an ON/OFF push button connected to the PMIC chip. This signal belongs to the VSYS - system power domain and is active low (the PMIC internal pullup ties it to VSYS). The PMIC power-up event is propagated through its NRESPWRON output pin to the OMAP sys_nrespwron pad (that is, the OMAP device SYS_NRESPWRON input signal) when the PMIC power-up sequence is achieved. The reset pad sys_nrespwron (signal SYS_NRESPWRON) is used to reset all the chip at power-on reset (POR) when the chip core voltage and I/O voltage are correctly set (cold reset). The OMAP.SYS_NRESPWRON input pin is held low all the time during VDD core and I/O power-up. Because this signal is also provided to the audio-management IC companion, it resets its state-machine and gets some available functions even if the VDD-2V1 power supply is not provided.

28.2.3.3.2 Warm Reset

A warm reset can be asserted by the OMAP device, by an external button (typically for development platform), or by any other chip connected to it (normally tied to PMIC companion NRESWARM output pin).

The OMAP warm reset pad (sys_nreswarm - OMAP bidirectional signal SYS_NRESWARM) is used to trigger a warm reset on the OMAP device, which resets part of the device when it has already booted (for example, to recover from a software crash). The OMAP SYS_NRESWARM signal is a bidirectional reset. When an internal OMAP reset occurs, SYS_NRESWARM output goes low and resets all the peripherals. Because the SYS_NRESWARM output is open drain, an external pull up resistor is required.

The OMAP device releases the SYS_NRESWARM output signal after NRESPWRON is deasserted.

28.2.3.3.3 Peripheral Reset by GPIO

Most peripherals are reset and powered on or off by GPIO. By default, under POR, most OMAP device signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of the device control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the device registers to validate GPIO use and the default configuration of the control module.

28.2.3.3.4 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event occurs, the output buffer is disabled. Consequently, two different behaviors can be defined with regard to what is expected by the platform:

- GPIO sensitive to warm reset:

  To prevent a floating pad, user software is designed to have the internal pad PU and PD resistors enabled immediately, before the software warm reset action, because the warm reset-sensitive GPIO controllers will change I/O direction to input after an OMAP warm reset. This is necessary if the warm reset-sensitive GPIO controller pin has been configured for output before the warm reset occurrence. The pulls-enabled-before-warm-reset condition should be set by default in case the user has configured a GPIO as an input, because in this case the user is expected to have enabled the internal PU and PD pads during GPIO configuration (unless external pull resistors were used).

NOTE: If the PU and PD resistors are enabled immediately by software after a POR (cold reset) for a GPIO that is planned to be used only as an output, then unnecessary consumption can occur.

While the dynamically-enable-the-pull-just-before-warm-reset condition is possible during a software warm reset (because the user software is aware of the exact moment a warm reset event occurs), it is not possible when the warm reset is triggered by hardware (for example, a watchdog reset, SYS_NRESWARM signal assertion, and so forth), because the software is not aware of the exact moment of these warm reset assertions.

- GPIO not sensitive to warm reset:

  To avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time a dedicated GPIO register is accessed.

NOTE: To avoid unnecessary consumption, the user software must ensure that internal pull resistor is disabled when the GPIO buffer is driving.

For the description of the reset sequences, see Section 3.5, *Reset Management Functional Description*, in Chapter 3, *Power, Reset and Clock Management*.

NOTE:

- For more information about the OMAP device reset management, see Section 3.5, *Reset Management Functional Description* in Chapter 3, *Power, Reset, and Clock Management*.
- To determine the cause of the last reset, see Section 3.5, *Reset Management Functional Description* in Chapter 3, *Power, Reset, and Clock Management*.

28.2.3.4 Power and Audio-management IC Companions Control

- I^2C:

  The OMAP device interfaces: system interface (sys_x) I/Os, SR_PMIC, I2C1_PMIC are involved in system interractions between the OMAP and external power, reset and clock management IC companions.

  The OMAP and PMIC companion implement the basic power-management interface (SYS), as follows:

  – 32-kHz clock single input
  – Two system resets: power-on (cold) reset and warm reset
  – One power request
  – One interrupt

  The OMAP device and PMIC companion implement:

  – A dedicated (I2C1_PMIC) HS interface for control and configuration
  – A SmartReflex (SR_PMIC) interface for dynamic core voltages setting

  The device and battery charger IC companion chip implement a communication channel for battery charging control and configuration over the platform companion ICs control interface (I2C1_PMIC).

  The OMAP and audio-managment IC companion implement a communication channel for audio control and configuration over the platform companion ICs control interface (I2C1_PMIC).

  Internal pullup resistors are provided on the OMAP I2C1_PMIC interface pads. For more information, see the device *Data Manual*. The I^2C links must first be started in fast-speed mode. Therefore, the buffer default pullup value must support this mode.

  Some of the PMIC chip power resources are controlled through the SmartReflex link (I^2C-like). This control allows the host to drive the dynamic voltage frequency scaling (DVFS) and adaptive voltage scaling (AVS) operations of these resources. As with its I^2C interfaces, some internal pullup resistors are provided on the OMAP device SmartReflex I/Os. The link must be run at the highest speed allowed by the voltage controller of the OMAP device (lower than I^2C HS mode frequency).

- INT:

  Both PMIC and audio-management IC companion devices can activate their output interrupt request signal (INT) at any time when they require the OMAP (host) device to monitor their activity. When receiving such an interruption, the OMAP checks, through the I^2C, to determine the source of the interrupt. These INT pins are active low.

28.2.3.5 PMIC Request Signals

The PMIC drives three external enable-output signals, which allows switching on some external resources at different stages of the power-up sequence:

- REGEN1 and REGEN2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VSYS power domain. REGEN1 can typically be used for buck boost control.
- SYSEN is driven high immediately after the VCORE power output is turned on. SYSEN allows switching on the additional power regulator to supply the MPU subsystem. SYSEN belongs to the VIO power domain.

The PMIC companion chip can receive three power resource requests: ENABLE[1, 2, 3] (only ENABLE2 is used). These pins allow an external device to request PMIC internal resources. The PMIC companion power behavior when pins are activated must be programmed after the first boot. Typically, ENABLE2 is allocated for a modem group.

28.2.4 Boot Configuration

The OMAP device implements six sampled-on-reset sys_boot pads.

Four external pads (sys_boot[3:0]) are used to select interfaces or devices for the booting list, as follows:

- sys_boot3 selects the peripheral (sys_boot3 = 0b0) or memory booting (sys_boot3 = 0b1) scheme.
- sys_boot[2:0] select the boot mode.

The sys_boot[5:4] pads select the OMAP clock source configuration.

All six pins are sampled and latched onto the CTRL_MODULE_CORE.CONTROL_STATUS[5:0] SYS_BOOT bit field after POR. After booting, these pads can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. For more information about pad multiplexing configuration, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*.

NOTE: If used as GPIOs, the sys_boot[5:0] pads must be used only in output mode to ensure that the input values always match a certain hardware predefined boot pattern, interpreted after each POR.

28.2.4.1 System Clock Source Selection

Figure 28-5 is an overview of the system clock selection. Table 28-4 summarizes the selection.

Figure 28-5. System Clock Selection Diagram

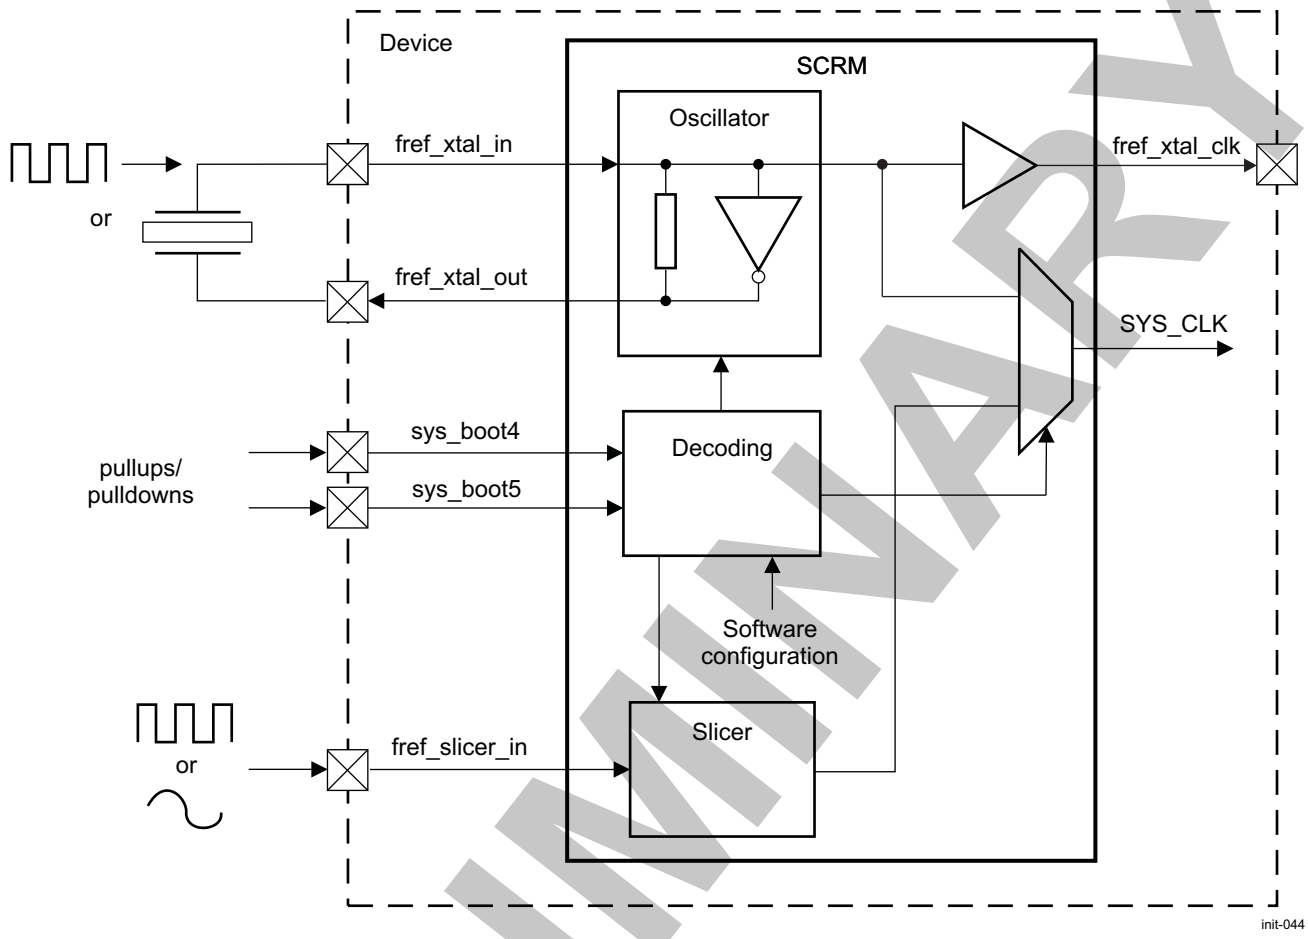


Table 28-4. System Clock Selection Summary

sys_boot[5:4]	SYS_CLK Source	Oscillator Mode	Slicer Mode	fref_clk_ioreq Mode
0b00	fref_xtal_in	Active	Power-down	Input
0b01[(1)]	fref_xtal_in	Bypass	Power-down	Output
0b10	fref_slicer_in	Power-down	Active	Output
0b11	fref_slicer_in	Power-down	Bypass	Output

(1) In the oscillator bypass case, the fref_xtal_out pin is left unconnected.

The OMAP device clock source settings description:

- sys_boot[5:4] = 0b00:
  - The system clock source is the on-chip oscillator tied between the fref_xtal_in and fref_xtal_out pads.
  - The slicer is powered down.
  - The fref_clk_ioreq signal is a clock request input by default In this mode.
- sys_boot[5:4] = 0b01:
  - The system clock source is external. The internal oscillator is bypassed to inject a square-wave system clock.
  - The slicer is powered down.
  - In this mode, the fref_clk_ioreq signal is an output that requests the clock from the external clock supplier.
- sys_boot[5:4] = 0b10:

  - The system clock source is the on-chip slicer, supplied with a sine-wave clock from the external oscillator. The internal crystal oscillator cell is powered down.
  - The slicer is active.
  - The fref_clk_ioreq signal is an output that requests the clock from the external clock supplier.
- sys_boot[5:4] = 0b11:
  - The system clock source is external, bypassing the slicer to inject a square-wave system clock.
  - The internal oscillator is powered down.
  - The fref_clk_ioreq signal is an output that requests the clock from the external clock supplier.

NOTE: The options to supply an external sine-wave clock or a square-wave clock (in the slicer-bypassed mode) through the fref_slicer_in pad are valid only for the OMAP5430 device. For more information on the slicer input restrictions in the OMAP5432 device, see Section A.11.2, *Clock and Reset*, in Appendix A, *OMAP5432 Multimedia Device*.

28.2.4.2 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from two locations:

- The first location is the sys_boot[3:0] external configuration pins sensed in the OMAP device CTRL_MODULE_CORE.CONTROL_STATUS register. The sys_boot[3:0] configuration pads have two main purposes: configure ROM code software in terms of interfaces and devices used for booting and configuring hardware after a POR or cold reset.
- The second location is the software booting configuration stored in the nonvolatile SAR memory, and used after a global warm reset.
- The third location is an on-board EEPROM (connected through I2C1) whenever sys_boot[3:0] value indicates this mode.

The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the third devices.

The following names are used in the tables:

- Memory types:
  - Execute in place (XIP): XIP memory without wait-signal monitoring enabled (NOR flash memory or other XIP device)
  - XIP wait: XIP memory with wait-signal monitoring
  - NAND: NAND flash memories (non-XIP)
  - OneNAND™: OneNAND and Flex-OneNAND™ flash memories
  - SD: SD card device on the device SDCARD I/O port (associated with the MMC1 controller instance.)
  - eMMC: eMMC™ memory device on the OMAP device eMMC I/O port (associated with the MMC2 controller instance). See Section 28.2.4.3, *Boot Peripheral Pin Multiplexing*.
  - SATA interface compatible storage devices such as solid state drives (SSDs) or hard-disk drives (HDDs). See Section 28.2.4.3, *Boot Peripheral Pin Multiplexing*.
- Peripheral interfaces:
  - USB: USB - HS and SS interface over the OMAP device USBD0 port
  - Universal asynchronous receiver/transmitter (UART): UART3 interface
- Table 28-5 lists the permanent booting devices in bold typeface.

NOTE: If no valid software booting configuration is found in case of a warm reset, the ROM code builds a device list featuring only the permanent booting devices (in bold) defined by one of the following conditions:

- The sys_boot[3:0] configuration latched into the CTRL_MODULE_CORE.CONTROL_STATUS[3:0] SYSBOOT bit field upon POR
- Data stored in the I2C1 connected on-board EEPROM (the EEPROM itself selected in a sys_boot[3:0] value)

Hence, peripheral booting devices are skipped when the OMAP restarts from warm resets and no software booting configuration is invoked.

NOTE: Users can force the execution of the peripheral booting procedure after warm reset by using the software booting configuration feature.

Table 28-5 lists the booting device order when it is preferred to boot from a memory type device. This table is selected by ROM code when the sys_boot3 pin is tied high (= 1) after reset and before booting completes. If fast XIP booting is selected, the sys_boot3 pin controls the XIP wait-signal monitoring (that is, a logical high level enables wait-signal monitoring).

Table 28-5. Memory Preferred Booting

sys_boot[3:0]	Booting Devices Order		
	First	**Second**	**Third**
0b1000	**eMMC**	USB	N/A
0b1001	**NAND**	USB	N/A
0b1010	**SD**	**eMMC**	USB
0b1011	**SATA**	**SD**	USB
0b1100	**XIP**	USB	UART
0b1101	**OneNAND**	UART	N/A
0b1110	**eMMC** (boot partition only)	N/A	N/A
0b1111	**Fast XIP booting. Wait monitoring ON**	UART	USB

NOTE: When sys_boot[3:0] is tied to 1110, the ROM code boots from eMMC boot partition. If the ROM code fails to retrieve the booting image, it does not try boot from the user area contrary to other eMMC options in the table. This option does not provide the peripheral booting support (for example, USB).

Table 28-6 lists the booting device order when it is preferred to boot from a peripheral-type device. This table is selected by ROM code when the sys_boot3 pin is tied low (= 0). If fast XIP booting is selected, the sys_boot3 pin controls the XIP wait-signal monitoring (that is, a logical low level disables wait-signal monitoring).

Table 28-6. Peripheral Preferred Booting

sys_boot[3:0]	Booting Devices Order		
	First	**Second**	**Third**
0b0000	USB	**eMMC**	N/A
0b0001	USB	**NAND**	N/A
0b0010	USB	**SD**	**eMMC**
0b0011	USB	**SATA**	**SD**
0b0100	USB	UART	**XIP**
0b0101	UART	**OneNAND**	N/A
0b0110	**I2C1**(1)	N/A	N/A

(1) The booting device list is retrieved from an on-board EEPROM connected to the OMAP device through I2C1.

Table 28-6. Peripheral Preferred Booting (continued)

sys_boot[3:0]	Booting Devices Order		
	First	Second	Third
0b0111	**Fast XIP booting. Wait monitoring OFF**	UART	USB

28.2.4.3 Boot Peripheral Pin Multiplexing

Table 28-7 lists the code pin multiplexing configuration supported by ROM according to boot peripheral.

Table 28-7. Pin Multiplexing According to Boot Peripheral

Boot Device	Boot Interface	Pads	Comments
eMMC	eMMC/JC64 memory component connected to the eMMC port	Only one device connected at the eMMC pads, on which MMC2 controller I/Os are muxed when MuxMode=0x0 (default)	Clock frequency: identification mode: 400 kHz. Booting from user area: Data transfer mode: 10 MHz (optionally up to 48 MHz with configuration header [CH]). Initial 1-bit single data rate (SDR) mode. Can optionally be extended to 4-bit and 8-bit SDR, as well as 4-bit and 8-bit double data rate (DDR) modes if a CH is used. Booting from boot partitions (Alternative Boot operation mode) is supported only at 8-bit/48 MHz/DDR. eMMC device powered by the companion chip or external supply. Supports 1.8-V I/O interface. Support for low- and high-capacity memory components.
SD	SD removable card connected to the SDCARD port	Only one device connected at the SD card pads, on which MMC1 controller I/Os are multiplexed when MuxMode=0x0 (default).	Clock frequency: identification mode: 400 kHz; Data transfer mode 10 MHz (optionally up to 19.2MHz) 3 V VCC power supply. Initial 1-bit mode, optional up to 4-bit mode. Support for low- and high-capacity memory components
NAND	Raw NAND flash	GPMC i/f signals, available when MuxMode=0x4 on different OMAP interface (UART1, UART2, and HSI2) pads .	8/16 bit IO width Support for Single-level and Multi-level cell NAND Flash from 512Mb to 64Gibit Supports identification through ONFI Connected to GPMC interface Chip Select 0 (gpmc_ncs0)
OneNAND	OneNAND / FlexOneNAND flash memory		NAND flash with integrated controller and NOR like bus Connected to GPMC interface Chip Select 0.
XIP	NOR flash		NOR (CFI) or other XIP device, connected to GPMC interface Chip Select 0.
SATA	SSD, HDD	SATA i/f pads (no MuxMode)	Serial ATA device (hard drive or flash device integrating a SATA controller e.g SSD) connected to the SATA interface.

Table 28-7. Pin Multiplexing According to Boot Peripheral (continued)

Boot Device	Boot Interface	Pads	Comments
USB	USB OTG SS/HS	USBD0 i/f pads, as follows: • MuxMode=0x0 - USBD0_HS pads • USBD0_SS pads (no MuxMode)	USB OTG Super Speed (USB_OTG_SS) controller through the OMAP embedded Super Speed (USB3_PHY) and High Speed (USB_PHY_CORE) PHY transceivers, hence only UTMI port is utilized. **ROM Code does NOT support booting through external for the OMAP device USB PHY transceivers connected on the device USB ULPI port.** No support for OTG features.
UART	UART3 port serial interface	UART3 RX and TX signals available on UART3 pads (MuxMode=0x0)	No flow control is required

NOTE: The general-purpose memory controller (GPMC) chip-select pads gpmc_ncs[1:4] have selected pull-downs at device level after reset. Because ROM code alters only the gpmc_ncs[0] configuration, it is not possible to accomplish the GPMC boot on CS0, if user has connected other GPMC devices on CS1, CS2, CS3, or CS4. That is, more than one chip-select signals would be activated at the time of GPMC boot. Booting devices that take advantage of GPMC are XIP, fast XIP, NAND, and OneNAND.

NOTE: The ROM code examines the interfaces that are selected to be searched until a valid bootable interface or device is found. The activities on the pads of the searched interfaces must be considered if they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

28.3 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the OMAP device.

28.3.1 Booting Overview

28.3.1.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the OMAP. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. Asoftware (warm) reset can be performed after the image is burned.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory, memory cards, or SATA SSD or HDD memory devices and executes it. This process is normally performed after a cold or warm OMAP reset.

The ROM code detects whether the OMAP device should download software from a peripheral interface (USB or UART) by using the sys_boot[3:0] pad configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

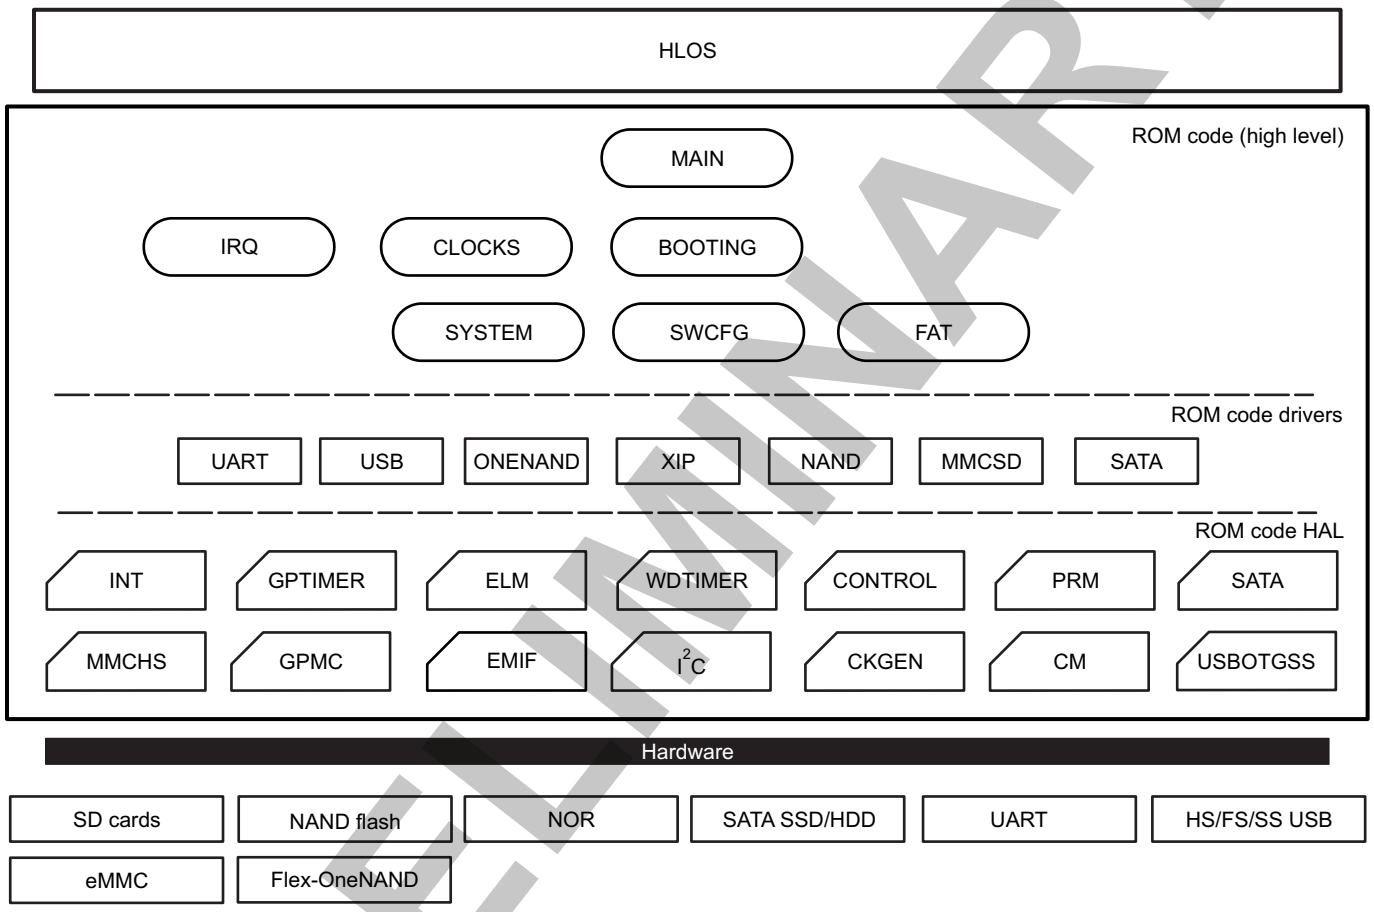
28.3.1.2 ROM Code Architecture

Figure 28-6 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices (typically external flash components) are attached to the device I/O pads.

Figure 28-6 shows the three layers with their modules.

Figure 28-6. ROM Code Architecture

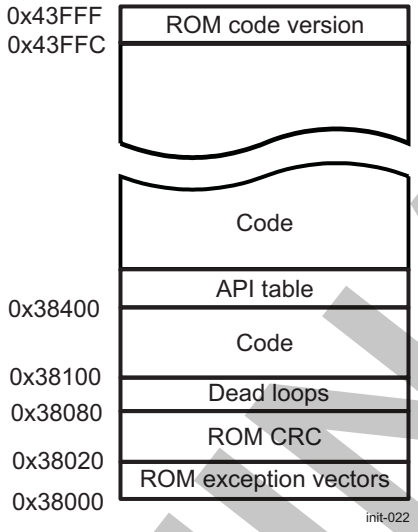


28.3.2 Memory Maps

28.3.2.1 ROM Memory Map

Figure 28-7 shows the 48-KiB ROM memory map.

Figure 28-7. ROM Memory Map



- ROM exception vectors

  Exceptions are redirected to ROM exception vectors (see Table 28-8). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

Table 28-8. ROM Exception Vectors

Address	Exception	Content
0x38000	Reset	Branch to the ROM code startup
0x38004	Undefined	PC = 0x4031 F004
0x38008	Software interrupt (SWI)	PC = 0x4031 F008
0x3800C	Prefetch abort	PC = 0x4031 F00C
0x38010	Data abort	PC = 0x4031 F010
0x38014	Unused	PC = 0x4031 F014
0x38018	IRQ	PC = 0x4031 F018
0x3801C	FIQ	PC = 0x4031 F01C

- ROM code cyclic redundancy check (CRC)

  The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x38000–0x43FFF. The 4-byte CRC code is stored at location 0x38020.

- Dead loops

  Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see Table 28-9).

Table 28-9. Dead Loops

Address	Purpose
0x38080	Undefined exception default handler
0x38084	SWI exception default handler
0x38088	Prefetch abort exception default handler
0x3808C	Data abort exception default handler
0x38090	Unused exception default handler
0x38094	IRQ exception default handler
0x38098	FIQ exception default handler

- Code

  This space is used to hold code and constant data.
- API table

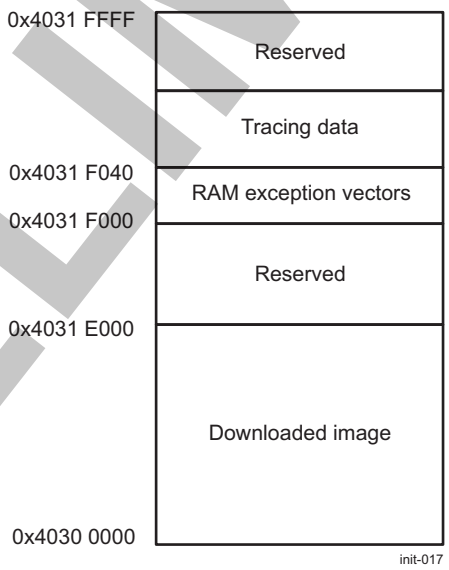
  The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.
- ROM code version

  The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM code release version burned in a given IC. The ROM code version is a 32-bit hexadecimal value at address 0x43FFC.

28.3.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in Figure 28-8 is used during the booting process. Tracing areas can also be accessed when calling API functions.

Figure 28-8. RAM Memory Map



- Downloaded image

  This space is used by the public ROM code to store a downloaded booting image. It can be up to 120KiB.
- RAM exception vectors

  The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. Table 28-10 lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are ARM instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop.

Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4031 F024 to 0x4031 F03C, or by overriding the branch (load into PC) instruction between addresses from 0x4031 F004 to 0x4031 F01C.

Table 28-10. RAM Exception Vectors

Address	Exception	Content
0x4031 F000	Reserved	Reserved
0x4031 F004	Undefined	PC = [0x4031 F024]
0x4031 F008	SWI	PC = [0x4031 F028]
0x4031 F00C	Prefetch abort	PC = [0x4031 F02C]
0x4031 F010	Data abort	PC = [0x4031 F030]
0x4031 F014	Unused	PC = [0x4031 F034]
0x4031 F018	Interrupt request (IRQ)	PC = [0x4031 F038]
0x4031 F01C	Fast interrupt request (FIQ)	PC = [0x4031 F03C]
0x4031 F020	Reserved	0x38090
0x4031 F024	Undefined	0x38080
0x4031 F028	SWI	0x38084
0x4031 F02C	Prefetch abort	Address of default prefetch abort handler(1)
0x4031 F030	Data abort	Address of default data abort handler (1)
0x4031 F034	Unused	0x38090
0x4031 F038	IRQ	Address of default IRQ handler
0x4031 F03C	FIQ	0x38098

(1) The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:
- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (38088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (3808Ch).

- Tracing data

  This area contains trace vectors reflecting the execution path of the ROM code. Table 28-11 describes the public ROM code tracing data. For more information about ROM code tracing, see Section 28.3.9, *Tracing*.

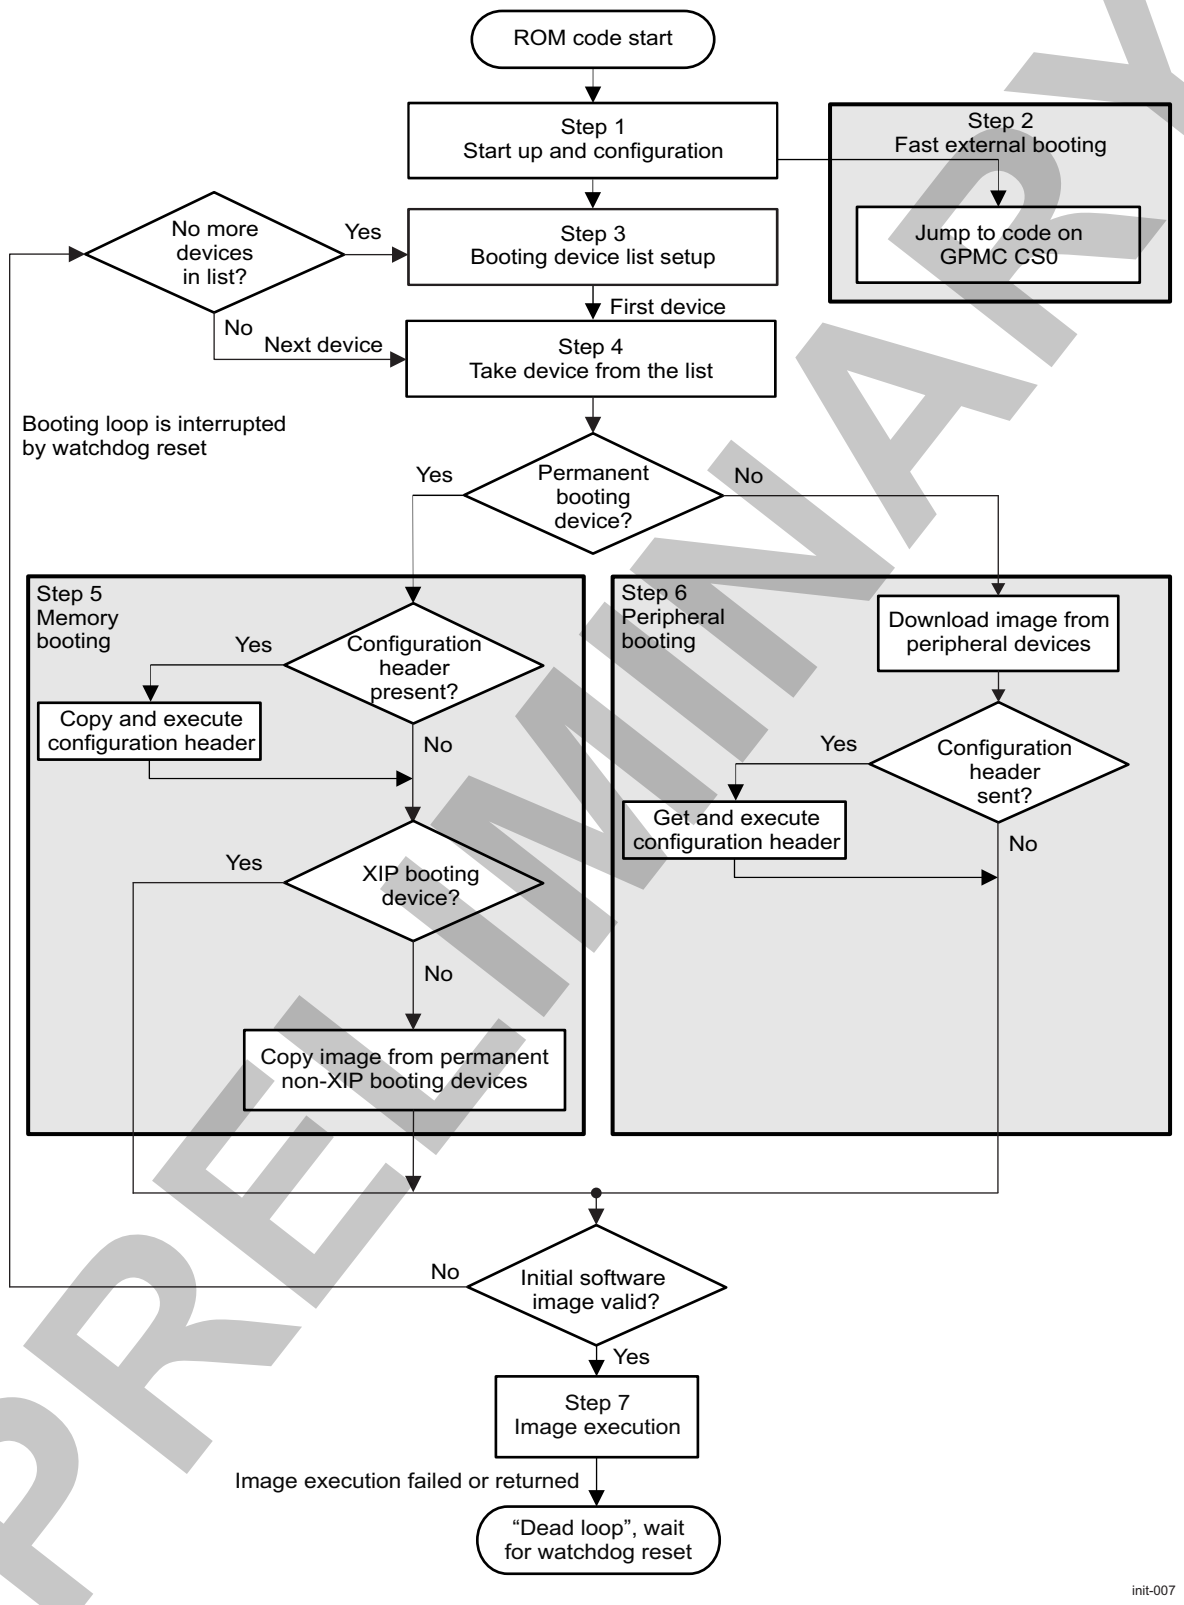
Table 28-11. Tracing Data

Address	Size (Bytes)	Description
0x4031 F040	4	Current tracing vector, word 1
0x4031 F044	4	Current tracing vector, word 2
0x4031 F048	4	Current tracing vector, word 3
0x4031 F04C	4	Current tracing vector, word 4
0x4031 F050	4	Cold reset run tracing vector, word 1
0x4031 F054	4	Cold reset run tracing vector, word 2
0x4031 F058	4	Cold reset run tracing vector, word 3
0x4031 F05C	4	Cold reset run tracing vector, word 4
0x4031 F060	4	Current copy of the PRM_RSTST register (reset reasons)

28.3.3 Overall Booting Sequence

Figure 28-9 shows the ROM code flow chart.

Figure 28-9. Overall Booting Sequence



The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

Step 1. Basic configuration and initialization. Reading of SYSBOOT pins or software booting configuration.

Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See Section 28.3.6, *Fast External Booting.*

Step 3. A booting device list is created (see Section 28.3.4.3, *Booting Device List Setup*). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins, the on-board EEPROM, or the software booting configuration described in Section 28.3.4.5, *Software Booting Configuration*. The software booting configuration structure is in the SAR memory and can be written by software before executing a software reset. After a software reset, the software booting configuration has priority over the sys_boot signals and EEPROM (also selected by sys_boot signals) configuration.

Step 4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or when the watchdog expires. If an image is found, ROM code executes memory booting or peripheral booting, depending on the type of the current booting device:

- Memory booting is executed when the booting device is XIP memory, NAND, OneNAND/Flex-OneNAND, eMMC or SD, SATA SSD/HDD.
- Peripheral booting is executed when the booting device is UART or USB.

Step 5. Memory booting reads data from memory-type devices. Memory booting is described in detail in Section 28.3.7, *Memory Booting*.

Step 6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in Section 28.3.5, *Peripheral Booting*.

Step 7. For the GP device, the image automatically starts.

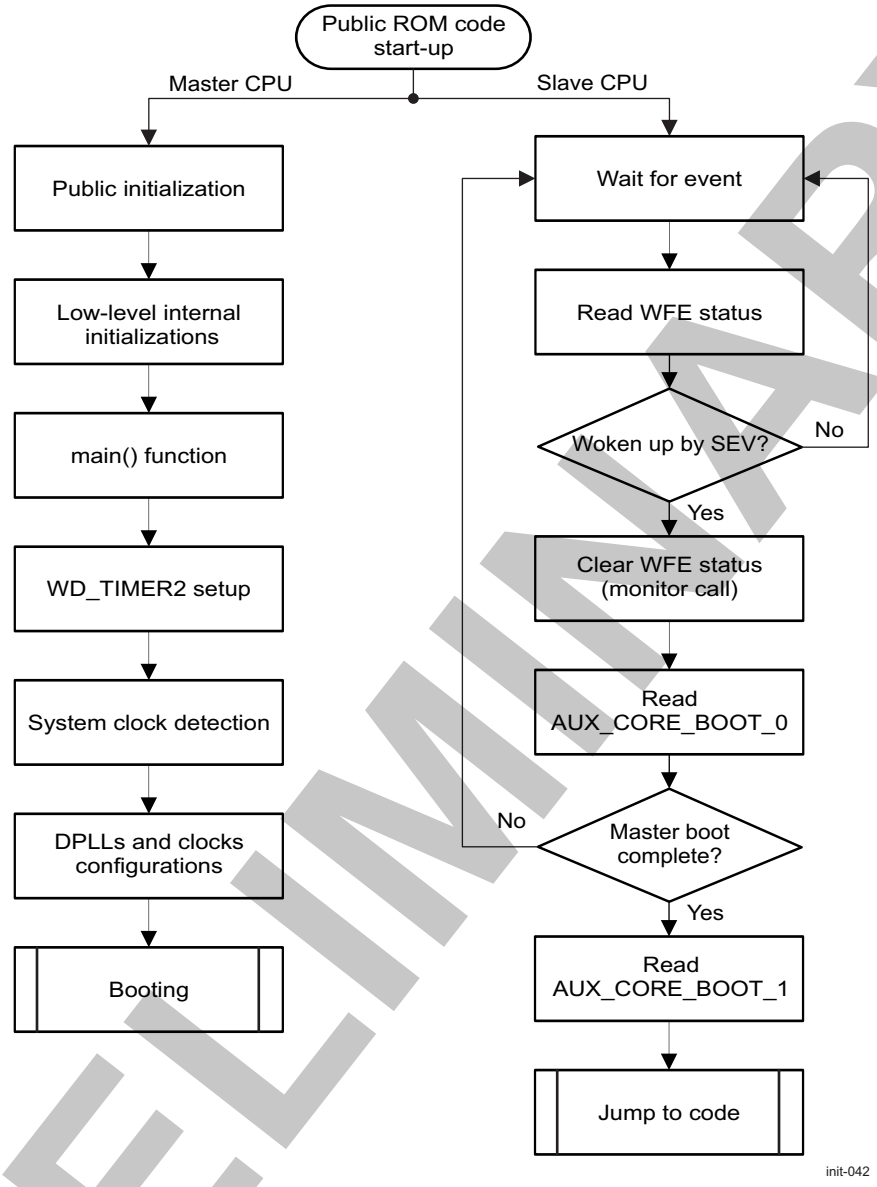
An additional feature of the booting module is the execution of the Configuration Header (CH). The CH configures the system for faster and more flexible booting from the selected permanent or peripheral booting device. The CH, which is optional, is described in *Section 28.3.8.2, Configuration Header*.

28.3.4 Startup and Configuration

28.3.4.1 Startup

Figure 28-10 shows the ROM code start-up sequence.

Figure 28-10. ROM Code Multiprocessor Start-Up Sequence



The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The base address of the public vector is configured to the reset vector of ROM code (0x38000). The memory management unit (MMU) remains switched off during boot (thus, L1 data cache is off). The master CPU performs the basic initialization of the public side. Next, the MMU configures WD_TIMER2 (set to 3 minutes), detects system clock, and configures the system clock. Finally, the MMU jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of the base address of the public vector). The slave CPU is rapidly held in wait-for-event (WFE) state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 registers are in the MPU WakeupGen domain.

- AUX_CORE_BOOT_0 is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.

- AUX_CORE_BOOT_1 contains the physical address location to which the slave CPU must jump after wakeup.

See the memory mapping of these registers in Chapter 4, *Dual Cortex-A15 MPU Subsystem*.

28.3.4.2 Clocking Configuration

The ROM code detects the system input clock frequency (gauging feature of TIMER1). The supported system frequencies in the OMAP device are:

- 12 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- DPLL_PER: locked to provide clocks to peripheral blocks
- DPLL_CORE: locked to provide L3_MAIN interconnect, L4 interconnect, and EMIF clocks
- DPLL_MPU: locked
- DPLL_USB_OTG_SS / DPLL_USB DPLLs: Locked only in case of USB peripheral booting. It is left untouched otherwise.
- DPLL_SATA: locked only in the case of the SATA memory booting. It is left untouched otherwise.

The DPLLs and PRCM clock dividers are configured with the default values of the ROM code (depending on the detected system input clock) after cold or warm reset in order to give the same working conditions to the ROM code sequence.

Table 28-12 summarizes the default ROM code clock settings.

Table 28-12. ROM Code Default Clock Settings

Clock	Frequency (MHz)	Source
DPLL_CORE clock with F_{DPLL} locked frequency	2128	DPLL_CORE.REF_CLK input
EMIF_PHY_GCLK[1]	44.33	DPLL_CORE (M2)
CORE_DPLL_SCRM_CLK	266	DPLL_CORE (M3)
CORE_DLL_GCLK	266	DPLL_CORE.HSDIVIDER (H11)
CORE_X2_CLK	266	DPLL_CORE.HSDIVIDER (H12)
CORE_CLK	266	CORE_X2_CLK
CORE_USB_OTG_SS_LFPS_TX_CLK	34.3	DPLL_CORE.HSDIVIDER (H13)
CORE_GPU_CLK	212.8	DPLL_CORE.HSDIVIDER (H14)
CORE_IPU_ISS_BOOST_CLK	212.8	DPLL_CORE.HSDIVIDER (H22)
CORE_ISS_MAIN_CLK	152	DPLL_CORE.HSDIVIDER (H23)
BB2D_GFCLK	177.3	DPLL_CORE.HSDIVIDER(H24)
L3_ICLK	133	CORE_CLK
L4_ICLK	66.5	L3_ICLK
MPU_DPLL_HS_CLK	266	CORE_X2_CLK
IVA_DPLL_HS_CLK	266	CORE_X2_CLK
DPLL_PER – clock with Fdpll locked frequency	768	DPLL_PER.REF_CLK input
FUNC_192M_CLK	192	DPLL_PER (M2)

(1) This clock is intentionally set up at low frequency to ensure correct initialization of external DRAM components.

Table 28-12. ROM Code Default Clock Settings (continued)

Clock	Frequency (MHz)	Source
PER_DPLL_SCRM_CLK	192	DPLL_PER (M3)
FUNC_256M_CLK	256	DPLL_PER.HSDIVIDER (H11)
DSS_GFCLK	192	DPLL_PER.HSDIVIDER (H12)
PER_GPU_CLK	192	DPLL_PER.HSDIVIDER (H14)
DPLL_MPU - clock with Fdpll locked frequency	2200	DPLL_MPU.REF_CLK input (MPU_DPLL_CLK)
MPU_DPLL_CLK	550	PRM
MPU_GCLK	550	DPLL_MPU (M2)
DPLL_USB - clock with Fdpll locked frequency (2)	960	DPLL_USB. REF_CLK
L3INIT_480M_GFCLK	480	DPLL_USB (M2)
L3INIT_60M_GFCLK	60	L3INIT_480M_GFCLK
DPLL_USB_OTG_SS - clock with F_{DPLL} locked frequency (2)	2500	DPLL_USB_OTG_SS. REF_CLK
DPLL_SATA - clock with Fdpll locked frequency (3)	1500	DPLL_SATA. REF_CLK

(2) This clock is locked specifically if USB peripheral or SATA memory booting is selected.
(3) This clock is locked specifically if USB peripheral or SATA memory booting is selected.

However it is possible to override the default clock settings. There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in Table 28-12. They are always applied at any reset.
- Software booting configuration after a software reset, described in Section 28.3.4.5, *Software Booting Configuration*
- The CH, described in Section 28.3.8.2, *Configuration Header*. The CH lets users have a known configuration (about GPMC and clock registers) after memory or peripheral booting. This configuration can be blocked by the software booting configuration. For more information, see Table 28-14, *Software Booting Configuration Strcuture*.

28.3.4.3 Booting Device List Setup

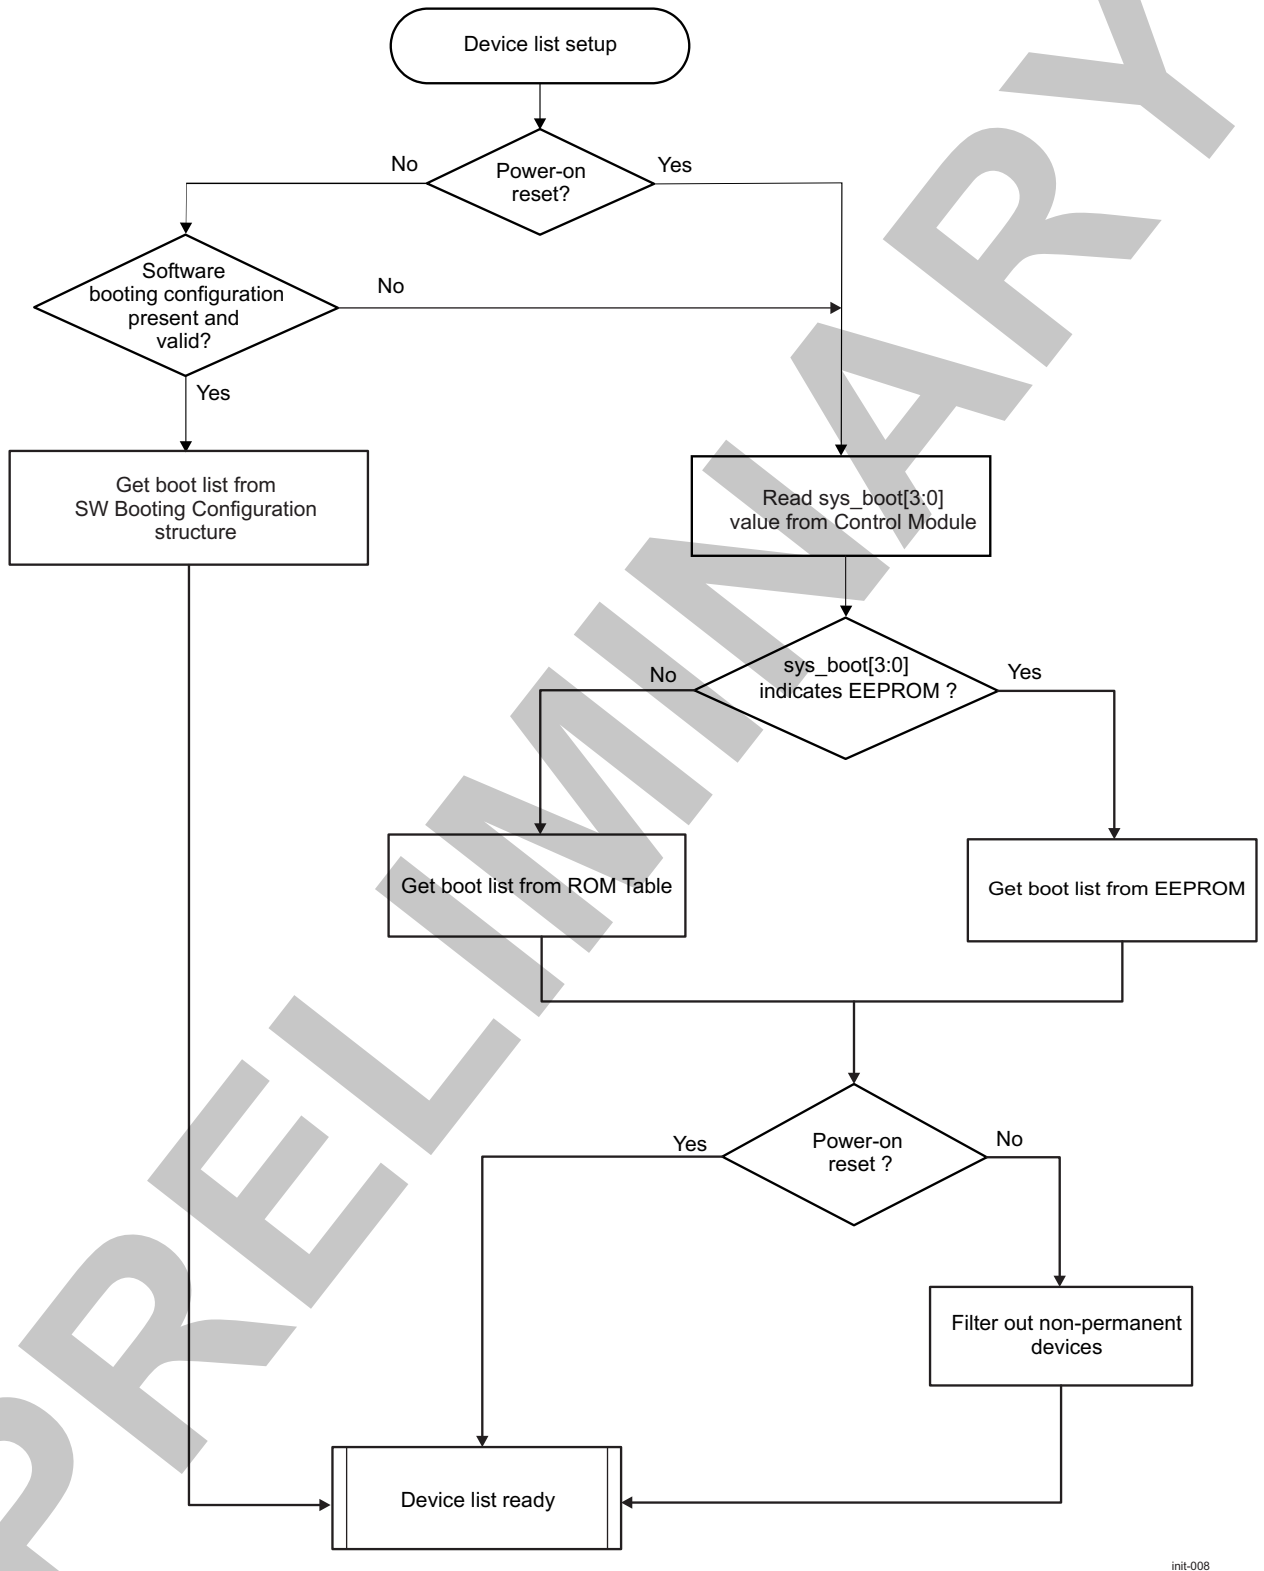
The ROM code creates a device list based on two sources:

- The software booting configuration (if present after a warm reset). The software booting configuration structure is stored in nonvolatile RAM SAR memory.
- The sys_boot[3:0] signals latched in the control module are used to index the device table from which the list of devices is extracted.
- One of the values of the sys_boot pins defines the device list that is extracted from an on-board EEPROM (if available).

Figure 28-11 shows how the ROM code sets up the device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys_boot pins or on-board EEPROM. Users can force peripheral booting after software reset using the software booting configuration.

Figure 28-11. Device List Setup



28.3.4.4 Boot Device List Retrieved from EEPROM

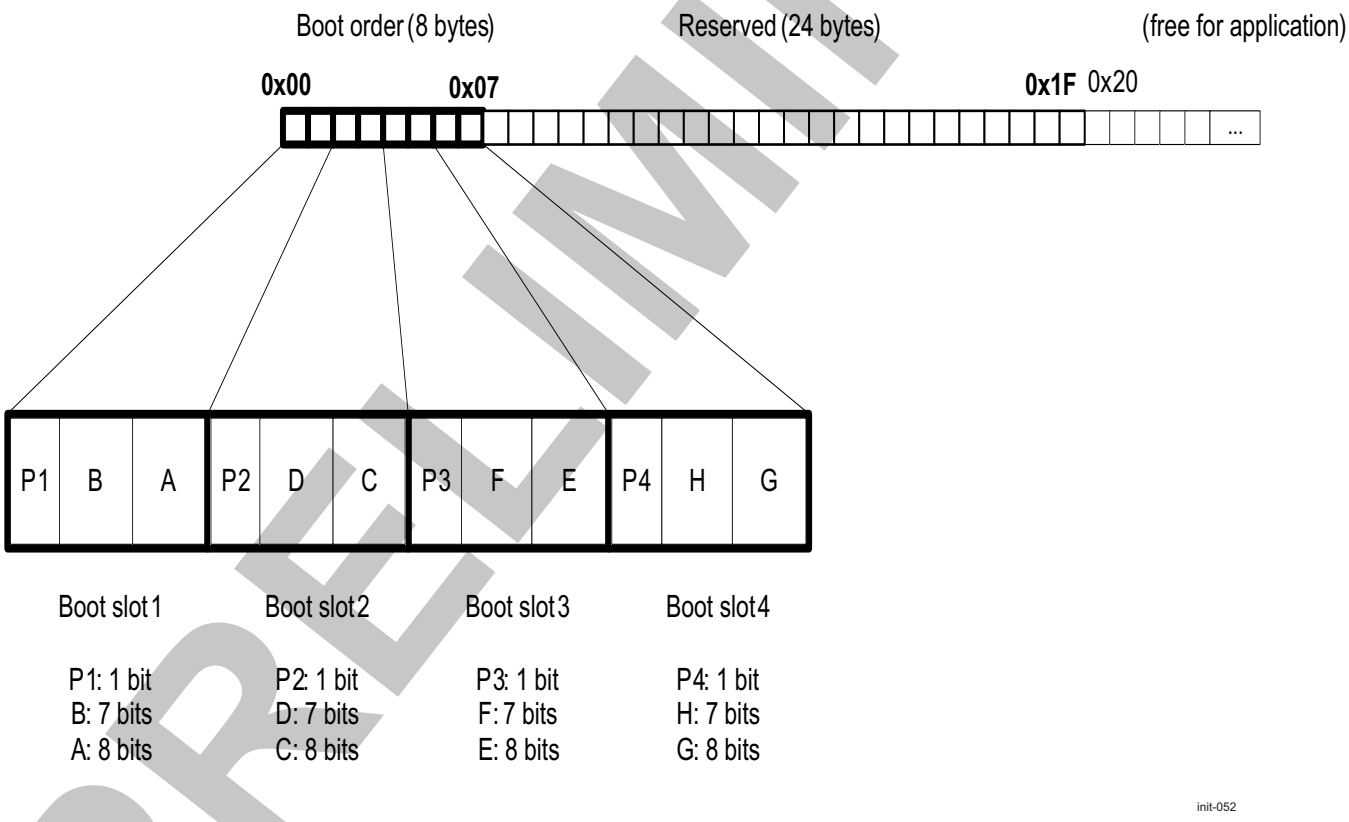
It is possible for the ROM code to retrieve the boot device list from on-board EEPROM connected to I2C1. The end user can reconfigure the boot-device order to match the expectation of the ROM code if the various options proposed in Table 28-5 and Table 28-6 do not fit the application.

NOTE: The I^2C option listed in Table 28-6 is not a boot option, because it is not intended to retrieve a booting image from the EEPROM. This option is defined for the purpose of retrieving the boot device order.

When sys_boot[3:0] pins indicates the I^2C boot option (value 0110 as defined in Table 28-6), then the ROM code initializes the I2C1 interface and reads eight consecutive bytes from address zero of the non-volatile EEPROM. The component is assumed to be wired at I^2C address 0x50. This address is hardcoded and cannot be changed, so the system must comprehend this non-flexible aspect. Even though the ROM code only makes use of the first eight bytes, it is recommended to leave the first 24 remaining bytes reserved for future evolution.

As shown in Figure 28-12, it is possible to configure a maximum of four boot slots, which can hold two boot devices each. Each boot slot has a permanent bit (P1 to P4). The boot slot is filtered out if the permanent bit is not set and a global warm reset occurs. If the bit is set, the boot slot is considered in any case of cold or warm boot.

Figure 28-12. EEPROM Non-Volatile Memory Layout



The device IDs to be populated in boot slots A, B, C, D, E, F, G, and H are defined as follows:

- 01h – XIP
- 02h – XIP (with wait monitoring)
- 03h – NAND
- 04h – OneNAND
- 05h – SD card
- 06h – eMMC (boot partition)

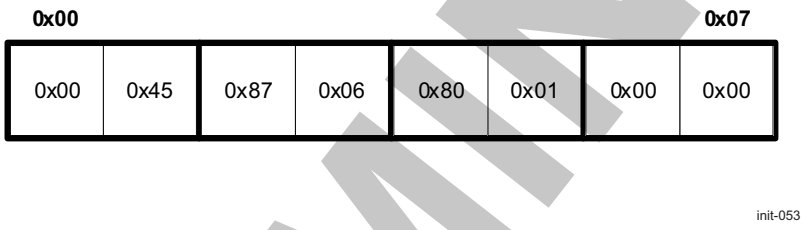
- 07h – eMMC
- 09h – SATA
- 43h – UART3
- 45h – USB
- Other values – Reserved

As an example, consider the following boot device order: USB → eMMC → XIP. This boot option does not exist in the SYSBOOT memory and peripheral booting table, so the I^2C option can be used. The following 8 bytes sequence would be stored:

- Boot slot 1: A=0x45 (USB), B=0x00 (No device, P1=0)
- Boot slot 2: C=0x06 (eMMC boot partition), D=0x87 (eMMC user area, P2=1)
- Boot slot 3: E=0x01 (XIP), F=0x80 (P3=1)
- Boot slot 4: G=0x0 (no device), H=0x00 (no device, P4=0)

Figure 28-13 shows the byte ordering. The system would boot with this boot device order after having configured the sys_boot[3:0] value to 0110 (see Table 28-6). In this example, eMMC and XIP are exercised on any reset (P2=P3=1), while the USB is skipped on a warm reset (P1=0).

Figure 28-13. Example of EEPROM Configuration for USB → eMMC → XIP



28.3.4.5 Software Booting Configuration

The software booting configuration is a logical structure stored in SAR RAM memory, which is not cleared after warm resets or wakeups from low-power modes.

28.3.4.5.1 Public Use of SAR RAM

At system level, the OMAP device SAR RAM memory is divided into four banks. The public ROM code uses only the first bank, which is always public-accessible.

The public ROM code offers some flexibility about the location of the software booting configuration structure. The PUBLIC_SW_BOOT_CFG_ADDR pointer defines the start address of the structure within the SAR RAM bank (see Table 28-13).

Table 28-13. Public Use of SAR RAM

Logical name	Address	Size (Bytes)	Description
PUBLIC_SW_BOOT_CFG_ADDR	0x4AE2 6DFC	4	Public software booting configuration pointer. The word value at this location is: - Reset (zero) on a cold reset. - Read on a warm reset.
PUBLIC_SAR_RAM_1_FREE	0x4AE2 6FC4	...	Recommended address for start of software booting configuration structure described in Section 28.3.4.5.2, *Software Booting Configuration Structure*.
PUBLIC_SAR_RAM_2_BASE	0x4AE2 7000	...	Start of SAR RAM bank 2

As mentioned previously, the software booting configuration feature is optional. Hence, the public ROM code decides to use the feature based on the value read on a warm reset at the address pointed to by the PUBLIC_SW_BOOT_CFG_ADDR pointer. If the value matches the range 0x4AE2 6FC8 to 0x4AE2 6FFC, the ROM code extracts the structure at that address. The value pointed to by PUBLIC_SW_BOOT_CFG_ADDR is always overwritten to 0 on a cold reset.

It is possible to use the public SAR RAM area for any other purpose, such as storing traces for HLOS use. Obviously, care must be taken not to overwrite the locations used for low-power modes and/or software booting configuration, if used.

28.3.4.5.2 Configuration Structure for Software Booting

Table 28-14 describes the configuration structure for software booting . It offers three levels of flexibility for redefining the ROM code defaults after a warm reset:

- Redefining the default device booting list (from ROM code defaults given by SYSBOOT pins configuration)
- Redefining the default clock settings
- Redefining time-out linked to the peripheral booting mechanism

NOTE: The sections are provided as a linked list; therefore, the order and number of items is not relevant.

The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration may override the CH settings, if the appropriate bit is set in the configuration structure for software booting.

Table 28-14. Software Booting Configuration Structure

Time-out boot message	2	Maximum time allowed for the host to send a booting message. • 0x0000: OMAP device waits indefinitely for the host to send a booting message. • Others: The value expressed in milliseconds defines the maximum time the OMAP device will wait for the host to send a booting message (maximum 65.5 seconds).
Padding	2	

28.3.5 Peripheral Booting

28.3.5.1 Description

The ROM code can boot from two different peripherals:

- USB: Super-, high-, and full-speed USB from internal transceiver
- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the OMAP device (for example, in the case of initial flashing, firmware update or servicing). Figure 28-16 shows the overall peripheral booting procedure. It consists of a synchronization phase (handshake between the host and the OMAP device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. Figure 28-14 shows this procedure.

Figure 28-14. Synchronization Phase for UART

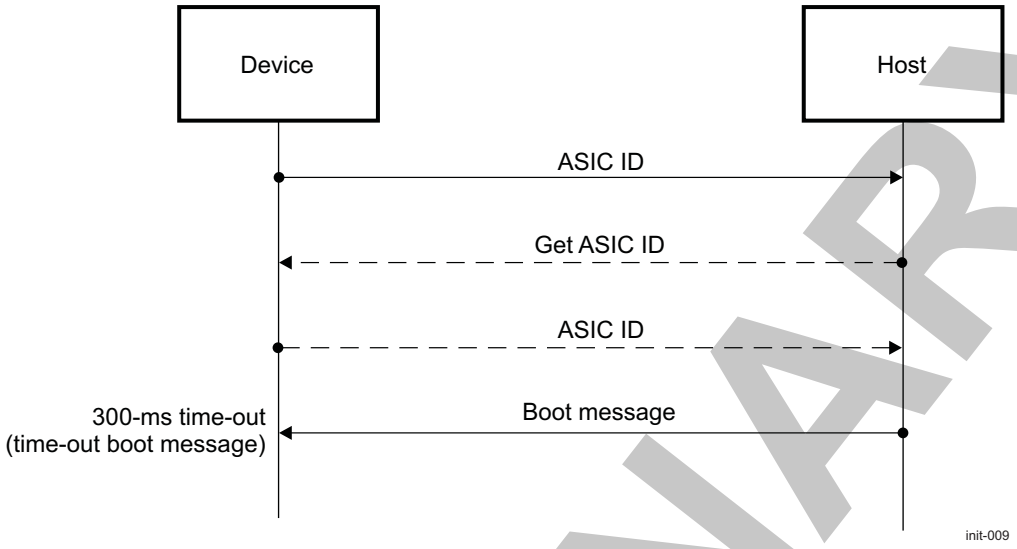

Figure 28-15 shows the procedure when booting from the USB.

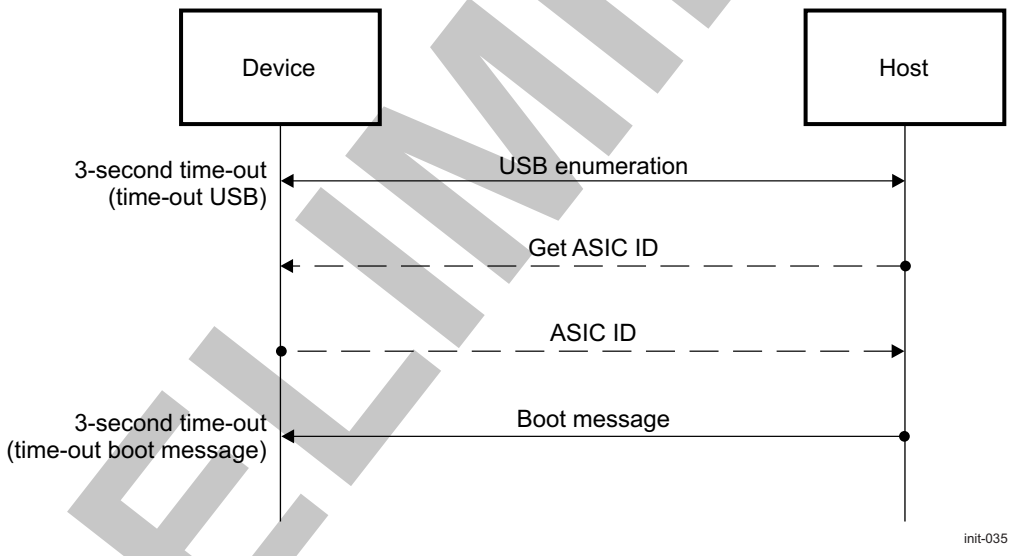
Figure 28-15. Synchronization Phase for USB



During the synchronization phase (see Figure 28-14 and Figure 28-15), the OMAP device can provide a small packet of data called the ASIC ID (described in Table 28-15). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The default time-outs involved during the synchronization phase can be redefined after a warm reset by means of the software booting configuration (described in Section 28.3.4.5, *Software Booting Configuration*). The host can decide the desired operation by providing a booting message (see Table 28-19). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the OMAP device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the OMAP device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting procedure aborts. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, then the image can be executed.

The flash loader image is downloaded directly into internal RAM from address 0x4030 0000 and the maximum size of the downloaded image is 120KiB.

NOTE: Sending an image size of zero skips the peripheral booting procedure.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can reuse the currently established connection. In the case of a USB connection, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

Table 28-15. ASIC ID Structure

ASIC ID Item	Size (Bytes)	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved subblock	4	This subblock is transmitted, but does not contain useful information in case of GP device.
Reserved subblock	23	This subblock is transmitted, but does not contain useful information in case of GP device.
Reserved subblock	35	This subblock is transmitted, but does not contain useful information in case of GP device.
Checksum subblock	11	CRC (4 bytes)

Table 28-16. Items

Offset	Size (Bytes)	Description
0x00	1	0x05: Number of subblocks USB 0x04: Number of subblocks UART(1)

(1) The checksum subblock is not transmitted over the UART.

Table 28-17. ID Subblock

Offset	Size (Bytes)	Description
0x01	1	0x01: Subblock ID
0x02	1	0x05: Subblock size
0x03	1	0x01: Fixed value
0x04	2	0x54, 0x30: OMAP5430 device

0x48	1	0x01: Fixed value
0x49	4	ROM CRC

(1) The checksum subblock is not transmitted over the UART.

Table 28-18. Checksum Subblock[1] (continued)

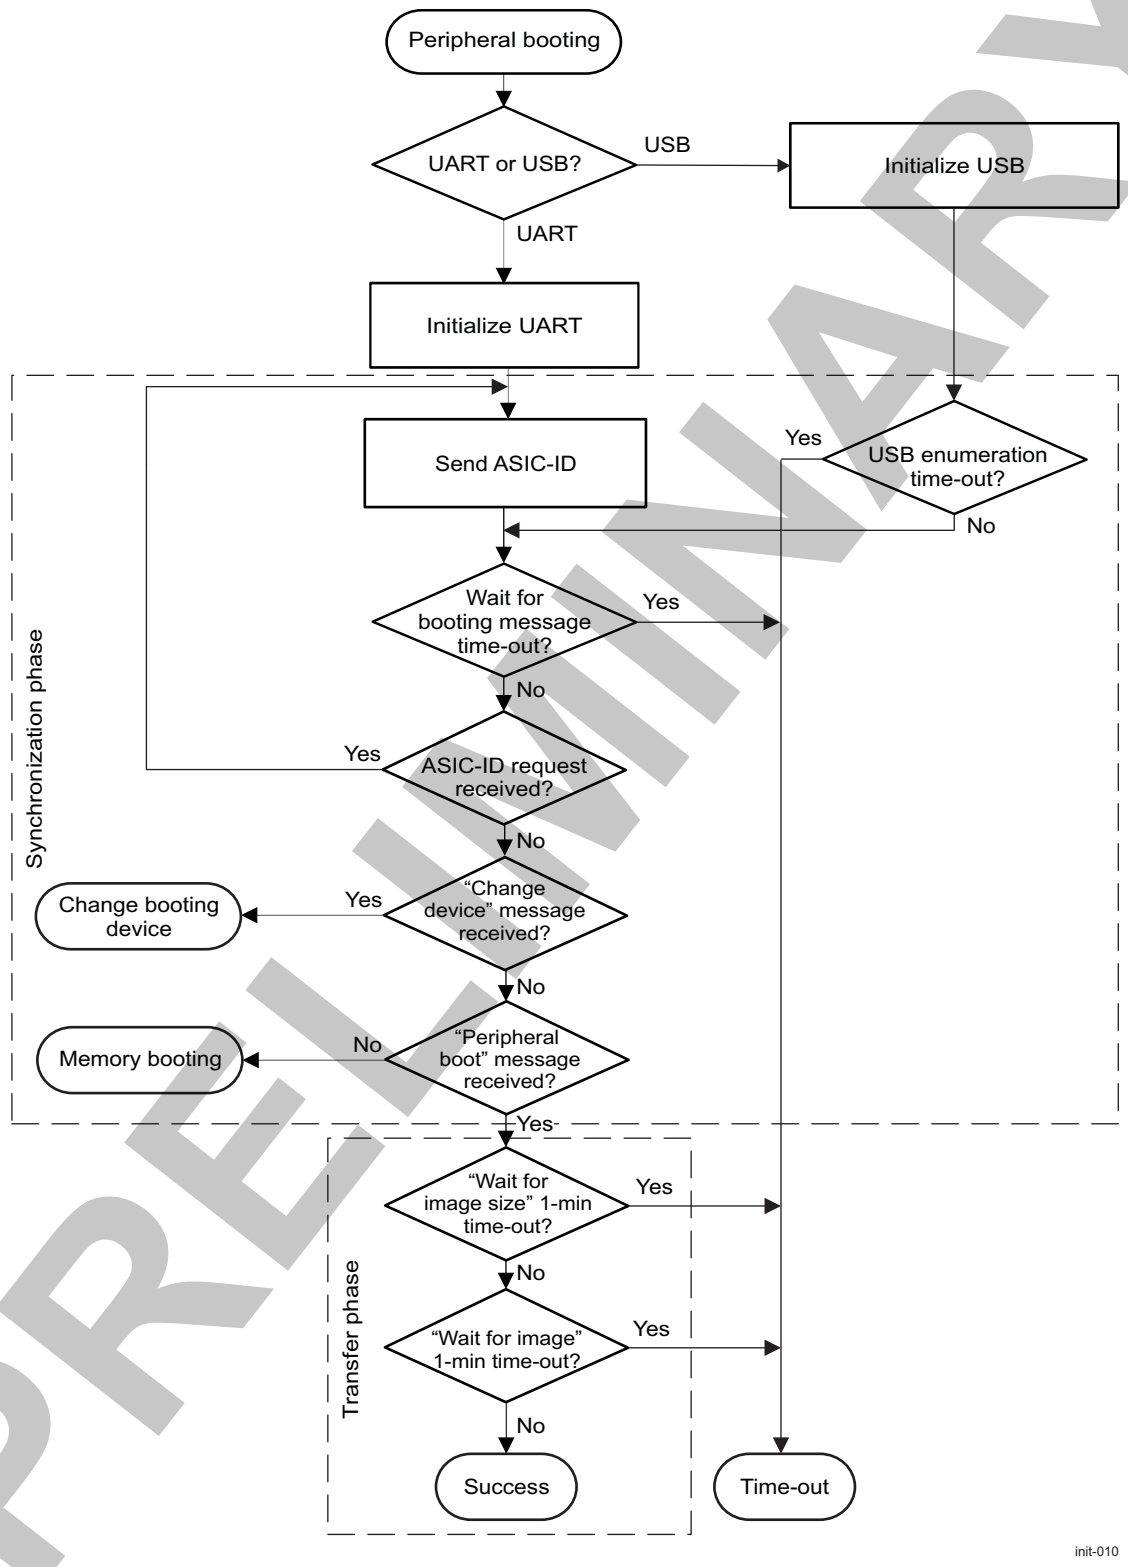
Offset	Size (Bytes)	Description
0x4D	4	0x0000 0000: For GP device

Table 28-19. Booting Messages

Message Name	Value	Description
Peripheral boot	0xF003 0002	Continue peripheral booting.
Get ASIC ID	0xF003 0003	ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. Table 28-15 describes the structure of the ASIC ID.
Change device	0xF003 xx06	Skip current peripheral booting and continue booting from device type indicated by xx: 0x01: XIP 0x02: XIP (with wait monitoring) 0x03: NAND 0x04: OneNAND 0x05: SD card 0x06: eMMC (from boot partition BP1 or BP2) 0x07: eMMC 0x09 SATA 0x43: UART 3 0x45: USB (from internal transceiver) Others: Reserved
Next device	0xFFFF FFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 28-16 shows the peripheral booting procedure.

Figure 28-16. Peripheral Booting Procedure



28.3.5.2 Initialization Phase for UART Boot

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit, no flow control
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

28.3.5.3 Initialization Phase for USB Boot

The ROM code supports booting from a USB interface with the following characteristics:

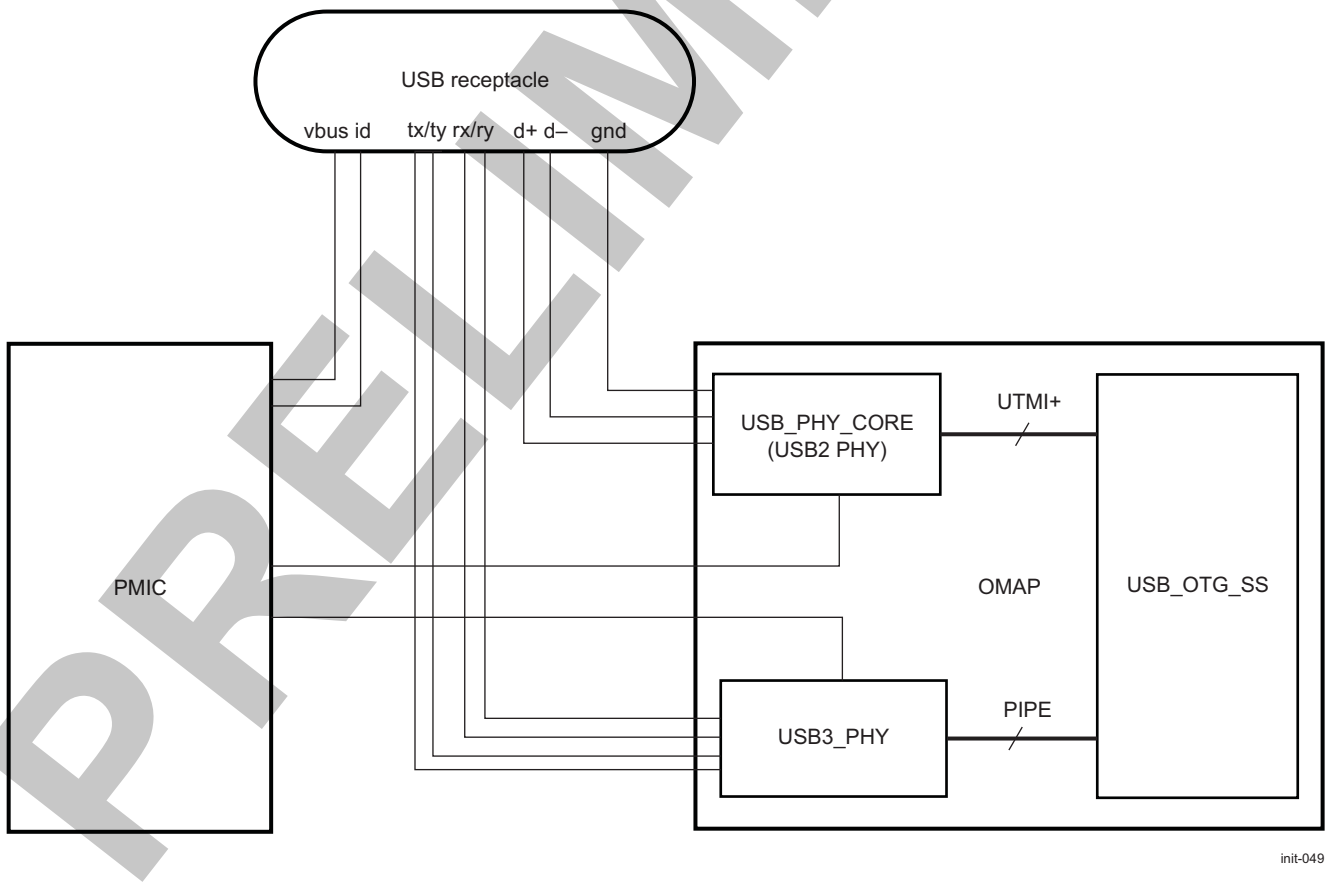
- Using the SS USB OTG (USBOTGSS) module through the USBD0 interface
- OMAP integrated USB transceiver (USB3_PHY or USB_PHY_CORE)
- Enumeration default time-out is 3 seconds (time-out USB)
- The boot message default time-out is 3 seconds (time-out boot message).

NOTE: Even though using OTG-capable hardware, the ROM code does not handle any OTG-specific features.

28.3.5.3.1 System Interconnection

Figure 28-17 shows the interconnection between the USB3 subsystem and its environment components

Figure 28-17. USB3 Subsystem



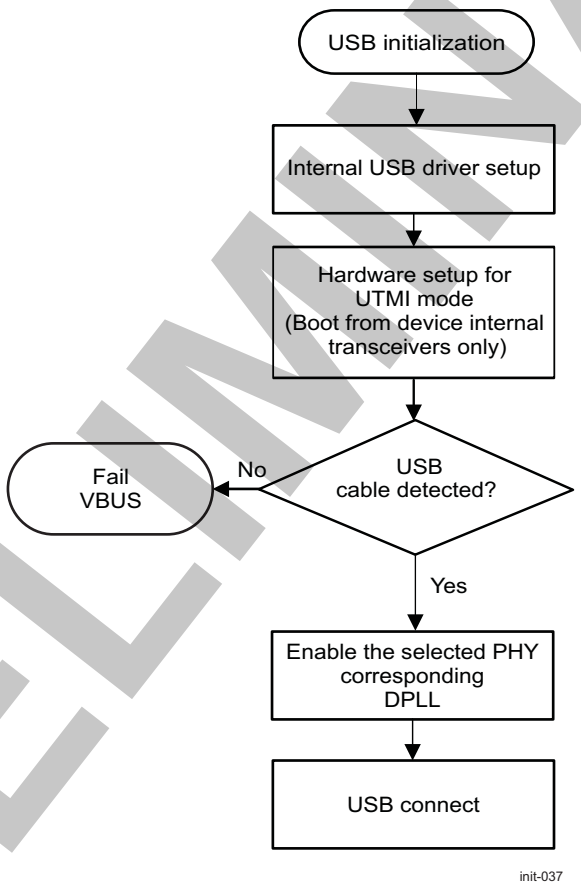
The ROM code supports booting through the USB3 subsystem and enumerates either as an USB2 or USB3 device depending on the nature of the cable connected to board receptacle. OMAP PHYs are assumed to be properly powered by the companion chip before entering the peripheral booting procedure (the ROM code does not take any action related to USB PHYs powering).

micro-B connector plugs into the on-board USB3 receptacle. If the host is USB2-compliant, then TXP/TXN/RXP/RXN differential pairs are left unconnected. In this case, the OMAP device enumerates as a USB2 device through legacy D+/D- differential pair. If an USB3 host is detected (USB3PHY receiver detection mechanism), then the OMAP device enumerates as a USB3 device.

NOTE: The internal USB3_PHY (SS) and USB_PHY_CORE (HS) transceivers must be powered and configured upon startup. No action is expected from the OMAP device ROM code for their configuration.

Figure 28-18 shows the USB initialization procedure.

Figure 28-18. USB Initialization Procedure



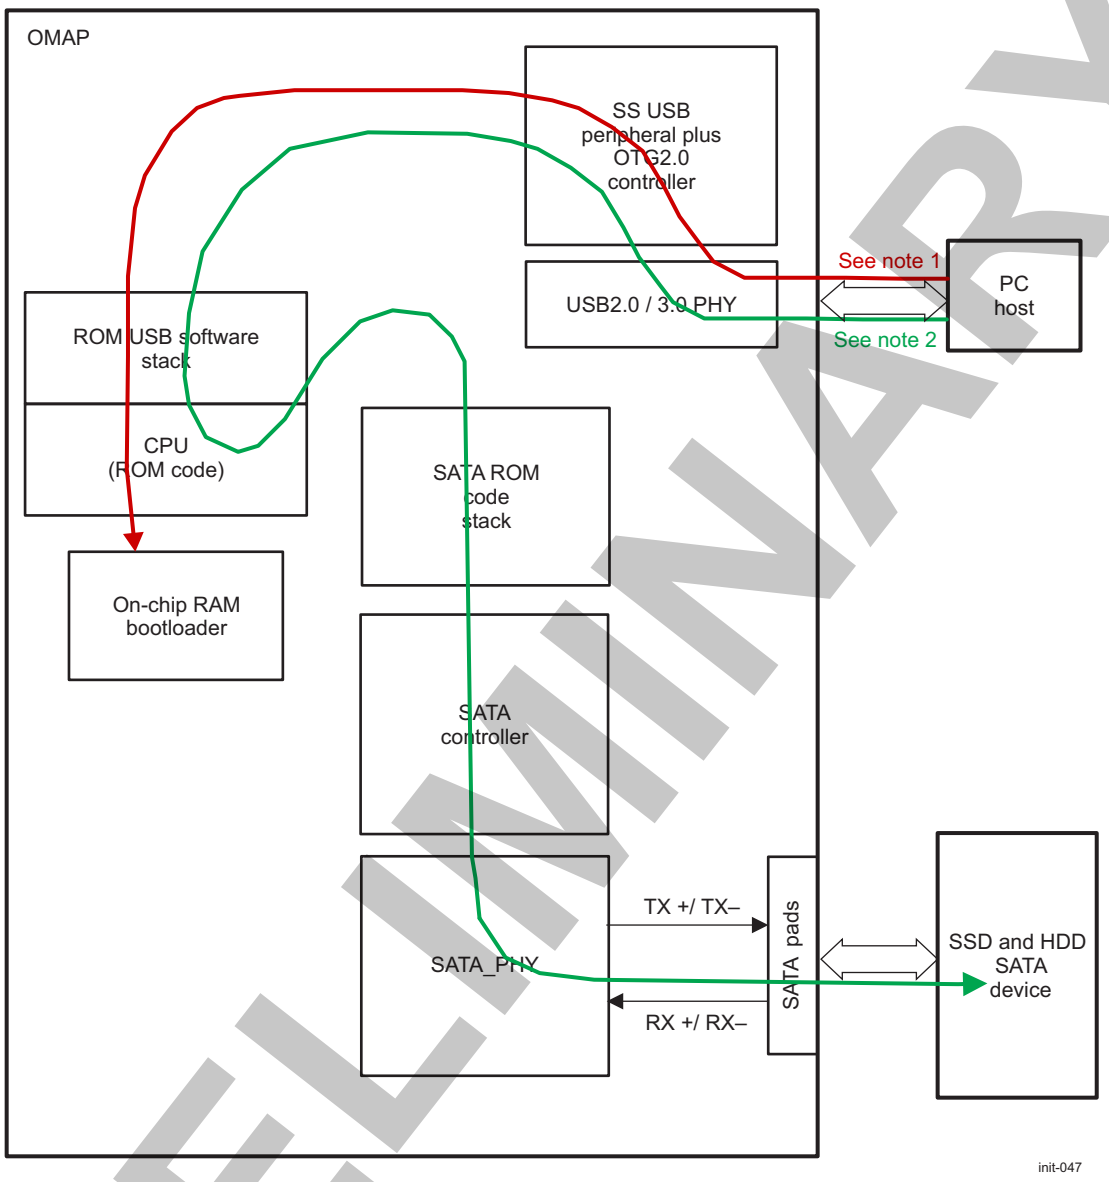
NOTE: The ROM code does not consider the USB PHYs charger detection circuitry status.

NOTE: The ROM code assumes that VBUS is always present.

28.3.5.3.2 SATA Peripheral Device Flashing over USB Interface

In the next scheme (see Figure 28-19), it is assumed that the new version of the firmware OMAPFlash Host is located in the PC host. In the same way, the application loaded to OMAP internal L3 On-chip RAM (using the peripheral boot function of the OMAP ROM code) is called OMAPFlash Second.

Figure 28-19. SATA Flashing Over USB



(1) ROM boots from USB controller and downloads OMAPFlash Second in RAM.

(2) The PC host is allowed to flash the OMAP firmware located in the SATA device.

28.3.5.3.3 USB Driver Descriptors

USB devices use descriptors to report their attributes. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

  A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. Table 28-20 lists the device descriptors.

Table 28-20. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (Texas Instruments), TI default value
idProduct	0xD01-	Product ID, TI default value
bcdDevice	0x0000	Device release number
iManufacturer	See Section 28.3.5.3.4.	Index of string descriptor describing manufacturer
iProduct	See Section 28.3.5.3.4.	Index of string descriptor describing product
iSerialNumber	See Section 28.3.5.3.4.	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

  The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). Table 28-21 lists the device-qualifier descriptors.

Table 28-21. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

  This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see Table 28-22).

Table 28-22. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor

  This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see Table 28-23).

Table 28-23. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

  This descriptor describes a specific interface in a configuration (see Table 28-24).

Table 28-24. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

  Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request (see Table 28-25 and Table 28-26).

Table 28-25. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See (1).	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 28-26. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device

Table 28-26. BULK OUT Endpoint Descriptor (continued)

Field	Value	Description
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See (1).	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

(1) The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

  String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

  For the description of the different string descriptors, see:

  – The language ID string descriptor (Table 28-27)
  – The manufacturer ID string descriptor (Table 28-28)
  – The product ID string descriptor (Table 28-29)
  – The configuration string descriptor (Table 28-30)
  – The interface string descriptor (Table 28-31)

Table 28-27. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 28-28. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x24	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Texas Instruments	Manufacturer string

Table 28-29. Product ID String Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	OMAP5430	Product string

Table 28-30. Configuration String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type

Field	Value	Description
bString	pbi	Interface string

28.3.5.3.4 USB Customized Vendor and Product IDs

When OMAP ROM Code enumerates through USB, one may want to use his/her own vendor and product IDs rather than TI defaults. Product and Vendor IDs are transmitted as part of the USB Standard Device Descriptor during the USB device enumeration process (resp. idProduct and idVendor 16 bits fields).

Product IDs (PIDs) and vendor IDs (VIDs) are stored as part of OMAP chip eFuses and readable from control module. The built-in USB ROM driver behaves differently whether the VID value is either left unfused, or fused with a customer-specific VID. Thus, two main cases are distinguished:

- VID is fused with a customer-specific ID value
- VID is left unfused

Table 28-32 lists standard USB ROM device descriptors. Table 28-33 lists USB ROM descriptor strings.

Table 28-32. USB ROM Standard Device Descriptor

Device Descriptor Field	Size (Bytes)	VID<>0x0000[1] (fused)	VID=0x0000 (unfused)[2]
bLength	1	0x12	
bDescriptorType	1	0x1	
bcdUSB	2	0x0200 (if enumerated in USB2.0 High or Full Speed) 0x0300 (if enumerated in USB3.0 Super Speed)	
bDeviceClass	1	0xFF	
bDeviceSubClass	1	0xFF	
bDeviceProtocol	1	0xFF	
bMaxPacketSize0	1	0x40 (64 bytes if enumerated in USB2.0 high or full speed) 0x09 (2^9 = 512 bytes if enumerated in USB3.0 super speed)	
idVendor	2	(VID value from control module)	0x0451
idProduct	2	(PID value from control module)	0xD011
bcdDevice	2	0x0000	
iManufacturer	1	0x20	0x21
iProduct	1	0x24	0x25
iSerialNumber	1	0	
bNumConfigurations	1	1	

(1) VID other than 0x0 and VID other than 0xFFFF and VID other than 0x0451 values
(2) VID==0x0 or VID==0xFFFF or VID==0x0451

Table 28-33. USB ROM Descriptor Strings

String Descriptor	Size (bytes)	VID<>0x0000	VID=0x0000(unfused)[1]
Serial Number		N/A	
Configuration	8	"pbc"	
Interface	8	"pbi"	
Product	8 / 18	N/A	"OMAP5430"
Manufacturer	8 / 36	N/A	"Texas Instruments"

(1) VID==0x0451

The ROM code transmits additional descriptors as part of the enumeration procedure: configuration descriptor, device qualifier, language ID string, configuration string, interface string, and function string descriptors. Those do not depend on the VID or PID value.

28.3.5.3.5 USB Driver Functionality

- Transactions supported:
  - Control transactions: Used for standard device requests
  - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the BULK IN endpoint and the image is transferred from the host over the BULK OUT endpoint.

  The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase succeeds, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.
- Standard device request restrictions:

  Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 28-34 lists the standard device requests supported by the driver.

Table 28-34. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets or clears a specific feature	Supported only for the ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for the ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

28.3.6 Fast External Booting

28.3.6.1 Overview

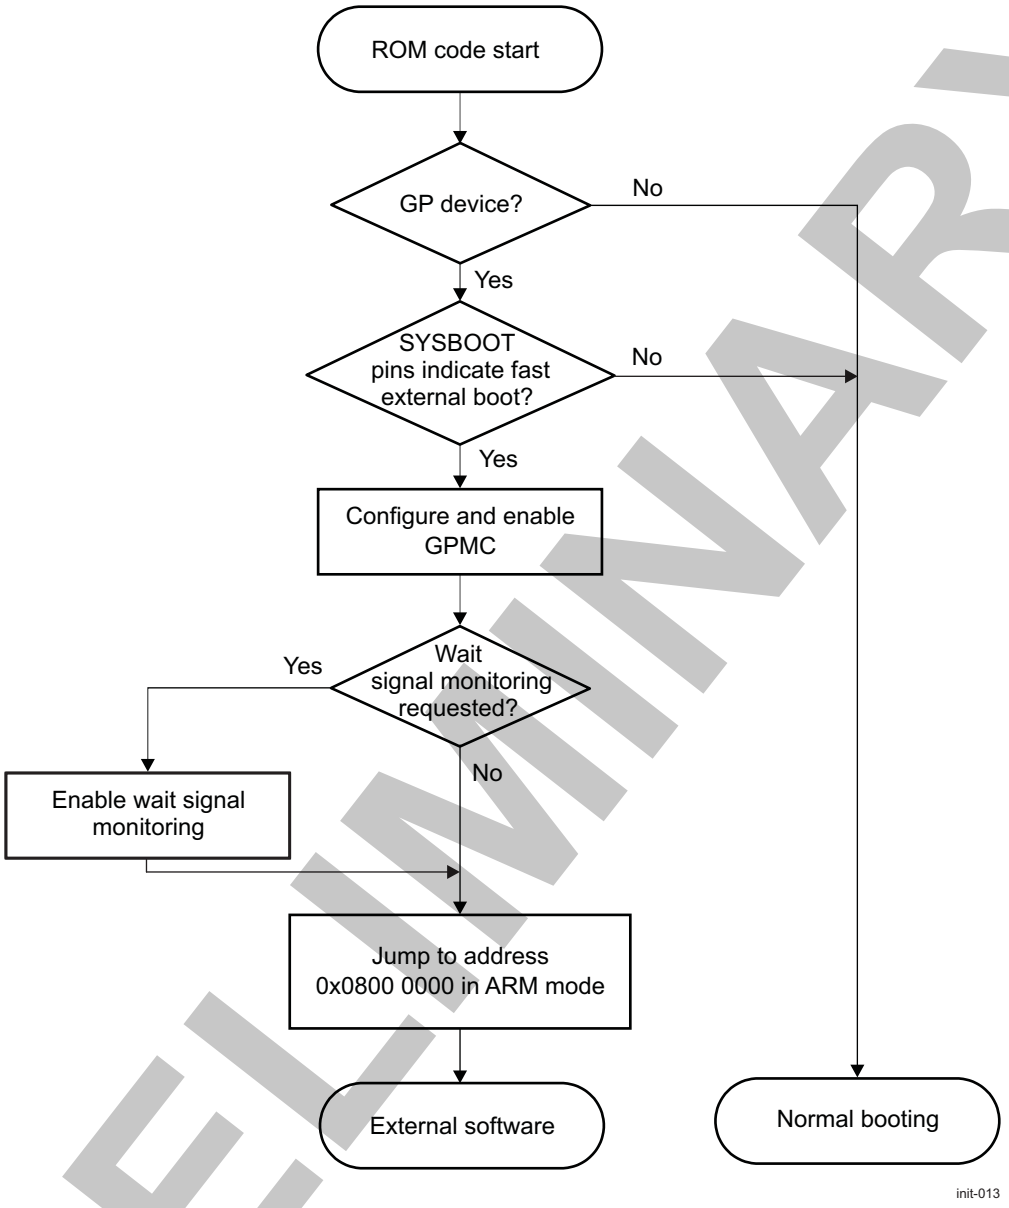
The fast external boot is a special memory booting mode, possible only on OMAP GP devices. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0. Fast external booting is set up by means of the SYSBOOT configuration pins and lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

28.3.6.2 Fast External Booting Procedure

Figure 28-20 shows the procedure for fast external boot. The code is at the beginning and is written in Assembly Language. The code does not use any RAM and is designed for fast execution.

Figure 28-20. Fast External Boot Procedure



28.3.7 Memory Booting

28.3.7.1 Overview

The memory booting process starts an external code in memory devices. ROM code can use only the memory type of booting devices as permanent booting devices (that is, devices examined after both cold [POR] and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- OneNAND and Flex-OneNAND devices
- eMMC memories
- SD cards
- SATA SSD and HDD storage memory devices

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

Figure 28-21 shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP device can temporarily lose a connection with XIP memory during CH execution (for example, while updating interface timings). The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

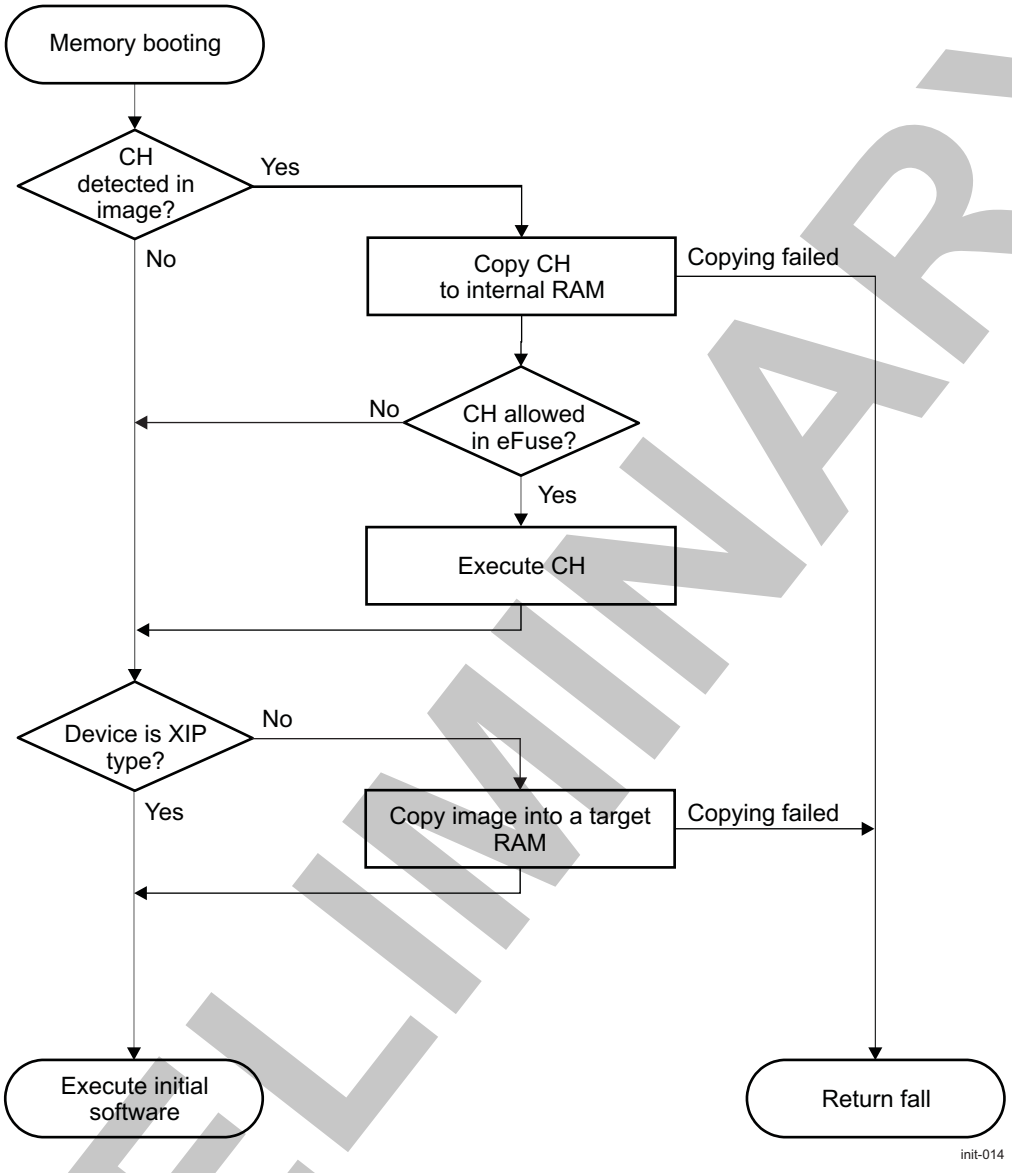
If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

A booting image is considered to be present on a GP device, when the first 4 bytes word of the sector is not equal to 0000 0000h or FFFF FFFFh.

During the first read sector (512 bytes) call, sectors are copied to a temporary OMAP on-chip SRAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target OMAP on-chip SRAM location so it is required to reread the first image sector. For a GP device, the GP header is not copied into target buffer location; therefore, only executable code is in device on-chip RAM, with the first executable instruction at the destination address.

eMMC, SD cards, NAND, OneNAND/Flex-OneNAND and SATA SSD or HDD devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four copies, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

Figure 28-21. Memory Booting Procedure

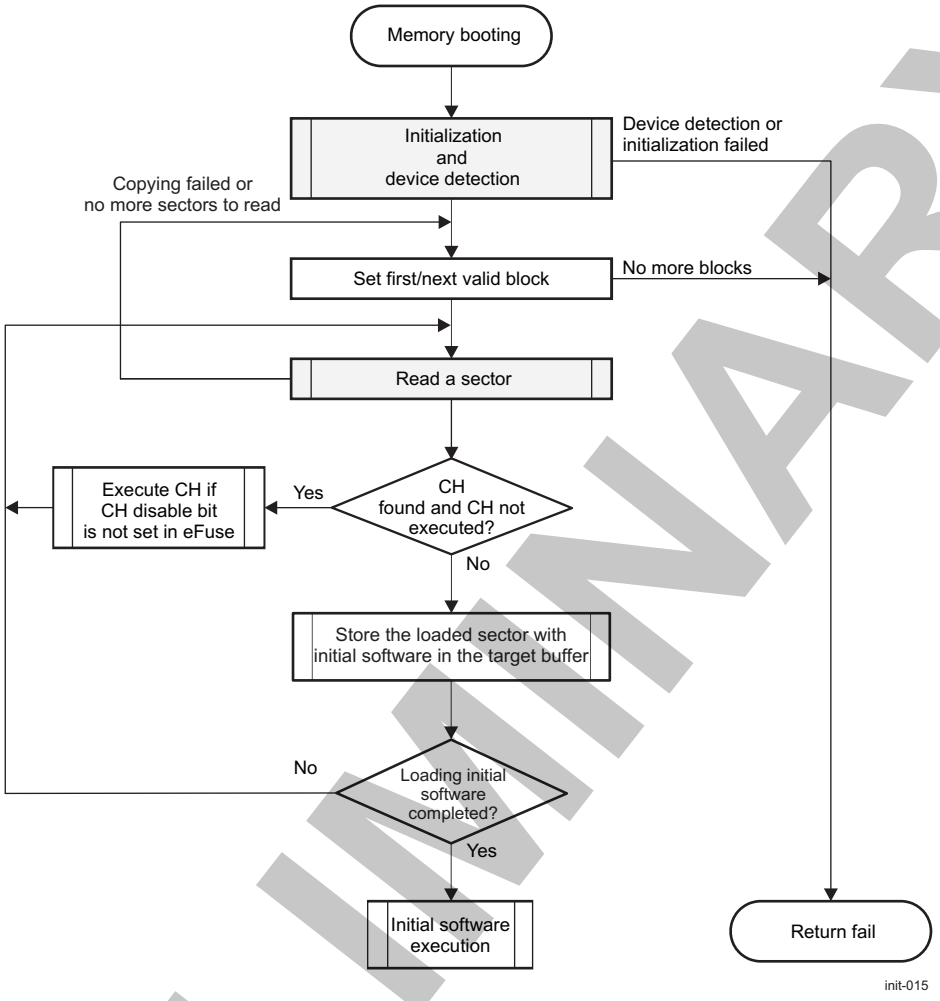


28.3.7.2 Non-XIP Memory

Figure 28-22 shows the procedure used when memory booting runs with non-XIP devices. The shaded procedures are specific to each device. NAND and OneNAND/Flex-OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 28-22. Image Shadowing on GP Device



For more information about the GPMC module, see Section 15.4.1, *GPMC Overview*, in Chapter 15, *Memory Subsystem*.

Section 28.3.7.4, Section 28.3.7.5, Section 28.3.7.6, and Section 28.3.7.7describe the supported device types.

28.3.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1Gibit (128MiB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 66.5 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin gpmc_wait0 signal is monitored according to the sys_boot configuration pins.

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

Booting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If the CH is present, copy the entire sector (512 bytes) to internal RAM and execute the CH.
3. Set the image location:
   - 0x0800 0000 if the CH is not found
   - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. If the image is found, execute it.
6. If the image is not found, return from XIP booting to the main booting loop.

28.3.7.3.1 GPMC Initialization

Table 28-35 lists the timing settings of the GPMC when set for XIP and other address-data accessible devices, such as OneNAND and Flex-OneNAND. Table 28-35 is included for debug information.

Table 28-35. XIP Timing Parameters

Parameter	Value (Clock Cycles)[1]	Register Initialization (where i = 0–7)
Write cycle period	17	GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x11.
Read cycle period	17	GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x11.
CS low time	1	GPMC_CONFIG2_i[3:0] CSONTIME = 0x1.
CS high time	16	GPMC_CONFIG2_i[12:8] CSRDOFFTIME = 0x10.
ADV low time	1	GPMC_CONFIG3_i[3:0] ADVONTIME = 0x1.
ADV high time	2	GPMC_CONFIG3_i[12:8] ADVRDOFFTIME = 0x2.
OE low time	3	GPMC_CONFIG4_i[3:0] OEONTIME = 0x3.
OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10.
WE low time	3	GPMC_CONFIG4_i[19:16] WEONTIME = 0x3.
WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF.
Data latch time	15	GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xF.

(1) The one clock cycle is approximately 15 ns, which corresponds to a 66.5-MHz frequency.

There is no specific identification routine executed before booting from an XIP device.

NOTE: The device ROM Code enables the gpmc_a16 to gpmc_a25 address signals on their device-corresponding pads in the control module (CTRL_MODULE_CORE_PAD) by setting the appropriate GPMC muxmode. Therefore, all GPMC address lines are accessible for GPMC booting. For more details, see Section 18.4.8.3, *Pad Multiplexing Register Fields*, of Chapter 18, *Control Module*.

28.3.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mibit (64MiB)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size (4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table

- ECC correction: 8 bits per sector for most devices (16 bits per sector for devices with large spare area)
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 66.5 MHz.
- The device is connected to CS0.
- The gpmc_wait0 wait-pin signal is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

28.3.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

  The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. Table 28-36 shows the GPMC configuration used during NAND boot. Table 28-36 is included for debug information.

Table 28-36. NAND Timing Parameters

Parameter	Value (Clock Cycles)	Register Initialization (where i = 0–7)
Write cycle period	20	GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14
Read cycle period	20	GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14
CS low time	0	GPMC_CONFIG2_i[3:0] CSONTIME = 0x0
CS low to OE low time	5	GPMC_CONFIG4_i[3:0] OEONTIME = 0x5
CS low to OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10
CS low to WE low time	1	GPMC_CONFIG4_i[19:16] WEONTIME = 0x1
CS low to WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF
CS low to data latch time	14	GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE

- Device detection and parameters

  The ROM code first performs an initial wait for device auto initialization (with a 250-ms time-out) with polling of the ready information. Then, it must identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with a 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in Table 28-37 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameter page stream are ignored.

Table 28-37. ONFI Parameters Page Description

Offset	Description	Size (Bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI), then the device is reset again with polling for device to be ready (with 100-ms time-out). Then, the standard Read ID (command 90h/address 00h) is sent. If the Device ID (second byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM code table. Table 28-38 lists the supported NAND devices.

Table 28-38. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in Bytes
512 Mibit	F0h	8	2048
512 Mibit	C0h	16	2048
512 Mibit	A0h	8	2048
512 Mibit	B0h	16	2048
512 Mibit	F2h	8	2048
512 Mibit	C2h	16	2048
512 Mibit	A2h	8	2048
512 Mibit	B2h	16	2048
1 Gibit	F1h	8	2048
1 Gibit	C1h	16	2048
1 Gibit	A1h	8	2048
1 Gibit	B1h	16	2048
2 Gibit	DAh	8	2048 (4096)
2 Gibit	CAh	16	2048 (4096)
2 Gibit	AAh	8	2048 (4096)
2 Gibit	BAh	16	2048 (4096)
2 Gibit	83h	8	2048 (4096)
2 Gibit	93h	16	2048 (4096)
4 Gibit	DCh	8	2048 (4096)
4 Gibit	CCh	16	2048 (4096)
4 Gibit	ACh	8	2048 (4096)
4 Gibit	BCh	16	2048 (4096)
4 Gibit	84h	8	2048 (4096)
4 Gibit	94h	16	2048 (4096)
8 Gibit	D3h	8	2048 (4096)
8 Gibit	C3h	16	2048 (4096)
8 Gibit	A3h	8	2048 (4096)
8 Gibit	B3h	16	2048 (4096)
8 Gibit	85h	8	2048 (4096)
8 Gibit	95h	16	2048 (4096)
16 Gibit	D5h	8	2048 (4096)
16 Gibit	C5h	16	2048 (4096)
16 Gibit	A5h	8	2048 (4096)
16 Gibit	B5h	16	2048 (4096)
16 Gibit	86h	8	2048 (4096)
16 Gibit	96h	16	2048 (4096)
32 Gibit	D7h	8	2048 (4096)
32 Gibit	C7h	16	2048 (4096)
32 Gibit	A7h	8	2048 (4096)
32 Gibit	B7h	16	2048 (4096)
32 Gibit	87h	8	2048 (4096)
32 Gibit	97h	16	2048 (4096)
64 Gibit	DEh	8	2048 (4096)

Table 28-38. Supported NAND Devices (continued)

Capacity	Device ID	Bus Width	Page Size in Bytes
64 Gibit	CEh	16	2048 (4096)
64 Gibit	AEh	8	2048 (4096)
64 Gibit	BEh	16	2048 (4096)

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2 Gibit have these parameters updated. Therefore, the ROM code supports 4-KiB page devices, but only if their size, according to the table, is at least 2 Gibit. Devices that are smaller than 2 Gibit have the block size parameter set to 128 KiB (when the page size is 2 KiB). Table 28-39 lists the fourth ID data byte encoding used in the ROM code.

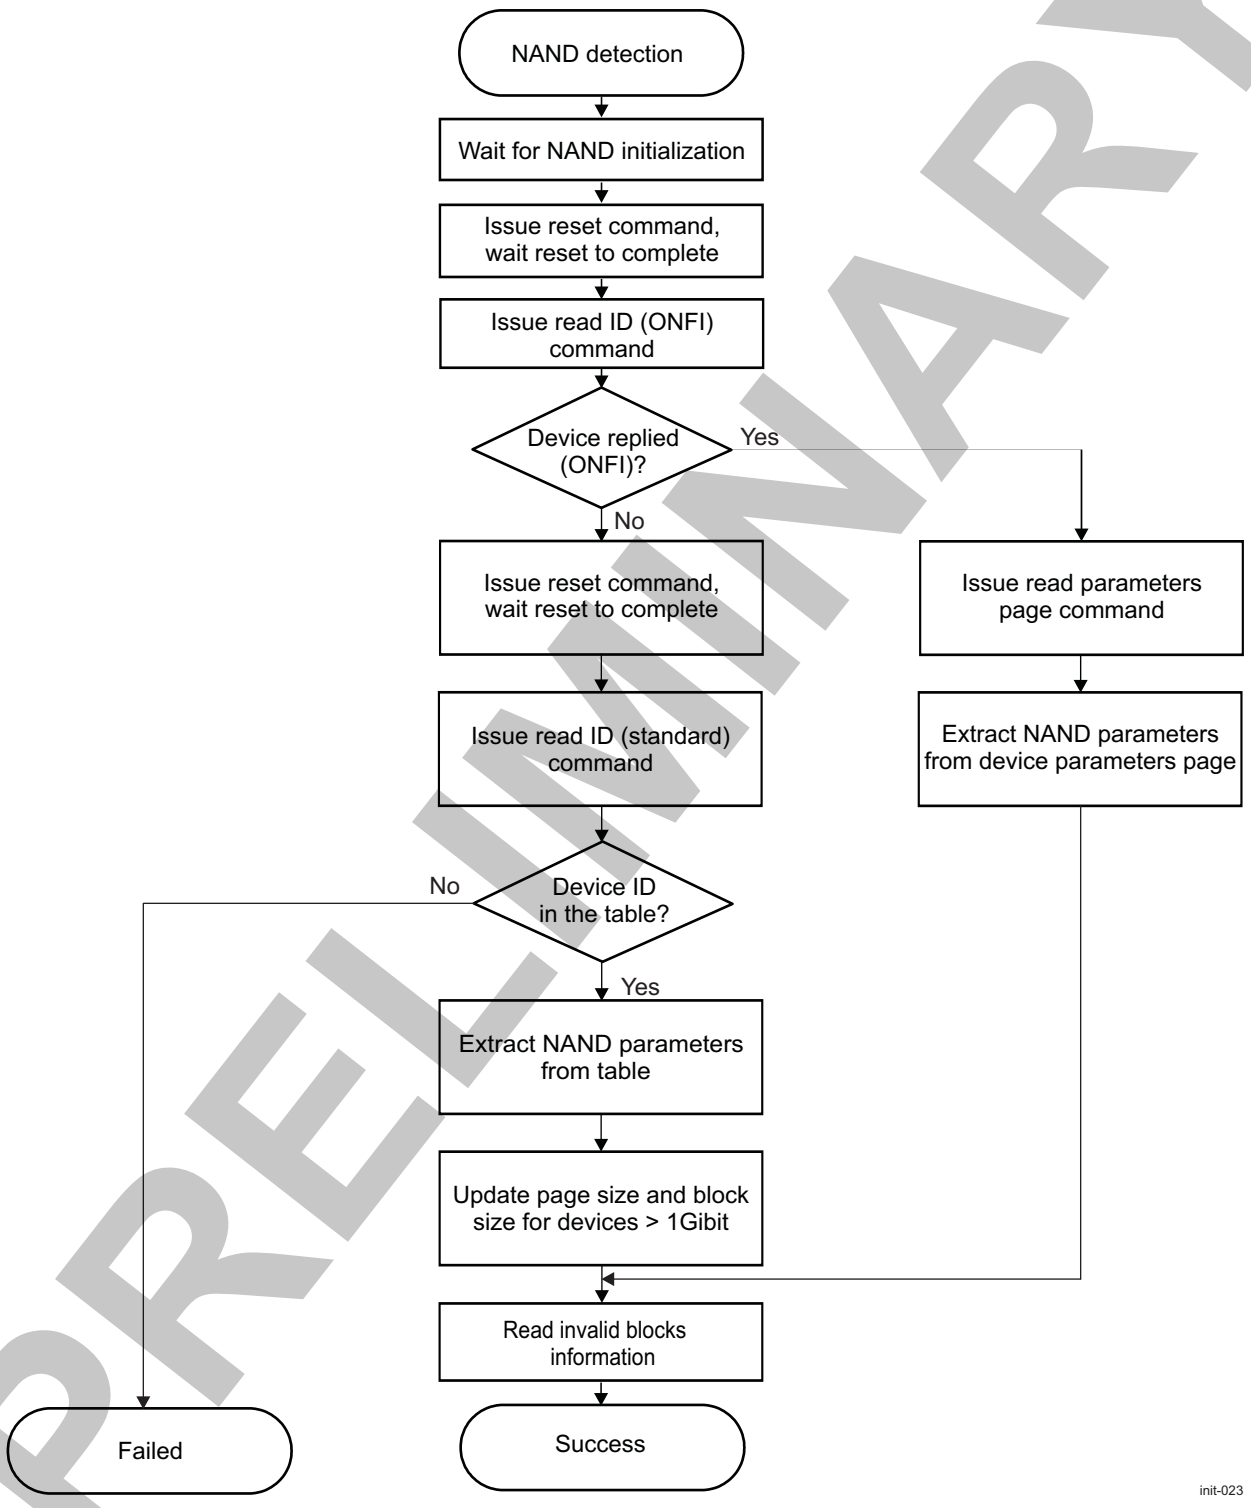
Table 28-39. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page size	512 bytes							0	0
	2048 bytes							0	1
	4096 bytes							1	0
	8192 bytes							1	1
Cell type (1)	2 levels					0	0		
	4 levels					0	1		
	8 levels					1	0		
	16 levels					1	1		
Block size	64 KiB			0	0				
	128 KiB			0	1				
	256 KiB			1	0				
	512 KiB			1	1				

(1) Read by ROM code only when the manufacturer code (first ID byte) is 98h

Figure 28-23 shows the detection procedure. When the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

Figure 28-23. NAND Device Detection



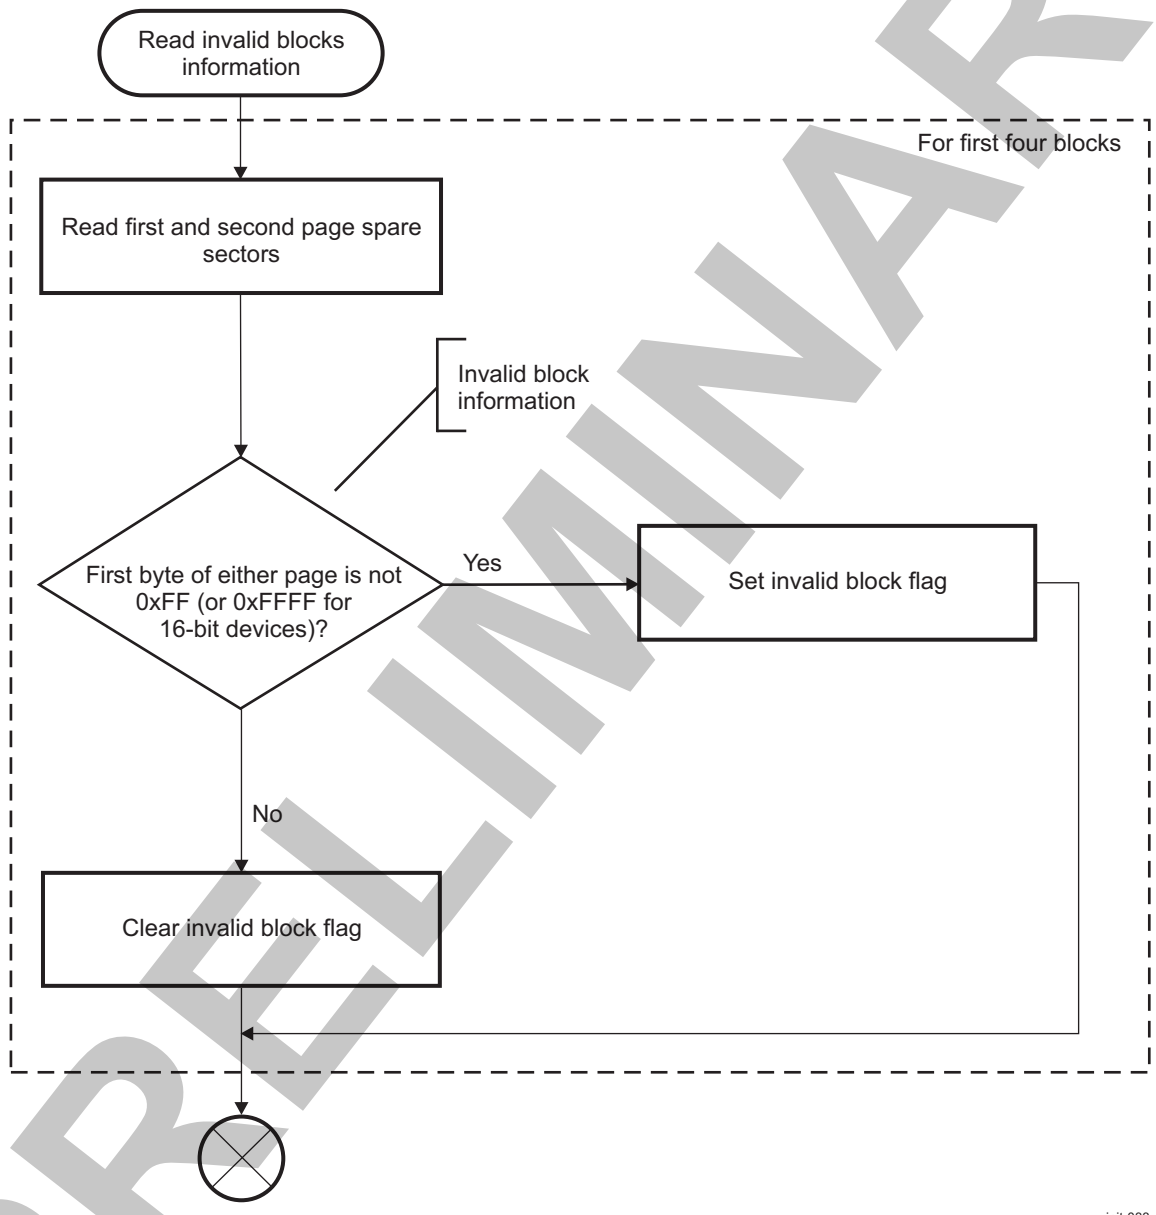
- Bad block verification

  Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code

looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 28-24 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

Figure 28-24. Bad NAND – Invalid Block Detection



28.3.7.4.2 NAND Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, and CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the fourth byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. Figure 28-25 and Figure 28-26 show the mapping of ECC data inside the spare area for 2-KiB page and 4-KiB page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct errors in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

Figure 28-25. ECC Data Mapping for 2-KiB Page and 8b BCH Encoding

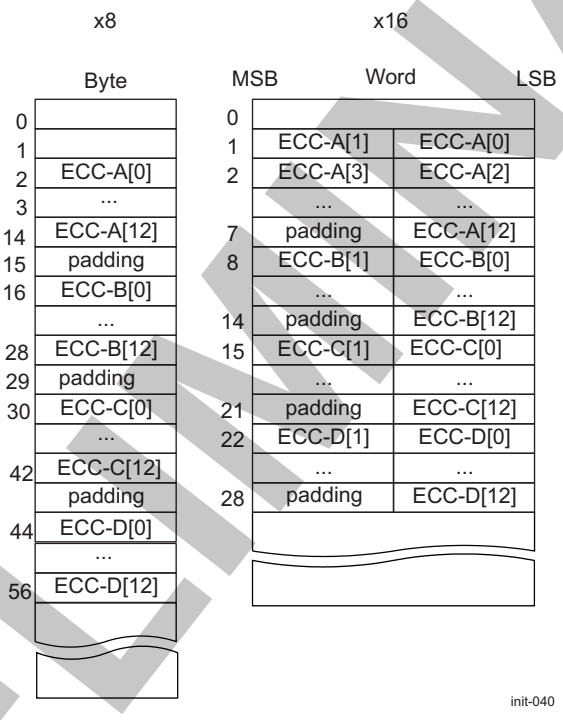


Figure 28-26. ECC Data Mapping for 4-KiB Page and 16b BCH Encoding

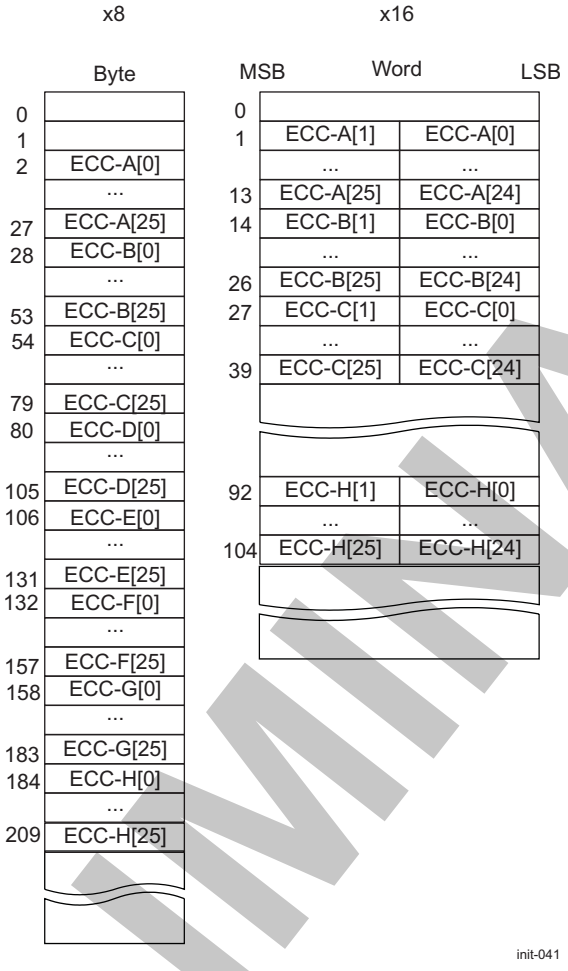


28.3.7.5 OneNAND/Flex-OneNAND

The ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512 Mibits
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 66.5 MHz.
- The device is connected to GPMC CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for an image. The block size is 128KiB (typically).
- The image size must NOT exceed the block size
- Data correction is fully handled by the OneNAND/FlexOneNAND device

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is required. The information in the following sections is included for debugging. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

28.3.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and device detection with parameter determination.

- GPMC initialization

  The ROM code first initializes the GPMC interface in XIP mode (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled.

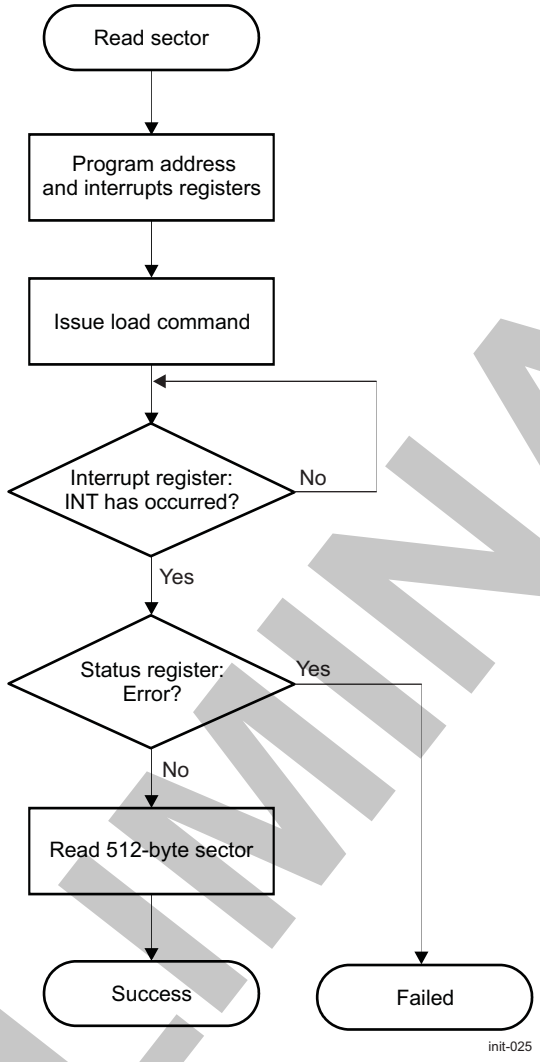
- Device detection and parameters

  The ROM code identifies a OneNAND/Flex-OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory-mapped registers. The ROM code reads identification data using both methods and compares the results. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (number and size of data buffers) and configures it for asynchronous mode (default).

28.3.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code performs the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. Figure 28-27 shows this procedure.

Figure 28-27. OneNAND/Flex-OneNAND Read Sector



28.3.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in Section 28.3.7.5.1, *Initialization and OneNAND/Flex-OneNAND Detection*, the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported Flex-OneNANDs in ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four 512-byte sectors. In case of OneNAND/Flex-OneNAND, with 4096-byte pages, divided into eight sectors, users must program only the first sectors (sectors 0 through 3) of each page. Sectors 4 through 7 of each page are not considered by the driver.

28.3.7.6 eMMC Memories and SD Cards

The OMAP device allows booting from eMMC embedded memories or SD cards connected to OMAP embedded MMC2 or MMC1 controllers I/Os, respectively. The booting interface is selected by configuration of the SYS_BOOT pins.

The OMAP device high speed MMC/SD/SDIO host controller (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

The SD card interface supports 1.8-V/3-V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the SD card device. The eMMC interface supports only 1.8-V digital I/Os.

The OMAP device supports three booting modes:

- Raw (Boot): The booting image is read from one of the selectable partitions in raw mode (this mode is also called Alternative Boot Operation mode and applies to eMMC only).
- Raw (UDA): The booting image is read from the user data area (eMMC and SD).
- File system (FAT12/16/32 with or without master boot record): The image data is read from a booting file within a file system in the user data area (eMMC and SD).

NOTE: File system mode is not supported when booting from an eMMC partition.

28.3.7.6.1 eMMC Memories

The ROM code supports booting from eMMC cards, with the following conditions:

- eMMC memory devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.5* from the MMCA Technical Committee. The exception is the hardware reset feature. For example, if the user software requires eMMC device hardware reset, it can be accomplished with a GPIO. To correctly boot from eMMC when using Alternative Boot Operation mode, it is recommended to tie the eMMC RST_N signal to the signal indicating a platform warm reset (nRESWARM).
- eMMC device connected to the OMAP MMC2 controller I/O interface available on the OMAP eMMC pads (one device only connected to the bus).
- The eMMC memory device is powered externally by a PMIC or other power supply.
- When booting from user area: Initial (default) 1-bit SDR mode, optional 4-bit and 8-bit SDR- and DDR-modes using Configuration Header
- Initial SDR- and DDR- modes supported
- Clock frequency when booting from user area:
  - Identification mode: 400 kHz
  - Data transfer mode: 10 MHz, optionally up to 48 MHz by Configuration Header
  - Support for eMMC boot partitions. eMMC booting from boot partitions (BPs), which is typical for booting in Alternative Boot operation mode, is always done at 8-bit / 48 MHz / DDR.

28.3.7.6.1.1 System Conditions and Limitations

The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.

NOTE: The ROM Code does not support large 4-KiB sectors as defined in the latest standard.

The ROM code expects that the eMMC device is powered externally and supplies are set and stable when entering the booting procedure.

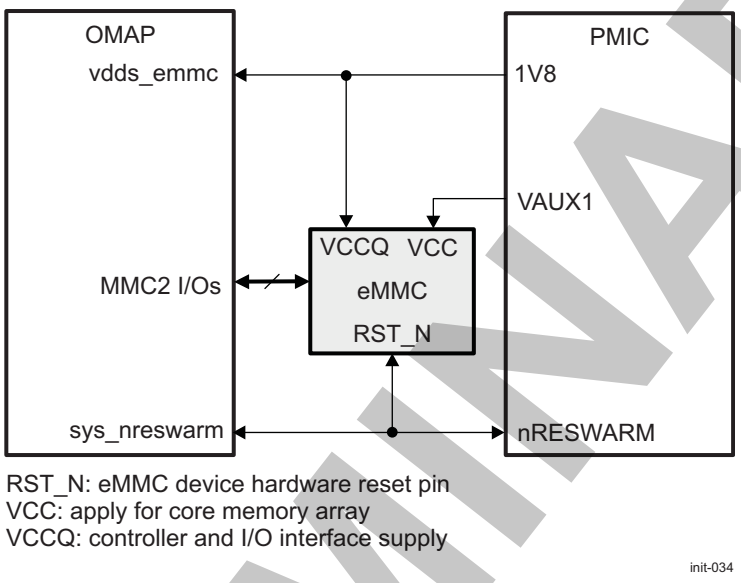
The ROM code supports the alternative boot operation mode specific to eMMC devices as described in the *Partition Management* and *Boot Operation Mode* sections of the eMMC Standard. It does not support the hardware boot operation mode (CMD line held low for 74 emmc_clk cycles) described in the same document.

28.3.7.6.1.2 eMMC Memory Connection

An eMMC device typically requires two supplies: one for the core memory array (VCC) and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

Figure 28-28 shows an example of the system connection between the PMIC, memory device, and OMAP device.

Figure 28-28. eMMC Connection



NOTE: For correct handling of eMMC boot partitions when using alternative boot operation mode, it is recommended to tie the eMMC RST_N signal to the signal indicating a platform warm reset (nRESWARM).

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 I/O signals on the eMMC pads depending on the selected SYSBOOT configuration.

28.3.7.6.2 SD Cards

The ROM code supports booting from SD cards under the following conditions:

- SD cards compliant with *SD Specifications Part 1 Physical Layer Specification Version 4.00*and the *SD Specifications Part 2 File System Specification Version 3.00* from the SD Association. These include low- (SDSC) and high-capacity (SDHC) cards.
- SD card connected to SDCARD pads interface (OMAP MMC1 controller I/Os). Only one card is allowed to be connected to the bus.
- 3-V VCC power supply
- Initial 1-bit MMC mode, optional 4-bit mode
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: Up to 10 MHz (optionally up to 19.2 MHz)

28.3.7.6.2.1 System Conditions and Limitations

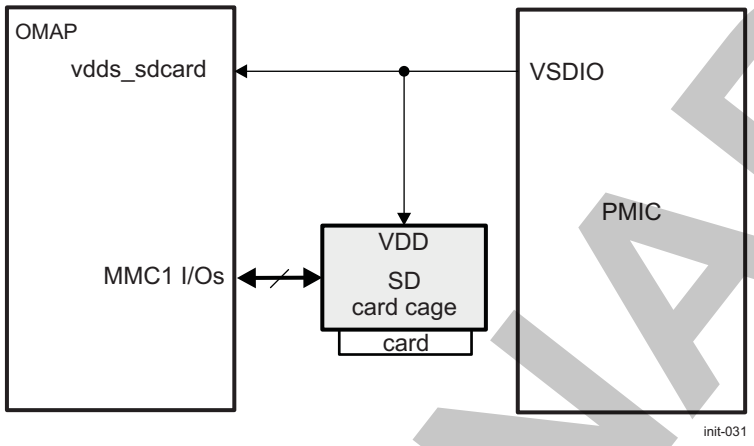
Even though the ROM Code identities SDXC cards, it does not handle its specificities such as exFAT support. It does neither support UHS-I nor UHS-II speed grades.

28.3.7.6.2.2 SD Card Connection

A, SD card can be connected to the SD card interface, typically through a card cage.

Figure 28-29 shows the typical connection between the power IC, the card, and the OMAP device.

Figure 28-29. MMC/SD Card Connection



NOTE: The ROM code does not handle the card detection feature on the card cage.

28.3.7.6.2.3 Booting Procedure

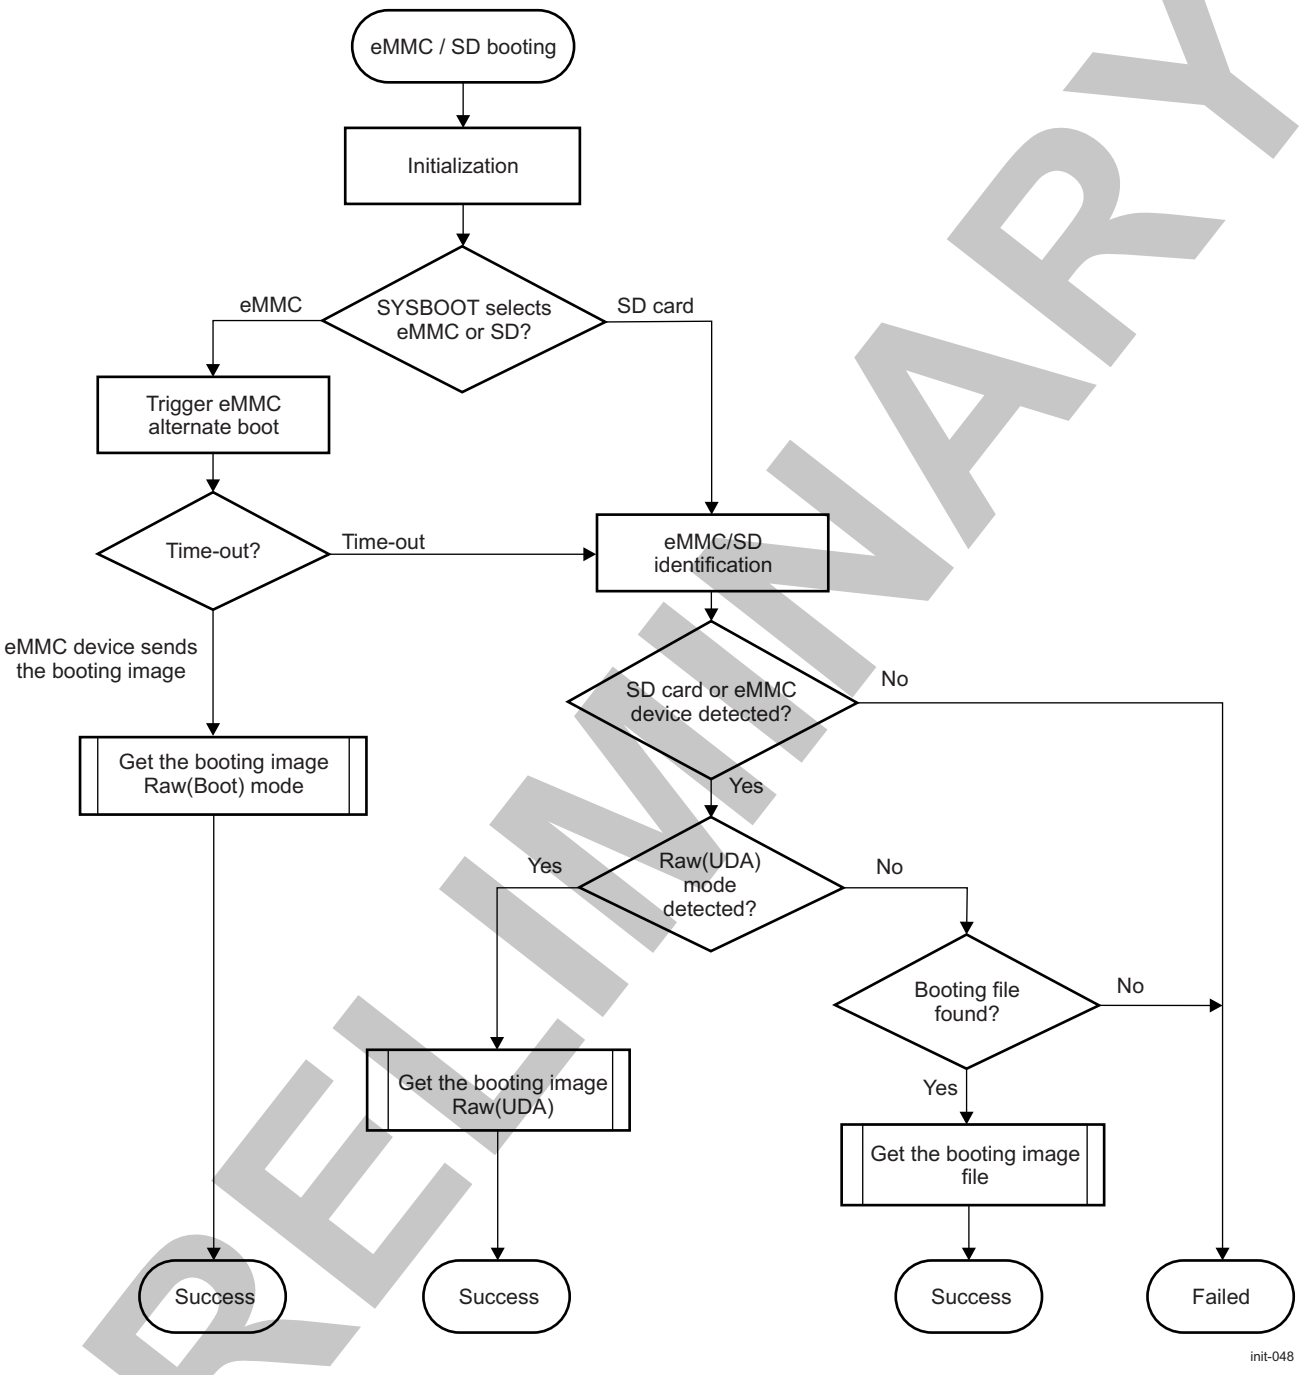
If the selected booting device is eMMC, then a first attempt to trigger alternative boot operation mode is tried. If the eMMC device replies within a fixed timeout, then the booting image is directly retrieved from one of the possible partitions specified in the local EXT_CSD.BOOT_PARTITION_ENABLE bit field for the eMMC device (this is referred to as the Raw(Boot) mode). Raw(Boot) mode improves the boot time by avoiding the regular eMMC/SD identification phase (usually done at low speed). When the booting image is retrieved, the ROM code continues the boot process.

If the time-out elapses, then the ROM code proceeds with normal identification. SD cards do not support Alternative Boot Operation mode, and therefore are always going through normal identification.

If normal identification succeeds, then it next determines whether the SD card or eMMC device contains a known file system. If the file system is known, then the booting image is extracted from the file system hierarchy. If a file system is not detected, then the Raw(UDA) mode is assumed.

Figure 28-30 is the high level flow chart of the eMMC and SD booting procedure.

Figure 28-30. eMMC and SD Booting



28.3.7.6.2.4 eMMC Partitions Handling in Alternative Boot Operation Mode

To trigger alternative boot operation mode, the ROM code sends a specific CMD0 + Argument 0xFFFF FFFA. Then, the ROM code waits up to 50 ms for the eMMC device to return a boot-acknowledge signal. If the time-out elapses, then the ROM code skips alternative boot operation mode. Booting from eMMC partitions can be done in 8-bit mode at 48 MHz / DDR. This configuration is static and cannot be changed.

28.3.7.6.2.4.1 eMMC Devices Preflashing

For correct handling of eMMC partitions in alternative boot operation mode, it is necessary to prepare the eMMC device at flashing time with the following settings applied to the device EXT_CSD register:

- The BOOT_ACK and BOOT_PARTITION_ENABLE fields must be updated accordingly (EXT_CSD[179], bit 6 and bits [5:3], respectively) to activate the boot acknowledge signal and select the partition from which to boot. There are several boot options selectable in the BOOT_PARTITION_ENABLE bit field, as follows:
  - Booting from boot partition 1 (BP1)
  - Booting from boot partition 2 (BP2)
  - Booting from User Area

  For more details, see the eMMC Standard documentation.
- RST_N must be enabled for correct handling of the warm reset cases (EXT_CSD[162] bits [1:0] = 0x1).
- The BOOT_BUS_WIDTH fields (EXT_CSD[177]) must be updated properly based on OMAP alternate boot operation: 8-bit / 48 MHz / DDR mode.
- Optionally the BOOT_CONFIG_PROT (EXT_CSD[178]) may be updated for altering access permissions to the selected partitions.

NOTE: Although an alternate boot from user area is possible, alternate booting from BP1 or BP2 is recommended.

NOTE: It is possible to permanently or temporarily lock the boot configuration through the use of the BOOT_CONFIG_PROT register. For more details, see the eMMC Standard documentation.

NOTE:

- It is highly recommended to refer to the eMMC Standard for details on EXT_CSD handling.
- The EXT_CSD is updated by using a SWITCH command as detailed in the eMMC standard.
- The mentioned EXT_CSD fields are retained after a power cycle so only one “flashing” phase is required

28.3.7.6.2.4.2 eMMC Device State After ROM Code Execution

If alternative boot operation mode is successful, and the booting image is properly retrieved, then the eMMC device state remains in the BOOT state even after the execution has passed to the initial software. The initial software must bring the device out of the BOOT state.

28.3.7.6.2.4.3 Consideration on OMAP Global Warm Reset

Once the system has booted and upon triggering a warm reset at OMAP level (it can be triggered by the warm-reset push button, a timer, watchdog, etc.), it is important that the eMMC device is properly brought to its PRE-IDLE state so that the next Alternative Boot operation succeeds. This is ensured by the RST_N pin to be connected to OMAP sys_nreswarm ball and eMMC device nRESWARM pin. Not doing so would make the boot procedure fail after a warm reset.

28.3.7.6.2.4.4 Booting Image Size

In Raw(Boot) mode, the size of the booting image is determined after the first sector read access. In case of GP device, the boot image size is contained within the GP header. This ensures that the ROM code is only retrieving the necessary size of data and not the full contents of the partition.

28.3.7.6.2.4.5 Booting Image Layout

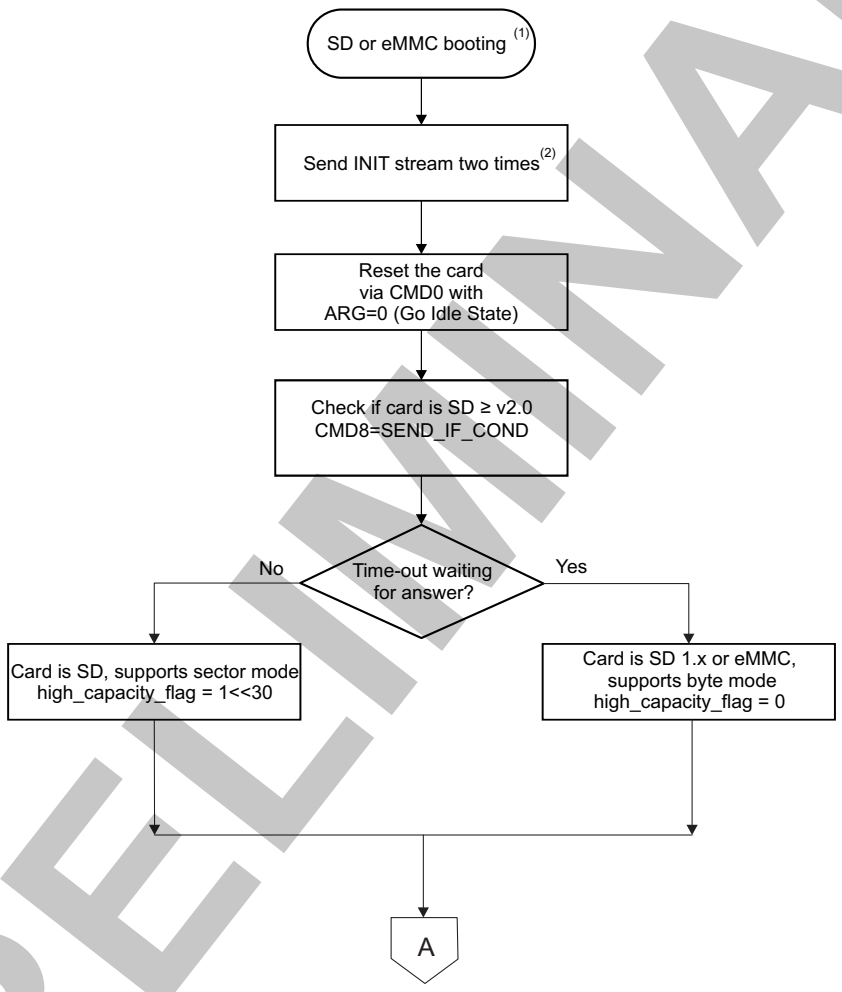
In Raw(Boot) mode only one copy of the booting image is maintained, as opposed to up to four copies in Raw(UDA) mode.

28.3.7.6.3 SD and eMMC Initialization and Detection

If the eMMC Alternate Boot operation fails in time-out, or the requested boot device is an SD card, the ROM code initializes the memory device or card connected on the eMMC and SD card interface using 1.8 V for eMMC and standard high-voltage range (3.0 V) for SD card I/Os. If neither a card nor memory device is detected, the ROM code moves to the next booting device. The standard identification process and relative card address (RCA) assignment are performed. The ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and eMMC memory devices. The eMMC and SD standards describe this phase as the initialization phase.

Figure 28-31 shows the eMMC and SD detection procedure.

Figure 28-31. SD and eMMC Detection Procedure

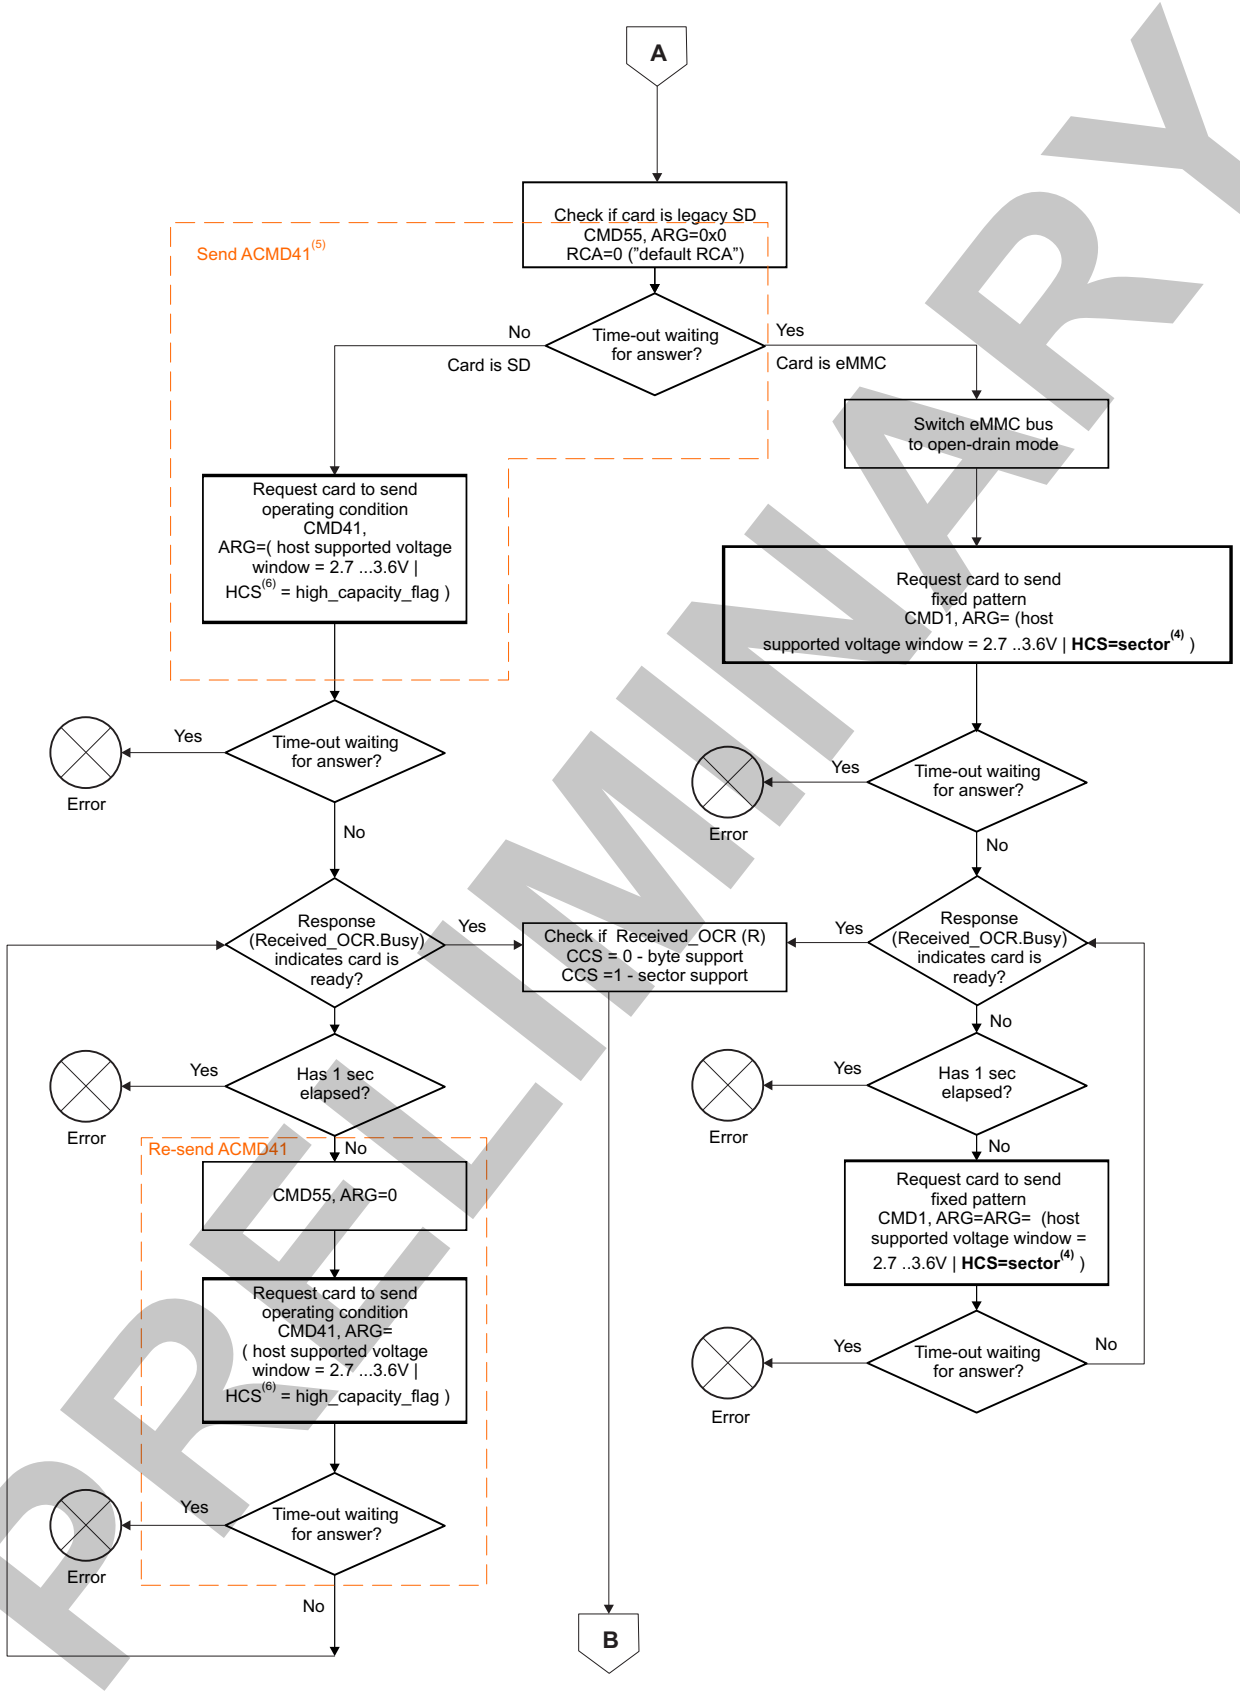


Note 1: MMC bus clk = 160 kHz

Note 2: MMC bus clk = 400 kHz

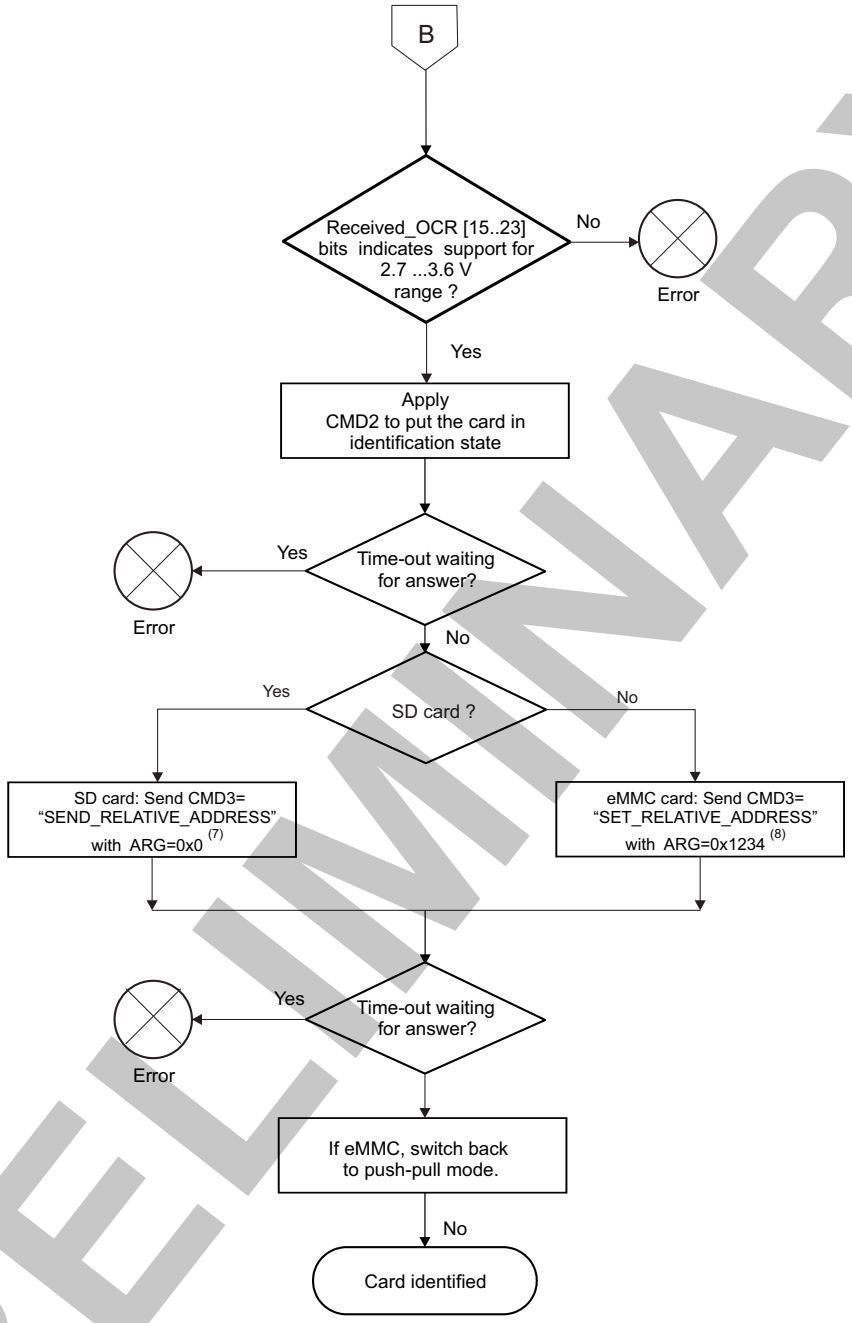
Note3: VHS / test pattern are specific to SD standard in this state.
eMMC CMD8 (=SEND_EXT_CSD) is NOT relevant in this state and this is the way to discriminate the SD v eMMC card

init-026a



Note 4: Host indicates it is capable of sector addressing
Note 5: Refered to as the first ACMD41 that starts initialization in SD standard. Subsequent ACMD41 provide same argument
Note 6 : Host sets hcs per response from CMD8 as described in SD standard

init-026b



Note 7 : Card sends back a new RCA value that ROM Code keeps internally
Note 8: Card stores the new RCA value provided by the ROM Code.

init-026c

28.3.7.6.4 Read Sector Procedure

The contents of an eMMC or SD card may be formatted as raw binary (referred to as Raw(UDA) or within a FAT file system. The ROM Code reads out sectors from raw image or the booting file within the file system and boots from it.

- **Raw mode**

  In Raw(UDA) mode, an image can be at one of the four consecutive locations in the main area: offset 0x0 (0 KiB)/0x20000 (128 KiB)/0x40000 (256 KiB)/0x60000 (384 KiB). For this reason, the size of a

booting image must not exceed 128 KiB. However, a device with an image greater than 128 KiB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. For a GP device, a GP header must be located at the beginning of the booting image, as described in Section 28.3.8.2, *Configuration Header*. Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.

- File system handling

  The read sector procedure uses the standard SD/eMMC read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

28.3.7.6.5 File System Handling

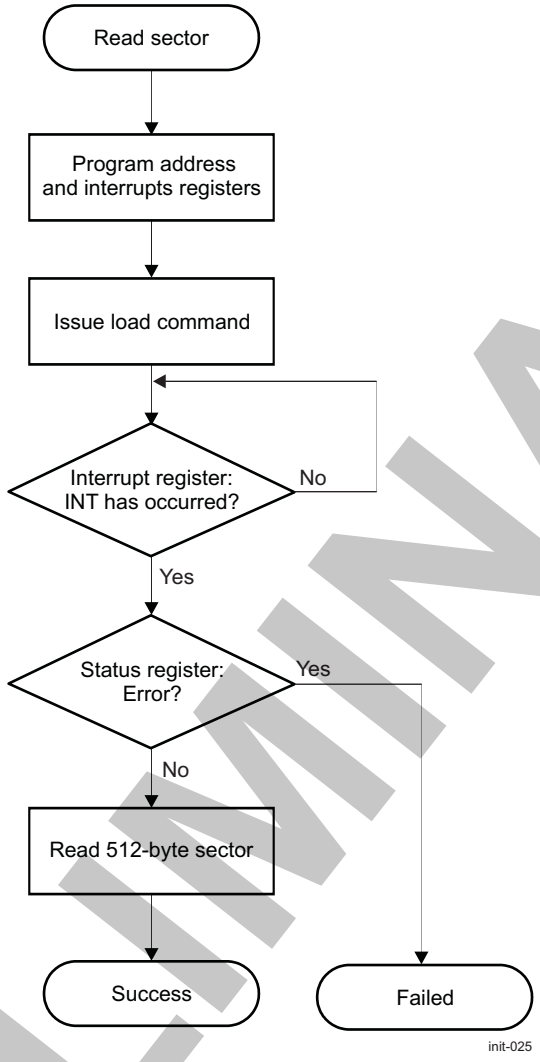
The eMMC / SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an ***active*** primary partition of type FAT12/16 or FAT32.

An eMMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except when using a floppy-like file system. However, depending on the operating system used, the eMMC / SD card is formatted with or without partitions (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT. The booting file map is a collection of all FAT entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. Figure 28-32 shows the complete process.

Figure 28-32. SD/MMC Get Booting File



28.3.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows®). Table 28-40 describes this structure, and Table 28-41 describes the partition table entry.

Table 28-40. Master Boot Record Structure

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry

Table 28-40. Master Boot Record Structure (continued)

Offset	Length (Bytes)	Entry Description
01EEh	16	Partition table entry
01FEh	2	Signature (0xAA55)

Table 28-41. Partition Table Entry

Offset	Length (Bytes)	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0] – Cs[9:8] – Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	1	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs = Cs.H.S + Hs.S + Ss – 1
000Ch	4	Number of sectors in partition	LBAe = Ce.H.S + He.S + Se – 1 Nb s = LBAe – LBAs + 1

SD/eMMC booting consists of the following steps:

1. Detection of MBR

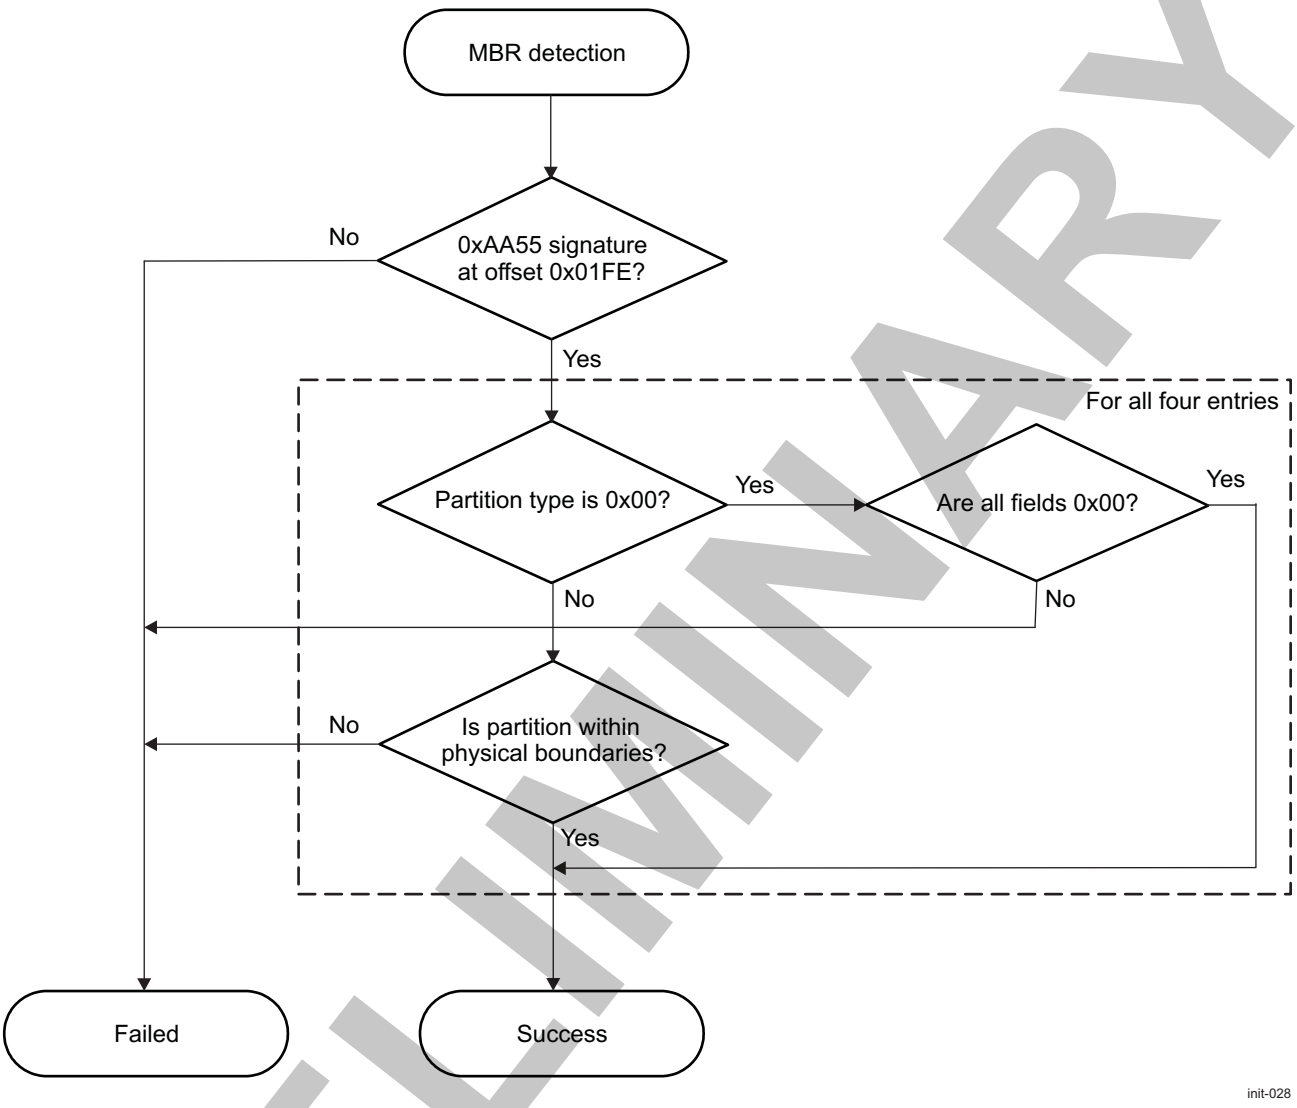
   The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked to determine the following:

   (a) If the partition type is set to 00h, all fields in the entry must be 00h.

   (b) The partition is within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

   See Figure 28-33 for more information about MBR detection.

Figure 28-33. MBR Detection Procedure



2. Get the MBR partition.

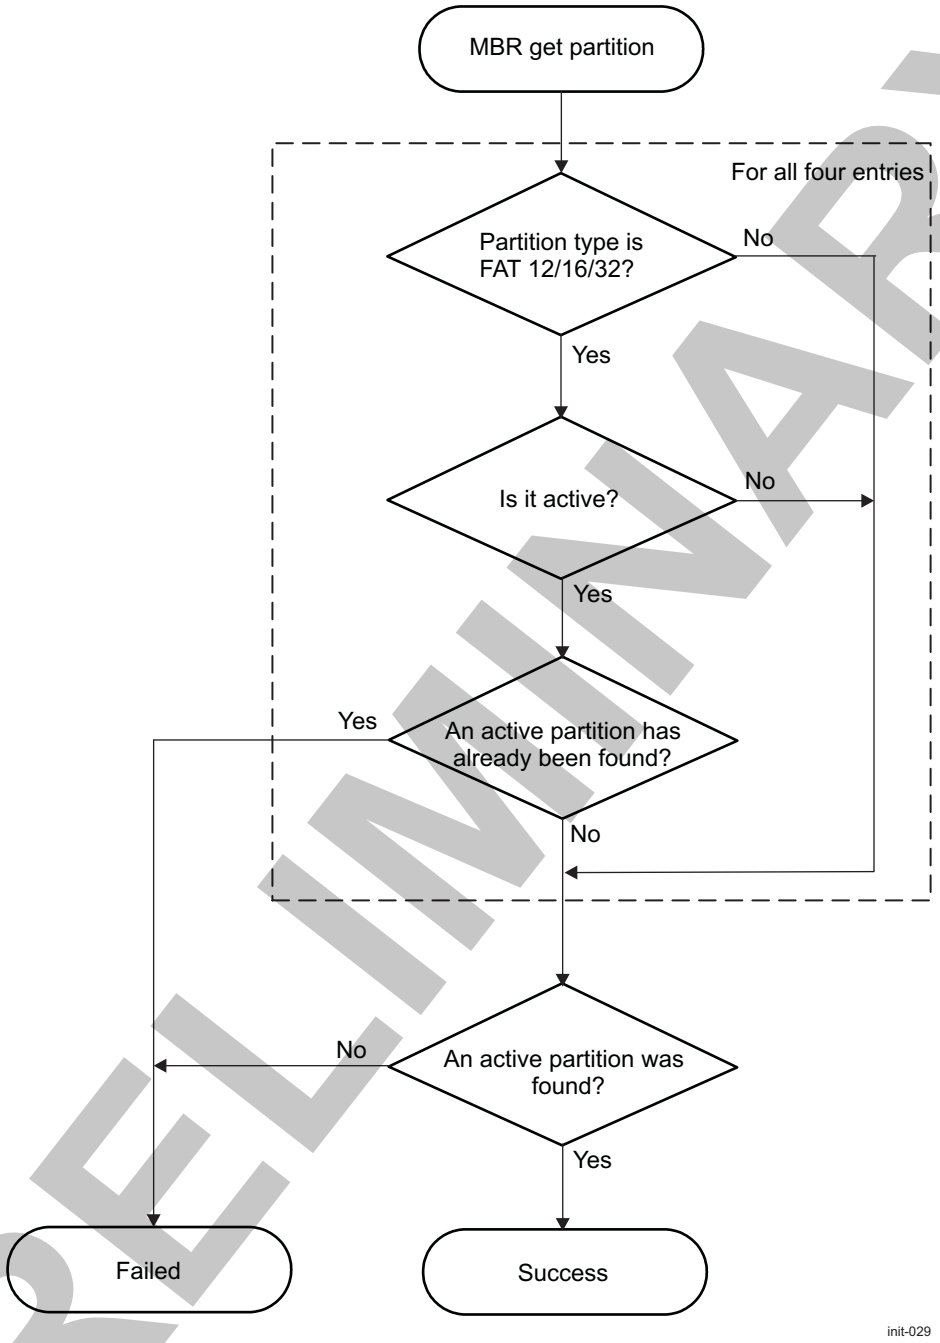
   Once identified, the ROM code gets the partition using the procedure described in Figure 28-33. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active). The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

   The FAT file system consists of several parts:

   - Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
   - FAT, which describes the use of each cluster of the partition
   - Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

   To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that require specific values are checked. Figure 28-34 shows more about getting the partition.

Figure 28-34. MBR, Get Partition



3. Find the booting file.

   When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$Cluster_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_NumFATs \cdot BPB\_FATSz + Cluster \cdot BPB\_SecPerCLus$$

init-E001

NOTE: BPB_FATSz is BPB_FATSz16 for FAT12/16, or BPB_FATSz32 for FAT32.

NOTE: The BPB_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, and so forth). See Table 28-42.

Table 28-42. FAT Directory Entry

Offset	Length (Bytes)	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File attributes: 01h – ATTR_READ_ONLY 02h – ATTR_HIDDEN 04h – ATTR_SYSTEM 08h – ATTR_VOLUME_ID 10h – ATTR_DIRECTORY 20h – ATTR_ARCHIVE 0Fh – ATTR_LONG_NAME
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see Table 28-42) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Therefore, handling this directory is straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. Step 4 describes the way in which the FAT is handled.

4. Buffer FAT entries in the FAT buffer.

   When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in the FAT buffer that is used during boot to access the booting file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BP\_FatSz \cdot n$$

init-E002

   The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if the values are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

   The FAT is a simple array of values, each referring to a cluster in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the

cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. Table 28-43 describes the meaning of an entry.

NOTE: For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFF8h and 0FFFFFFFh (for FAT32)

Table 28-43. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	00000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h–FEFh	0002h–FFEFh	00000002h–0FFFFFEFh	Used cluster; value points to next cluster
FF0h–FF6h	FFF0h–FFF6h	0FFFFFF0h–0FFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFF7h	Bad cluster
FF8h–FFFh	FFF8h–FFFFh	0FFFFFF8h–0FFFFFFFh	Last cluster in file

NOTE: FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must remain untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

28.3.7.7 SATA Device Boot Operation

The SATA is a host interface dedicated for mass storage memory devices. SATA aims to connect SATA disk drive compliant SSD (SATA solid state drive) or HDD (hard disk drive) for mass storage use case only.

The mass storage device (SSD or HDD) is intended to be connected through SATA standard connector (in case of HDD) or directly soldered on the board (in case of SSD). In the latter case, the SATA mass-storage device is actually permanently attached to the OMAP device.

The OMAP embedded SATA host controller has a single port (P0) implementation, and one internal electrical transceiver (SATA_PHY). For more information on the device-embedded SATA (SATA AHCI core and wrapper), see Section 23.12, *SATA Controller*. For more details on SATA subsystem integrated SATA PHY transceiver components, see Section 27.1, *SATA PHY Subsystem*. A system integration block diagram is provided in following section.

28.3.7.7.1 SATA Booting Overview

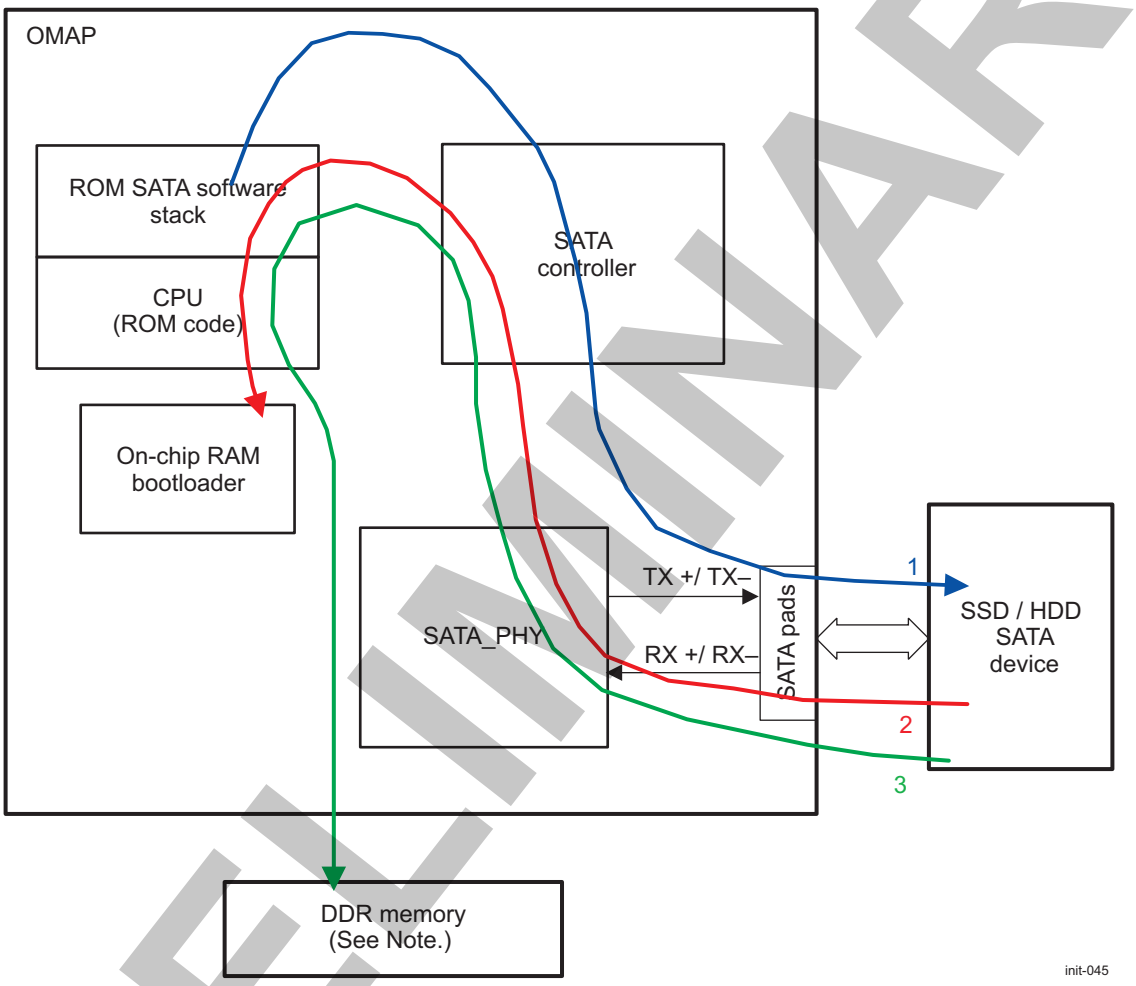
The device attached to the OMAP SATA for boot operation must meet the following requirements:

- It must be compliant with the *Serial ATA Standard* specification, rev. 2.6.
- It must support READ SECTOR(s) ATA command (code 0x20) as defined in the ATA / ATAPI - 7 specification.
- It must be connected directly to the OMAP SATA IOs – sata_tx / sata_ty, sata_rx / sata_ry (no port multiplier connected).

- It must have been already powered by the companion chip or external supply before start of the boot procedure.
- It must be taken in consideration for the device that maximum power on ready time allowed by ROM Code is 900ms. First COMRESET procedure targeting the attached device is triggered 300ms after OMAP SATA subsystem initialization by ROM Code.

Figure 28-35 highlights the booting of the platform from the SSD device.

Figure 28-35. Booting from a Permanently-Attached SSD Device



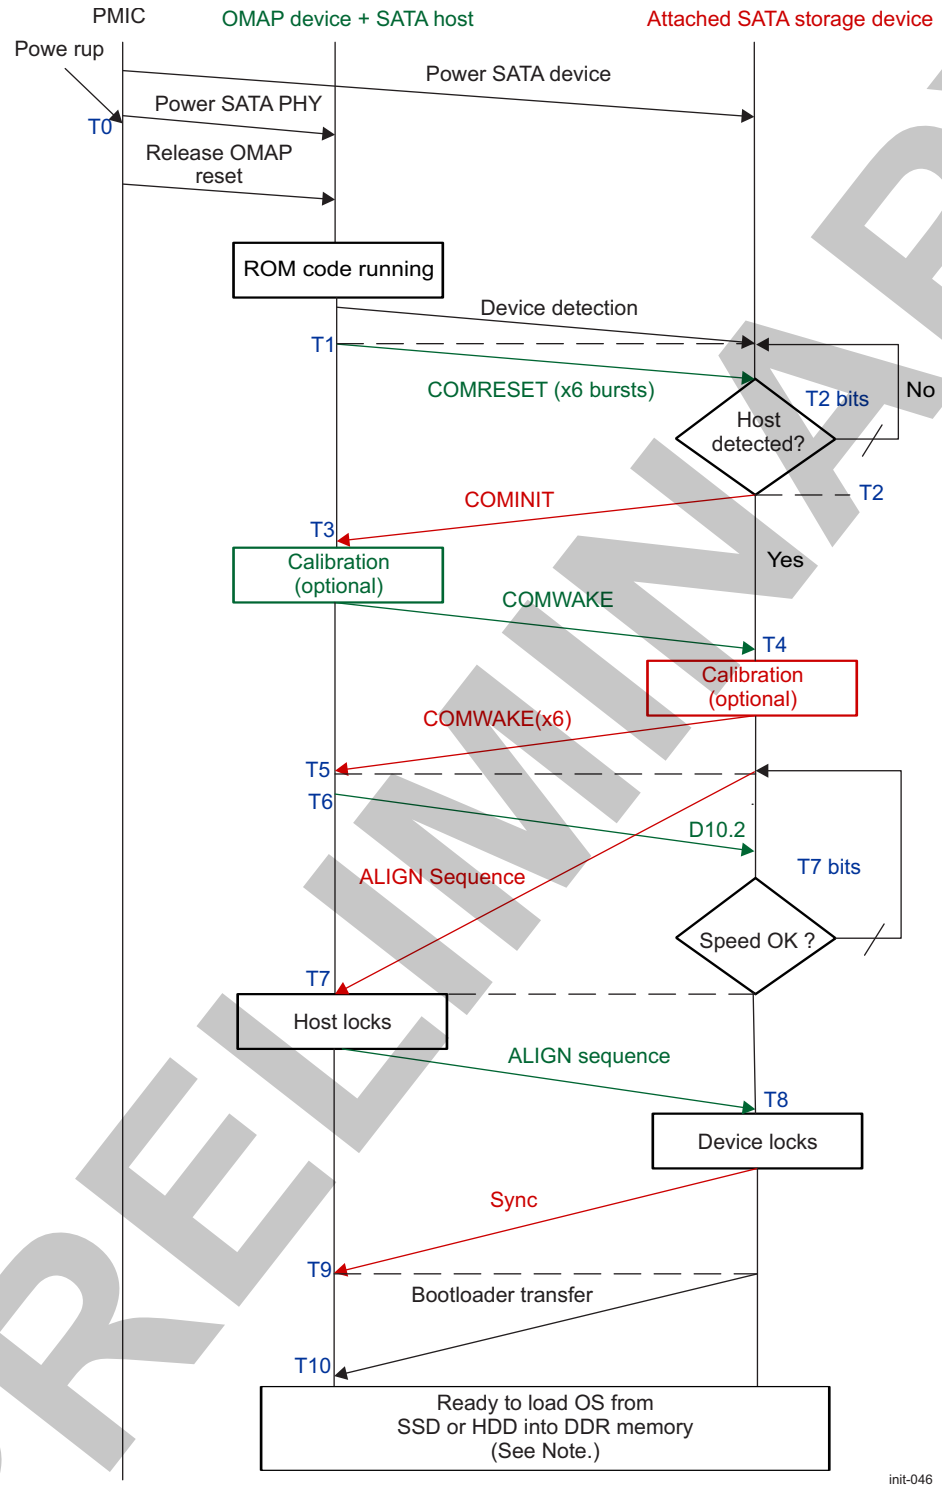
The OMAP booting from an attached SATA mass storage memory device is performed in the following steps:

1. At reset or power on, the OMAP device ROM code boots and checks for the SSD / HDD to be ready.
2. The SSD / HDD transfers the boot-loader to the internal RAM of device.
3. The OS in the SSD or HDD is downloaded into DDR memory and the platform is ready.

28.3.7.7.2 SATA Power-Up Initialization Sequence

Figure 28-36 shows all messages exchanges between power-on event up to when the platform is ready. The sequencing aims to depict the complete sequence without any specific connecting issues that may appear.

Figure 28-36. SATA Power-on Initialization Sequencing



The following time phases can be identified during booting from SATA interface:

- T0: the SATA_PHY is powered and OMAP reset is maintained until all Power-management IC companion powers are set.
- T1: the ROM code validates a SATA SSD device detection.
- Within the T1-T2 time interval: the SATA host issues a COMRESET sequence for a minimum of 6 bursts (and a multiple of 6) to force a hardware reset to the SATA peripheral device.

- T2: As long as the attached SATA SSD device does not explicit reset request (COMINIT), the host issues COMRESET sequences
- Within the T2-T3 time interval, once the host release the COMRESET sequence (made of 6 bursts minimum), the device responds with a COMINIT to request a communication initialization (It requests a reset from the host).
- Within the T3-T4 time interval, the SATA host controller may calibrate at T3, but issues a COMWAKE sequence to the peripheral in order to inform the other part the wish to use the link.
- Within the T4-T5 time interval, the SSD device responds and may calibrate. The device response is made of 6 burst COMWAKE sequence.
- Within the T5-T6 time interval, SATA host controller shall start transmitting D10.2 characters no later than a defined moment.
- Within the T6-T7 time interval, when the OMAP host detects the COMWAKE from the device, it starts transmitting D10.2 character at its lowest speed.
- At the same time within T5-T7 time interval, continuous stream of device ALIGN sequence (following the 6 bursts COMWAKE sequence) starting at the device highest speed.
- T7: Without any SATA host's answer (D10.2 character), the device ALIGN sequence is repeated for as many slower speeds as are supported. When host receives ALIGN sequence, it locks.
- in case no proposed speeds are supported by the host, the device enters in error state.
- in case no ALIGNp sequence is received by the host within a defined time gap after detecting the release of the device COMWAKE, the host restarts the power on sequence indefinitely until stop by user intervention.
- Within the T7-T8 time interval, as soon as the OMAP device SATA host locks, it issues an ALIGN sequence to the attached SATA SSD device that also locks
- Within the T8-T9 time interval, the SATA peripheral device sends a SYNC primitive to inform the communication link is established.
- Within the T9-T10 time interval, once the link has been set successfully, the boot loader is transferred from the SATA peripheral device to OMAP internal on-chip RAM

After passing through all above described phases, the OMAP is ready to load OS source from SSD to the device DDR RAM (LPDDR2 or DDR3).

28.3.7.7.3 System Conditions and Limitations for SATA Boot

The following system conditions and limitations are defined by ROM Code implementation:

- The ROM Code sets Gen2 speed (3 Gbps) for a SATA boot operation.
- The ROM Code expects that the SATA I/Os are connected to OMAP SATA subsystem at system reset (i.e. a permanently attached boot device).
- The ROM Code expects that the SATA device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM Code does not perform any software action to the companion device with respect to powering the SATA device.
- The ROM Code allows the SATA device 300ms power on ready time before starting the device detection. In case that the detection fails, the ROM Code retries 3 times with 200ms delay before returning and reporting a SATA boot failure.
- The ROM Code does not handle or enable advanced SATA power modes (slumber and partial).

The ROM Code initializes SATA subsystem after SATA boot is started, as defined in this chapter. The ROM Code does not close SATA connection after it was initialized following procedure defined in Section 28.3.4.3, *Booting Device List Setup*.

28.3.7.7.4 SATA Read Sector Procedure in FAT Mode

The booting medium may hold a FAT file system which the ROM Code is able to read and process. The image used by the booting procedure is taken from a specific booting file named "HLO". This file has to be located in the root directory on an active primary partition of FAT12 / 16 or FAT32 type.

A SATA drive can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any **Master Boot Record (MBR)** holding a partition table.
- When acting as hard-drive-like, a **MBR** is present in the first sector of the card. This **MBR** holds a table of partitions, one of which must be **FAT 12/ 16 / 32, primary and active**.

Refer to the Section 28.3.7.6.5.1, *MBR and FAT File System*, for a more detailed description of FAT file system support.

28.3.8 Image Format

28.3.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

The CH can contain several parameters set by users to speed up booting. It is further described in Section 28.3.8.2, *Configuration Header*.

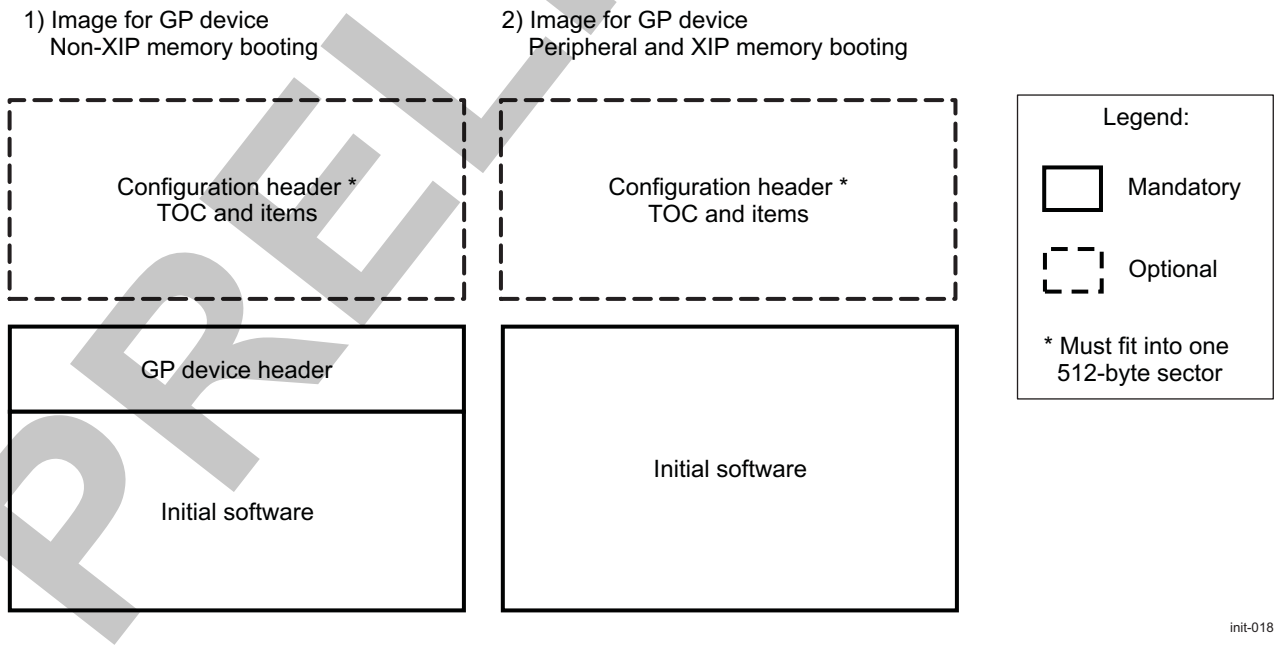
The second part contains the software that is loaded into the memory and executed.

Figure 28-37 is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, eMMC). A GP image for non-XIP memory may NOT contain a CH and start straight from the GP header. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.
2. When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

NOTE: A GP image for non-XIP memory may NOT contain a CH and start straight from the GP header.

Figure 28-37. Image Formats



28.3.8.2 Configuration Header

The ROM code default settings (such as clock frequencies, EMIF, GPMC, or MMCHS interfaces) can be tuned by the user by using the CH.

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- RAM: EMIF settings
- FLASH: Flash interface (GPMC) settings
- eMMC / SD: MMC2 / MMC1 interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in Figure 28-38. Each TOC item is a simple structure described in Table 28-44. The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Next, the TOC is identified and searched until a 0xFFFF FFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

Figure 28-38. CH Format

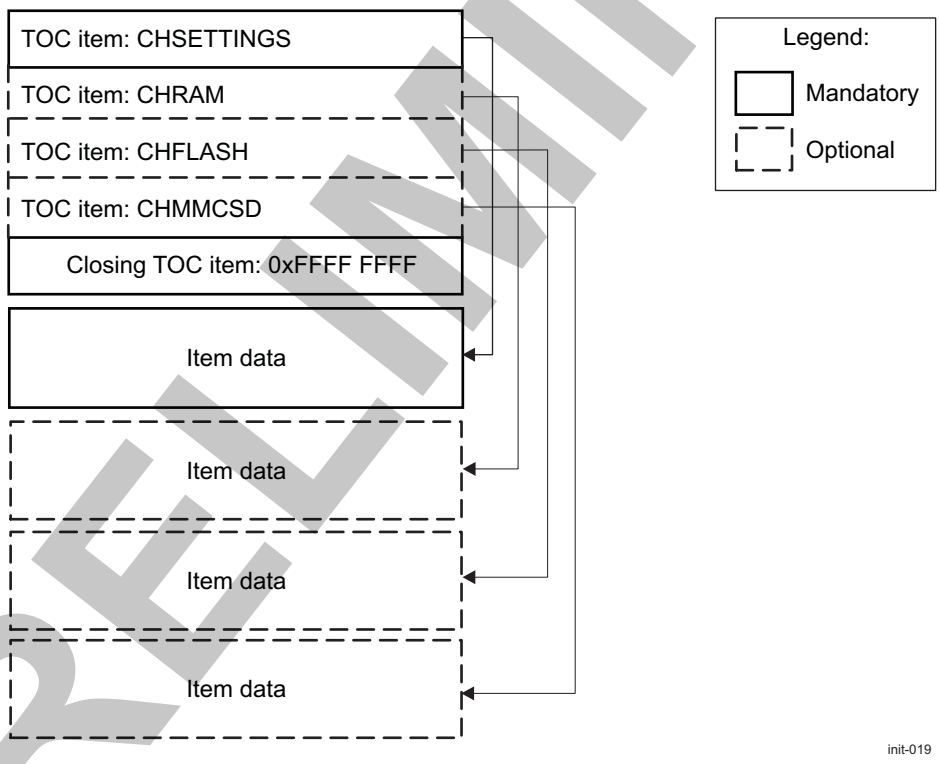


Table 28-44. CH TOC Item

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of the TOC to the actual address of item contents
0x0004	Size	4	Size of item
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused

Table 28-44. CH TOC Item (continued)

Offset	Field	Size (Bytes)	Description
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a item, including the zero termination character(\0)

The ROM Code recognizes sections pointed to by the TOC based on the filename as described in Table 28-45

- The 'X-LOADER', '2ND', 'MLO', 'ULO', or 'HLO' section contains the Initial Software
- Optionally, TOC may contain CH sections. The "CHSETTINGS" is a mandatory section of CH and is used to recognize CH presence.

Table 28-45. TOC Filenames

Filename	Item Type	Usage	Description
X-LOADER	Initial Software	XIP Memory Booting	"eXternal LOADER"
MLO	Initial Software	eMMC / SD Memory Booting	"Mmc LOader"
HLO	Initial Software	SATA Memory Booting	"Hdd LOader"
ULO	Initial Software	USB Peripheral Booting	"Usb LOader"
2ND	Initial Software	UART Peripheral Booting	"Secondary Loader"
CHSETTINGS	Configuration Header	Memory & Peripheral Booting	Configuration Header General Setting Item
CHRAM	Configuration Header	Memory & Peripheral Booting	Configuration Header EMIF Item
CHFLASH	Configuration Header	Memory & Peripheral Booting	Configuration Header GPMC Item
CHMMCSD	Configuration Header	Memory & Peripheral Booting	Configuration Header eMMC/SD Item

28.3.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in Section 28.3.4.2, *Clocking Configuration*. The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

Table 28-46 describes the fields. The clocking procedure and the clocking setting structure are described in Section 28.3.4.5, *Software Booting Configuration*.

Table 28-46. CHSETTINGS Item

Offset	Field	Description
0000h	Section key	Key used for item verification: C0C0C0C1h
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Version	Configuration header version 01h Others: Reserved
0006h	Reserved	
0008h	Clocking settings	Described in Table 28-14, *Software Booting Configuration Structure*, starting from the FLAGS field.

28.3.8.2.2 CHRAM Item

The CHRAM configuration header contains settings specific to the SDRAM memory controller (EMIF). Table 28-47 describes the fields. The ROM code does not configure the EMIF by default, because it cannot assume any external SDRAM type. Therefore, if the ROM code is needed to configure the SDRAM access, the user must provide the appropriate timing details in the CHRAM structure. For more information, see Section 15.3.6, *EMIF Register Manual*, in Section 15.3, *EMIF Controller*.

NOTE: If the boot image contains an optional Configuration Header for EMIF configuration at boot time, I/O settings must be provided (in below listed CHRAM Item structure) to override the default Control Module reset values.

Table 28-47. CHRAM Item

Offset	Field	Size (Bytes)	Description
0000h	Section key	4	Key used for section verification: C0C0C0C2h.
0004h	Valid	1	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	3	Reserved
0008h	SdramConfig (EMIF1,2)	4	SDRAM configuration register (EMIF1,2.EMIF_SDRAM_CONFIG)
000Ch	SdramConfig2 (EMIF1,2)	4	SDRAM configuration2 register (EMIF1,2.EMIF_SDRAM_CONFIG_2)
0010h	SdramRefresh (EMIF1,2)	4	SDRAM Refresh control register (EMIF1,2.EMIF_SDRAM_REFRESH_CONTROL)
0014h	SdramRefreshShdw (EMIF1,2)	4	SDRAM Refresh Control Shadow Register (EMIF1,2.EMIF_SDRAM_REFRESH_CONTROL_SHADOW)
0018h	SdramTim1 (EMIF1,2)	4	SDRAM timing 1 register (EMIF1,2.EMIF_SDRAM_TIMING_1)
001Ch	SdramTim2 (EMIF1,2)	4	SDRAM timing 2 register (EMIF1,2.EMIF_SDRAM_TIMING_2)
0020h	SdramTim3 (EMIF1,2)	4	SDRAM timing 3 register (EMIF1,2.EMIF_SDRAM_TIMING_3)
0024h	SdramTim1Shdw (EMIF1,2)	4	SDRAM timing 1 shadow register (EMIF1,2.EMIF_SDRAM_TIMING_1_SHADOW)
0028h	SdramTim2Shdw (EMIF1,2)	4	SDRAM timing 2 shadow register (EMIF1,2.EMIF_SDRAM_TIMING_2_SHADOW)
002Ch	SdramTim3Shdw (EMIF1,2)	4	SDRAM timing 3 shadow register (EMIF1,2.EMIF_SDRAM_TIMING_3_SHADOW)
0030h	PwrMgtCtrl (EMIF1,2)	4	Power mgt control Register (EMIF1,2.EMIF_POWER_MANAGEMENT_CONTROL)
0034h	PwrMgtCtrlShdw (EMIF1,2)	4	Power mgt control Shadow Register (EMIF1,2.EMIF_POWER_MANAGEMENT_CONTROL_SHADOW)
0038h	DdrPhyCtrl1 (EMIF1,2)	4	DDR PHY Control 1 Register (EMIF1,2. EMIF_DDR_PHY_CONTROL_1)
003Ch	DdrPhyCtrl2 (EMIF1,2)	4	DDR PHY Control 2 Register (EMIF1,2. EMIF_DDR_PHY_CONTROL_2)
0040h	DdrPhyCtrl1Shdw (EMIF1,2)	4	DDR PHY Control 1 Shadow Register (EMIF1,2. EMIF_DDR_PHY_CONTROL_1_SHADOW)
0044h	ExtPhyCtrl [1..24] (EMIF1,2)	96	External PHY Control Registers
00A4h	ControlLpDdr2Ddr3ChX_0	4	LPDDR2: CONTROL_LPDDR2CH1_0 / CONTROL_LPDDR2CH1_1 DDR3: CONTROL_DDR3CH1_0 / CONTROL_DDR3CH2_0
00A8h	ControlDdrChX_0	4	CONTROL_DDRCH1_0 / CONTROL_DDRCH2_0
00ACh	ControlDdrChX_1	4	CONTROL_DDRCH1_1 / CONTROL_DDRCH2_1

Table 28-47. CHRAM Item (continued)

Offset	Field	Size (Bytes)	Description
00B0h	EmifXSdramConfigExt	4	EMIF1_SDRAM_CONFIG_EXT / EMIF2_SDRAM_CONFIG_EXT
00B4h	Reserved	8	Reserved
00BCh	ModeReg1 (EMIF1,2)	1	MR1 mode register value (LPDDR2 only, reserved for DDR3)
00BDh	ModeReg2 (EMIF1,2)	1	MR2 mode register value (LPDDR2 only, reserved for DDR3)
00BEh	ModeReg3 (EMIF1,2)	1	MR3 mode register value (LPDDR2 only, reserved for DDR3)
00BFh	Reserved	1	Reserved
00C0h	CoreFreqConfigM2Div	1	CORE M2 divider value after PRCM Frequency update
00C4h	DMM LISA Map 0	4	DMM LISA section 0 mapping (for more information about the DMM module architecture, see Section 15.2, *Dynamic Memory Manager*, in Chapter 15, *Memory Subsystem*)
00C8h	Flags	4	Setting bits 0 to 3 requests ROM code to configure the appropriate channel/chip select: Bit[0]: Configure EMIF1 CS0 Bit[1]: Configure EMIF1 CS1 Bit[2]: Configure EMIF2 CS0 Bit[3]: Configure EMIF2 CS1 Bits[8:11] - EMIF temperature monitoring timeout 0x0: Temperature monitoring disabled 0x1: Timeout 1 second 0x2: Timeout 2 seconds 0x3: Timeout 3 seconds 0x5: Timeout 5 seconds 0xA: Timeout 10 seconds Bits[4:7] and Bits[12:31] - Reserved

NOTE:

- The ROM code supports different types of SDRAM memory, LPDDR2 or DDR3 memory (as set in the SDRAM configuration register and indicated e-fuse), which depend on the OMAP device package. For more details, see Section 1.1, *Overview*, in Chapter 1, *Introduction*.
- The same kind of SDRAM (same type, timings, and density) must be attached to both chip selects (CSs) of the same controller when requesting the configuration of both CSs for a given EMIF interface (for example, if bits 0 and 1 of the Flags field are set, it is assumed that both EMIF1 CSs are attached to the same kind of memory).

NOTE: It is mandatory that the same type of SDRAM memory (same type and timings) is attached to both EMIF controllers. The ROM Code does not support hybrid configurations, such as EMIF1 tied to LPDDR2 memory and EMIF2 is tied to DDR3 memory.

Similarly, the ROM Code does not support assymetric densities on both controllers.

28.3.8.2.2.1 Enabling of LPDDR2 Temperature Monitoring Feature

When the LPDDR2 memory type is used, the temperature monitoring feature can be enabled by setting the appropriate bits in the CHRAM Flags field:

- • If the value is 0, the temperature monitoring feature is disabled.
- If the value is non-zero, the ROM Code checks the MR4 register inside the LPDDR2 SDRAM component by mode register read operations, at the time of memory initialization. As long as the SDRAM Refresh Rate field is not 0x3 (Temperature ≤ 85° C), it indicates an abnormal temperature state, and the ROM Code waits for MR4 to return to the 0x03 value. The waiting loop cannot exceed

the timeout indicated by the “EMIF temperature monitoring timeout” value in the Flags field. If the timeout expires, the ROM Code simply resumes EMIF initialization.

28.3.8.2.3 CHFLASH Item

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see Section 15.4.1, *GPMC Overview*, in Chapter 15, *Memory Subsystem*. Table 28-48 describes the fields.

Table 28-48. CHFLASH Item

Offset	Field	Description
0000h	Section Key	Key used for section verification: C0C0C0C3h.
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register values
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Reserved	

28.3.8.2.4 CHMMCSD Item

The CHMMCSD configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see Chapter 24, *MMC/ SD/ SDIO*. Table 28-49 describes the fields.

Table 28-49. CHMMCSD Item

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	MMCHS_SYSCTRL(MSW)	Update MMCHS SYSCTL interface register with the value specified in these fields. The register is not updated if the value is 0xFFFFFFFF.
000Ah	MMCHS_SYSCTRL(LSW)	

Table 28-49. CHMMCSD Item (continued)

Offset	Register Modified	Description
000Ch	MMCHS interface bus width	Configure the MMCHS interface bus width according to the field value : 1: Configured to 1 bit (SDR) 2: Configured to 4 bits (SDR) 4: Configured to 8 bits (SDR)(1) 8: Configured to 4 bits (DDR)(1) 16: Configured to 8 bits (DDR)(1) 0xFFFF FFFF: Do not update bus width. Others: Reserved

(1) The 8 bits SDR and 4 / 8-bits DDR (resp. value 4,8 and 16) are ONLY applicable to eMMC devices.

The ROM code provides a booting parameter structure to the initial software (see Section 28.3.8.4, *Image Execution*). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCSD item, if the MMCHS_SYSCTL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCSD section has not been executed, regardless of the value of the Valid field.

28.3.8.3 GP Header

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. Table 28-50 describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 28-50. GP Header Format

Field	Non-XIP Device Offset	XIP Device Offset	Size (Bytes)	Description
Size	0x0000	–	4	Size of the image
Destination	0x0004	–	4	Address where to store the image or code entry point
Image	0x0008	0x0000	x	Executable code

NOTE: The Destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

28.3.8.4 Image Execution

The image is executed when the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. Table 28-51 shows the booting parameter structure.

Table 28-51. Booting Parameter Structure

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message

Table 28-51. Booting Parameter Structure (continued)

Offset	Field	Size (Bytes)	Description
0x04	Memory booting device descriptor	4	Pointer to the memory device descriptor that has been used during the memory booting process
0x08	Current booting device	1	Code of device used for booting: 0x01: XIP 0x02 XIP (with wait monitoring) 0x03: NAND 0x04: OneNAND 0x05: SD cards 0x06: eMMC (boot partition) 0x07: eMMC 0x9: SATA 0x43: UART3 0x45: USB Others: Reserved
0x09	Reset reason	1	Current reset reason bit mask (bit = 1, event present): direct copy from lower byte of PRM_RSTST: [0]: Power-on (cold) reset [1]: Global software warm reset [2]: Reserved [3]: MPU watchdog reset [4]: Reserved [5]: External warm reset [6]: VDD MPU voltage manager reset [7]: VDD IVA voltage manager reset
0x0A	CH flags	1	Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMCSD Other bits: Reserved

28.3.9 Tracing

Tracing in the public ROM code consists in three 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. Table 28-52 through Table 28-54 list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors (Table 28-11). The first set is the current trace information (after a cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after a cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during a cold reset.

Table 28-52 lists the organization of tracing vector 1.

Table 28-52. Tracing Vector 1

Bit	Group	Meaning
0	Boot	Passed the public reset vector
1	Boot	Entered main function
2	Boot	Running after the cold reset
3	Boot	Main booting routine entered
4	Memory boot	Memory booting started
5	Peripheral boot	Peripheral booting started
6	Boot	Booting loop reached last device
7	Boot	GP header found
8	Peripheral Boot	Booting message Skip peripheral booting received

28.4 Services for HLOS Support

The ROM code provides different services that can be called on GP devices for L1 and L2-cache maintenance, Enter in Low Power, etc. These services are implemented in monitor mode and must be called by using the SMC instruction. The caller must ensure the save and restore of the processor registers before and after calling the Monitor Service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```
;-------------------------------------------------------------------------------
; FUNCTION: SetL2CacheLatency
;
; DESCRIPTION: Function calls the Monitor Service to setup the L2 Cache Latency
;
; INPUTS:  r0 Tag RAM Latency to set
;          r1 Data RAM Latency to set
; RETURN:
;
;-------------------------------------------------------------------------------
SetL2CacheLatency           FUNCTION

28.4.1 Caches Maintenance

Table 28-56. Clean L1 and/or L2 cache

Function ID	**Description**	
R12 = 0x103	This function cleans and invalidates the CPU L1-cache and if requested in the input parameter R0, clean the full L2-cache.	
Parameters		
Type	*Location*	*Description*
Input	R0	if not equal to 0, clean L2-cache
Output		
Return		

28.4.2 CP15 Registers

Table 28-57. Write L2 Cache Auxiliary Control

Function ID	**Description**	
R12 = 0x104	This function writes the CP15 L2 Cache Auxiliary Control Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

Table 28-58. Write Tag and Data RAM Latency Control Register

Function ID	Description	
R12 = 0x105	This function writes the L2 Cache Tag and Data RAM Latency in the CP15 L2 Control Register with the input given value in R0 and R1.	
Parameters		
Type	**Location**	**Description**
Input	R0 R1	Tag RAM Latency to set Data RAM Latency to set
Output		
Return		

Table 28-59. Write L2 Cache Prefetch Control Register

Function ID	Description	
R12 = 0x106	This function writes the CP15 L2 Cache Prefetch Control Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

Table 28-60. Write Auxiliary Control Register

Function ID	Description	
R12 = 0x107	This function writes the CP15 Auxiliary Control Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	Value to set in the register
Output		
Return		

28.4.3 Wakeup Generator

Table 28-61. Write AMBA IF Register

Function ID	Description	
R12 = 0x108	This function writes the WakeupGen AMBA I/F Register with the input given value in R0.	
Parameters		
Type	**Location**	**Description**
Input	R0	value to set in the register
Output		
Return		

28.4.4 Low Power

Table 28-62. Enter in Low Power

Function ID	Description	
R12 = 0x100	This function configures the MPU Subystem and CPU to enter in the given Low Power Mode.	
Parameters		
Type	**Location**	**Description**
Input	R0	R0- pointer to target modes structure (see the below table)
Output		
Return		

Table 28-63. Power API - PWR_Modes_t Structure

Offset	Field	Size	Value
0x0	Cpu_Mode	1 Byte	0: NO_CHANGE (doesn't change the CPU setting) 1: ON 2: INACTIVE 3: CSWRET 4: Reserved 5: OFF 6: FORCED_OFF (only on CPU 1)
0x4	Mpu_Mode	1 Byte	0: NO_CHANGE (doesn't change the MPU setting) 1: ON 2: INACTIVE 3: CSWRET 4,5: Reserved
0x8	Core_Mode	1 Byte	0: ON 1,2: Reserved

On-Chip Debug Support

This chapter describes the on-chip debug support.

Topic **Page**

29.1 Introduction

Debugging a system that contains an embedded processor involves an environment that connects high-level debugging software running on a host computer to a low-level debug interface supported by the target device. Between these levels, a debug and trace controller (DTC) facilitates communication between the host debugger and the debug support logic on the target chip.

The DTC is a combination of hardware and software that connects the host debugger to the target system. The DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG® commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

The device provides the following on-chip debug support features:

- External debug interfaces:
  - Primary debug interface - IEEE1149.1 (JTAG) or IEEE1149.7 (complementary superset of JTAG)
    - Used for debugger connection
    - Default mode is IEEE1149.1 but debugger can switch to IEEE1149.7 via an IEEE1149.7 adapter module
    - Controls ICEPick™ (generic test access port [TAP] for dynamic TAP insertion) to allow the debugger to access several debug resources through its secondary (output) JTAG ports (for more information, see Section 29.3.3.1, *ICEPick Secondary TAPs*).
    - For more information about IEEE1149.1, see Section 29.2.1, *IEEE1149.1*.
    - For more information about IEEE1149.7, see Section 29.2.2, *IEEE1149.7*.
  - Secondary debug interface – MIPI® Narrow Interface for Debug and Trace (NIDnT)
    - Used for end product debug
    - Debugger can be plugged instead of SD card
    - For more information about NIDnT, see Section 29.2.4, *Narrow Interface for Debug and Trace (NIDnT)*.
  - Debug (trace) port
    - Can be used to export processor or system trace off-chip (to an external trace receiver)
    - Can be used for cross-triggering with an external device
    - Configured through debug resources manager (DRM) module instantiated in the debug subsystem
    - For more information about debug (trace) port, see Section 29.2.3, *Debug (Trace) Port* , and Section 29.10, *Concurrent Debug Modes*.
- Dynamic TAP insertion
  - Controlled by ICEPick
  - For more information, see Section 29.3.3, *Dynamic TAP Insertion.*
- Power and clock management
  - Debugger can get the status of the power domain associated to each TAP.
  - Debugger may prevent the application software switching off the power domain.
  - Application power management behavior can be preserved during debug across power transitions.

  - For more information, see Section 29.5.1, *Power and Clock Management.*
- Reset management
  - Debugger can configure ICEPick to assert, block, or extend the reset of a given subsystem.
  - For more information, see Section 29.5.2, *Reset Management.*
- Cross-triggering
  - Provides a way to propagate debug (trigger) events from one processor, subsystem, or module to another:
    - Subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device.
    - Subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.
  - Two global trigger lines are implemented
  - Device-level cross-triggering is handled by the XTRIG (TI cross-trigger) module implemented in the debug subsystem
  - Various ARM® CoreSight™ cross-trigger modules implemented to provide support for CoreSight triggers distribution
    - CoreSight Cross-Trigger Interface (CS_CTI) modules
    - CoreSight Cross-Trigger Matrix (CS_CTM) modules
  - For more information about cross-triggering, see Section 29.4.2, *Cross-Triggering.*
- Suspend
  - Provides a way to stop a closely coupled hardware process running on a peripheral module when the host processor enters debug state
  - For more information about suspend, see Section 29.4.3, *Suspend.*
- MPU watchpoint
  - Embedded in MPU subsystem
  - Provides visibility on MPU to EMIF direct paths
  - For more information, see Section 29.7, *MPU Memory Adaptor.(MA_MPU) Watchpoint*
- Processor trace
  - Only Cortex™-A15 (MPU) trace is supported
  - Program trace only (no data trace)
  - Supported by a CoreSight Program Trace Macrocell (CS_PTM) module (per MPU core)
  - Three exclusive trace sinks:
    - CoreSight Trace Port Interface Unit (CS_TPIU) – trace export to an external trace receiver
    - CTools Trace Buffer Router (CT_TBR) in system bridge mode – trace export through USB
    - CT_TBR in buffer mode – trace history stored into on-chip trace buffer
  - For more information, see Section 29.8, *Processor Trace.*
- System instrumentation (trace)
  - Supported by a CTools System Trace Module (CT_STM), implementing:
    - MIPI System Trace Protocol (STP1.0) for trace export througn Parallel Trace Interface (PTI)
    - MIPI STP2.0 for trace export through Advanced Trace Bus (ATB)
  - Real-time software trace
    - MPU software instrumentation through CoreSight STM (CS_STM) (STP2.0)
    - System-on-chip (SoC) software instrumentation through CT_STM (STP2.0)
  - OCP watchpoint (OCP_WP_NOC)
    - OCP target traffic monitoring: OCP_WP_NOC can be configured to generate a trigger upon watchpoint match (that is, when target transaction attributes match the user-defined attributes).
    - SoC events trace

    - DMA transfer profiling
  - Statistics collector (performance probes)
    - Computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface
    - Embedded in the L3_MAIN interconnect
    - Three instances:
      - One instance dedicated to target load monitoring
      - Two instances dedicated to master latency monitoring
  - IVA instrumentation (hardware accelerator [HWA] profiling)
    - Supported through a software message and system trace event (SMSET) module embedded in the IVA subsystem
  - Power-management events profiling (PM instrumentation [PMI])
    - Monitoring major power-management events. The PM state changes are handled as generic events and encapsulated in STP messages.
  - Clock-management events profiling (CM instrumentation [CMI])
    - Monitoring major clock management events. The CM state changes are handled as generic events and encapsulated in STP messages.
    - Two instances, one per CM
      - CM1 Instrumentation (CMI1) module mapped in the PD_CORE_AON power domain
      - CM2 Instrumentation (CMI2) module mapped in the PD_CORE power domain
  - For more information, see Section 29.9, *System Instrumentation.*
- Performance monitoring
  - Supported by subsystem counter timer modules (SCTMs) for digital signal processor (DSP) and interrup processing unit (IPU) subsystems
  - Supported by performance monitoring unit (PMU) for MPU subsystem
  - For more information, see Section 29.6, *Performance Monitoring*.

For easy integration into applications, a set of application-programming interfaces (APIs) for debug-IP programming and a software message library are provided. CToolsLib is a library of embedded target APIs to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

http://processors.wiki.ti.com/index.php/CToolsLib

The previous link connects to TI community resources. Linked contents are provided as is by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

29.2 Debug Interfaces

29.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968™ processor
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 or 20 pins) in the JTAG header of the device

Table 29-1 describes the IEEE1149.1 signals.

Table 29-1. IEEE1149.1 Signals

Pin Name	Internal Signal Name	Type(1)	Pull Type (2)	Function	Description
jtag_ntrst	nTRST	I	PD	Test reset	When asserted (active low), resets all test and debug logic in the device along with the IEEE1149.1 interface
jtag_tck	TCK	I	PD	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is either a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring.
jtag_rtck	RTCK	O	N/A	Returned (synchronized) test clock	Depending on the DTC attached to the device, the JTAG signals are either clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK.
jtag_tms_tmsc	TMS	I	PU	Test mode select	Directs the next state of the IEEE1149.1 TAP state-machine.
jtag_tdi	TDI	I	PU	Test data input	Scans data input to the device.
jtag_tdo	TDO	O	PU	Test data output	Scans data output by the device.
drm_emu0	EMU0	I/O	PU	Emulation 0	Channel 0 trigger or boot mode or trace port
drm_emu1	EMU1	I/O	PU	Emulation 1	Channel 1 trigger or boot mode or trace port
drm_emu2(3)	EMU2(3)	O	PD	Emulation 2	Trace port
drm_emu3(3)	EMU3(3)	O	PD	Emulation 3	Trace port
drm_emu4(3)	EMU4(3)	O	PD	Emulation 4	Trace port

(1) I = Input; O = Output; I/O = bidirectional

(2) PU = internal pullup; PD = internal pulldown

(3) 20-pin JTAG header only

The device JTAG ID code can be accessed through ICEPick. For information about the JTAG ID code value, see Chapter 1, *Introduction*.

29.2.2 IEEE1149.7

In addition to the legacy standard JTAG mode of operation, the target debug interface can also be switched to a compressed JTAG mode of operation; this mode is commonly called the IEEE1149.7 standard. An IEEE1149.7 adapter module runs a 2-pin communication protocol on top of an IEEE1149.1 JTAG TAP. Using a variety of compression formats, the debug-IP logic serializes the IEEE1149.1 transactions to reduce the number of pins needed to implement a JTAG debug port. The device implements only a subset of the IEEE1149.7 protocol (see Table 29-3).

NOTE: At power-on reset (POR), the default debug interface mode is IEEE1149.1. For the scan sequence required to switch modes, see the IEEE1149.7 specification.

The IEEE1149.7 communication protocol can switch between serial and parallel formats. The parallel format consists of the IEEE1149.1 signals, TCK, TMS, TDI, TDO, nTRST, and a return clock (RTCK), if stalls are required. The serial format uses two signals, TCK and TMSC. The values of the TMS, TDI, TDO, and RTCK signals are multiplexed on the bidirectional pin, jtag_tms_tmsc, by the Debug-IP logic. Each TCK of the DTC is serialized into a packet, which is transmitted to the IEEE1149.7 adapter, where it is converted back to parallel. The TDO and RTCK information are returned during the packet transmission.

NOTE: Only MScan, Oscan0, and Oscan4 formats can be used if the device requires stalls.

Table 29-2 describes the IEEE1149.7 signals.

Table 29-2. IEEE1149.7 Signals

Pin Name	Internal Signal Name	Type[1]	Pull Type [2]	Function	Description
jtag_tck	TCK	I	PD	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is either a free-running or a gated clock, depending on the DTC attached to the device and the TMSC RDY field monitoring.
jtag_tms_tmsc	TMSC	I/O	PU	Test mode control and data scan	Compressed JTAG packet. The TMSC signal is driven only when the TCK signal is low. The signal level must be maintained by a keeper while the TCK signal is high.

(1) I = Input; O = Output; I/O = bidirectional
(2) PU = internal pullup; PD = internal pulldown

The device provides a NODE ID identifier to support platform with up to four identical OMAP5430 devices for multidrop debug. The identifier is provided by two external pins (sys_nodeid[1:0]) sensed during the boot sequence.

NOTE: An PCB pull is required on each of the sys_nodeid[1:0] pins.

Table 29-3 summarizes the IEEE1149.7 features subset supported by the device.

Table 29-3. IEEE1149.7 Features Subset

	IEEE1149.7 Feature	Device Support	Comment
Configuration	Class 4 TAP	✓	Supports 2-pin operation
	Class 5 TAP	✓	BDX or CDX channel (CT_UART)
Optional Components	FRST	–	Functional reset (done through ICEPick)
	TRST	–	Test reset
	RDBK capability	✓	Read back of register data
	Auxiliary pin functions	–	Reuse of TDI and TDO pins
	TCKWID	✓	Programmable TCK width

Table 29-3. IEEE1149.7 Features Subset (continued)

	IEEE1149.7 Feature	Device Support	Comment
Scan Formats	JScan0	✓	Parallel mode
	JScan1	✓	Parallel with firewall
	JScan2	✓	Parallel with super-bypass select
	JScan3	✓	Parallel with register select
	SScan0	–	Segmented scan
	SScan1	–	Segmented scan + stalls
	SScan2	–	Segmented scan
	SScan3	–	Segmented scan + stalls
	Oscan0	✓	Support stalls
	Oscan1	✓	Nonstall mode
	Oscan2	✓	Bidirectional transfers
	Oscan3	✓	Host to target only
	Oscan4	✓	Support stalls
	Oscan5	✓	Pipelined
	Oscan6	✓	Bidirectional transfers
	Oscan7	✓	Host to target only
	Mscan	✓	Multi devices mode + stalls
Power Control	Power down logic	–	Handled by ICEMelter

The debug subsystem instantiates a CTools UART (CT_UART) module (see row 2 of Table 29-3) responsible for providing a way to send and receive blocks of data, which is compliant with the IEEE1149.7 data channel interface specification. The CT_UART module contains two buffers, one for sending data to the DTC controller (the TX buffer) and one for receiving data from the DTC controller (the RX buffer). The CT_UART module generates an interrupt (DEBUGSS_IRQ_CT_UART) to the INTC_MPU (MPU_IRQ_90 interrupt line) when one of the following conditions occurs:

- TX buffer empty
- Data ready on RX buffer

29.2.3 Debug (Trace) Port

On-chip debug and trace events can be exported to external equipment through the debug (trace) port of the device. The following exportable debug events and trace sources are supported:

- Debug events
  - Triggers. For more information about triggers, see Section 29.4.2, *Cross-Triggering*.
- Trace sources
  - Processor trace: Cortex-A15 MPU trace supported by the CS_PTM module. For more information about the processor trace, see Section 29.8, *Processor Trace*.
  - System trace: Trace coming from various system instrumentation modules, and supported by the CT_STM module. For more information about the system trace, see Section 29.9, *System Instrumentation*.

Not all debug and trace features can be supported concurrently because of the limited number of pins allocated to debug. Thus, multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection occur through the DRM module embedded in the debug subsystem.

Table 29-4 describes the trace port signals.

Table 29-4. Trace Port Signals

Pin Name	Internal Signal Name	I/O[1]	Pull Type [2]	Description
drm_emu19	EMU19	O	PD	Debug resource manager pin 19
drm_emu18	EMU18	O	PD	Debug resource manager pin 18
drm_emu17	EMU17	O	PD	Debug resource manager pin 17
drm_emu16	EMU16	O	PD	Debug resource manager pin 16
drm_emu15	EMU15	O	PD	Debug resource manager pin 15
drm_emu14	EMU14	O	PD	Debug resource manager pin 14
drm_emu13	EMU13	O	PD	Debug resource manager pin 13
drm_emu12	EMU12	O	PD	Debug resource manager pin 12
drm_emu11	EMU11	O	PD	Debug resource manager pin 11
drm_emu10	EMU10	O	PD	Debug resource manager pin 10
drm_emu9	EMU9	O	PD	Debug resource manager pin 9
drm_emu8	EMU8	O	PD	Debug resource manager pin 8
drm_emu7	EMU7	O	PD	Debug resource manager pin 7
drm_emu6	EMU6	O	PD	Debug resource manager pin 6
drm_emu5	EMU5	O	PD	Debug resource manager pin 5
drm_emu4	EMU4	O	PD	Debug resource manager pin 4
drm_emu3	EMU3	O	PD	Debug resource manager pin 3
drm_emu2	EMU2	O	PD	Debug resource manager pin 2
drm_emu1	EMU1	I/O	PU	Debug resource manager pin 1
drm_emu0	EMU0	I/O	PU	Debug resource manager pin 0

(1) I = Input; O = Output; I/O = bidirectional
(2) PU = internal pullup; PD = internal pulldown

NOTE: The drm_emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the drm_emu[19:0] pins, the user must program the device application pin manager (control module) appropriately. For more information, see Chapter 18, *Control Module*.

For more information about DRM multiplexing and concurrent debug modes, see Section 29.10, *Concurrent Debug Modes*.

29.2.4 Narrow Interface for Debug and Trace (NIDnT)

Typically, the device-wide debug port is no more available on a packaged end product phone due to connectivity and footprint constraints. The device provides a NIDnT on MMC connector compliant to the MIPI NIDnT specification. The NIDnT port provides the following pins:

- 1 clock – n_clk
- 4 data – n_d[3:0]

Table 29-5 summarizes the NIDnT debug pins mapping.

Table 29-5. NIDnT Mapping

Module	Control Module Multiplexing				
	MUX0	MUX3	MUX4	MUX5	MUX6
SD card (MMC)	sdcard_clk	jtag_rctk	–	n_clk	–
	sdcard_cmd	jtag_tdo	uart6_rx	–	n_d2
	sdcard_dat0	jtag_tdi	–	n_d0	–
	sdcard_dat1	jtag_ntrst	–	n_d1	–
	sdcard_dat2	jtag_tms_tmsc	–	n_d2	–
	sdcard_dat3	jtag_tck	–	n_d3	–

The NIDnT standard supports several overlay modes. A DRM register provides a means of switching NIDnT overlay modes by software. The overlay mode selection register is immune to warm reset and functional (that is, nondebug) power and voltage transitions.

Table 29-6 shows the NIDnT overlay modes supported in the device.

Table 29-6. NIDnT Overlay Modes in the Device

NIDnT Overlay Mode 0 (Functional)	NIDnT Overlay Mode 1[1] (MIN-pin debug)	NIDnT Overlay Mode 2[1] (Legacy debug)	NIDnT Overlay Mode 3[1] (Not supported in the device)	NIDnT Overlay Mode 4[1] (Debug + PTIv1/PTIv2 [dedicated clk] + user extension)	NIDnT Overlay Mode 5[1] (Debug + PTIv1/PTIv2 [dedicated clk])	NIDnT Overlay Mode 6 (PTIv1/PTIv2 + user extension)	NIDnT Overlay Mode 7 (Not supported in the device)
CLK out	–	RTCK out	N/A	TRC_CLK out	TRC_CLK out	TRC_CLK out	N/A
CMD in/out	–	TDO out	N/A	USER_EXT[2] in/out	TRC_DATA[2] out	USER_EXT[2] in/out	N/A
DAT0 in/out	–	TDI in	N/A	TRC_DATA[0] out	TRC_DATA[0] out	TRC_DATA[0] out	N/A
DAT1 in/out	–	nTRST in	N/A	TRC_DATA[1] out	TRC_DATA[1] out	TRC_DATA[1] out	N/A
DAT2 in/out	TMSC in/out	TMS in	N/A	TMSC in/out	TMSC in/out	TRC_DATA[2] out	N/A
DAT3 in/out	TCKC in	TCK in	N/A	TCKC in	TCKC in	TRC_DATA[3] out	N/A

(1) The NIDnT overlay modes with the TCKC or TCK pin function do not work when external level shifters are used.

(2) USER_EXT is a user-defined signal and can be either input or output. A common implementation uses this pin for UART_RX (that is, input to the SoC).

The NIDnT overlay mode selection will override SDCARD pin mapping. For example, selecting overlay mode 5 will override the SDCARD pin mapping as follows:

- Sdcard_clk = MUX5 = n_clk (TRC_CLK)
- Sdcard_cmd = MUX6 = n_d2 (TRC_DATA[2])
- Sdcard_data0 = MUX5 = n_d0 (TRC_DATA[0])
- Sdcard_data1 = MUX5 = n_d1 (TRC_DATA[1])
- Sdcard_data2 = MUX3 = jtag_tmsc (TMSC)
- Sdcard_data3 = MUX3 = jtag_tck (TCKC)

For more information about the NIDnT concept, see the *MIPI Alliance Test and Debug – NIDnT-Port* specification.

29.2.5 IEEE1149.1 Expansion Port

The device also provides a JTAG expansion port (with inverted JTAG signals) to attach a MODEM device (or other IC). Table 29-7 describes the JTAG expansion port signals.

Table 29-7. IEEE1149.1 Expansion Port Signals

Pin Name	Internal Signal Name	Type	Function
jtagtapext_ntrst	nTRST	O	Test reset for external modem or other IC
jtagtapext_tck	TCK	O	Test clock for external modem or other IC
jtagtapext_rtck	RTCK	I	Returned (synchronized) test clock for external modem or other IC
jtagtapext_tmsc	TMS	O	Test mode select for external modem or other IC
jtagtapext_tdi	TDI	I	Test data input for external modem or other IC
jtagtapext_tdo	TDO	O	Test data output for external modem or other IC

The JTAG expansion is handled by:

- Inserting the MDM secondary TAP in the ICEPICK scan chain (see Table 29-9 for ICEPICK scan chain).
- Routing the MDM secondary TAP to device pads (for more details, see Chapter 18, *Control Module*).

29.2.6 Trace Connector and Board Layout Considerations

Because the device supports processor trace and system trace exports, one of the following header configurations may be required at board level:

- A 60-pin header in place of the traditional TI 14-pin
- A TI 20-pin emulation header

For more information about the trace connectors and board layout considerations for these high-speed signals, see *Emulation and Trace Headers* (TI literature number SPRU655).

29.3 Debugger Connection

29.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the IEEE1149.7 adapter connected to the ICEPick module embedded in the debug subsystem.

NOTE: ICEPick version D (ICEPick-D) is used in the device.

SoC designs typically have multiple processors, each having a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  - Serially linking up to 16 TAP controllers (the device implements 7 TAPs)
  - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management (PRCM)
  - Provides the power and clock states of each domain
  - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  - Applies system reset
  - Provides wait-in-reset (WIR) boot mode
  - Provides global and local WIR release
  - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see Section 29.3.3, *Dynamic TAP Insertion*.

For more information about ICEPick PRCM features, see Section 29.5, *Power, Reset, and Clock Management Debug Support*.

29.3.2 ICEPick Boot Modes

The initial configuration of ICEPick is determined by the level of the drm_emu0 and drm_emu1 pins at POR release. At POR, drm_emu0 and drm_emu1 are automatically configured as inputs. The drm_emu0 and drm_emu1 pins are free when POR is released.

Table 29-8 summarizes the ICEPick boot modes.

Table 29-8. ICEPick Boot Modes at POR

drm_emu1	drm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + WIR mode

Table 29-8. ICEPick Boot Modes at POR (continued)

drm_emu1	drm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
1	1	ICEPick	TAP only (default mode)

29.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This mode is the recommended boot mode.

29.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors can be released from reset (local), or all processors held in the reset state can be released at the same time (global).

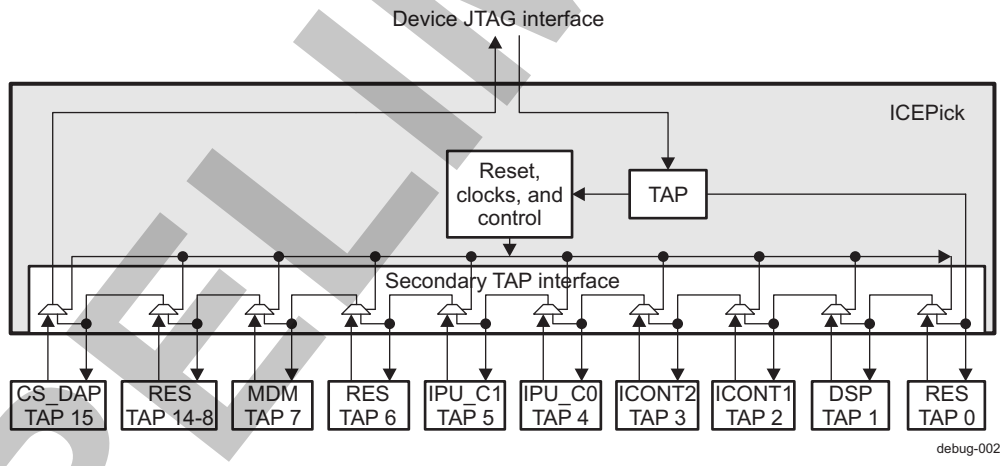
29.3.3 Dynamic TAP Insertion

29.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From the external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Figure 29-1 shows the TAPs in the ICEPick scan chain.

Figure 29-1. ICEPick Scan Chain



NOTE: RES = Reserved/not used

Table 29-9 lists the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

Table 29-9. ICEPick Secondary Debug TAP Mapping

Secondary JTAG Port	CoreSight	TAP Number	Modules Accessed Through That JTAG Port
Reserved	No	0	–
DSP	No	1	C64x+™/ICEMaker
IVA ICONT1	No	2	ARM968/ICECrusher™-9

(1) Embedded in MPU
(2) Embedded in DEBUGSS

NOTE: MA_MPU watchpoint programming is restricted to the MPU. Programming from the CS_DAP APB access port is not supported.

The MPU timestamp registers are part of the PRCM_MPU programming model and can be accesses from the two MPU cores.

For more information about ICEPick scan sequences (adding one or more TAPs to the scan chain), see:

http://processors.wiki.ti.com/images/f/f6/Router_Scan_Sequence-ICEpick-D.pdf

The preceding links connects to TI community resources. Linked contents are provided as is by the respective contributors. They do not constitute TI specifications and do not necessarily reflect the views of TI; see the TI Terms of Use.

Besides secondary debug TAPs, ICEPick also supports power, reset, and clock controls for non-JTAG debug cores. The debug cores are accessible through CS_DAP.

Table 29-10 summarizes the ICEPick debug core mapping.

29.4 Primary Debug Support

29.4.1 Processor Native Debug Support

29.4.1.1 Cortex-A15 Processor

The dual Cortex-A15 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watchpoints
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A15 native debug support features, see the *Cortex-A15 Technical Reference Manual*.

29.4.1.2 Cortex-M4 Processor

The Cortex-M4 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watchpoint on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M4 native debug support features, see the *Cortex-M4 Technical Reference Manual*.

29.4.1.3 DSP

The DSP core supports limited advanced event triggering (AET) with the following capabilities:

- Hardware program breakpoints: Specify addresses or address ranges that can generate events, such as halting the processor or triggering the trace capture.
- Data watchpoints: Specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture.

Known restrictions of this DSP core:

- No DSP processor trace support
- No real-time mode debug mode support
- Limited AET support, only two watchpoint units
- No HSRTDX support

29.4.1.4 IVA ARM968

The ARM968E-S processor (in each ICONT) supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watchpoints/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about ARM968 native debug support features, see the *ARM968E-S Technical Reference Manual*.

29.4.1.5 IVA Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SYNCBOX module:

- Manual halt: Halt occurs at the SYNCBOX task boundary when requested by the debugger.
- Single-step execution at SYNCBOX task level (from 1 to *n* macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt (after the execution of current SYNCBOX task) based on trigger event detection.
- Global run

Table 29-11 summarizes the debug capabilities of the hardware accelerator SYNCBOX.

Table 29-11. Hardware Accelerator Debug Capability Options

Feature	IME3	IPE3	MC3	CALC3	ILF3	ECD3
Core reset	–	–	–	–	–	–
Execution request	–	–	–	–	–	–
Trigger output	–	–	–	–	–	–
Trigger input	✓	✓	✓	✓	✓	✓
Number of trigger channels	1	1	1	1	1	1
Number of counters	0	0	0	0	0	0
Number of watchpoints	0	0	0	0	0	0
Number of hardware breakpoints	0	0	0	0	0	0

29.4.2 Cross-Triggering

The device supports a cross-triggering feature that provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given subsystem A can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another subsystem B can be programmed to be sensitive to the trigger line input and to generate an action on trigger detection.

Examples of debug events are: Processor entering debug state, watchpoint match, CS_PTM trigger, CT_TBR full, CT_TBR acquisition complete, and so forth.

Examples of debug actions are: Debug request generation, restart (Cortex-A15 synchronous run), interrupt request generation, start/stop trace, and so forth.

Subsystem cross-triggering is consolidated at the device level by the XTRIG module, which is embedded in the debug subsystem.

NOTE: XTRIG is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

29.4.2.1 MPU Subsystem Cross-Triggering

The MPU subsystem provides:

- Support for cross-triggering between MPU cores using CS_CTI_MPU_C0 and CS_CTI_MPU_C1, programmable through AXI bus accesses or by debugger from the CS_DAP APB bus directly
- CS_CTM_MPU matrix to carry cross-triggers
  - Between CS_CTI_MPU_C0 and CS_CTI_MPU_C1
  - Outside Cortex-A15 MPCore, to CS_CTM_S
- CS_CTI_S to collect trigger events from CS_STM and DAP_PC
- CS_CTM_S to combine the triggers from CS_CTI_S with system and MPU core triggers:
- Trigger interface from CS_CTM_S to debug subsystem

- Support for global or synchronous run when both Cortex-A15 CPUs are halted
- Support for COMMTX/COMMRX routing through CS_CTI_MPU_C0 and CS_CTI_MPU_C1 to the interrupt line (MPU_IRQ_1 for CS_CTI_MPU_C0, MPU_IRQ_2 for CS_CTI_MPU_C1)
- Cross-triggering between CS_PTMs and CT_TBR:
  - CS_PTM can generate a trigger that can be used to stop CT_TBR data capture
  - CT_TBR can send buffer-full or acquisition-complete events to the CS_PTM

The MPU subsystem cross-triggering logic allows stopping one MPU core at debug event detection in the other MPU core. For example, a watchpoint detected by MPU_C0 can break MPU_C1 execution, and vice versa. This is also known as symmetric multiprocessor platform (SMP) debug and is supported through CS_CTI_MPU programming.

The MPU subsystem may export/import trace triggers events to/from the debug subsystem through the CoreSight SoC triggering channels:

- CS_PTM
- CS_STM
- CT_TBR
- CS_TPIU

Figure 29-2 highlights the cross-triggering scheme implemented at the MPU subsystem level. A debug event from either processor core can be programmed to have a specific debug action on the other core or drive a SoC trigger line and generate a debug action into another application subsystem or debug and trace component. In addition to that, a watchpoint capability is implemented in the MPU subsystem memory adapter (MA_MPU), thus allowing the user to track the MA transactions from/to external memory through trigger to any of the MPU cores. For more information, see Section 29.7, *MPU Memory Adaptor (MA_MPU) Watchpoint*..

Figure 29-2. MPU Subsystem Cross-Triggering

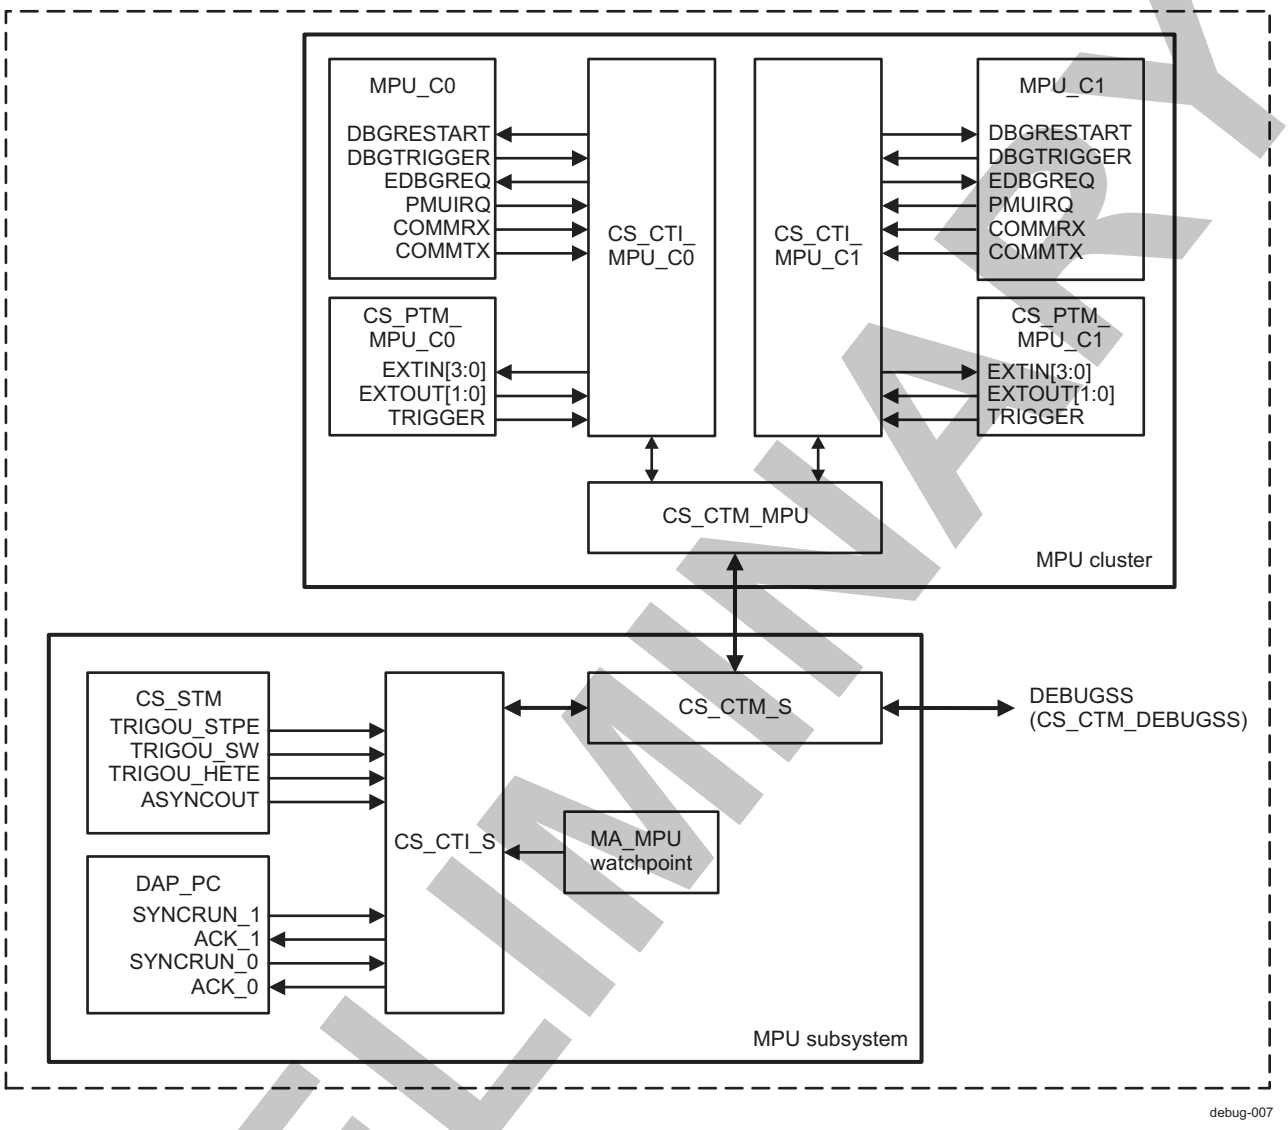

Table 29-12 and Table 29-13 summarize the CS_CTI_MPU connections inside the MPU cluster.

Table 29-12. CS_CTI_MPU Trigger Sources

CS_CTI_MPU Trigger Input CTITRIGIN[7:0]	Source Module	Source Module Output	Description

For more information about Cortex-A15 CPU, CS_CTI, and CS_PTM signals description, see the ARM *Cortex™-A15 Technical Reference Manual*.

29.4.2.2 Debug Subsystem Cross-Triggering

The debug subsystem implements two cross-triggering schemes:

- TI cross-triggering scheme
- CoreSight cross-triggering scheme

The debug subsystem provides cross-triggering support in three different ways:

- XTRIG module (TI cross-trigger module) to support merge and distribution of TI asynchronous triggers (two channels per interface)
- CS_CTM_DEBUGSS (CoreSight cross-trigger matrix) to support merge and distribution of CoreSight triggers (four channels per interface) to CoreSight components inside and outside of the debug subsystem
- CT_CTA module (CTools cross-trigger adapter) to support conversion between TI asynchronous trigger format (two channels) and CoreSight handshake based asynchronous trigger format

This cross-triggering architecture of the debug subsystem allows it to provide the following features:

- Migration of a trigger originating from a CoreSight trigger source and ending at a TI trigger sink
- Migration of a trigger originating from a TI trigger source and ending at a CoreSight trigger sink
- Migration of a trigger originating from a CoreSight trigger source and ending in the debug subsystem at a CoreSight trigger sink using the four available CoreSight trigger channels
- Migration of a trigger originating from a CoreSight source in the debug subsystem to a CoreSight trigger sink outside the debug subsystem using the four available CoreSight trigger channels
- Support for routing CoreSight cross-triggers (from the MPU subsystem) to CoreSight modules within the debug subsystem:
  - CT_TBR
  - CS_TPIU
- Support for routing TI cross-triggers to CoreSight modules within the debug subsystem:
  - CT_TBR
  - CS_TPIU
- Support for routing input triggers from CT_TBR (buffer full, acquisition complete) outside of the debug subsystem

Figure 29-3 highlights the cross-triggering scheme implemented at the debug subsystem level.

Figure 29-3. Debug Subsystem Cross-Triggering

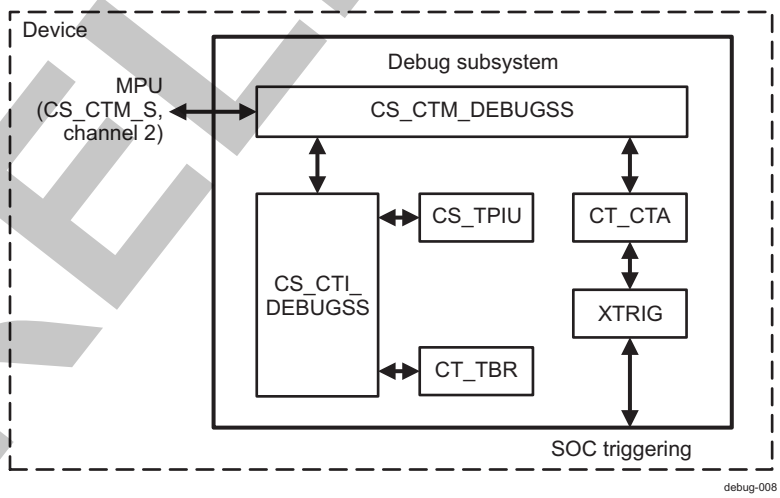

Table 29-17 and Table 29-18 summarize the CS_CTI_DEBUGSS connections inside the debug subsystem.

Table 29-17. CS_CTI_DEBUGSS Trigger Sources

CS_CTI_DEBUGSS Trigger Input CTITRIGIN[7:0]	Source Module	Source Module Output	Description
CTITRIGIN[0]	–	–	Unused
CTITRIGIN[1]	–	–	Unused
CTITRIGIN[2]	CT_TBR	ACQCOMP	Acquisition complete
CTITRIGIN[3]	Warm reset	–	Warm reset detection(1)
CTITRIGIN[7:4]	–	–	Unused

(1) Can be used to halt the trace formatter in CT_TBR or CS_TPIU to support a use case of stopping trace upon warm reset detection.

Table 29-18. CS_CTI_DEBUGSS Trigger Outputs

CS_CTI_MPU Trigger Output CTITRIGOUT[7:0]	Destination Module	Destination Module Input	Description

- NOC_SC

29.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a closely coupled hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1 bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

29.4.3.1 Debug Aware Peripherals and Host Processors

Table 29-20 lists the mapping of the device processors to the suspend control input lines.

29.5 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
  - Current power setting indicating whether the power domain is on or off
  - Loss of power detected since the software last checked the status
  - Current clock setting indicating whether the clock domain is on or off
  - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  - Subsystem reset state
  - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

ICEPick handles debug power management at the device level. In addition, the device implements a second level of debug power management through the DAP_PC module integrated in the MPU subsystem, which provides the same capabilities as ICEPick for the two Cortex-A15 CPUs. Each Cortex-A15 CPU core is in its own independent power domain, which DAP_PC manages. The hierarchical debug power-management approach provided by DAP_PC at the subsystem level and by ICEPick at the device level ensures a theoretically independent debug capability for each Cortex-A15 CPU core.

NOTE: The debugger must properly sequence global ICEPick and local DAP_PC commands:

- To force clocks/power:
  1. The debugger must first force it for the MPU subsystem at the ICEPick level.
  2. The debugger must then force it for a specific Cortex-A15 CPU at the DAP_PC level.
- To release clocks/power:
  1. The debugger must first release it for a specific Cortex-A15 CPU at the DAP_PC level.
  2. The debugger must then release the MPU subsystem controls at the ICEPick level.

29.5.1 Power and Clock Management

29.5.1.1 Power and Clock Control Override From Debugger

The debugger can override the application software power and clock management settings through the ICEPick module. It can configure ICEPick to force a domain active or prevent it from going to sleep once it is active. This can be achieved through the following debugger directives:

- FORCEACTIVE
- INHIBITSLEEP

29.5.1.1.1 Debugger Directives

29.5.1.1.1.1 FORCEACTIVE Debugger Directive

To ensure that the subsystem debug registers can always be accessed, regardless of the application power-management scenarios, a FORCEACTIVE directive can be issued through the debugger along the entire debug session. From an application standpoint, the system state, status, and timing are preserved, but the subsystem power domain is never shut down. Therefore, the emulation setup is preserved across power transitions, regardless of where the debug hardware is implemented.

If the debugger connects and the subsystem were previously powered down, a FORCEACTIVE directive wakes up the system and allows the debugger to take control of the system.

29.5.1.1.1.2 INHIBITSLEEP Debugger Directive

The debugger can use the INHIBITSLEEP directive to keep a subsystem powered and clocked, even if the applicative settings request that this subsystem go to sleep. Contrary to the FORCEACTIVE directive, the INHIBITSLEEP command does not wake up a subsystem that is already powered down by the application.

The typical use of the INHIBITSLEEP directive is to prevent power and clock transitions on the subsystem during a debug session. In this situation, when the applicative scenario initiates a transition, the transition does not take place, but from an applicative point of view the subsystem is not accessible.

29.5.1.1.2 Intrusive Debug Model

The use of debugger directives is intrusive from the standpoint of the power and clock controls, because they affect the power-management behavior of the application.

29.5.1.2 Debug Across Power Transition

29.5.1.2.1 Nonintrusive Debug Model

To preserve the power-management behavior of the device and allow the subsystem power and clock to be switched off by application software, the subsystem TAP must be disconnected from the ICEPick scan chain. The subsystem is then completely ignored by the debugger and the host-to-target communication is no longer affected by the state of the subsystem power and clocks. The debugger can still be informed that the disconnected subsystem entered the debug state by polling the Debug Attention status bit from ICEPick. The debugger can then insert the TAP, take control of the subsystem power and clock, and examine the system state.

This debug model is nonintrusive, because it allows the power-management behavior of the application to be preserved.

29.5.1.2.2 Debug Context Save and Restore

29.5.1.2.2.1 Debug Context Save

The device partitioning is such that not all the debug components are mapped to an always-on domain. Typically, the programmer wants the debug setup to be preserved along a debug session, including subsystem power cycling. When debug registers are memory mapped and not implemented within the emulation power domain, the application software must save the state of the debug registers before going to sleep and restore them upon wakeup.

29.5.1.2.2.2 Debug Context Restore

When the application software performs a context restore, it must be able to write to all the debug registers to restore their contents, regardless of the previous ownership. After subsystem power domain ramp up, the debug resources are in the available state, and ownership is restored. The debug context save and restore sequences are protected. All debug functionality is disabled and debugger accesses are blocked.

29.5.2 Reset Management

The debugger can take control of the system reset for each subsystem through ICEPick. The debugger can configure ICEPick to assert, block, or extend the subsystem reset.

29.5.2.1 Debugger Directives

29.5.2.1.1 Assert Reset

The debugger can program ICEPick to generate a subsystem reset request to the device reset management module. The debugger reset event is then merged with system reset events.

29.5.2.1.2 Block Reset

The debugger can program ICEPick to request the device reset management module to block an unsafe application system or subsystem reset event.

A reset originated by some safe reset sources cannot be blocked by the debugger.

29.5.2.1.3 Wait-In-Reset

WIR mode is latched from boot mode (see Section 29.3.2, *Boot Modes*) and allows the user to hold a secondary TAP module in reset state when a reset is applied (and thus, extend the reset). This mode lets the user control the following system level activities:

- Gain emulation control of any processor in a power domain at POR
- Capture and extend system-generated functional resets while running (under emulation control or not)
- Hold an entire power domain in reset until emulation control of the subsystem can be established
- Stall the entire system while reset is extended to a power domain
- Reset extension is visible external to the power domain.
- Debug execution of code from the first cycle of execution
- Prevent processor execution of random instructions in uninitialized program memory at power up
- Download code before any code execution takes place
- Coordinate debug initialization across multiple cores before code execution begins

WIR mode extends only the processor reset. During reset extension, the debugger can still access modules such as L2 memory and MMU, even if they are embedded in the device subsystem affected by WIR.

When the debugger task is complete, the DTC releases the subsystem reset by programming the corresponding ICEPick TAP control register.

29.6 Performance Monitoring

29.6.1 MPU Subsystem Performance Monitoring

29.6.1.1 Performance Monitoring Unit

The Cortex-A15 processor includes a PMU that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A15. Upon counter overflow, PMU can generate an interrupt on its PMUIRQ output. This interrupt signal is mapped to the CTITRIGIN[1] input and routed to an INTC_MPU input (MPU_IRQ_131 for Cortex-A15 CPU0 PMU; MPU_IRQ_132 for Cortex-A15 CPU1 PMU).

The Cortex-A15 PMU outputs 52 events (PMUEVENT[51:0]) to CS_PTM (see Table 29-22).

Table 29-22. PMU Events

PMU Event	Description
0	Software increment
1	Instruction fetch that causes a refill
2	Instruction fetch that causes a TLB refill
3	Data read or write operation that causes a refill
4	Data read or write operation that causes a cache access
5	Data read or write operation that causes a TLB refill
6	Data read architecturally executed
7	Data write architecturally executed
8,9	Number of instructions renamed: b00 = No instructions renamed b01 = One instruction renamed b10 = Two instructions renamed
10	Exception taken
11	Exception return architecturally executed
12	Change to context ID retired
13	Software change of PC
14	Immediate branch architecturally executed
15	Number of predictable function returns
16	Unaligned access architecturally executed
17	Branch mispredicted or not predicted
18	Branches or other change in program flow
19	Java byte code executed
20	Software Java byte code executed
21	Jazelle® backward branches executed
22	Coherent line fill request that misses in other uniprocessors
23	Request for coherent line fill that hits in other uniprocessors
24	Instruction cache dependent stalls
25	Data cache dependent stalls
26	TLB miss dependent stalls
27	STREX passed
28	STREX failed
29	Data eviction
30	Issue does not dispatch any instruction.
31	Issue is empty.
32	Main execution unit pipe
33	Second execution unit pipe

Table 29-22. PMU Events (continued)

PMU Event	Description
34	Load/store pipe
35, 36	Number of floating-point instructions renamed: b00 = No floating-point instruction renamed b01 = One floating-point instruction renamed b10 = Two floating-point instructions renamed
37, 38	Number of Neon instructions renamed: b00 = No Neon instruction renamed b01 = One Neon instruction renamed b10 = Two Neon instructions renamed
39	PLD stall
40	Write stall
41	Instruction main TLB miss stall
42	Data main TLB miss stall
43	Instruction micro TLB miss stall
44	Data micro TLB miss stall
45	DMB stall
46	Integer core clock enabled
47	Data engine clock enabled
48	ISB
49	DSB
50	DMB
51	External interrupt

For more information about Cortex-A15 PMU, see the *ARM Cortex-A15 Technical Reference Manual*.

29.6.1.2 L2 Cache Controller

The MPU subsystem includes 2 MiB of L2 cache (L2CACHE_MPU) and L2 cache controller (L2CACHE_CTRL_MPU). The L2 cache controller includes logic to support cache event monitoring.

Table 29-23 summarizes the L2 cache events.

Table 29-23. L2 Cache Events

Event	Event Description
0	Eviction of a line from the L2 cache
1	Data read hit in the L2 cache
2	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
3	Data write hit in the L2 cache
4	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
5	Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss.
6	Instruction read hit in the L2 cache
7	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
8	Prefetch line-fill sent to L3
9	Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss

The L2 cache controller implements two 32-bit event counters. The L2 cache controller can be configured to generate interrupts on error conditions or event counter overflow or increment. The L2 cache controller interrupt is routed to MPU_IRQ_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

29.6.2 IPU Subsystem Performance Monitoring

29.6.2.1 Subsystem Counter Timer Module

The IPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M4 cores (one sleep and one deep sleep event per core)

Table 29-24 describes the repartition of the IPU SCTM counters.

Table 29-24. IPU SCTM Counters Repartition

Counters	Features
0–1	Timer and event
2–3	64-bit chained + shadowing
4–5	64-bit chained + shadowing
6–7	Event

29.6.2.2 Cache Events

Table 29-25 summarizes the SCTM events for the IPU subsystem.

Table 29-25. SCTM Events for IPU Subsystem

Input Index	Event Description
1	Cache locks
2	Cache line replacements
3	Cache evictions
4	Cache maintenance operations (slave 0)
5	Cache maintenance operations (slave 1)
6	Cache maintenance operations (slave 2)
7	Cache maintenance operations (slave 3)

40	Cache misses (slave 3)
41	Cache hits (slave 0)
42	Cache hits (slave 1)
43	Cache hits (slave 2)
44	Cache hits (slave 3)
45	IPU_C1 deep sleep
46	IPU_C1 sleep
47	IPU_C0 deep sleep
48	IPU_C0 sleep

NOTE: Input index [0] is reserved for free-running subsystem clock (used for total cycle profiling).

29.6.3 DSP Subsystem Performance Monitoring

29.6.3.1 Subsystem Counter Timer Module

The DSP subsystem includes an SCTM, which is embedded in the DSP megamodule and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect L1 and L2 events.

Table 29-24 describes the repartition of the DSP SCTM counters.

Table 29-26. DSP SCTM Counters Repartition

Counters	Features
0–1	Timer and event
2–7	Event (no chaining)

29.6.3.2 L1 and L2 Events

Table 29-27 summarizes the SCTM events for DSP subsystem.

Table 29-27. SCTM Events for DSP Subsystem

Event	Event Description
1	L1 Slave0 (program) tag hit
2	L1 Slave1 (data) tag hit
3	L1 Slave0 (program) tag miss
4	L1 Slave1 (data) tag miss
5	L1 Slave0 (program) fill buffer hit
6	L1 Slave1 (data) fill buffer hit
7	L1 Slave1 (data) write buffer access
8	L1 Allocation FIFO
9	L1 Slave0 (program) bank conflict
10	L1 Slave1 (data) bank conflict
11	L1 Slave0 (program) cached request
12	L1 Slave1 (data) cached request
13	L1 Slave0 (program) waiting for fill buffer
14	L1 Slave1 (data) waiting for fill buffer
15	L1 Slave0 (program) waiting for maintenance
16	L1 Slave1 (data) waiting for maintenance
17	L1 Eviction occurred
18	L1 Replacement occurred
19	L1 Allocation failed due to locked lines occurred
20	L2 tag hit
21	L2 tag miss
22	L2 fill buffer hit
23	L2 write buffer access
24	L2 allocation FIFO
25	L2 cached request
26	L2 waiting for fill buffer
27	L2 waiting for maintenance
28	L2 eviction occurred
29	L2 replacement occurred
30	L2 allocation failed due to locked lines occurred
31	Tied-off to 0

NOTE: Input index [0] is reserved for the free-running subsystem clock (used for total cycle profiling).

29.7 MPU Memory Adaptor (MA_MPU) Watchpoint

The MPU subsystem implements a watchpoint allowing the user tracking the MA_MPU transactions from/to external memory.

The watchpoint can be programmed to generate a trigger when a MA_MPU transaction satisfies a set of user-defined attributes:

- Access within or outside an address region
- Access type (instruction, data, read, write)
- Transaction target (on-chip, memory channel, chip select)
- Qualifier
- Transaction originating from a specific core
- Specific transaction followed by memory barrier (DSB, DMB)
- Memory barrier (DSB, DMB) followed by specific transaction

When the MA_MPU transaction attributes match the debug use case setup, the MPU debug logic captures the transaction data and associated qualifiers:

- Read or write data (128-bit) for the specific beat of the burst
- Address (MSB field)
- MReqInfo (19-bit)
- Byte enables
- Burst type
- Burst length
- Target

When the MA_MPU watchpoint is configured to track memory barriers in order to investigate potential ordering issues, the debugger will report:

- Attributes of the transaction immediately following the memory barrier
- Attributes of the matching transaction chained to the memory barrier

29.8 Processor Trace

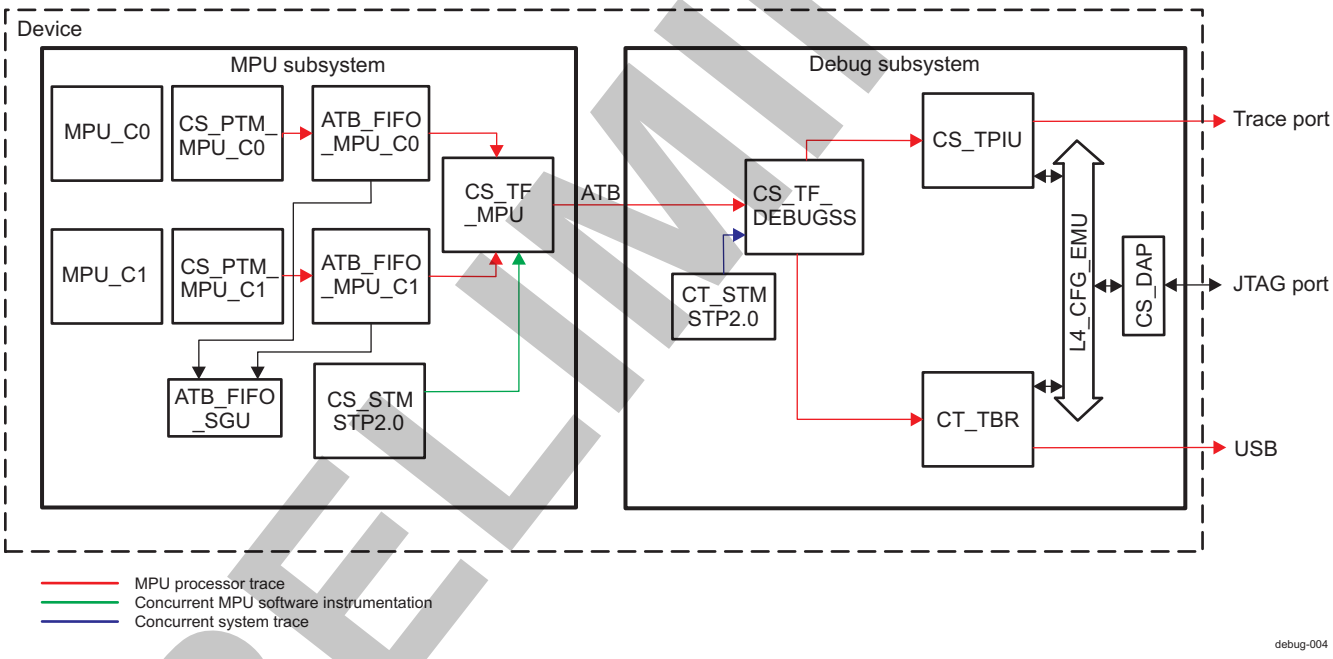
The device supports only Cortex-A15 (MPU) trace. The main MPU trace characteristics are:

- Program trace only (no data trace)
- Separate CS_PTM for each MPU core
- Three exclusive trace sinks:
  - CS_TPIU – trace exported to an external trace receiver
  - CT_TBR (buffer mode) – trace stored into on-chip buffer
  - CT_TBR (system bridge mode) – trace exported through USB
- Trace can be optionally:
  - Cycle accurate useful for profiling sections of code
  - Interleaved dynamically between the two MPU cores by CS_TF_MPU

NOTE: Depending on use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

Figure 29-4 shows an overview of the processor trace flow.

Figure 29-4. Processor Trace Flow



29.8.1 MPU Trace Export

The debug subsystem implements three exclusive trace sinks:

- CS_TPIU
- CT_TBR (buffer mode)
- CT_TBR (system bridge mode)

Two MPU trace streams are supported, one per MPU core. The two MPU cores program traces are exported to the PD_EMU domain (through asynchronous bridges) and then interleaved by the CS_TF_MPU.

A concurrent software instrumentation flow from the local CS_STM component (STP 2.0) can also be interleaved with the MPU program traces.

Two ATB_FIFO modules (ATB_FIFO_MPU_C0 and ATB_FIFO_MPU_C1) are implemented in the trace path between the Cortex-A15 CPUs and the CS_TF_MPU module. The ATB_FIFO allows concurrent trace capture and export. It provides buffering in the trace export path and therefore allows absorbing peaks of trace data. The depth of the ATB_FIFOs is 16 entries.

The CS_TF_MPU sends the MPU trace (or CS_STM software instrumentation) to a trace funnel in the debug subsystem (CS_TF_DEBUGSS) through a single ATB interface. The CS_TF_DEBUGSS redirects the MPU trace to the three exclusive trace sinks.

NOTE: It is strongly recommended to disable trace sinks not in use when generating trace to an in-use trace sink to eliminate undesirable throughput throttling effects.

Besides the ATB_FIFOs, the MPU subsystem also instantiates an ATB_FIFO statistics gathering unit (ATB_FIFO_SGU) which provides silicon and presilicon characterization information of ATB_FIFO. The FIFO_LEVEL_OUT output of ATB_FIFO, which gives visibility of the number of used entries, is used for the statistics gathering. ATB_FIFO may be full under the following conditions:

- Arbitration collisions in the trace funnel when more than one ATB trace stream is being generated at the same time (tracing of multiple CPUs simultaneously)
- Trace sink does not have the bandwidth to meet peak bandwidth demands from the trace generator on a single ATB trace stream

The following statistics are gathered per ATB_FIFO:

- Peak utilization depth of the FIFO
- Number of consecutive cycles that FIFO level is at or above the programmable FIFO threshold when there is an ATB command pending
- Number of ATB bus stall cycles

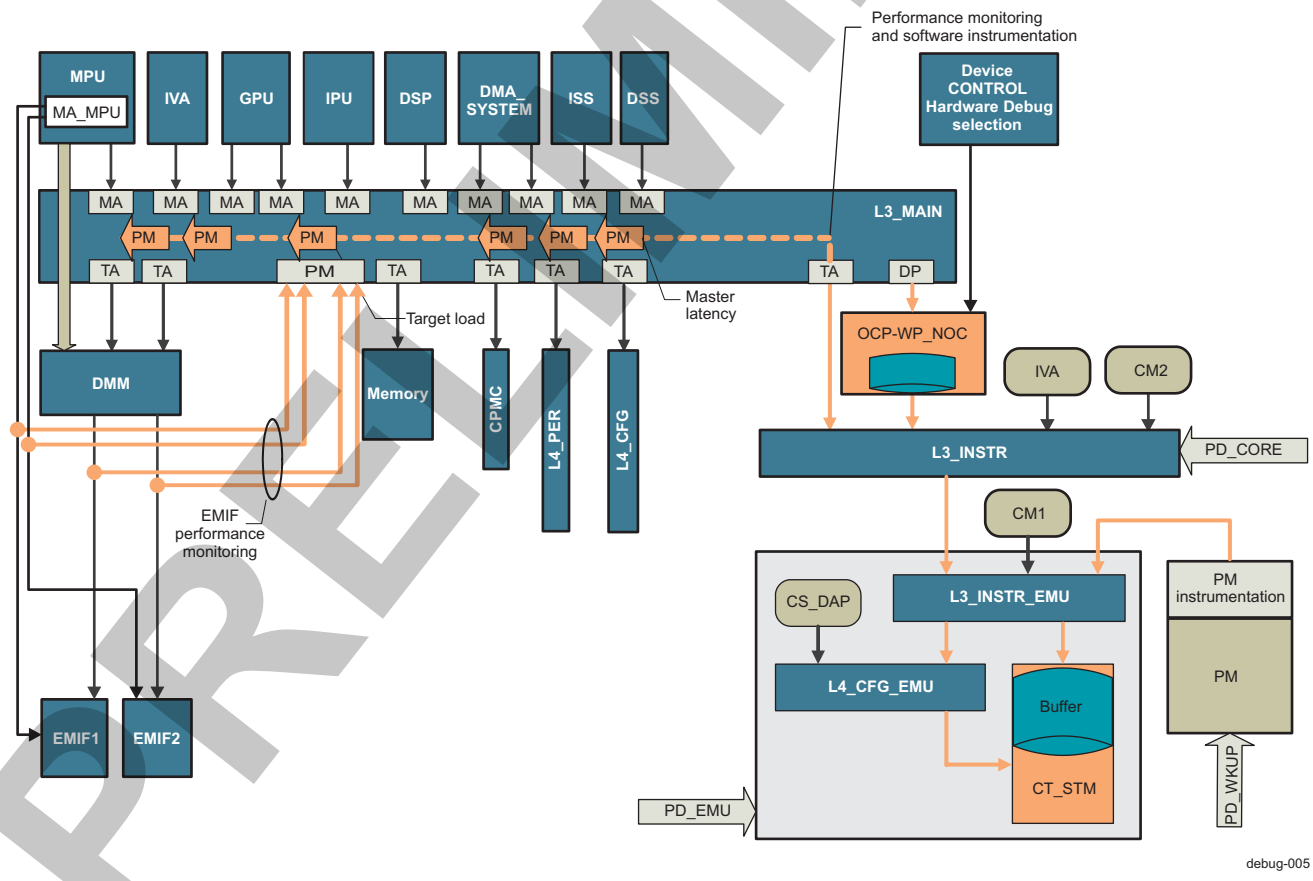
29.9 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace
  - MPU software instrumentation via CS_STM (STP2.0) (see Section 29.9.3.1, *MPU Software Instrumentation*)
  - SoC software instrumentation via CT_STM (STP2.0) (see Section 29.9.3.2, *SoC Software Instrumentation*)
- OCP watchpoint
  - OCP target traffic monitoring (see Section 29.9.4.1, *OCP Target Traffic Monitoring*)
  - SoC events trace (see Section 29.9.4.2, *Messages Triggered from System Events*)
  - DMA transfer profiling (see Section 29.9.4.3, *DMA Transfer Profiling*)
- Statistics collector
  - Target load monitoring (see Section 29.9.6.1, *Target Load Monitoring*)
  - Master latency monitoring (see Section 29.9.6.2, *Master Latency Monitoring*)
- HWA load monitoring (see Section 29.9.5, *IVA Pipeline*)
- PM events trace (see Section 29.9.7, *PM Instrumentation* [PMI])
- CM events trace (see Section 29.9.8, *CM Instrumentation* [CMI])

Figure 29-5 is an overview of the device system instrumentation framework.

Figure 29-5. System Instrumentation Framework



29.9.1 MIPI STM (CT_STM)

CT_STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0 for PTI export; rev 2.0 for ATB export) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from hardware agents:
    - OCP_WP_NOC
    - PMI
    - CMI
    - SMSET
    - L3 NoC statistics collectors
- Supports the following trace export paths:
  - Parallel Trace Interface (PTI) export - directly to an external trace receiver
  - ATB export - to CS_TPIU or CT_TBR
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Dedicated 128 × 48-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

29.9.2 System Trace Export

29.9.2.1 CT_STM PTI Export

System trace can be exported to an external trace receiver through the PTI of the CT_STM module. To achieve this, the debugger or application software must ensure to program the DRM module properly (that is, according to Table 29-37). The messages are encoded as defined by MIPI STP-1.0.

The CT_STM has a configurable export width of 1, 2, or 4 data (STM_DATA) pins plus a dedicated export clock (STM_CLK). The CT_STM can operate in DDR or SDR mode.

The device system trace does not make use of CT_TBR for buffering when the trace stream is exported to an external trace receiver through the PTI. The CT_STM implementing a dedicated buffer allows a CS_PTM trace to be concurrently captured into CT_TBR.

29.9.2.1.1 CT_STM Trace Export Clock Configuration

The CT_STM trace export clock is derived from DPLL_DEBUGSS output clock.

The CT_STM trace export frequency can be tuned independently of the CS_TPIU trace export frequency.

The CT_STM trace capture clocking is restricted to the L3_INSTR_EMU interconnect clock.

Table 29-28 shows possible CT_STM clock configurations. The following equations apply:

- DPLL_DEBUGSS output clock frequency when locked = 2 × [M / (N+1)] × SYS_CLK frequency.
- STM_CLK frequency = DPLL_DEBUGSS frequency / 2 × (M5 +1).

Table 29-28. STM_CLK Frequency

DEBUGSS Clock Source	SYS_CLK Frequency, MHz	DPLL_DEBUGSS M / N	DPLL_DEBUGSS Frequency, GHz	HS_DIV Factor	CS_TPIU (2x)	STM_CLK, MHz
SYS_CLK	38.4	125/5	1.6	M5 = 7	2	100
		75/3	1.44	M5 = 7		90
		125/3	2.4	M5 = 11		100

29.9.2.2 CT_STM ATB Export

If a trace receiver cannot be attached to the device, or relevant CT_STM trace port pins are unavailable for a particular reason, the user can configure the CT_STM module to redirect the STP trace stream as an ATB stream to the CS_TPIU or CT_TBR and enable local timestamp. This is accomplished by outputting a local timestamp granularity (LTSG) message, which is a TI addition to the MIPI standard messages.

NOTE: For CT_STM timestamps when output to the ATB interface, the timestamp (TS) field is no longer the CT_STM FIFO depth, but is the time from the previous message.

Granularity is a function of the instrumentation port clock frequency.

29.9.2.3 Trace Streams Interleaving

Two levels of interleaving system instrumentation flows and arbitrating between instrumentation masters are implemented:

- CORE L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - OCP_WP_NOC
  - L3 NoC statistics collectors, or software instrumentation (interleaving at the L3 level)
  - CMI2
  - IVA SMSET and ARM968 (software instrumentation)
- EMU L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - CORE L3 instrumentation interconnect
  - CMI1
  - PMI

29.9.3 Software Instrumentation

29.9.3.1 MPU Software Instrumentation

The CS_STM embedded in the MPU subsystem provides extended stimulus port registers designated to be accessible by software with minimum instrumentation cycles overhead.

Each extended stimulus port occupies 256 consecutive bytes in the memory map and is write-only. Up to 64K instrumentation channels are available at MPU level.

The CS_STM supports "guaranteed" or invariant timing transactions:

- Guaranteed transactions are guaranteed to be traced. This might involve stalling the MPU core to ensure the transaction is accepted by the CS_STM.
- Invariant timing transactions are not guaranteed to be traced. These transactions take an invariant amount of time regardless of the state of the CS_STM.

The CS_STM implements tracing of software writes to its stimulus ports using a dedicated AXI slave interface. In addition to the AXI interface, the CS_STM provides a hardware event input interface (HWEVENTS[31:0]). The HWEVENTS[31:0] input bus is connected to the MPU hardware debug observability signals going out to the MPU hardware debug port (MPUHWDBGOUT[31:0]). This enables any of the signals observed on MPUHWDBGOUT[31:0] to act as a hardware event to the CS_STM. The

CS_STM can be programmed to generate a debug packet on a rising edge transition on any signal of the HWVENTS[31:0] input bus. Because some of the signals mapped on the MPUHWDBGOUT[31:0] bus are active low, a 32-bit programmable register – MPU.STM_HWEVENTS_INV, is implemented for polarity inversion. Each bit of MPU.STM_HWEVENTS_INV when set to 0x1 inverts the polarity of the corresponding signal of MPUHWDBGOUT[31:0] going to HWEVENTS[31:0]. This programmable register is part of the WUGEN_MPU address map (see Section 4.4.10, *WUGEN_MPU Registers*, in Chapter 4, *Dual Cortex-A15 MPU Subsystem*, for its description).

NOTE: The MPUHWDBGOUT[31:0] signals can be routed to the hw_dbg[31:0] device pads through various hardware debug observability MUXes controlled by device control module (CTRL_MODULE). For more information, see Section 18.4.11, *Hardware Observability*, in Chapter 18, *Control Module*.

To save power, the output port can be gated off (to all zeros) by setting the CTRL_MODULE. CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE bit to 0x0. Ungated version of MPUHWDBGOUT[31:0] (not gated with CTRL_MODULE. CONTROL_HWOBS_CONTROL[0] HWOBS_MACRO_ENABLE) is sent to HWEVENTS[31:0] input of STM so each of these signals can generate a debug packet on the trace port.

The message structures in STP-2.0 are optimized to provide an efficient transport.

29.9.3.2 SoC Software Instrumentation

The CT_STM module embedded in the debug subsystem provides a flexible interface for trace instrumentation.

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the ongoing debugging task. The message structures in STP-2.0 are optimized to provide an efficient transport for software data through the CT_STM module.

The software masters are:

- MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- IPU subsystem
- SDMA controller write port (DMA_SYSTEM_WR)
- IVA subsystem

Each software master has a master ID assigned to it.

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

29.9.4 OCP Watchpoint

29.9.4.1 OCP Target Traffic Monitoring

The L3_MAIN interconnect provides six functional probes embedded and attached to the following L3_MAIN targets:

- GPMC
- L4_PER
- L4_CFG
- DMM_P1 (DMM target port 1)

- DMM_P2 (DMM target port 2)
- OCMC_RAM

The probes output are muxed together and then sent to the L3_MAIN interconnect debug port. A component called OCP_WP_NOC is used to collect data from functional probes and then transmit captured data to the CT_STM module. The OCP_WP_NOC drives a Probe-ID signal to the L3_MAIN interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP_WP_NOC provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
  - Address range
  - Initiator-ID (see Table 29-30)
  - Transaction type
  - Transaction qualifier
- Generating a trigger upon watchpoint match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- Profiling DMA transfers
- Generating hardware message upon system event
- OCP_WP_NOC messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

NOTE: The OCP_WP_NOC is restricted to monitor request flow only.

Table 29-29 summarizes the OCP targets that can be monitored by the OCP_WP_NOC and their respective probe-ID.

Table 29-29. L3_MAIN Interconnect Functional Probe Mapping

Probe-ID	L3 OCP Target
000	Reserved
001	GPMC
010	L4_PER
011	L4_CFG
100	DMM_P1 (DMM target port 1)(1)
101	DMM_P2 (DMM target port 2)(1)
110	OCMC_RAM
111	Reserved

(1) Does not allow tracking MPU transactions routed through Memory Adapter and DMM.

The user can program the OCP_WP to extract the traffic from a specific set of initiators (maximum four master IDs). Table 29-30 lists the master ID reported by the L3_MAIN debug port for the device initiators.

Table 29-30. Master ID Mapping (Debug View)

Master ID	Initiator
0x0	MPU
0x4	CS_DAP
0x8	DSP
0xC	IVA
0xD	IVA ICONT1 (software instrumentation)
0xE	IVA ICONT2 (software instrumentation)
0x10	ISS
0x11	IPU
0x12	FDIF
0x14	DMA_SYSTEM_RD
0x15	DMA_SYSTEM_WR
0x16	BB2D_P1
0x17	BB2D_P2
0x18	GPU_P1
0x19	GPU_P2
0x1C	DSS
0x24	HSI
0x28	MMC1
0x29	MMC2
0x2A	SATA
0x30	USB_HOST_HS
0x33	USB_OTG_SS

NOTE: For information about master ID values from a protection/error logging point of view, see , *Master NIU Identification*, in Chapter 14, *Interconnect*.

29.9.4.2 Messages Triggered from System Events

The OCP_WP_NOC can be programmed to export a message through the CT_STM upon detection of a system event (interrupt, DMA request, etc.). A bus of 16 system events pre-selected at SoC level from a large number of observable events is routed to the OCP_WP_NOC. This can be useful to determine interrupts latencies:

- Interrupt request traced through OCP_WP_NOC system event detection
- ISR boundary tracked either through CT_STM software trace or OCP_WP_NOC address range detection

The OCP_WP_NOC implements a dedicated port for the 16 system events that is connected to the device control module (CTRL_MODULE) hardware debug (hw_wkdbg[15:0] and hw_dbg[31:16]) output bus. The CTRL_MODULE handles the selection and exports a user-defined subset of the SoC observable events to the OCP_WP_NOC. The mapping of these events is presented in Chapter 18, *Control Module*.

29.9.4.3 DMA Transfer Profiling

The OCP_WP_NOC can be configured to profile DMA transfers. This feature provides to the user visibility on:

- DMA logical channel interleaving
- DMA channel ID
- DMA transfer duration (time stamp)
- DMA burst size

- DMA reads
- DMA writes

When operating in this mode, the OCP_WP_NOC exports to CT_STM:

- DMA channel ID
- Burst size
- R/W

The CT_STM module encapsulates the information above in a compact STP message.

The address range filtering remains active but OCP address data are not encapsulated into the trace message to maximize CT_STM throughput.

29.9.5 IVA Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA microtask sequencing. This is supported through a SMSET module instantiated in the IVA subsystem. The microtask boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the CT_STM module.

The IVA instrumentation scheme allows the user to understand microtask dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA events. Software messages from ARM968 execution can be interleaved with IVA events.

29.9.6 NOC Statistics Collector

The L3_MAIN interconnect supports a built-in performance monitoring feature by implementing a statistics collector (NOC_SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the CT_STM interface. Three NOC_SC instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – SC_SDRAM (see Section 29.9.6.1, *Target Load Monitoring*, for more information)
- Two statistics collectors dedicated to master latency monitoring – SC_LAT0 and SC_LAT1 (see Section 29.9.6.2, *Master Latency Monitoring* , for more information)

Statistics collectors (SDRAM and LAT0/1) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- Percent link occupancy on the request link (for store transactions) during a sampling window
- Percent link occupancy on the response link (for load transactions) during a sampling window
- Percent arbitration conflict cycles on the request link
- Percent initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16, 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3_MAIN interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the NTTP and OCP link events summarized in Table 29-31.

Table 29-31. Performance Monitoring Events Detection

Link Event	NTTP	OCP	Definition
NONE	✓	✓	No event selected
ANY	✓	✓	Any clock cycles
TRANSFER	✓	✓	Word has been accepted by the receiver.
WAIT	✓	–	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	✓	✓	Receiver applies flow control
PKT	✓	✓	Transfer of a new packet header
DATA	✓	✓	Transfer of a payload word
IDLES	✓	✓	No communication over the link
LATENCY	✓	–	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in Table 29-32.

Table 29-32. Performance Filtering Options

Probe Filtering Options	Comment
Master address	Mask and match
Slave address(1)	
UserInfo	
Read	
Write	
Error	
OCP address(2)	

(1) SC_LAT0/1 only
(2) SC_SDRAM only

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are accessible by application software.

Table 29-33 summarizes the performance probe aggregation modes.

Table 29-33. Aggregation Modes

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range. – Payload length (bytes) – Pressure value – Request/response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits. Payload length (bytes) Pressure value Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

29.9.6.1 Target Load Monitoring

The L3_MAIN interconnect implements five performance monitoring probes on LPDDR2 memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the CT_STM interface.

SC_SDRAM supports the following main features:

- Five probe inputs:
  - Probe 0 (128 bit-wide) – EMIF1_SYS
  - Probe 1 (128 bit-wide) – EMIF2_SYS
  - Probe 2 (128 bit-wide) – MA_MPU_P1
  - Probe 3 (128 bit-wide) – MA_MPU_P2
  - Probe 4 (64 bit-wide) – EMIF1_LL
- Eight 32-bit counters shared concurrently:
  - Counter 0 with two filters
  - Counter 1 with one filter
  - Counter 2 with two filters
  - Counter 3 with one filter
  - Counter 4 with one filter
  - Counter 5 with one filter
  - Counter 6 with one filter
  - Counter 7 with one filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
  - Initiator of traffic
  - Access priorities
  - OCP address
- No latency counter. Only bandwidth measurement on this collector.
- 32-bit collecting window counter
- Dump identifier is 0x0 (tie-off value)
- Dumps frames at L3_MAIN interconnect slave address 0x19 (L3_INSTR)

Table 29-34 summarizes the SC_SDRAM configuration.

Table 29-34. SC_SDRAM Configuration

Counters	Min Max	Filter Elements	L3 Target				
Counter 0	Yes	2	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 1	Yes	1	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 2	Yes	2	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 3	Yes	1	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 4	Yes	1	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 5	Yes	1	EMIF1_SYS	EMIF2_SYS	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 6	Yes	No	No	No	MA_MPU_P1	MA_MPU_P2	EMIF1_LL
Counter 7	Yes	No	No	No	MA_MPU_P1	MA_MPU_P2	EMIF1_LL

29.9.6.2 Master Latency Monitoring

The device L3_MAIN interconnect implements twelve performance monitoring probes on the main L3 initiators:

- MPU
- DSP
- DMA_SYSTEM_RD
- DMA_SYSTEM_WR
- IVA
- IPU
- DSS
- ISS
- GPU_P1
- GPU_P2
- BB2D_P1
- BB2D_P2

The master latency statistics are computed within a user-defined window and periodically reported to the user through the CT_STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with ongoing execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

29.9.6.2.1 SC_LAT0 Configuration

SC_LAT0 supports the following main features:

- Eight probe inputs:
  - Probe 0: MPU
  - Probe 1: DSP
  - Probe 2: DMA_SYSTEM_RD
  - Probe 3: DMA_SYSTEM_WR
  - Probe 4: DSS
  - Probe 5: ISS
  - Probe 6: GPU_P1
  - Probe 7: BB2D_P1
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 29-35 summarizes the SC_LAT0 configuration.

Table 29-35. SC_LAT0 Configuration

Counters	Min Max	Filter Elements	L3 Master							
Counter 0	Yes	1	MPU	DSP	DMA_SYSTEM_RD	DMA_SYSTEM_WR	DSS	ISS	GPU_P1	BB2D_P1
Counter 1	Yes	1	MPU	DSP	DMA_SYSTEM_RD	DMA_SYSTEM_WR	DSS	ISS	GPU_P1	BB2D_P1
Counter 2	Yes	1	MPU	DSP	DMA_SYSTEM_RD	DMA_SYSTEM_WR	DSS	ISS	GPU_P1	BB2D_P1
Counter 3	Yes	1	MPU	DSP	DMA_SYSTEM_RD	DMA_SYSTEM_WR	DSS	ISS	GPU_P1	BB2D_P1

29.9.6.2.2 SC_LAT1 Configuration

SC_LAT1 supports the following main features:

- Six probe inputs:
  - Probe 0: IVA
  - Probe 1: MPU
  - Probe 2: DMA_SYSTEM_WR
  - Probe 3: GPU_P2
  - Probe 4: IPU
  - Probe 5: BB2D_P2
- Four 32-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 32-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (L3_INSTR)

Table 29-36 summarizes the SC_LAT1 configuration.

Table 29-36. SC_LAT1 Configuration

Counters	Min Max	Filter Elements	L3 Master					
Counter 0	Yes	1	IVA	MPU	DMA_SYSTEM_WR	GPU_P2	IPU	BB2D_P2
Counter 1	Yes	1	IVA	MPU	DMA_SYSTEM_WR	GPU_P2	IPU	BB2D_P2
Counter 2	Yes	1	IVA	MPU	DMA_SYSTEM_WR	GPU_P2	IPU	BB2D_P2
Counter 3	Yes	1	IVA	MPU	DMA_SYSTEM_WR	GPU_P2	IPU	BB2D_P2

29.9.6.2.3 Statistics Collector Alarm Mode

Statistic collectors can be used to provide the application software with information about the NoC or SDRAM reaching corner cases (for example, too much traffic for a given OPP) while in application mode where for an end product use case the debug subsystem (which is normally exporting the statistic frames) is off. An interrupt-based scheme using a dedicated signal (L3_MAIN_IRQ_STAT_ALARM) is implemented to avoid CPU polling periodically statistic registers. This interrupt alert is mapped to the MPU_IRQ_16 interrupt line and is fired when a given metric is out of specified range (below the programmed MIN threshold or above the programmed MAX threshold).

NOTE: NTTP statistic collectors (SC_LAT0/1) support latency measurement. However, comparison cannot be done on the latency counter. In case of latency measurement the comparison has to be done on number of latencies in user defined range, not on the latency value itself.

29.9.6.2.4 Statistics Collector Suspend Mode

The statistics collector module implements a suspend input that is used to avoid statistics collector counters to be updated while the processor has entered the debug state. This avoids triggering false alerts upon execution resume. When the statistics collector is asserted to 1, it freezes the monitoring process. When it goes back to 0, the monitoring resumes.

NOTE: If a frame is being dumped, it will not be stopped by suspend.

Each statistic collector has an ignore suspend register, which can be used to disable the suspend feature.

29.9.7 PM Instrumentation

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power-management events. This is supported through a PMI module (PM profiler) instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the CT_STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at CT_STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master ID assigned to it.

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user can size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

29.9.8 CM Instrumentation

The device instantiates two CMI modules (CM profilers), one in CM1 (CMI1), and one in CM2 (CMI2). CMI1 and CMI2 are instantiations of the same debug-IP and can operate concurrently. Each of them has a separate unique hardware master ID assigned to it.

The CM events profiling is similar to the PMI. Two exclusive instrumentation modes are supported:

- Clock activity:
  - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
  - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
  - Exposes to the user periodically the active cycles count of the target modules
  - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
  - Clock domain state
  - DPLL settings update
  - Clock frequency divider ratio
  - Clock source selection update
- Module activity collection mode – two classes:
  - Target module activity
  - Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user can size the capture sampling window.

29.10 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

Table 29-37 summarizes the trace port configuration.

Table 29-37. Trace Port Configuration

Pin Name	Internal Signal Name	I/O	Trigger	JTAG 20-Pin Header	CS_TPIU (MPU Trace [CS_PTM] interleaved with software instrumentation [CS_STM])	CT_STM (System Trace)
					16-Bit Mode (up to 16 data pins)	
drm_emu19	EMU19	O		EMU4	TRACEDATA[15]	STM_DATA[x] / STM_CLK
drm_emu18	EMU18	O		EMU3	TRACEDATA[14]	STM_DATA[x] / STM_CLK
drm_emu17	EMU17	O		EMU2	TRACEDATA[13]	STM_DATA[x] / STM_CLK
drm_emu16	EMU16	O			TRACEDATA[12]	STM_DATA[x] / STM_CLK
drm_emu15	EMU15	O			TRACEDATA[11]	STM_DATA[x] / STM_CLK
drm_emu14	EMU14	O			TRACEDATA[10]	STM_DATA[x] / STM_CLK
drm_emu13	EMU13	O			TRACEDATA[9]	STM_DATA[x] / STM_CLK
drm_emu12	EMU12	O			TRACEDATA[8]	STM_DATA[x] / STM_CLK
drm_emu11	EMU11	O			TRACEDATA[7]	STM_DATA[x] / STM_CLK
drm_emu10	EMU10	O			TRACEDATA[6]	STM_DATA[x] / STM_CLK
drm_emu9	EMU9	O			TRACEDATA[5]	STM_DATA[x] / STM_CLK
drm_emu8	EMU8	O			TRACEDATA[4]	STM_DATA[x] / STM_CLK
drm_emu7	EMU7	O			TRACEDATA[3]	STM_DATA[x] / STM_CLK
drm_emu6	EMU6	O			TRACEDATA[2]	STM_DATA[x] / STM_CLK
drm_emu5	EMU5	O			TRACEDATA[1]	STM_DATA[x] / STM_CLK
drm_emu4	EMU4	O			TRACEDATA[0]	STM_DATA[x] / STM_CLK
drm_emu3	EMU3	O			TRACECTL	STM_DATA[x] / STM_CLK
drm_emu2	EMU2	O			TRACECLK	STM_DATA[x] / STM_CLK
drm_emu1	EMU1	I/O	Trigger1	EMU1		STM_DATA[x] / STM_CLK
drm_emu0	EMU0	I/O	Trigger0	EMU0		STM_DATA[x] / STM_CLK

NOTE: The configuration of the trace port must comply with Table 29-37; otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU10 and Trigger1 is programmed on EMU11, this configuration is ignored.

CT_STM (STMv1) port configuration provides full flexibility to map either STM_CLK or any STM_DATA line to any device debug port pin. Examples (recommended mapping) with no concurrent CS_TPIU trace:

- In 1-pin mode:
  - STM_CLK mapped to drm_emu0
  - STM_DATA[0] mapped to drm_emu1
- In 2-pin mode:
  - STM_CLK mapped to drm_emu2
  - STM_DATA[0] mapped to drm_emu0
  - STM_DATA[1] mapped to drm_emu1
- In 4-pin mode:
  - STM_CLK mapped to drm_emu2
  - STM_DATA[0] mapped to drm_emu0
  - STM_DATA[1] mapped to drm_emu1
  - STM_DATA[2] mapped to drm_emu4
  - STM_DATA[3] mapped to drm_emu5

The CS_STM (STMv2) trace clock is always mapped to drm_emu2 (as shown in Table 29-37).

Table 29-38 summarizes the concurrent debug and trace in the device.

Table 29-38. Concurrent Debug and Trace

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock
0	CS_PTM		18	1	1
	CT_STM				
	Triggers				
1	CS_PTM		16	1	1
	CT_STM				
	Triggers	2			
2	CS_PTM		16	1	1
	CT_STM		1	–	1
	Triggers				
3	CS_PTM		8	1	1
	CT_STM		4	–	1
	Triggers	2			
4	CS_PTM		11	1	1
	CT_STM		4	–	1
	Triggers	2			

29.11 Memory Mapping

Table 29-39 summarizes the memory mapping of the debug modules.

Table 29-39. Debug Modules Memory Mapping

Memory Space	Module Name	Start Address (hex)	End Address (hex)	Size

OMAP5432 Multimedia Device

This appendix describes the functional differences between the OMAP5432 and OMAP5430 multimedia devices.

Topic **Page**

A.1 Introduction

A.1.1 Overview

OMAP5432 multimedia device is based on enhanced OMAP™ architecture and uses 28-nm technology. It is offered in a non-POP, DDR3-enabled package and has a subset of the OMAP5430 communication interfaces and system balls.

For the terminal assignment and ball characteristics, see the *OMAP5432 Data Manual*.

A.1.2 Description

The OMAP5432 is offered in a 754-ball; 17 × 17 mm; 0.5-mm ball pitch s-PBGA package, which does not support the package-on-package (POP) concept. Also, some of the OMAP device pads are not available on the package balls. As a consequence:

- Stacked mode and LPDDR2 memories are not supported. The OMAP5432 supports DDR3/DDR3L memory interface through bottom ballout.
- Some of the interfaces offered in the die are not available.
- Some of the interfaces offered in the die are restricted.
- Some of the device system pins are not supported.

CAUTION

Because all subsystems and modules are still present on the die, the removed functionality must be carefully handled to maintain reliability.

A.1.2.1 Unsupported Interfaces

The following interfaces are not supported in the OMAP5432 device:

- LPDDR2 EMIF memory interface
- MIPI® HSI modem interface port 1
- Universal asynchronous receiver/transmitter 6 (UART6)
- HS USB host subsystem high-speed interchip 1 (HSIC1) interface
- HS USB host subsystem ULPI TLL interface
- SS USB DRD subsystem ULPI PHY interface
- MMC/SD/SDIO5

A.1.2.2 Interface Restrictions

The following restrictions apply to the OMAP5432 interfaces:

- General-purpose memory controller (GPMC)
  - Chip-select 7 signal (gpmc_ncs7) is not available at the device ballout.
- UART1
  - UART1 is available on different device balls, that is, on balls timer11_pwm_evt, timer5_pwm_evt, timer6_pwm_evt,and timer8_pwm_evt in mux mode 2.
- UART4
  - UART4 is a 2-wire (TX/RX) interface. UART4 flow-control (RTS/CTS) pins are not available.
- MCSPI1
  - Chip-selects 2 and 3 (CS2 and CS3) are not available.
- HS USB Host subsystem
  - USB host port 2 (USBB2) in FS serial mode is limited to 2-/3-wire serial mode.
- General-purpose input/output (GPIO)

  - The following GPIO channels are not available:
    - gpio1_wk8 to gpio1_wk10
    - gpio3_64 to gpio3_75
    - gpio3_92 and gpio3_93
    - gpio5_145 and gpio5_146
    - gpio5_149 to gpio5_151

A.1.2.3 Unsupported System Pins

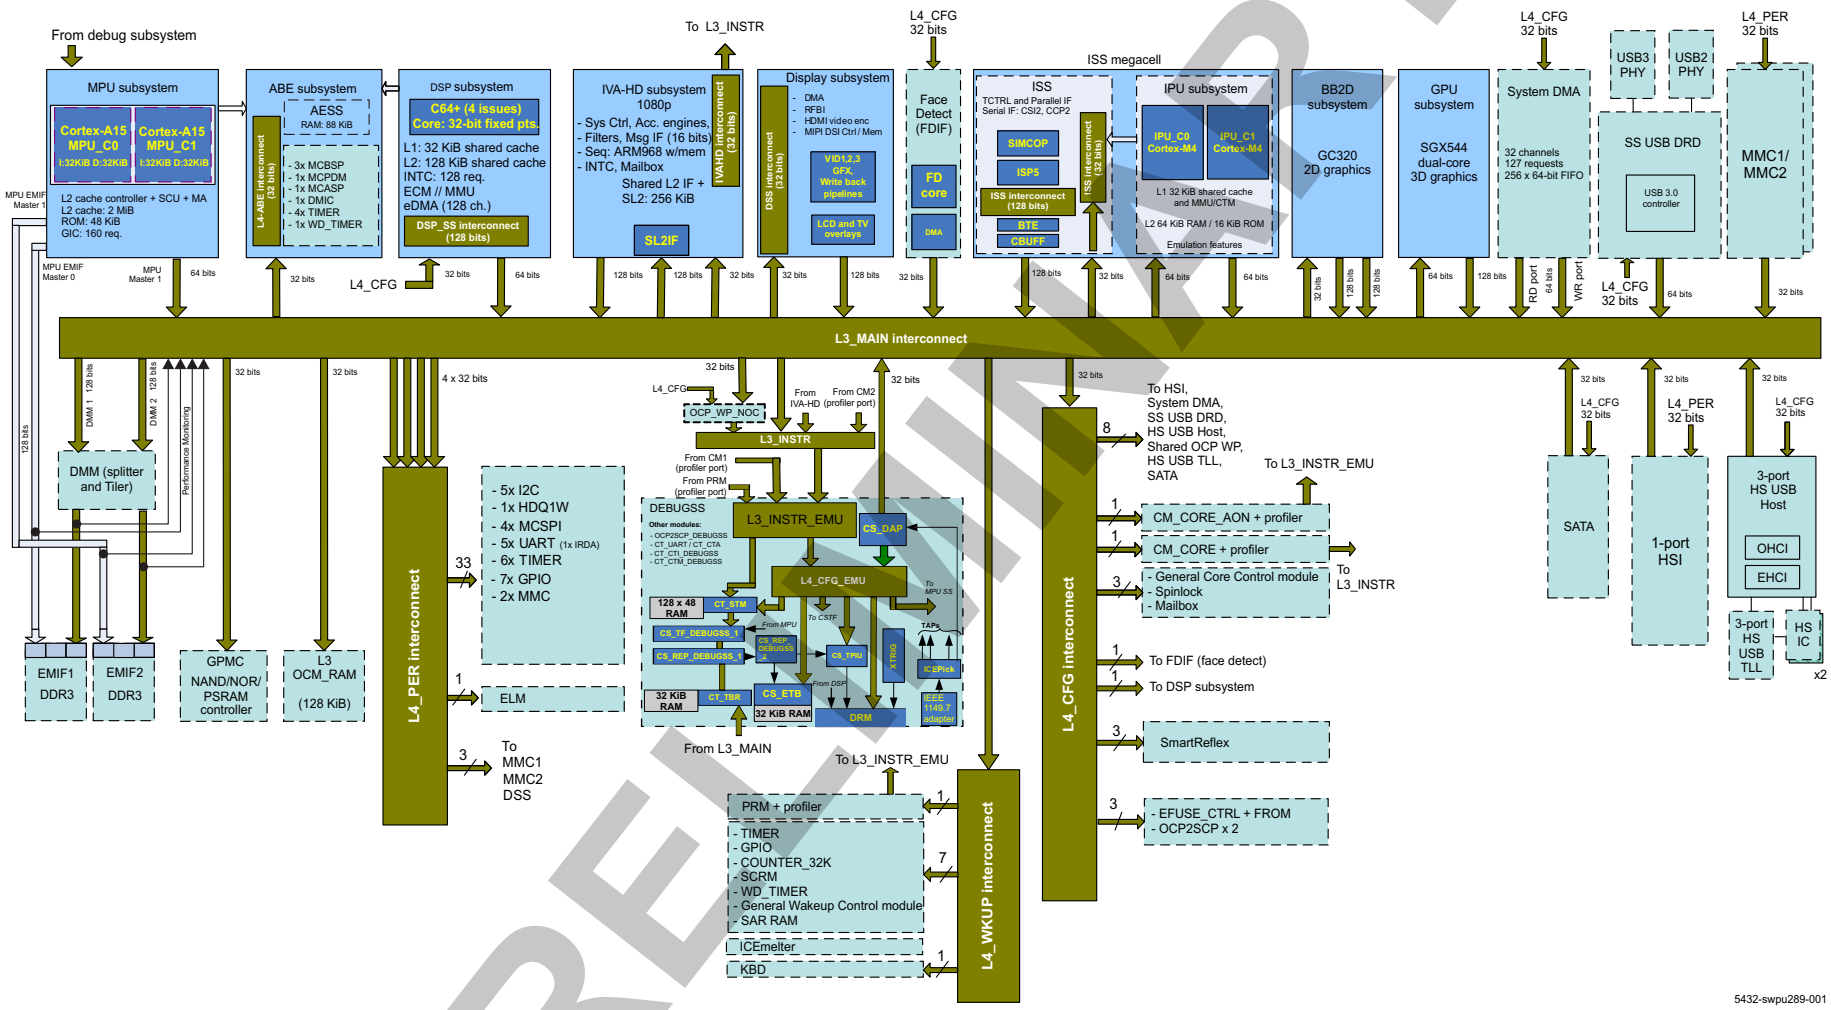
The following restrictions apply to the OMAP5432 system interfaces:

- PRCM
  - On-chip slicer cell is not supported. That is, system clock source can be only the oscillator cell (crystal, or external square input).
  - Clock outputs fref_clk2_out and fref_clk3_out are not available.
  - Hardware clock requests fref_clk1_req and fref_clk2_req are not supported.
- System DMA (DMA_SYSTEM) controller
  - External DMA request 1 (sys_ndmareq1) is not supported. sys_ndmareq0 is available on different device ball (on uart6_rts in mux mode 1)
- Debug subsystem
  - Hardware observability signals hw_wkdbg10, hw_wkdbg11, and hw_wkdbg12 are not available.

A.1.2.4 Block Diagram

Figure A-1 describes the supported subsystems in OMAP5432 devices.

Figure A-1. OMAP5432 Block Diagram



A.2 Memory Mapping

NOTE: This subsection provides a quick reference about the unavailable modules and their memory mapping. Table rows highlighted in orange indicate modules that are not functional in OMAP5432. These modules are still present on the die; therefore, their mappings are provided to control their activity and for debug purposes.

A.2.1 L4_CFG Memory Space Mapping

The L4_CFG interconnect is a 16-MB space composed of the L4_CFG interconnect configuration registers and the module registers.

Table A-1 describes the mapping of the registers for the L4_CFG interconnect.

Table A-1. L4_CFG Memory Space Mapping

A.2.2 L4_PER Memory Space Mapping

The L4_PER interconnect is a 16-MB memory space composed of the L4_PER interconnect configuration registers and the module registers.

Table A-2 describes the mapping of the registers for the L4_PER interconnect.

NOTE: All memory spaces described as modules provide direct access to the module registers outside the L4_PER interconnect. All other accesses are internal to the L4_PER interconnect.

Table A-2. L4_PER Memory Space Mapping

A.3 Power, Reset, and Clock Management

A.3.1 PRCM Environment

The following signals are supported by the PRCM module, but are not available at the OMAP5432 device boundary:

- On-chip slicer cell is not supported. That is, system clock source can be only the oscillator cell with crystal or external square input.
- Clock outputs fref_clk2_out and fref_clk3_out are not available.
- Hardware clock requests fref_clk1_req and fref_clk2_req are not supported.

Table A-3 lists the external clock signals, I/Os, and module reset values. Highlighted rows represent nonfunctional pins in OMAP5432 devices.

Table A-3. External Clock Signals

Pin	Signal	I/O[1]	PMFW Module	Description
sys_32k	SYS_32K	I	SCRM	32-kHz clock input (sleep clock)
fref_clk_ioreq	SYSCLK_REQ	I/O	SCRM	System clock request. Input when pins sysboot4 = 0 and sysboot5 = 0 (oscillator mode). Output when pins sysboot4 = 0 and sysboot5 = 1 (CLOCK_SLICER mode).
fref_slicer_in	SLICER_IN	I	SCRM	System clock input to the CLOCK_SLICER. It can be sinusoidal or square input signal.
fref_slicer_az	SLICER_AZ	I	SCRM	Connected to ground at package level
fref_xtal_in	XTAL_IN	I	SCRM	Oscillator drive input from crystal
fref_xtal_out	XTAL_OUT	O	SCRM	Oscillator drive output to crystal
fref_xtal_clk	XTAL_CLK	O	SCRM	Oscillator buffered output
fref_clk[1:2]_req	CLK[1:2]_REQ	I	SCRM	Auxiliary clocks request
fref_clk[0:1]_out	CLK[0:1]_OUT	O	SCRM	Auxiliary clocks outputs 0 to 1
fref_clk[2:3]_out	CLK[2:3]_OUT	O	SCRM	Auxiliary clocks outputs 2 to 3

(1) I = Input; O = Output; I/O = Input and output (bidirectional)

A.3.2 PRCM Use Guidelines

- Use a crystal or a external clock oscillator IC for the system clock input. Sine clock input option is not supported.
- Functional and interface clocks for the unsupported modules must be gated (disabled) (see Section 3.6, *Clock Management Functional Description,* in Chapter 3, *Power, Reset, and Clock Management*). All unsupported modules and functionality are listed in Section A.1, *Introduction.*
- Because of DDR3 memories used in place of LPDDR2:
  - At boot time, software must set the EMIF clock domain into SW_WKUP mode (CM_EMIF_CLKSTCTRL[1:0] CLKTRCTRL=0x2).
  - The static dependency between MPU and EMIF, which is set by default at reset, must never be cleared by the software (CM_MPU_STATICDEP[4] EMIF_STATDEP = 1).
- All wake-up events from the unsupported modules must be disabled (see Section 3.6, *Clock Management Functional Description,* in Chapter 3, *Power, Reset, and Clock Management*).

A.4 Memory Subsystem

A.4.1 GPMC Controller

The following signals are supported by the GPMC but are not available outside OMAP5432 device:

- Chip-select signal 7 (gpmc_ncs7)

NOTE: Cells highlighted in orange in Table A-4, *GPMC I/O Description*, indicate signals with no dedicated balls in OMAP5432 device.

Table A-4 lists the GPMC subsystem I/O pins of the OMAP5432 device.

Table A-4. GPMC I/O Description

Pin Name	Device Signal	I/O[1]	Description
A[26:17]	gpmc_a[25:16]	O	Address
A[16:1]/D[15:0]	gpmc_ad[15:0]	I/O	Multiplexed address/data
nCS[6:0]	gpmc_ncs[6:0]	O	Chip-selects (active low)
nCS7	gpmc_ncs7	O	Chip-select (active low)
CLK	gpmc_clk	O[2]	Clock generated for the external memory or device
nADV/ALE	gpmc_nadv_ale	O	Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories.
nOE/nRE	gpmc_noe_nre	O	Output enable (active low). Also used as read enable (active low) for NAND protocol memories.
nWE	gpmc_nwe	O	Write enable (active low)
nBE0/CLE	gpmc_nbe0_cle	O	Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories.
nBE1	gpmc_nbe1	O	Upper-byte enable (active low).
nWP	gpmc_nwp	O	Write protect (active low)
WAIT[2:0]	gpmc_wait[2:0]	I	External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-selects.

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

A.4.2 EMIF Controller

NOTE: The OMAP5432 is designed to interface with DDR3/DDR3L memories mounted on board (PCB). LPDDR2-SDRAM memories are not supported.

NOTE: Orange highlighting in Table A-5 indicate signals with no dedicated balls in OMAP5432 device.

Table A-5 describes the module signals and specifies their links to functions used to connect LPDDR2 type of memories. The LPDDR2 data PHY signals are shared with the DDR3 ones.

Table A-5. I/O Signals (LPDDR2)

Module Pin	Device I/O Signal	I/O[1]	Description
EMIF1 Data PHYs			
DQ[31:0]	ddrch1_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch1_dm[3:0]	I/O	Data mask
DQS[3:0]	ddrch1_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch1_ndqs[3:0]	I/O	Data strobe invert
EMIF1 LPDDR2 Command PHY			
CA[9:0]	lpddr2ch1_ca[9:0]	O	Double-data rate (DDR) command/address
CK	lpddr2ch1_ck	O	Clock
NCK	lpddr2ch1_nck	O	Clock invert
NCS[1:0]	lpddr2ch1_ncs[1:0]	O	Chip-selects 1:0 (active low)
CKE[1:0]	lpddr2ch1_cke[1:0]	O	Clock-enables 1:0
EMIF2 Data PHYs			
DQ[31:0]	ddrch2_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch2_dm[3:0]	I/O	Data mask
DQS[3:0]	ddrch2_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch2_ndqs[3:0]	I/O	Data strobe invert
EMIF2 LPDDR2 Command PHY			
CA[9:0]	lpddr2ch2_ca[9:0]	O	DDR command/address
CK	lpddr2ch2_ck	O	Clock
NCK	lpddr2ch2_nck	O	Clock invert
NCS[1:0]	lpddr2ch2_ncs[1:0]	O	Chip-selects 1:0 (active low)
CKE[1:0]	lpddr2ch2_cke[1:0]	O	Clock-enables 1:0

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

Table A-6 describes the module signals and specifies their links to functions used to connect DDR3 type of memories. DDR3 data PHY signals are shared with the LPDDR2 ones.

Table A-6. I/O Signals (DDR3)

Module Pin	Device I/O Signal	I/O[1]	Description
EMIF1 Data PHYs			
DQ[31:0]	ddrch1_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch1_dm[3:0]	I/O	Data mask
DQS[3:0]	ddrch1_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch1_ndqs[3:0]	I/O	Data strobe invert
EMIF1 DDR3 Command PHYs			
A[15:0]	ddr3ch1_a[15:0]	O	Row/column address bus
BA[2:0]	ddr3ch1_ba[2:0]	O	Bank select
CKA	ddr3ch1_cka	O	Differential clock, set a (DDR3 command PHY 0)
NCKA	ddr3ch1_ncka	O	Differential clock, set a (DDR3 command PHY 0)
C KiB	ddr3ch1_ckb	O	Differential clock, set b (DDR3 command PHY 1)
NC KiB	ddr3ch1_nckb	O	Differential clock, set b (DDR3 command PHY 1)

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

Table A-6. I/O Signals (DDR3) (continued)

Module Pin	Device I/O Signal	I/O[1]	Description
NCS[1:0]	ddr3ch1_ncs[1:0]	O	Rank select 1:0 (active low)
CKE[1:0]	ddr3ch1_cke[1:0]	O	Clock enable for rank 1:0
NCAS	ddr3ch1_ncas	O	Command
NRAS	ddr3ch1_nras	O	Command
NWE	ddr3ch1_nwe	O	Command
NRESET	ddr3ch1_nreset	O	Asynchronous reset (active low)
ODT[1:0]	ddr3ch1_odt[1:0]	O	On-die termination for rank 1:0
EMIF2 Data PHYs			
DQ[31:0]	ddrch2_dq[31:0]	I/O	Data bus
DQM[3:0]	ddrch2_dm[3:0]	I/O	Data mask
DQS[3:0]	ddrch2_dqs[3:0]	I/O	Data strobe
NDQS[3:0]	ddrch2_ndqs[3:0]	I/O	Data strobe invert
EMIF2 DDR3 Command PHYs			
A[15:0]	ddr3ch2_a[15:0]	O	Row/column address bus
BA[2:0]	ddr3ch2_ba[2:0]	O	Bank select
CKA	ddr3ch2_cka	O	Differential clock, set a (DDR3 command PHY 0)
NCKA	ddr3ch2_ncka	O	Differential clock, set a (DDR3 command PHY 0)
C KiB	ddr3ch2_ckb	O	Differential clock, set b (DDR3 command PHY 1)
NC KiB	ddr3ch2_nckb	O	Differential clock, set b (DDR3 command PHY 1)
NCS[1:0]	ddr3ch2_ncs[1:0]	O	Rank select 1:0 (active low)
CKE[1:0]	ddr3ch2_cke[1:0]	O	Clock enable for rank 1:0
NCAS	ddr3ch2_ncas	O	Command
NRAS	ddr3ch2_nras	O	Command
NWE	ddr3ch2_nwe	O	Command
NRESET	ddr3ch2_nreset	O	Asynchronous reset (active low)
ODT[1:0]	ddr3ch2_odt[1:0]	O	On-die termination for rank 1:0

A.5 System DMA

A.5.1 DMA_SYSTEM Environment

The external DMA request sys_ndmareq1cannot be used with the OMAP5432 device. Also, sys_ndmareq0 is available on different device ball than in OMAP5430, that is, on uart6_rts in mux mode 1.

Table A-7 describes the external DMA_SYSTEM request signals.

Table A-7. External DMA_SYSTEM Request Signals

Module Signal Name	Device Signal Name	I/O[1]	Description
EXT_SYS_DREQ_0	sys_ndmareq0	I	External DMA request 0 (system expansion)
EXT_SYS_DREQ_1	sys_ndmareq1	I	External DMA request 1 (system expansion)

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

A.5.2 DMA_SYSTEM Integration

A.5.2.1 DMA Requests to the DMA_SYSTEM Controller

NOTE: This subsection provides a quick reference about the unavailable modules, which interact with the DMA_SYSTEM. Cells highlighted in orange in the tables indicate modules with removed functionality in the OMAP5432 device. These modules are still present on the die; therefore, their mappings are provided to control their activity and for debug purposes.

Table A-8 lists the DMA_SYSTEM request mapping of the OMAP5432 devices.

Table A-8. DMA_SYSTEM Controller Request Mapping

DMA Request Line	Source	Description
DMA_SYSTEM_DREQ_0	Reserved	Reserved
DMA_SYSTEM_DREQ_1	EXT_SYS_DREQ_0	External DMA request 0 (system expansion)
DMA_SYSTEM_DREQ_2	EXT_SYS_DREQ_1	External DMA request 1 (system expansion)

A.6 Interrupt Controllers

A.6.1 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Table A-9 describes the I/O signals that can be used by external devices to generate interrupts to the INTC_MPU or INTC_IPU. Orange highlighting indicates the unavailable external interrupts in OMAP5432.

Table A-9. Interrupt Controllers I/O Signals

Signal Name	I/O[1]	Reset Value	Description	INTC_MPU	INTC_IPU
sys_nirq1	I	1	TWL-Power IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–
sys_nirq2	I	1	TWL-Audio IC can use this pin to generate a system wake-up event to INTC_MPU.	✓	–
gpio1_[7:0]	I/O	–	External devices can use GPIO modules to generate interrupts to INTC_MPU or INTC_IPU. There are eight dedicated interrupt lines (for GPIO1 to GPIO8) to the INTC_MPU and two dedicated interrupt lines (for GPIO1 and GPIO2) to the INTC_IPU. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs.	✓	✓
gpio1_[10:8]	I/O	–		✓	✓
gpio1_[31:11]	I/O	–		✓	✓
gpio2_[63:32]	I/O	–		✓	✓
gpio3_[75:64]	I/O	–		✓	–
gpio3_[91:76]	I/O	–		✓	–
gpio3_[93:92]	I/O	–		✓	–
gpio3_[95:94]	I/O	–		✓	–
gpio4_[127:96]	I/O	–		✓	–
gpio5_[144:128]	I/O	–		✓	–
gpio5_[146:145]	I/O	–		✓	–
gpio5_[148:147]	I/O	–		✓	–
gpio5_[151:149]	I/O	–		✓	–
gpio5_[159:152]	I/O	–		✓	–
gpio6_[191:160]	I/O	–		✓	–
gpio7_[223:192]	I/O	–		✓	–
gpio8_[255:224]	I/O	–		✓	–

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

A.6.2 Interrupt Controllers Integration

NOTE: This subsection provides a quick reference about the unavailable modules, which have their interrupt requests mapped on the MPU and IPU interrupt controllers (INTCs). Rows highlighted in orange indicate modules with removed functionality in the OMAP5432. These modules are still present on the die; therefore, their mappings are provided to control their activity and for debug purposes.

A.6.2.1 Interrupt Requests to INTC_MPU

Table A-10 shows the INTC_MPU interrupt mapping.

Table A-10. INTC_MPU Interrupt Mapping

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
MPU_IRQ_0	MPU_CLUSTER_IRQ_INTERR	MPU_CLUSTER	Illegal writes to interrupt controller memory map region(1)
MPU_IRQ_1	CS_CTI_MPU_C0_IRQ	CS_CTI_MPU_C0	TRIGOUT[6] of Cross Trigger Interface 0 (CTI0)(1)
MPU_IRQ_2	CS_CTI_MPU_C1_IRQ	CS_CTI_MPU_C1	TRIGOUT[6] of Cross Trigger Interface 1 (CTI1)(1)
MPU_IRQ_3	MPU_CLUSTER_IRQ_AXIERR	MPU_CLUSTER	Error indication for AXI write transactions with a BRESP error condition(1)
MPU_IRQ_4	ELM_IRQ	ELM	Error location process completion(2)
MPU_IRQ_5	Reserved	Reserved	Reserved
MPU_IRQ_6	Reserved	Reserved	Reserved
MPU_IRQ_7	EXT_SYS_IRQ_1	EXT_SYS	External interrupt (active low)
MPU_IRQ_8	Reserved	Reserved	Reserved
MPU_IRQ_9	L3_MAIN_IRQ_DBG_ERR	L3_MAIN	Reports debug errors on L3
MPU_IRQ_10	L3_MAIN_IRQ_APP_ERR	L3_MAIN	Reports application or nonattributable errors on L3
MPU_IRQ_11	PRM_IRQ_MPU	PRM	PRCM module
MPU_IRQ_12	DMA_SYSTEM_IRQ_0	DMA_SYSTEM	System DMA interrupt request 0(3)
MPU_IRQ_13	DMA_SYSTEM_IRQ_1	DMA_SYSTEM	System DMA interrupt request 1(3)
MPU_IRQ_14	DMA_SYSTEM_IRQ_2	DMA_SYSTEM	System DMA interrupt request 2(4)
MPU_IRQ_15	DMA_SYSTEM_IRQ_3	DMA_SYSTEM	System DMA interrupt request 3(4)
MPU_IRQ_16	L3_MAIN_IRQ_STAT_ALARM	L3_MAIN	L3 NoC Statistic Collector Alarm
MPU_IRQ_17	MCBSP1_IRQ	MCBSP1	McBSP1 / PORCOMMONIRQ: Common Synchronous Interrupt Request line(2)
MPU_IRQ_18	SMARTREFLEX_MPU_IRQ	SMARTREFLEX_MPU	SmartReflex MCU interrupt request
MPU_IRQ_19	SMARTREFLEX_CORE_IRQ	SMARTREFLEX_CORE	SmartReflex Core interrupt request
MPU_IRQ_20	GPMC_IRQ	GPMC	General-purpose memory controller module(2)
MPU_IRQ_21	GPU_IRQ	GPU	3D graphics module interrupt
MPU_IRQ_22	MCBSP2_IRQ	MCBSP2	McBSP 2 / PORCOMMONIRQ: Common Synchronous Interrupt Request line(2)
MPU_IRQ_23	MCBSP3_IRQ	MCBSP3	McBSP 3 / PORCOMMONIRQ: Common Synchronous Interrupt Request line(2)
MPU_IRQ_24	ISS_IRQ_5	ISS	Imaging subsystem interrupt request(4)
MPU_IRQ_25	DISPC_IRQ	DISPC	Display controller interrupt request(3)
MPU_IRQ_26	MAILBOX_IRQ_USER0	MAILBOX	Mailbox user 0 interrupt request
MPU_IRQ_27	Reserved	Reserved	Reserved
MPU_IRQ_28	DSP_IRQ_MMU	DSP	DSP MMU interrupt

Table A-10. INTC_MPU Interrupt Mapping (continued)

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
MPU_IRQ_29	GPIO1_IRQ_1	GPIO1	GPIO module 1 - interrupt 1[4]
MPU_IRQ_30	GPIO2_IRQ_1	GPIO2	GPIO module 2 - interrupt 1[4]
MPU_IRQ_31	GPIO3_IRQ_1	GPIO3	GPIO module 3 - interrupt 1
MPU_IRQ_32	GPIO4_IRQ_1	GPIO4	GPIO module 4 - interrupt 1
MPU_IRQ_33	GPIO5_IRQ_1	GPIO5	GPIO module 5 - interrupt 1
MPU_IRQ_34	GPIO6_IRQ_1	GPIO6	GPIO module 6 - interrupt 1
MPU_IRQ_35	GPIO7_IRQ_1	GPIO7	GPIO module 7 - interrupt 1
MPU_IRQ_36	WD_TIMER3_IRQ	WD_TIMER3	Watchdog timer module 3 overflow (watchdog controlled by Mini64)
MPU_IRQ_37	TIMER1_IRQ	TIMER1	General-purpose timer module 1 (Timer 1ms / Wakeup domain)
MPU_IRQ_38	TIMER2_IRQ	TIMER2	General-purpose timer module 2 (Timer 1ms / CORE domain)
MPU_IRQ_39	TIMER3_IRQ	TIMER3	General-purpose timer module 3[4]
MPU_IRQ_40	TIMER4_IRQ	TIMER4	General-purpose timer module 4[4]
MPU_IRQ_41	TIMER5_IRQ	TIMER5	General-purpose timer module 5 (Audio BE)[2]
MPU_IRQ_42	TIMER6_IRQ	TIMER6	General-purpose timer module 6 (Audio BE)[2]
MPU_IRQ_43	TIMER7_IRQ	TIMER7	General-purpose timer module 7 (Audio BE)[2]

A.6.2.2 Interrupt Requests to INTC_IPU

Table A-11 shows the INTC_IPU interrupt mapping.

Table A-11. INTC_IPU Interrupt Mapping

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
IPU_IRQ_0	–	–	MSP initial value in exception vector table
IPU_IRQ_1	RESET_IRQ	RESET	Reset
IPU_IRQ_2	NMI_IRQ	NMI	External NMI inputs(1)
IPU_IRQ_3	HARD_FAULT_IRQ	HARD_FAULT	All fault conditions, if the fault handle is not enabled(1)
IPU_IRQ_4	MEM_MANAGE_FAULT_IRQ	MEM_MANAGE_FAULT	Memory management fault; access to illegal locations(1)
IPU_IRQ_5	BUS_FAULT_IRQ	BUS_FAULT	Bus error (on AHB interface)(1)
IPU_IRQ_6	USAGE_FAULT_IRQ	USAGE_FAULT	Program error(1)
IPU_IRQ_7	Reserved	Reserved	Reserved
IPU_IRQ_8	Reserved	Reserved	Reserved
IPU_IRQ_9	Reserved	Reserved	Reserved
IPU_IRQ_10	Reserved	Reserved	Reserved
IPU_IRQ_11	SV_CALL_IRQ	SV_CALL	Service system call(1)
IPU_IRQ_12	DEBUG_MON_IRQ	DEBUG_MON	BP, WP or external debug request(1)
IPU_IRQ_13	Reserved	Reserved	Reserved
IPU_IRQ_14	PEND_SV_IRQ	PEND_SV	Pendable request for system device(1)
IPU_IRQ_15	SYS_TICK_TIMER_IRQ	SYS_TICK_TIMER	System tick timer has fired(1)
IPU_IRQ_16	XLATE_MMU_FAULT_IRQ	XLATE_MMU_FAULT	xlate_mmu_fault (from L2_MMU)(2)
IPU_IRQ_17	SCACHE_MMU_IRQ	SCACHE_MMU	Shared cache or MMU maintenance complete(2)
IPU_IRQ_18	CTM_TIM_EVENT1_IRQ	CTM_TIM_EVENT1	CTM timer event (timer 1)(2)
IPU_IRQ_19	SPINLOCK_IRQ	SPINLOCK	Semaphore interrupt (1 to each core)(2)
IPU_IRQ_20	ICE_NEMU_IRQ	ICE_NEMU	ICECrusher (1 to each core)(2)
IPU_IRQ_21	IPU_IMP_FAULT_IRQ	IPU_IMP_FAULT	Ducati imprecise fault (from interconnect)(2)
IPU_IRQ_22	CTM_TIM_EVENT2_IRQ	CTM_TIM_EVENT2	CTM timer event (timer 2)(2)
IPU_IRQ_23	DISPC_IRQ	DISPC	Display controller interrupt request(3)
IPU_IRQ_24	DSI1_A_IRQ	DSI1_A	Display DSI1_A interrupt request(3)
IPU_IRQ_25	Reserved	Reserved	Reserved
IPU_IRQ_26	HDMI_IRQ	HDMI	Display HDMI interrupt request(3)
IPU_IRQ_27	ISS_IRQ_0	ISS	Interrupt from ISS
IPU_IRQ_28	ISS_IRQ_1	ISS	Interrupt from ISS
IPU_IRQ_29	ISS_IRQ_2	ISS	Interrupt from ISS
IPU_IRQ_30	ISS_IRQ_3	ISS	Interrupt from ISS
IPU_IRQ_31	ISS_IRQ_4	ISS	Interrupt from ISS(4)
IPU_IRQ_32	ISS_IRQ_5	ISS	Interrupt from ISS(5)
IPU_IRQ_33	FDIF_IRQ_1	FDIF	Face detect interrupt 1
IPU_IRQ_34	DMA_SYSTEM_IRQ_0	DMA_SYSTEM	System DMA interrupt request 0(3)
IPU_IRQ_35	DMA_SYSTEM_IRQ_1	DMA_SYSTEM	System DMA interrupt request 1(3)
IPU_IRQ_36	DMA_SYSTEM_IRQ_2	DMA_SYSTEM	System DMA interrupt request 2(5)

Table A-11. INTC_IPU Interrupt Mapping (continued)

Interrupt Line (Destination)	Interrupt Line (Source)	Root Source Module	Description
IPU_IRQ_37	DMA_SYSTEM_IRQ_3	DMA_SYSTEM	System DMA interrupt request 3(5)
IPU_IRQ_38	IVA_IRQ_MAILBOX_2	IVA	IVA-HD subsystem interrupt request (Mailbox interrupt 2)
IPU_IRQ_39	IVA_IRQ_SYNC_1	IVA	Sync interrupt from ICONT2 (VDMA)(3)
IPU_IRQ_40	IVA_IRQ_SYNC_0	IVA	Sync interrupt from ICONT1(3)
IPU_IRQ_41	I2C1_IRQ	I2C1	I^2C module 1(5)
IPU_IRQ_42	I2C2_IRQ	I2C2	I^2C module 2(5)
IPU_IRQ_43	I2C3_IRQ	I2C3	I^2C module 3(5)
IPU_IRQ_44	I2C4_IRQ	I2C4	I^2C module 4(5)
IPU_IRQ_45	UART3_IRQ	UART3	UART module 3 (also infrared - IRDA)(3)
IPU_IRQ_46	L3_MAIN_IRQ_APP_ERR	L3_MAIN	Reports application or nonattributable errors on L3
IPU_IRQ_47	PRM_IRQ_IPU	PRM	PRCM module
IPU_IRQ_48	SMARTREFLEX_CORE_IRQ	SMARTREFLEX_CORE	SmartReflex Core or SmartReflex MM
IPU_IRQ_49	HSI_IRQ_MPU_DMA	HSI	HSI - MPU DMA interrupt request(5)
IPU_IRQ_50	MAILBOX_IRQ_USER2	MAILBOX	Mailbox user 2 interrupt request
IPU_IRQ_51	GPIO1_IRQ_1	GPIO1	GPIO module 1 - interrupt 1(5)
IPU_IRQ_52	GPIO2_IRQ_1	GPIO2	GPIO module 2 - interrupt 1(5)
IPU_IRQ_53	TIMER3_IRQ	TIMER3	General-purpose timer module 3(5)
IPU_IRQ_54	TIMER4_IRQ	TIMER4	General-purpose timer module 4(5)

(4) Shared with INTC_DSP
(5) Shared with INTC_MPU

A.6.3 INTCs Use Guidelines

All interrupts that are highlighted in orange must be kept masked (reset default state) during normal operation.

For information about the INTC_MPU, see *ARM Cortex-A15 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

For information about the INTC_IPU (NVIC), see *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

A.7 System Control Module

A.7.1 Control Module Signals

Table A-12 lists the control module hardware observability outputs configured to observe the debug signals of the device module. It describes the module signals and specifies their links to functions. Highlighted signals are not available in OMAP5432.

Table A-12. Control Module I/O Description

Signal	I/O(1)	Description	Reset Value(2)
hw_dbg[9:0]	O	Internal hardware observability signals 0 to 9	HiZ
hw_dbg[12:10]	O	Internal hardware observability signals 10 to 12	HiZ
hw_dbg[31:13]	O	Internal hardware observability signals 13 to 31	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

A.7.2 Pad Multiplexing Register Fields

NOTE: This subsection provides a quick reference about the device pads, that are not connected to any pin. Cells highlighted in orange in the tables indicate pads with removed functionality in the OMAP5432 device. These pads are still present on the die; therefore, their configuration settings are provided to control their activity and for debug purposes.

Table A-13 and Table A-14 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad.

A.7.3 CTRL_MODULE_WKUP Registers

To select a default read latency of 8 for DDR3 in OMAP5432, the CONTROL_PROT_EMIF1_SDRAM_CONFIG[13:10] EMIF1_SDRAM_CL and CONTROL_PROT_EMIF2_SDRAM_CONFIG[13:10] EMIF2_SDRAM_CL bits have a reset value of 0x8.

A.7.4 SCM Use Guidelines

- All PADCONF bit fields, which appear in orange in Table A-13 and Table A-14, must be left in mux7, safe mode.

A.8 Serial Communication Intrefaces

A.8.1 UART/IrDA/CIR

The OMAP5432 device has the following restrictions to UART controllers:

- UART6 is not available for use
- UART4 has a 2-pin (TX/RX) interface. Flow-control pins (CTS/RTS) are not available.

Table A-15 lists UART modules signals. Highlighted signals are not mapped on any pad in OMAP5432 device.

Table A-15. UART I/O Description

Signal	I/O[1]	Description	Reset
uart1_rx	I	Serial data input	HiZ
uart1_tx	O	Serial data output	1
uart1_cts	I	Clear to send	HiZ
uart1_rts	O	Request to send	1
uart2_rx	I	Serial data input	HiZ
uart2_tx	O	Serial data output	1
uart2_cts	I	Clear to send	HiZ
uart2_rts	O	Request to send	1
uart3_rx_irrx	I	Serial data input, IR and remote RX	HiZ
uart3_tx_irtx	O	Serial data output, IR TX	1
uart3_cts_rctx	I/O	Clear to send (input), remote TX (output)	1
uart3_rts_irsd	O	Request to send, IR enable	1
uart4_rx	I	Serial data input	HiZ
uart4_tx	O	Serial data output	1
uart4_cts	I	Clear to send	HiZ
uart4_rts	O	Request to send	1
uart5_rx	I	Serial data input	HiZ
uart5_tx	O	Serial data output	1
uart5_cts	I	Clear to send	HiZ
uart5_rts	O	Request to send	1
uart6_rx	I	Serial data input	HiZ
uart6_tx	O	Serial data output	1
uart6_cts	I	Clear to send	HiZ
uart6_rts	O	Request to send	1

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

Table A-16 lists the base address and address space for the UART/IrDA/CIR module instances in the OMAP5432 device.

NOTE: Orange highlighting in Table A-16 indicates modules with removed functionality in the OMAP5432 device. The modules are still present on the die; therefore, their mappings are provided to control their activity and for debug purposes.

Table A-16. UART/IrDA/CIR Instance Summary

Module Name	Base Address	Size
UART1[1]	0x4806 A000	4 KiB
UART2[1]	0x4806 C000	4 KiB

(1) UART mode only

Table A-16. UART/IrDA/CIR Instance Summary (continued)

Module Name	Base Address	Size
UART3[2]	0x4802 0000	4 KiB
UART4[1]	0x4806 E000	4 KiB
UART5[1]	0x4806 6000	4 KiB
UART6[1]	0x4806 8000	4 KiB

(2) UART, IrDA, or CIR mode

A.8.1.1 UART/IrDA/CIR Use Guidelines

For the unsupported UART1 and UART6 module, the following guidelines must be followed:

- Keep SYSC_REG[4:3] IDLEMODE = 0x0.
- Keep SYSC_REG[2] ENWAKEUP = 0x0.
- Set SYSC_REG[0] AUTOIDLE = 0x1.
- Keep all interrupts masked.

A.8.2 Multichannel SPI

The OMAP5432 device has the following limitations to MCSPI controllers:

- MCSPI1 chip-selects 2 and 3 (mcspi1_cs2 and mcspi1_cs3) are not available for use.

Table A-17 shows MCSPI signals. Signals that are not mapped to any pads on the OMAP5432 device are highlighted.

Table A-17. McSPI I/O Description

Signal Name	I/O	Description	Reset
mcspi1_clk	I/O[1]	SPI1 module serial clock[2]	HiZ[3]
mcspi1_simo	I/O[1]	SPI1 module serial data (slave input, master output)	HiZ
mcspi1_somi	I/O[1]	SPI1 module serial data (slave output, master input)	HiZ
mcspi1_cs0	O	SPI1 module chip-select 0	HiZ
mcspi1_cs1	O	SPI1 module chip-select 1	0
mcspi1_cs2	O	SPI1 module chip-select 2	0
mcspi1_cs3	O	SPI1 module chip-select 3	0
mcspi2_clk	I/O[1]	SPI2 module serial clock[2]	HiZ
mcspi2_simo	I/O[1]	SPI2 module serial data (slave input, master output)	HiZ
mcspi2_somi	I/O[1]	SPI2 module serial data (slave output, master input)	HiZ
mcspi2_cs0	O	SPI2 module chip-select 0	HiZ
mcspi2_cs1	O	SPI2 module chip-select 1	0
mcspi3_clk	I/O[1]	SPI3 module serial clock[2]	HiZ
mcspi3_simo	I/O[1]	SPI3 module serial data (slave input, master output)	HiZ
mcspi3_somi	I/O[1]	SPI3 module serial data (slave output, master input)	HiZ
mcspi3_cs0	I/O[1]	SPI3 module chip-select 0	HiZ
mcspi4_clk	I/O[1]	SPI4 module serial clock[2]	HiZ

(1) Depends on mode selection - master or slave SPI.
(2) This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).
(3) HiZ = High impedance

Table A-17. McSPI I/O Description (continued)

Signal Name	I/O	Description	Reset
mcspi4_simo	I/O[1]	SPI4 module serial data (slave input, master output)	HiZ
mcspi4_somi	I/O[1]	SPI4 module serial data (slave output, master input)	HiZ
mcspi4_cs0	I/O[1]	SPI4 module chip-select 0	HiZ

A.8.3 MIPI HSI

The OMAP5432 device has the following restrictions to HSI controller:

- HSI port 1 is not available for use.

Table A-18 describes the HSI module I/O signals. The unavailable pins are highlighted with orange.

Table A-18. HSI I/O Signals

Pin Name	I/O[1]	Description	Reset Value[2]
hsi1_cawake	I	HSI port 1 wake-up signal from an external serial transmitter	HiZ
hsi1_cadata	I	HSI port 1 receiver data from an external transmitter	HiZ
hsi1_caflag	I	HSI port 1 receiver flag from an external transmitter	HiZ
hsi1_acready	O	HSI port 1 synchronization signal to an external transmitter	1
hsi1_acwake	O	HSI port 1 wake-up signal to an external serial receiver	0
hsi1_acdata	O	HSI port 1 transmission data (level transmission signaling) to an external receiver	0
hsi1_acflag	O	HSI port 1 transmission flag (bit transition signaling) to an external receiver	1
hsi1_caready	I	HSI port 1 synchronization signal from an external receiver	HiZ
hsi2_cawake	I	HSI port 2 wake-up signal from an external serial transmitter	HiZ
hsi2_cadata	I	HSI port 2 receiver data from an external transmitter	HiZ
hsi2_caflag	I	HSI port 2 receiver flag from an external transmitter	HiZ
hsi2_acready	O	HSI port 2 synchronization signal to an external transmitter	1
hsi2_acwake	O	HSI port 2 wake-up signal to an external serial receiver	0
hsi2_acdata	O	HSI port 2 transmission data (level transmission signaling) to an external receiver	0
hsi2_acflag	O	HSI port 2 transmission flag (bit transition signaling) to an external receiver	1
hsi2_caready	I	HSI port 2 synchronization signal from an external receiver	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

A.8.4 High-Speed USB Host Subsystem

The HS USB host subsystem has the following limitations in the OMAP5432 device:

- The HS ULPI TLL interface is not supported.
- The serial TLL interface is limited to 2-/3-pin modes.
- The HSIC1 interface is not supported.

Table A-19 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

Table A-19. ULPI – 12-Pin/8-Bit Data SDR Version I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
HS USB Host Controller Port 1 (Device port USBB1)				
CLK	usbb1_ulpiphy_clk	I	Clock input from remote PHY IC	HiZ
DIR	usbb1_ulpiphy_dir	I	Data direction control from remote PHY IC	HiZ
STP	usbb1_ulpiphy_stp	O	Stop signal to remote PHY IC	1
NXT	usbb1_ulpiphy_nxt	I	Next signal from remote PHY IC	HiZ
DAT0	usbb1_ulpiphy_dat0	I/O	Bidirectional 8-bit data bus	HiZ
DAT1	usbb1_ulpiphy_dat1	I/O	Bidirectional 8-bit data bus	HiZ
DAT2	usbb1_ulpiphy_dat2	I/O	Bidirectional 8-bit data bus	HiZ
DAT3	usbb1_ulpiphy_dat3	I/O	Bidirectional 8-bit data bus	HiZ
DAT4	usbb1_ulpiphy_dat4	I/O	Bidirectional 8-bit data bus	HiZ
DAT5	usbb1_ulpiphy_dat5	I/O	Bidirectional 8-bit data bus	HiZ
DAT6	usbb1_ulpiphy_dat6	I/O	Bidirectional 8-bit data bus	HiZ
DAT7	usbb1_ulpiphy_dat7	I/O	Bidirectional 8-bit data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-20 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode. None of the pins are available in OMAP5432 device.

Table A-20. ULPI TLL Interface – 12-Pin/8-Bit Data SDR Version I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
HS USB Host Controller Port 2 (Device port USBB2)				
CLK	usbb2_ulpitll_clk	O	Clock output to remote ULPI link controller	0
DIR	usbb2_ulpitll_dir	O	Data direction control from remote ULPI link controller	0
STP	usbb2_ulpitll_stp	I	Stop signal to remote ULPI link controller	HiZ
NXT	usbb2_ulpitll_nxt	O	Next signal from remote ULPI link controller	0
DAT0	usbb2_ulpitll_dat0	I/O	Bidirectional 8-bit data bus	0
DAT1	usbb2_ulpitll_dat1	I/O	Bidirectional 8-bit data bus	0
DAT2	usbb2_ulpitll_dat2	I/O	Bidirectional 8-bit data bus	0
DAT3	usbb2_ulpitll_dat3	I/O	Bidirectional 8-bit data bus	0
DAT4	usbb2_ulpitll_dat4	I/O	Bidirectional 8-bit data bus	0
DAT5	usbb2_ulpitll_dat5	I/O	Bidirectional 8-bit data bus	0
DAT6	usbb2_ulpitll_dat6	I/O	Bidirectional 8-bit data bus	0
DAT7	usbb2_ulpitll_dat7	I/O	Bidirectional 8-bit data bus	0

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-21 describes the I/O of the HS USB host subsystem serial interface. The highlighted rows indicate the unavailable pins. The highlighted cells in description indicate the unavailable modes of that pin.

Table A-21. Multiple-Mode FS/LS Serial Interface I/O Description

Device Signal Name	I/O[1]	Description	Value at Reset[2]
HS USB Host Controller Port 2 (Device port USBB2)			
usbb2_mm_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode	
	I/O	SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DM-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txdat	I/O	DAT function in 3-pin bidirectional DAT/SE0 mode	HiZ
	I/O	DP function in 4-pin bidirectional DP/DM mode	
	O	DAT output in 6-pin unidirectional DAT/SE0 mode	
	O	DP output in 6-pin unidirectional DAT/SE0 mode	
	I/O	DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DP-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txen	O	Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes	1
	I	Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes)	
usbb2_mm_rxrcv	I	Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode)	HiZ
	O	Differential receiver signal output in the 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdp	I	Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes)	HiZ
	O	Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes)	HiZ
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-22 describes the I/O of the HSIC interface of the HS USB host subsystem. The unsupported pins by HSIC modules in OMAP5432 are highlighted in orange.

Table A-22. HSIC Interface I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
HS USB Host Controller Port 1 (Device port USBB1)				
DATA	usbb1_hsic_data	I/O	HSIC1 module data signal	HiZ
STROBE	usbb1_hsic_strobe	I/O	HSIC1 module strobe signal	HiZ
HS USB Host Controller Port 2 (Device port USBB2)				
DATA	usbb2_hsic_data	I/O	HSIC2 module data signal	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-22. HSIC Interface I/O Description (continued)

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
STROBE	usbb2_hsic_strobe	I/O	HSIC2 module strobe signal	HiZ
HS USB Host Controller Port 3 (Device port USBB3)				
DATA	usbb3_hsic_data	I/O	HSIC3 module data signal	HiZ
STROBE	usbb3_hsic_strobe	I/O	HSIC3 module strobe signal	HiZ

A.8.5 SuperSpeed USB OTG Subsystem

The OMAP5432 device has the following restrictions to USB OTG subsystem:

- The alternative to internal USB2.0 PHY, ULPI PHY interface is not available for use.

Table A-23 describes the I/O signals of the SuperSpeed USB subsystem interfaces. The unavailable pins are shown in orange.

Table A-23. Input/Output Description

Module Pin	Device-Level Signal Name	I/O[1]	Description	Reset Value[2]
ULPI interface				
CLK	usbd0_ulpiphy_clk	I	Clock input from external transceiver	HiZ
DIR	usbd0_ulpiphy_dir	I	Data direction control from external transceiver	HiZ
STP	usbd0_ulpiphy_stp	O	Output to external transceiver to stop data stream	1
NXT	usbd0_ulpiphy_nxt	I	Next signal control from external transceiver	HiZ
DATA0	usbd0_ulpiphy_data0	I/O	Data bit 0 to/from external transceiver	HiZ
DATA1	usbd0_ulpiphy_data1	I/O	Data bit 1 to/from external transceiver	HiZ
DATA2	usbd0_ulpiphy_data2	I/O	Data bit 2 to/from external transceiver	HiZ
DATA3	usbd0_ulpiphy_data3	I/O	Data bit 3 to/from external transceiver	HiZ
DATA4	usbd0_ulpiphy_data4	I/O	Data bit 4 to/from external transceiver	HiZ
DATA5	usbd0_ulpiphy_data5	I/O	Data bit 5 to/from external transceiver	HiZ
DATA6	usbd0_ulpiphy_data6	I/O	Data bit 6 to/from external transceiver	HiZ
DATA7	usbd0_ulpiphy_data7	I/O	Data bit 7 to/from external transceiver	HiZ
USB2PHY				
CE	usbphy_ce	O	Charging enable signal	0
DP	usbd0_hs_dp	I/O	USB2 half-duplex differential pair	HiZ
DM	usbd0_hs_dm	I/O		HiZ
USB3PHY				
TX	usbd0_ss_tx	O	USB3 transmitter differential pair	HiZ
TY	usbd0_ss_ty	O		HiZ
RX	usbd0_ss_rx	I	USB3 receiver differential pair	HiZ
RY	usbd0_ss_ry	I		HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

A.9 MMC/SD/SDIO

The OMAP5432 device has the following restrictions to MMC/SD/SDIO controllers:

- MMC/SD/SDIO controller 5 is not available for use.

Table A-24 describes MMC/SD/SDIO1 signals.

Table A-24. MMC/SD/SDIO1 I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
CLK	sdcard_clk	O	Clock	0
CMD	sdcard_cmd	I/O	Command	HiZ
DATA0	sdcard_data0	I/O	Data bus	HiZ
DATA1	sdcard_data1	I/O	Data bus	HiZ
DATA2	sdcard_data2	I/O	Data bus	HiZ
DATA3	sdcard_data3	I/O	Data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-25 describes MMC/SD/SDIO2 signals.

Table A-25. MMC/SD/SDIO2 I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
CLK	emmc_clk	O	Clock	0
CMD	emmc_cmd	I/O	Command	HiZ
DATA0	emmc_data0	I/O	Data bus	HiZ
DATA1	emmc_data1	I/O	Data bus	HiZ
DATA2	emmc_data2	I/O	Data bus	HiZ
DATA3	emmc_data3	I/O	Data bus	HiZ
DATA4	emmc_data4	I/O	Data bus	HiZ
DATA5	emmc_data5	I/O	Data bus	HiZ
DATA6	emmc_data6	I/O	Data bus	HiZ
DATA7	emmc_data7	I/O	Data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-26 describes MMC/SD/SDIO3 signals.

Table A-26. MMC/SD/SDIO3 I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
CLK	wlsdio_clk	O	Clock	0
CMD	wlsdio_cmd	I/O	Command	HiZ
DATA0	wlsdio_data0	I/O	Data bus	HiZ
DATA1	wlsdio_data1	I/O	Data bus	HiZ
DATA2	wlsdio_data2	I/O	Data bus	HiZ
DATA3	wlsdio_data3	I/O	Data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-27 describes MMC/SD/SDIO4 signals.

Table A-27. MMC/SD/SDIO4 I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
CLK	sdio4_clk	O	Clock	0
CMD	sdio4_cmd	I/O	Command	HiZ
DATA0	sdio4_data0	I/O	Data bus	HiZ
DATA1	sdio4_data1	I/O	Data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-27. MMC/SD/SDIO4 I/O Description (continued)

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
DATA2	sdio4_data2	I/O	Data bus	HiZ
DATA3	sdio4_data3	I/O	Data bus	HiZ

Table A-28 describes MMC/SD/SDIO5 signals. The signals that are not supported in OMAP5432 are highlighted with orange.

Table A-28. MMC/SD/SDIO5 I/O Description

Signal	Device Signal Name	I/O[1]	Description	Reset Value[2]
CLK	sdio5_clk	O	Clock	0
CMD	sdio5_cmd	I/O	Command	HiZ
DATA0	sdio5_data0	I/O	Data bus	HiZ
DATA1	sdio5_data1	I/O	Data bus	HiZ
DATA2	sdio5_data2	I/O	Data bus	HiZ
DATA3	sdio5_data3	I/O	Data bus	HiZ
DATA4	sdio5_data4	I/O	Data bus	HiZ
DATA5	sdio5_data5	I/O	Data bus	HiZ
DATA6	sdio5_data6	I/O	Data bus	HiZ
DATA7	sdio5_data7	I/O	Data bus	HiZ

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)
(2) HiZ = High impedance

Table A-29 describes MMC/SD/SDIO instance summary. The modules that are not supported in OMAP5432 are highlighted with orange.

Table A-29. MMC/SD/SDIO Instance Summary

Module Name	Base Address	Size
MMC1	0x4809 C000	4 KiB
MMC2	0x480B 4000	4 KiB
MMC3	0x480A D000	4 KiB
MMC4	0x480D 1000	4 KiB
MMC5	0x480D 5000	4 KiB

A.10 General-Purpose Interface

Table A-30 describes the GPIO channels.

Table A-30. GPIO Channels Description

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
GPIO1 Module				
[5:0]	O	gpio1_wkout[5:0]	Yes	Wake-up path
[7:6]	I/O	gpio1_wk[7:6]	Yes	Wake-up path
[10:8]	I/O	gpio1_wk[10:8]	Yes	Wake-up path
[31:11]	I/O	gpio1_wk[31:11]	Yes	Wake-up path

(1) I = Input; O = Output; I/O = Input/Output (bidirectional)

Table A-30. GPIO Channels Description (continued)

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
GPIO2 Module				
[31:0]	I/O	gpio2_[63:32]	Yes [2]	GPIO
GPIO3 Module				
[11:0]	I/O	gpio3_[75:64]	Yes [2]	GPIO
[21:12]	I/O	gpio3_[85:76]	Yes [2]	GPIO
[22][3]	I/O	gpio3_86 thermal shutdown comparator output signal (TSHUT)	Yes [2]	GPIO
	I		Yes [2]	Bandgap internal TSHUT
[27:23]	I/O	gpio3_[91:87]	Yes [2]	GPIO
[29:28]	I/O	gpio3_[93:92]	Yes [2]	GPIO
[31:30]	I/O	gpio3_[95:94]	Yes [2]	GPIO
GPIO4 Module				
[31:0]	I/O	gpio4_[127:96]	Yes [2]	GPIO
GPIO5 Module				
[16:0]	I/O	gpio5_[144:128]	Yes [2]	GPIO
[18:17]	I/O	gpio5_[146:145]	Yes [2]	GPIO
[20:19]	I/O	gpio5_[148:147]	Yes [2]	GPIO
[23:21]	I/O	gpio5_[151:149]	Yes [2]	GPIO
[29][3]	I	gpio5_in157	Yes [2]	GPIO (input only)
	I	CHGDETECT	Yes [2]	USB charge detect
[31:30]	I/O	gpio5_[159:158]	Yes [2]	GPIO
GPIO6 Module				
[31:0]	I/O	gpio6_[191:160]	Yes [2]	GPIO
GPIO7 Module				
[31:0]	I/O	gpio7_[223:192]	Yes [2]	GPIO
GPIO8 Module				
[11:0]	I/O	gpio8_[235:224]	Yes [2]	GPIO
[31:12]	I	gpio8_[255:236]		GPIO (inputs only)

(2) Only when the PER power domain is active

(3) The GPIO channel provides additional internal functionality (see the Comments column), besides its general-purpose I/O capabilities, when it is not connected to a pad of the device. For more information about pad configuration and multiplexing, see Section 18.4.8, *Pad Functional Multiplexing and Configuration*, in Chapter 18, *Control Module*.

A.11 Initialization

A.11.1 Power Connections

Table A-31 describes the device power balls. The highlighted balls are not used and not in OMAP

Table A-31. Power Balls

Voltage Ball Name	Power Supplied OMAP Internal Modules / Peripherals
vdd_core	OMAP subsystems/modules supplied in the CORE voltage domain
vdd_mpu	• MPU subsystem
vdd_mm	• IVA subsystem • DSP subsystem • GPU subsystem
vdda_ldo_emu_wkup	• Wakeup • Emulation subsystem
vddq_ddr_ch1	EMIF channel 1 DQ I/Os (OMAP side only)
vddq_ddr_ch2	EMIF channel 2 DQ I/Os (OMAP side only)
vddq_vref_ddrch1	Supplies VDDQ_VREF generator for EMIF channel 1
vddq_vref_ddrch2	Supplies VDDQ_VREF generator for EMIF channel 2
vddca_lpddr2ch1	EMIF channel 1 CA I/Os (OMAP side only)
vddca_lpddr2ch2	EMIF channel 2 CA I/Os (OMAP side only)
vddca_vref_lpddr2ch1	Supplies VDDCA_VREF generator for EMIF channel 1
vddca_vref_lpddr2ch2	Supplies VDDCA_VREF generator for EMIF channel 2
vdds_hsic	USBB1, USBB2, USBB3 HSIC I/Os
vdda_dsiporta	DSI port A lanes (dual voltage I/Os)
vdda_dsiportc	DSI port C lanes (dual voltage I/Os)
vdda_hdmi	HDMI dual voltage I/Os
vdda_csiporta	CSI port A lanes (dual voltage I/Os)
vdda_csiportb	CSI port B lanes (dual voltage I/Os)
vdda_csiportc	CSI port C lanes (dual voltage I/Os)
vdda_dpll_mm_l4per	Analog power supply for the DPLL_IVA and DPLL_PER
vdda_dpll_mpu	Analog power supply or the DPLL_MPU
vdda_dpll_core_emu_abe	Analog power supply fot the DPLL_CORE, DPLL_DEBUGSS, and DPLL_ABE
vdda_dpll_hdmi	Analog power supply for the DPLL_HDMI
vdda_ldo_mpu	Analog power supply for the OMAP internal MPU LDOs
vdda_ldo_core	Analog power supply for the OMAP internal CORE LDOs
vdda_ldo_mm	Analog power supply for the OMAP internal MM LDOs
vdda_vbgap_core	Analog power supply for the OMAP BANDGAPTS_CORE
vdda_usbhs33	Analog power supplies for the high-speed USB I/Os
vdds_usbhs18	Analog power supplies for the high-speed USB I/Os
vdda_usbss18	Analog power supply for SuperSpeed USB I/Os
vdda_sata	Analog power supply for SATA I/Os
vdds_sdcard	MMC1 module I/Os (SD Card I/Os)
vdds_bank2	Bank of I/Os: HSI1, UART1 (dual voltage)
vdds_bank4	Bank of I/Os: HSI2, UART2 (dual voltage)
vdds_bank5	Bank of I/Os: TIMER9, TIMER10, DSIPORT B, DSIPORT C I/Os (dual voltage)
vdds_bank8	Bank of I/Os: MCSPI2, I2C4 (dual voltage)
vdds_bank9	Bank of I/Os: RFBI, GPIO6 (dual voltage)
vdds_bank10	Bank of I/Os: TCTRL, TIMER5, TIMER6, TIMER8, TIMER11, I2C3, GPIO8 (dual voltage)
vdds_bank11	Bank of I/Os: ABE clocks, MCBSP2, MCPDM (dual voltage)
vdds_bank12	Bank of I/Os: DMIC (dual voltage)
vdds_bank15	Bank of I/Os: MMC3 module I/Os -(WLSDIO dual voltage I/Os)
vdds_bank16	Bank of I/Os: UART5, I2C2 (dual voltage)
vdds_bank18	Bank of I/Os: MCSPI1, I2C5 (dual voltage)
vdds_bank21	Bank of I/Os: UART6, UART3 (dual voltage)

Table A-31. Power Balls (continued)

Voltage Ball Name	Power Supplied OMAP Internal Modules / Peripherals
vdds_bank23	Bank of I/Os: JTAG®
vdds_bank24	Bank of I/Os: System interface
vdds_bank25	Bank of I/Os: System interface
vdds_bank26	Bank of I/Os: System interface, SmartReflex™PMIC I^2C, I2C1 PMIC interface (dual voltage)
vdds_osc	Fref XTAL oscillator (system interface I/Os)
vdda_slicer	Fref slicer oscillator (system interface I/Os)
vdds_emmc	MMC2 module I/Os (eMMC I/Os)

The OMAP5432 package does not provide any feedthrough balls.

A.11.2 Clock and Reset

Table A-32 lists the mapping for the OMAP clock input sources. Table A-33 lists the system clock source selection through sys_boot pins. The configurations that are not supported in OMAP5432 are highlighted with orange.

Table A-32. Mapping for Input Sources

Input Source	Mapping	Frequency Range/List	Type
Internal oscillator	fref_xtal_in/fref_xtal_out	12, 16.8, or 19.2 MHz	Crystal connection pins
External HS clock	fref_slicer_in	12, 16.8, 19.2, 26, or 38.4 MHz	Sine or square single ended
External 32k clock	sys_32k	32.768 kHz (nom.)	Square
Audio-management IC companion	abe_clks	19.2 MHz	Square

Table A-33. System Clock Selection Summary

sys_boot[5:4]	SYS_CLK Source	Oscillator Mode	Slicer Mode	fref_clk_ioreq Mode
0b00	fref_xtal_in	Active	Power down	Input
0b01 (1)	fref_xtal_in	Bypass	Power down	Output
0b10	fref_slicer_in	Power down	Active	Output
0b11	fref_slicer_in	Power down	Bypass	Output

(1) In the oscillator bypass case, fref_xtal_out pin is left unconnected

Glossary

1

1MS— One milisecond

2

2D— Two Dimensional

3

3A— AF + AE + AWB

3D— Three Dimensional

8

8B— 8 bits

A

A/D— Analog to Digital Converter

ABB— Adaptive Body Bias

ABBLDO— Adaptive Body Bias Low Drop Out

ABE— Audio Back End

ACB— ac–bias frequency

ACBI— ac–bias line transitions per interrupt

ACE— ASIC Compiler Environment.

ACK— Acknowledge

ADC— Analog–to–Digital Converter/Conversion.

ADMA— Audio DMA

ADPLL— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase–sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

ADPLLLJ— All Digital Phase-Locked Loop Low-Jitter

AE— Audio Engine. The AESS own processor.

AES— Advanced Encryption Standard

AESS— Audio Engine Subsystem

AEW— Auto Exposure and Auto White Balance

AF— Auto Focus

AFE— Analog Front End

AHB— Advanced High-performance Bus

AHB-AP— Advanced High-performance Bus - Access Port

AHCI— Advanced Host Controller Interface

ALE— Address Latch Enable

AMBA— Advanced Micro-Controller Bus Architecture

AMMU— Attribute Memory Management Unit

ANSI— American National Standards Institute

AP— Address Protection

APB— Advanced Peripheral Bus

APB-AP— Advanced Peripheral Bus - Access Port

APE— Application Engine

API— Application Programming Interface

AR— Automatic Reload

ARGB— Alpha Red Green Blue

ARM— Advanced RISC Machine

ASCII— American Standard Code for Information Interchange

ASIC— Application–Specific Integrated Circuit. A chip built for a particularapplication. In the context of this document, this refers to the FPGA that resides on the EVM board.

ASP— Application–Specific Peripheral

ATA— Interface standard for the connection of storage devices (Advanced Technology Attachment)

ATAPI— ATA Packet Interface

ATB— AMBA Advanced Trace Bus

ATC— Audio Traffic Controller

AVS— Adaptive Voltage Scaling

AWB— Auto White Balance

AXI— Adavced eXtensible Interface

B

B— Byte, 8 bits

BAYER— Bayer Filter mosaic. A color filter array (CFA) for arranging RGB color filters on a square grid of photosensors.

BB— Bus Busy

BBM— BITSTREAM Buffer Management

BCD— Binary–Coded Decimal.

BCH— Bose-ChaudhurI-Hocquenghem

BE— Big Endian.

BFSW— Buffer Switch

BGA— Ball Grid Array

BGAP— Band Gap

BIOS— Built–In Operating System

BIST— Built–In Self–Test

BIU— Bus Interface Unit

BL— Buffer Logic

BNC— British Naval Connector, Bayonet Nut Connector, or Bayonet Neill Concelman

BOF— Beginning of Frame

BPP— Bits Per Pixel

BS— Block Synchronization

BSC— Boundary Scan Chain

BSMEM— Bit Stream Memory

BTA— Bus Turn Around

BTE— Burst Translation Engine

BW— Band Width

BYS— Bayer Scaler

Bluetooth— A short–range radio technology aimed at simplifying communications among network devices and betweendevices and the Internet. It also aims to simplify data synchronizationbetween network devices and other computers.

C

C2C— Chip-to-Chip

CABAC— Context-Adaptive Binary Arithmetic Coding

CALC3— Transform and Quantization Calculation Engine

CAS— Column Address Strobe

CAVLC— Context-Adaptive Variable Length Coder

CB— Copy Back

CBP— Coded Block Pattern

CBUFF— Circular Buffer

CCC— Command Completion Coalescing feature

CCCR— Card Common Control Registers (SDIO)

CCP— Compact Camera Port

CDP— Coprocessor Data Operation

CDR— Clock Data Recovery

CE— Chip Enable

CEA-861-D— HDMI 1.3 video standart. It defines the video timing requirements, discovery structures, and data transfer structure.

CEC— Consumer Electronics Control

CFA— Color Filter Array

CFI— Common Flash Interface device

CH— Configuration Header. To use different settings than ROM Code defaults, i.e. clock frequencies, SDRAM/DDRAM settings, GPMC settings if the customer wants.

CID— Card Identification Number

CIR— Consumer Infra Red

CL— Command List

CLB— Command List Base Address

CLE— Command Latch Enable

CLK— Clock

CLO— Command List Override feature

CLUT— Color Look-Up Table

CM— Clock Management

CMEM— Coefficient Memory (also referred as COEFF)

CMOS— Complimentary Metal Oxide Semiconductor

CO— Controlled Oscillator

CODEC— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

COMINIT— An OOB Signal Sequence generated by physical layer of the attached SATA device as part of the SATA protocol

COMRESET— An OOB Signal Sequence generated by physical layer of the SATA host as part of the SATA protocol

COMWAKE— COMWAKE OOB signal defined in SATA protocol

CP15— Coprocessor 15. This coprocessor controls the operation andconfiguration of the TI925T.

CP7— USB3.0 CP7 transmit pattern

CP8— USB3.0 CP8 transmit pattern

CPFROM— Customer Programable eFuse ROM

CPI— Camera Parallel Interface

CPR— Clock, Power, Reset

CPS— Cell Search Platform

CPSR— Current Program Status Register

CPU— Central Processing Unit.

CRC— Cyclic Redundancy Check

CS— Chip–Select

CSI— Camera Serial Interface

CSL— Chip Support Library

CSW— Control Space Width

CSWR— Closed switch retention

CTM— Counter-Timer Module

CTRL— Control

CTS— Clear to Send

CTT— Clock Tree Tool

ConnID— Connection Identifier.An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is for error logging mechanism.

D

D2D— Die-to-Die

D2H— Device to Host transfer of a FIS

DBB— Digital Baseband

DBI— Display Buffer Interface

DC— Direct Current

DCC— Duty Cycle Correction Circuit

DCD— Data Carrier Detect

DCO— Digitally Controlled Oscillator

DCS— Display Command Set

DCT— Discrete Cosine Transform.

DDC— Display Data Channel

DDMA— DSP Subsystem Direct Memory Access module

DDR— Double Data Rate

DE— Data Enable

DES— Data Encryption Standard.

DFF— Digital Flip-Flop

DFT— Design For Test

DI— Data In

DISPC— Display Controller

DL— Data Lenght

DLB— Data Loopback.

DLL— Delay-Locked Loop

DMA— Direct Memory Access.

DMC— Data Memory Controller

DMEM— Data Memory

DMIC— Digital Microphone Controller

DMM— Dynamic Memory Management

DMT— Display Monitor Timing

DO— Data Out

DPC— Defect Pixel Correction

DPCM— Differential Pulse Code Modulation

DPI— Display Parallel Interface

DPLL— Digital Phase–Locked Loop. Digital implementation of PLL.

DPS— Digital Power Switching

DRD— Dual-Role Device (a type of OTG USB device)

DRDY— Data Ready

DRM— Digital Rights Management

DRQ— Data Transfer Requested flag in the SATA / ATA task file

DSI— Display Serial Interface

DSP— Digital Signal Processor.

DSR— Data Set Ready

DSS— Display Sub-System. Also DISS

DT— Data Type

DTBC— Data Buffer Controller

DTC— Debug and Trace Controller

DTCM— Data Tightly Coupled Memory

DTR— Data Transmit Ready

DVFS— Dynamic Voltage and Frequency Scaling

DVI— Digital Video Interface

DWORD— Double WORD (32-bit sized portion of data)

E

EA— Enumeration Address

EAV— End of Active Video

ECC— Error Checking and Correction. Also Error Correction Code.

ECD3— Entropy Coder/Decoder

ED— Endpoint Descriptor

EFUSE— Electrical Fuse. A one-time programmable memory location usually set at the factory

EHCI— Enhanced Host Controller Interface

EMC— External Memory Controller

EMI— Electromagneric interference

EMIF— External Memory Interface

EOB— End of Block

EOF— End of Frame

EOL— End of Line

EOT— End of Transfer

EP— Entry Point

ES— Erase Status

F

FAT— File Allocation Table

FB— Received FISes base address

FC— Frame Counter

FCLK— Functional Clock

FCS— Frame Check Sequence

FD— Face Detect

FE— Framing Error.

FEC— Frame End Code

FF— Flip-Flop

FIFO— First In First Out.

FIQ— Fast Interrupt Request. See ISR.

FIR— Fast Infrared

FIS— Frame Information Structure defined in SATA standard as user payload of a frame

FM— Frequency Modulate

FROM— eFuse ROM

FS— Full-Speed

FSC— Frame Start Code. Also Frame Start Count.

FSM— Finite State Machine.

FSR— Fault Status Register

FV— Focus Value

FW— Firewall

G

GBC— Green Balance Correction

GDP— Generic Dot Product

GFX— Graphics

GHB— Global History Buffer

GP— General-purpose

GPIO— Genreal Purpose Input Output

GPMC— General Purpose Memory Controller

GPU— Graphics-processing unit

GSM— Global System for Mobile Communications

GZ— Ground Zero

H

H.263— Video Codec Standart

H.264— Video Codec Standart

H/W— Hardware

H2D— Host to Device transfer of a FIS

H3A— Hardware 3A statistics engine. See 3A.

HAL— Hardware Abstraction Layer

HBA— Host bus adapter

HBP— Horizontal Back Porch

HC— Host Controller

HCI— Host Controller Interface

HD— High Definition

HDCP— High-bandwidth Digital Content Protection

HDD— Hard-disk drive

HDMI— High-Definition Multimedia Interface

HDQ— Single-wire communication interface

HDTV— High-Definition Television

HFP— Horizontal Front Porch

HLOS— High-Level Operating System

HNP— Host Negotiation Protocol (OTG feature)

HPF— High-Pass Filter

HPI— Host Port Interface

HS— High-Speed

HSE— Horizontal Sync End

HSI— High Speed Synchronous Serial Interface

HSS— Horizontal Sync Start

HSSCLL— High-Speed Serial Control Channel

HSW— Horizontal Synchronization Pulse Width

HSYNC— Horizontal Synchronization.

HW— Hardware

HWA— Hardware Accelerators.

HWOBS— Hardware Observability

HWSEQ— Hardware Sequencer

I

I/F— Interface

I/O— Input/Output

I2C— Inter–Integrated Circuit.

I2S— Inter–IC Sound.

IA— Identifier Address

ICE— In–Circuit Emulation

ICEPICK— Generic TAP for emulation control

ICLK— Interface Clock

ICONT— Imaging Controller

ICR— Intersystem Communication Registers

ID— Identification

IDCT— Inverse Discrete Cosine Transform. See DCT.

ILF3— Improved Loop Filter engine

IM— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors , DMA...).

IME3— Improved Motion Estimation engine

IMX— Image Extension coprocessor

INT— Interrupt .

INTC— Interrupt Controller

IP— Intellectual Property

IPC— Interprocessor Communication. (also referred to as “mailbox” on occasion)

IPE3— Intra Prediction Estimation engine

IPIPE— Image Pipe

IPIPEIF— Image Pipe Interface

IPU— Image-processing unit

IQ— Inverse Quantization

IR— Incremental Redundancy Buffer

IRQ— Interrupt Request.

ISA— Instruction Set Architecture

ISIF— Image Sensor Interface

ISO— Isochronous.

ISP— Image Signal Processor

ISR— Interrupt Service Routine.

ISS— Image SubSystem

IST— Interrupt Service Thread.

ITCM— Instruction Tightly Coupled Memory

IV— Initialization Vector

IVA— Image and Video Accelerator

IVA-HD— High Definition Image and Video Accelerator

IrDA— Infrared Data Association.

J

JEDEC— Joint Electronic Devices Engineering Council

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group.

K

KiB— Kibibyte, 1024 bytes

KBD— Keyboard

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect in OMAP platform

L4— Seconf level of interconnect in OMAP platform

LA— Logical Address

LAN— Local Area Network

LANGID— 16-bit Language ID

LBA— Logical Block Addressing

LC— Logical Channel

LCD— Liquid Crystal Display.

LCM— Logical Channel to Memory

LCh— Logical DMA Channel. Also LCH

LD— Lens Distortion

LDC— Load (from memory) to Coprocessor

LDC2— Lens Distortion Correction

LDM— Load Multiple

LDO— Low Dropout

LE— Little Endian.

LEC— Line End Code

LED— Light Emitting Diode.

LF— Loop Filter

LFN— Long File Name

LFPS— Low Frequency Periodic Signaling defined in USB 3.0 SuperSpeed standard

LFSR— Linear-Feedback Shift Register

LH— Local Host

LINK— Link Layer Device

LISA— Local Interconnect and Synchronization Agent

LLC— Link Layer Control

LLP— Low-Level Protocol

LP— Low-Power, operation mode for PHY

LPCM— Linear Pulse Code Modulation

LPDDR— Low Power Double Data Rate

LPF— Loop Filter

LPM— Low Power Mode (also refered as LPMODE)

LPP— Lines Per Panel

LS— Low-Speed

LSB— Least Significant Bit

LSC— Line Start Code

LSE— IVA Load and Store Engine

LSM— LISA Section Manager

LSR— Linear Shift Register

LSW— Least Significant Word

LUT— Look-up Table

M

M2— Micro Memory

MAC— Message Authentication Code

MiB— Mebibyte, 1024 KiB

MBAFF— MB-Level Adaptive Frame/Field

MBR— Master Boot Record

MC3— Motion Compensation Engine

MCSPI— Multichannel Serial Port Interface

MCU— Microcontroller Unit. Refers to the MPU.

ME— Motion Estimation

MEMIF— Memory Interface

MIF— Memory InterFace

MIPI— Mobile Industry Processor Interface

MIR— Medium Infrared

MJPEG— Motion JPEG

MMC— Multimedia Card

MMC/SD— Multimedia Card/Secure Data

MMR— Memory Mapped Register

MMU— Memory Management Unit.

MP3— MPEG Layer 3.

MPEG— Motion Pictures Expert Group.

MPEG1— The first MPEG compression scheme specification.

MPU— Microprocessor Unit.

MS— Memory Stick

MSB— Most Significant Bit

MSGIF— Message Interface

MUX— Multiplex/Multiplexer

Mb— Megabit

Mbps— Mega bits per second

McBSP— Multichannel Buffered Serial Port.

Modem— Modulator Demodulator

MuxMode— 3 bits field of the PIN Control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

N

N/A— Not Applicable

NAC— Network Access Control

NAK— Not Acknowledged

NAND— NAND Flash memory.

NC— Not Connected

NCQ— Native Command Queuing feature of SATA

NIU— Network Interface Unit

NMI— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.

NOP— No OPeration (DSP/CPU instruction)

NOR— A type of flash memory

NRZI— Non-Return-to-Zero Inverted

NSF— Noise Filter

NVB— Number of Valid Bytes

NVIC— Nested Vectored Interrupt Controller

NVM— Non-volatile Memory

O

OCM— On-chip Memory

OCP— Open–Core Protocol

OCPI— Open–Core Protocol Interface

OE— Output Enable

OHCI— Open Host Controller Interface. This is an industry standard USB Host Controller Interface.

OMAP— Open Multimedia Application Platform

OOB— Out of Band signaling

OPP— Operating Performance Point

OS— Operating System

OSI— (OSI model) Open Systems Interconnection Basic Reference Model

OTG— On-The-Go (USB 2.0 specification)

P

PA— Program Address

PATA— Parallel-ATA

PB— Peripheral Bus. Refers to the TIPB.

PBIAS— PMOS Bias transistor to provide the bias voltage to extended drain IOs

PC— Program Counter

PCB— Printed Circuit Board

PCI— Peripheral Component Interconnect.

PCLK— Pixel Clock

PCM— Pulse Code Modulation.

PCS— Personal Communication System.

PD— Program Data

PDC— Power-down Controller

PDM— Pulse Density Modulation

PE— Parity Error

PF— Packet Footer

PFPW— Prefetch and Prewrite posting engine

PH— Packet Header

PHY— Physical Layer Device

PI— Pixel Interpolation

PID— Protocol Identifier. The PID register is used in Windows CE mode only.

PIO— A programmed input/output transfer supported by IDE devices

PIPE3— A parallel data interface which connects USB OTG SS Controller with the USB3 PHY wrapper

PKA— Public Key Accelerator

PLD— Programmable Logic Devices

PLL— Phase–Locked Loop.

PM— Programming Model

PMA— Physical Media Attachment sublayer

PMC— Program Memory Controller

PMFW— Power Management FrameWork

PMIC— Power management Integrated Circuit

PMP— Power Management Port

PMU— Performance Monitoring Unit

POR— Power–On Reset

PPA— Primary Protected Application.

PPC— Palm–size PC

PPI— Physical Layer Protocol Interface

PPL— Pixels per Line

PRCM— Power, Reset, Clock Management module

PRD— Physical Region Descriptor

PRM— Power and Reset manager

PRT— PRD Table

PS— Packet Start

PSC— Prescaler Counter

PSS— Program Suspend Status

PT— Packet Type

PTI— Parallel Trace Interface

PTV— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.

PU/PD— Pull-Up / Pull-Down

PVT— Process, Voltage and Temperature; i.e. PVT dispertion

PWL— Pulse Width Light (modulator). A 4096–bit randomsequence generator that provides control of the LCD backlighting and keypad.

PWM— Pulse Width Modulation

PWR— Power

Q

QIQ— Quantization and Inverse Quantization

QM— Quantizer Matrix

QMEM— Quantizer Memory

QMR— Quantizer Matrix Reciprocal

QP— Quantization Parameter

QVGA— Quarter Video Graphics Array. One–fourth the resolution of VGA.

R

R/W— Read/Write. Also RW.

R5— Release 5 of 3GPP specifications on IMS and HSDPA standards

R6— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards

RAM— Random Access Memory.Fast-access but volatile memory type.

RCA— Relative Card Address

RDR— Receive Data Register

RE— Read Enable

REQ— Request

RF— Radio Frequency

RFB— Remote Frame Buffer

RFBI— Remote Frame Buffer Interface

RFF— Retention Flip-Flop

RGB— Red Green Blue

RGBA— Red Green Blue Alpha

RI— Ring Indicator

RM— Reed-Muller code

RNG— Random Number Generator

RO— Read Only

ROM— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

RSS— Reset System Simulator

RST— Reset

RT— Real–Time

RTA— Retention Till Access

RTL— Register Transfert Level

RTOS— Real–Time Operating System

RTS— Request to Send

RV— RealVideo (codec)

RVLC— Reversible Variable Length Coder

RX— Receive/Receiver

RXD— Receive Data

RXN— PHY differential receiver (de-serializer) negative line

RXP— PHY differential receiver (de-serializer) positive line

S

S/PDIF— Sony/Philips Digital Interface

S/W— Software

SAM— Signal Amplitude Modulation

SAR— Save and Restore. Hardware context saving for power saving.

SATA— Serial ATA

SATASS— SATA subsystem

SAV— Start of Active Video

SB— Silicon Backplane (Trade Mark)

SBC— Stream Buffer Controller

SBH— Synchronization Box Handler

SCL— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

SCM— System Control Module

SCP— Serial Configuration Port

SCR— SDIO Configuration Registers

SCRM— System Clock and Reset Manager

SCTM— System Counter Timer Module

SCU— Snoop Control Unit

SD— Secure Digital card. A non-volatile memory card.

SDA— Serial Data. Serial data bus in the I2C interface.

SDIO— Secure Digital Input/Output

SDMA— System Direct Memory Access module

SDR— Single Data Rate

SDRAM— Synchronous Dynamic Random Access Memory

SDRC— SDRAM Controller.

SFL— Subframe Length

SGX— Accronym for Grafics Accelerator (GFX in ES1.0)

SIMCOP— Still image coprocessor

SIMD— Single Instruction-Stream, Multiple Data-Stream

SIR— Slow Infrared

SL2— Shared Level 2 (memory/interface)

SL2IF— Shared L2 Interface

SLC— Single Level Cell devices

SLM— Static Leakage Management

SLVS— Scalable Low Voltage Signaling

SMC— Shared Message Channel

SMEM— Sample Memory

SMIA— Standard Mobile Imaging Architecture

SMP— Symmetric Multiprocessor Platform

SMPS— Switch Mode Power Supply

SMSET— Software Message and System Event Trace module

SN— Slave NIU

SNR— Signal-to-Noise Ratio

SOC— System-On-a-Chip

SOF— Start Of Frame

SP— Serial Port or Small Page

SPC— Serial Port Control

SPI— Serial Port Interface. A signaling protocol for exchanging serial data.

SR— SmartReflex

SR3-APG— SmartReflex3 Automatic Power Gating

SRAM— Static Random Access Memory

SRC— Sample Rate Conversion

SRG— Sample Rate Generator

SRMD— Single Request, Multiple Data

SRP— Session Request Protocol (OTG feature)

SS— Subsystem

SSC— Spread Spectrum Clocking

SSD— Solid State Drive

SSI— Serial Synchronous Interface

SSM— Security State Machine

ST— Start Timer

STC— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG2 encoder or decoder system.

STM— Synchronous Transfer Mode or Store Multiple.

STN— Super–Twist Nematic. A technique for improving LCD display screens by twisting light rays.

SW— Software

SWI— Software Interrupt

SXGA— Super eXtended Graphics Array

SYSC— System Control Module

SYSCTRL— IVA System Control module

SmartReflex— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

T

TA— Target Agent

TAP— Test Access Port

TC— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.

TCK— Test Clock

TCM— Tightly Coupled Memory

TCTRL— Timing Control module

TD— Transfer Descriptor

TDI— Test Data Input

TDM— Time Division Multiplex/Multiplexing

TDO— Test Data Output

TFT— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.

TI— Texas Instruments

TILER— Tiling Isometric Lightweight Engine for Rotation

TL— Transmission Line

TLB— Translation Lookaside Buffer. A cache that contains entries for virtual–to–physical address translation and access permission checking.

TLL— Transceiver Less Link. This is logic which allows the user to connect two USB transceiver interfaces together directly without the use of differential transceivers.

TM— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).

TMDS— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.

TMS— Test Mode Select

TOC— Table of Contents

TP— Tiny Page

TRM— Technical Reference Manual

TRST— Test Reset

TRX— USB Tranceiver. The USB analog driver/receiver.

TS— Transmission Start

TSHUT— Temperature Shutdown.

TTB— Translation Table Base. It points to the base of a table in physical memory that contains section and page table descriptors.

TTH— Translation Table Hierarchy

TTL— Transistor Transistor Logic

TWL— Table Walking Logic

TX— Transmit//Transmitter

TXD— Transmit Data

TXN— PHY differential transmitter (serializer) negative line

TXP— PHY differential transmitter (serializer) positive line

U

UART— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.

UE— Unrecoverable Error

UHS— Definition of SD cards with higher frequency

UI— Unit Intervals

ULPI— UTMI+ Low Pin Interface (12-pin interface standard for connecting USB core logic to a USB transceiver)

ULPM— Ultra Low Power Mode

ULPS— Ultra Low Power State

UMC— Unified Memory Controller

USB— Universal Serial Bus. An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

USSE— Universal Scalable Shader Engine

UTMI— USB 2.0 Transceiver Macrocell Interface

V

VA— Virtual Address

VBP— Vertical Back Porch

VC— Virtual Channel

VC-1— Video Codec Standart

VDMA— Video Direct Memory Access module

VESA— Video Electronics Standards Association

VFP— Vertical Front Porch

VGA— Video Graphics Array. An industry standard for video cards.

VLC— Variable Length Decoder

VLCD— Variable Length Coding and Decoding coprocessor

VLCDJ— Variable-Length Coder/Decoder for JPEG

VLD— Variable Length Coder

VLIW— Very Long Instruction Word

VMODE— Bi-level voltage control interface

VOLCON— Voltage Controller

VP— Video Port

VS— Vertical Synchronization

VSE— Vertical Sync End

VSS— Vertical Sync Start

VSW— Vertical Synchronization Pulse Width

VSYNC— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse–width defined as an integral number of lines (half–lines for interlaced mode). Also VS.

W

WB— Write Buffer

WC— Word Count

WD— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows and triggers a reset.

WDT— Watchdog Timer. See WD.

WE— Write Enable

WFI— Wait For Interrupt

WIR— Wait In Reset

WLAN— Wireless Local Area Network

WNP— Write Non-Posted

WP— Write Protect

WT— Write Through

WUGEN— Wake-Up Generator

Word16— 16 bits word

X

XIP— eXecution In Place

Y

YUV— Luminance-Bandwidth-Chrominance

e

eMMC— Embedded Multimedia Card

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have ***not*** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
