Bits	Field Name	Description	Type	Reset
31:14	RESERVED	reads return 0's	R	0x00000
13:12	DFSTRTPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
11:9	RESERVED	reads return 0's	R	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. 0 : Channel is idle. 1 : Channel is busy.	R	1
7	RESERVED	reads return 0's	R	0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter. Read 0x0: FIFO set is empty. Read 0x1: Dst FIFO contains 1 TR Read 0x2: Dst FIFO contains 2 TR Read 0x3: Dst FIFO contains 3 TR Read 0x4: Dst FIFO contains 4 TR	R	0x0
3	RESERVED	reads return 0's	R	0
2	WSACTV	Write Status Active 0 : Write status is not pending. Write status has been received for all previously issued write commands. 1 : Write Status is pending. Write status has not been received for all previously issued write commands.	R	0
1	SRCACTV	Source Active State 0 : Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). 1 : Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0
0	PROGBUSY	Program Register Set Busy 0 : Prog set idle and is available for programming. 1 : Prog set busy. User should poll for PROGBUSY equal to 0 prior to re-programming the Program Register set.	R	0

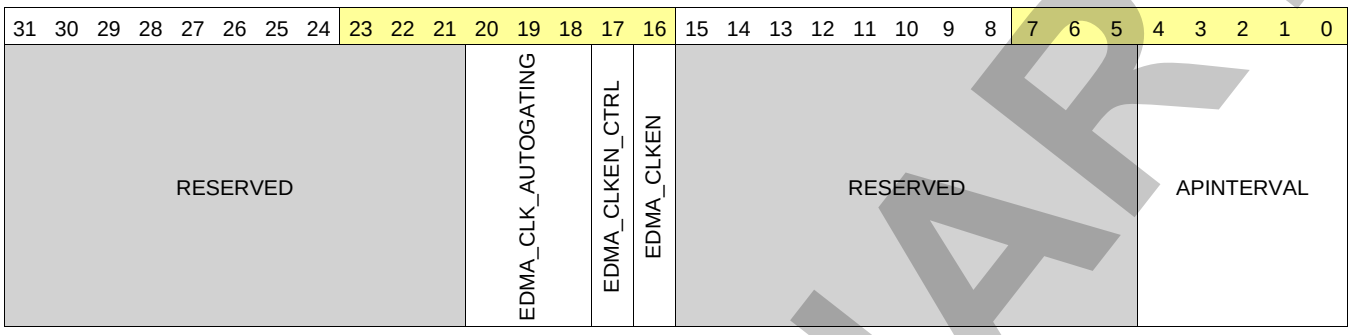
Table 5-390. SYSC_EDMA

Address Offset	0x0000 0048		
Physical Address	0x01C2 0048	**Instance**	SYSC
Description	This register allows controlling various parameters of the SCRM and SCRP local interconnects		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:18	EDMA_CLK_AUTOGATING	DMA_DSP clock autogating 0x0: DMA_DSP root clock is not autogated by hardware. 0x1: DMA_DSP root clock is autogated by hardware. [18] is for TPCC (no actual clock gating, same as IVA2.2). 19] is for TPTC0. [20] is for TPTC1.	RW	0x0
17	EDMA_CLKEN_CTRL	DMA_DSP clock control enable 0x0: DMA_DSP clock is controlled by hardware. 0x1: DMA_DSP clock is controlled by SYSC_EDMA [16] EDMA_CLKEN.	RW	0
16	EDMA_CLKEN	DMA_DSP clock enable When SYSC_EDMA_CTRL[17] EDMA_CLKEN_CTRL = 1, then: 0x0: DMA_DSP clock is disabled. 0x1: DMA_DSP clock is enabled. EDMA_CLKEN is for TPCC, TPTC0, and TPTC1.	RW	0
15:5	RESERVED	Reserved.	R	0x000
4:0	APINTERVAL	Control of the Aged Priority (priority inversion) for DMA accesses: When set to 0x0, the aged priority is disabled when set to another value. This controls how often the priority is adjusted: every APInterval cycle, the priority of the port is decreased until the associated request is accepted or the priority of the port equals 0. The priority of the port is reinitialized to the transaction priority each time a new VBUS command is generated, that is, the last one has been accepted. 0x0: Aged Priority Disabled: There is no aged priority in SCR. DMA transaction keeps the fixed priority defined internally, and has to wait for the bus to be freed by higher priority initiatorsAged Priority Disabled:	RW	0x00

Address Offset	0x0000 0100 + (0x4 * i)		
Physical Address	0x01C3 0500 + (0x4 * i)	**Instance**	SCACHE_SCTM
Description	These registers contain the control and status settings for a single counter in the module. There will be a CTCR for every counter in the module (WT: with timer)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INPSEL								RESERVED					RESTART	DBG	INT	CHNSDW	OVRFLW	IDLE	FREE	DURMODE	CHAIN	RESET	ENBL

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:16	INPSEL	Counter Timer input selection 0: Constantly asserted input that results in a free-running counter/timer 1-31: Index of event input signal selected	RW	0x00
15:11	RESERVED	Reserved.	R	0x00
10	RESTART	Restart the timer after an interval match 0: The timer stops after the first interval match. It must be manually reset by software before it starts counting again (run-once timer mode). 1: The timer immediately resets to 0 and begins incrementing again based on the current input configuration (restart timer mode).	RW	0
9	DBG	Signal debug logic on interval match 0: No debug event is generated. 1: Upon interval match, generates a debug event on the corresponding debug output event signal	RW	0
8	INT	Generate interrupt on interval match 0: No interrupt is generated. 1: Upon interval match, generates an interrupt on the corresponding interrupt output event signal	RW	0
7	CHNSDW	Counter has a shadow register for chain reads. 0: The read of the corresponding counter register returns the current value.	R	0

Bits	Field Name	Description	Type	Reset
		1: Read of the high-order counter register, simultaneously loads the current value of the 32 LSBs into a shadow register. The read of the counter register that corresponds to this counter returns the value of the shadow register. This is applicable only when the counter is chained.		
6	OVRFLW	Counter has wrapped since it was last read 0: The counter has not wrapped since the last read. 1: The counter has wrapped since the last read.	R	0
5	IDLE	Counter ignores processor IDLE state 0: The counter does not increment during IDLE state. 1: The counter continues to function during IDLE state; applicable if IDLEMODE = 1.	RW	0
4	FREE	Counter ignores processor debug halt state 0: The counter does not increment (decrement) during the debug halt state. 1: The counter continues to function during debug halt state.	RW	0
3	DURMODE	Counter is in duration or occurrence mode 0: The counter operates in event mode. The counter increments by 1 each time a rising edge is seen on the designated input event signal. 1: The counter operates in duration mode. The counter increments every time a clock cycle is seen and the corresponding input event signal is asserted.	RW	0
2	CHAIN	Counter is chained to an adjacent counter 0: The counter is not chained. 1: Reserved	RW	0
1	RESET	Counter reset control 0: No effect 1: The corresponding counter is reset to the initial value and the OVERFLW bit is cleared. It continues to function if it is still enabled.	RW	0
0	ENBL	Counter enable control 0: The counter does not increment. 1: The counter increments as configured.	RW	0

IVA Subsystem

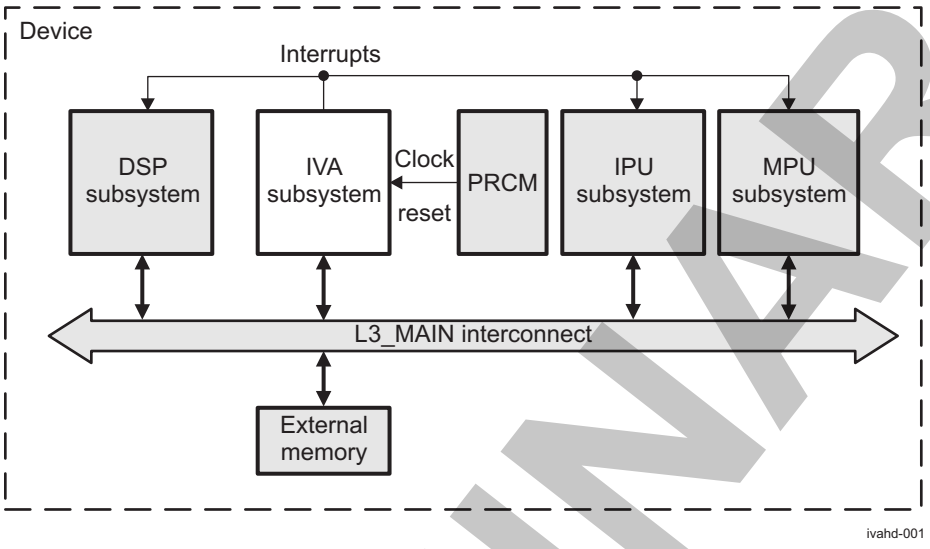
This chapter describes the IVA subsystem in the multimedia device.

Topic **Page**

6.1 IVA Overview

The IVA is the image and video imaging hardware accelerator subsystem. Figure 6-1 shows the IVA subsystem in the device.

Figure 6-1. IVA in the Device



The IVA supports resolutions up to 1080 p/i with full performance of 60 fps (or 120 fields), achievable for encode or decode only (not for simultaneous encode and decode). The IVA subsystem supports the following coder/decoder (codec) standards natively; that is, all functions of standards are accelerated (without intervention of the digital signal processor [DSP]):

- H.264: BP/MP/HP encode and decode
- H.264: Fast profile/RCDO encode and decode
- MPEG-4: SP/ASP encode/decode (no support for GMC)
- DivX 5.x and higher encode/decode (no lower version; for example, 3.11 and 4.x)
- H.263: Profile 0 and 3 for decode, profile 0 for encode
- Sorenson Spark: V0 and V1 decode (no encode support)
- MPEG-2 SP/MP encode/decode
- MPEG-1 encode/decode
- VC-1/WMV9/RTV: SP/MP/AP encode and decode
- On2™ VP6/VP7 decode
- RealVideo® 8/9/10 decode
- AVS 1.0 encode and decode
- JPEG (also MJPEG) baseline encode/decode
- H.264 annex G (SVC) scalable baseline profile to 480p–720p30
- H.264 annex H (MVC) up to 720p30

The IVA subsystem is composed of:

- A primary sequencer, including its memories and an imaging controller: ICONT1
- A video direct memory access (VDMA) processor, which can be used as a secondary sequencer: ICONT2
- A VDMA engine: DMA_IVA
- An entropy codec: ECD3
- A motion compensation engine: MC3
- A transform and quantization calculation engine: CALC3

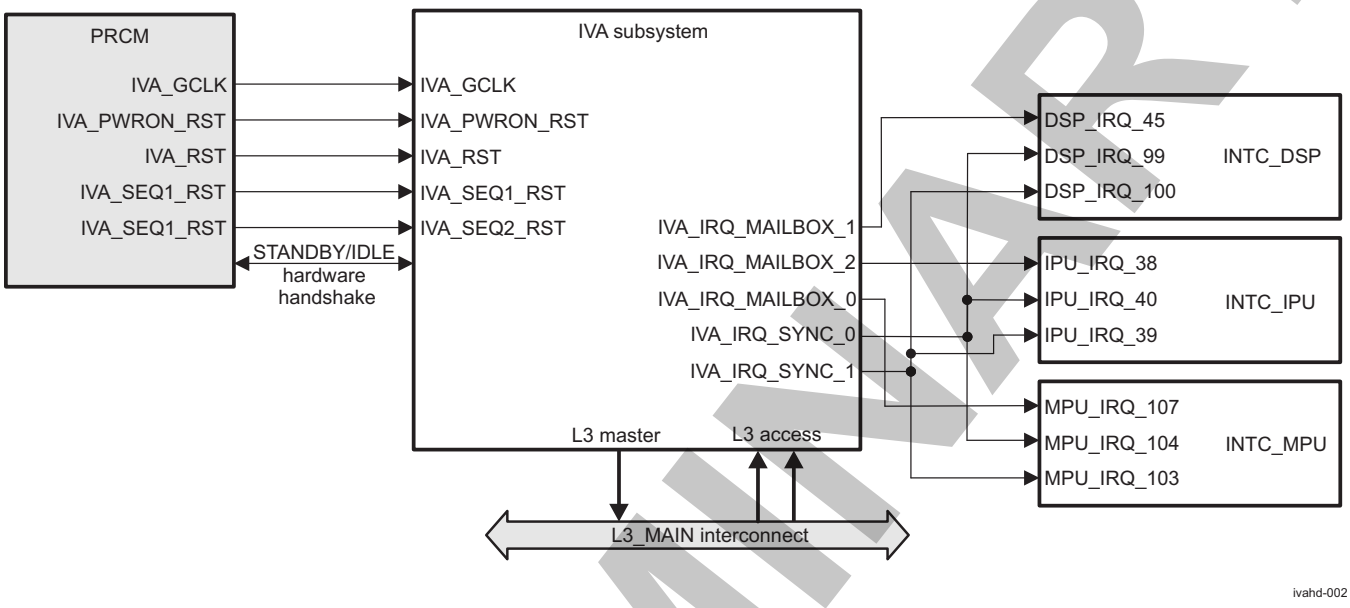
- A loop filter acceleration engine: ILF3
- A motion estimation acceleration engine: IME3
- An intraprediction estimation engine: IPE3
- Shared level 2 (L2) interface and memory
- Local interconnect (L4_IVA)
- A message interface for communication between SYNCBOXes
- Mailbox
- A debug module for trace event and software instrumentation: SMSET

6.1.1 IVA Integration

This section describes the IVA in the device, including information about clocks, resets, and hardware requests.

Figure 6-2 shows the IVA integration.

Figure 6-2. IVA Integration



NOTE: For more information about the STANDBY/IDLE hardware handshake and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in *Chapter 3, Power, Reset, and Clock Management*.

Table 6-1 through Table 6-3 summarize the integration of the module in the device.

Table 6-1. IVA Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IVA	PD_IVA	L3_MAIN

Table 6-2. IVA Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
IVA	IVA_GCLK	IVA_GCLK	PRCM	IVA clock (functional and interface)
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
IVA	IVA_PWRON_RST	IVA_PWRON_RST	PRCM	IVA power-on reset (POR)
IVA	IVA_RST	IVA_RST	PRCM	IVA global reset (all logic is reset)
IVA	IVA_SEQ1_RST	IVA_SEQ1_RST	PRCM	ICONT1 reset
IVA	IVA_SEQ2_RST	IVA_SEQ2_RST	PRCM	ICONT2 reset

Table 6-3. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
IVA	IVA_IRQ_MAILBOX_0	MPU_IRQ_107	INTC_MPU	IVA mailbox user 0 interrupt
IVA	IVA_IRQ_SYNC_0	MPU_IRQ_104	INTC_MPU	Sync interrupt from ICONT1
IVA	IVA_IRQ_SYNC_1	MPU_IRQ_103	INTC_MPU	Sync interrupt from ICONT2
IVA	IVA_IRQ_MAILBOX_1	DSP_IRQ_45	INTC_DSP	IVA mailbox user 1 interrupt
IVA	IVA_IRQ_SYNC_0	DSP_IRQ_99	INTC_DSP	Sync interrupt from ICONT1
IVA	IVA_IRQ_SYNC_1	DSP_IRQ_100	INTC_DSP	Sync interrupt from ICONT2
IVA	IVA_IRQ_MAILBOX_2	IPU_IRQ_38	INTC_IPU	IVA mailbox user 2 interrupt
IVA	IVA_IRQ_SYNC_0	IPU_IRQ_40	INTC_IPU	Sync interrupt from ICONT1
IVA	IVA_IRQ_SYNC_1	IPU_IRQ_39	INTC_IPU	Sync interrupt from ICONT2

NOTE:

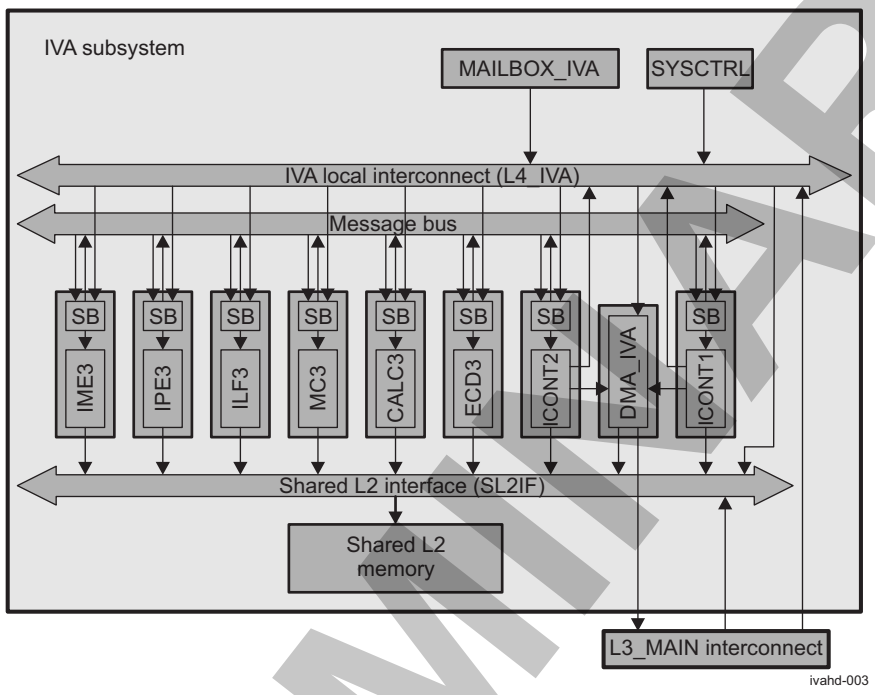
- For more information about the mailbox interrupt, see Section 19.1.

6.1.2 IVA Functional Description

6.1.2.1 IVA Block Diagram

Figure 6-3 is a block diagram of the IVA subsystem.

Figure 6-3. IVA Block Diagram



NOTE: SB stands for SYNCBOX.

NOTE: IPE3, MC3, CALC3, and ECD3 include a load and store engine (LSE), which is the same in each of these modules.

6.1.2.1.1 SYNCBOX

The SYNCBOX is a configurable module that schedules all embedded hardware modules within the IVA subsystem. The SYNCBOX handles all aspects of synchronization, data sharing, and parameters passing between accelerators. Also, the SYNCBOX permits the use of asynchronous messages.

6.1.2.1.2 ICONTs

The ICONT module is an ARM968E-S™-based microcontroller with 32 KiB of instruction tightly coupled memory and 16 KiB of data tightly coupled memory. It includes an interrupt controller (INTC), a local data mover, its own SYNCBOX module for synchronizing tasks with other modules, and its associated SYNCBOX handler.

Two identical instances of ICONT (ICONT1 and ICONT2) are present in the IVA subsystem. They can typically be used to perform high-level processing (at frame and slice levels), control bounding box computation at the macroblock level, and process other DMA_IVA tasks.

Software can map process equally on either ICONT module.

6.1.2.1.3 DMA_IVA

The DMA_IVA is a DMA engine that performs data transfers between external memories and shared L2 memory, and also memory-copies inside the SL2 and external memory.

6.1.2.1.4 IME3

The IME3 accelerator performs motion estimation in encode processing. The IME3 embeds its own SYNCBOX module for synchronizing tasks with other modules.

The IME3 compares a current macroblock to a reference area and provides area in a reference region (in terms of offsets) that differs least from the current macroblock. IME3 can also interpolate a block with half- or quarter-pixel precision, thus producing 4 (half pixel) or 16 (quarter pixel) interpolated blocks from the original block. Additionally, the IME3 supports searching for the best matching block within the interpolated planes.

6.1.2.1.5 IPE3

The IPE3 accelerator performs intraprediction estimation in encode. The IPE3 embeds its own SYNCBOX module for synchronizing tasks with other modules and an LSE to transfer data from internal memories to shared L2 memory.

The IPE3 supports two modes, depending on the video standard:

- Spatial intraprediction estimation for H.264 and AVS. It creates intraprediction macroblocks with given intramodes from the original macroblock and provides cost estimation between the original macroblock and each pseudo intraprediction macroblock, and then chooses a mode with the smallest cost to recommend as an optimal intraprediction mode.
- Spatial activity for MPEG-1/-/2/-4 and VC-1. It calculates the spatial activity of the original luminance samples with the specified block size. This mode provides information on the original Luma pixels. The values can be used to decide the coding parameters of the macroblock, such as the coding mode and quantization parameter.

6.1.2.1.6 MC3

The MC3 accelerator performs motion compensation. The MC3 embeds its own SYNCBOX module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

The MC3 creates an interprediction macroblock with given motion vectors and modes from the reference data.

6.1.2.1.7 CALC3

The CALC3 accelerator performs forward and inverse transform and quantization calculation. The CALC3 embeds its own SYNCBOX module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

The CALC3 can perform transform and inverse transform, Q/iQ, and DC/AC prediction.

6.1.2.1.8 ILF3

The ILF3 accelerator performs deblocking filtering and boundary strength computation. The ILF3 embeds its own SYNCBOX module for synchronizing tasks with other HWAs.

6.1.2.1.9 ECD3

The ECD3 accelerator encodes and decodes the stream. The ECD3 embeds its own SYNCBOX module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

The ECD3 supports Huffman codes and arithmetic codes.

For encode, the ECD3 encodes the macroblock information and residual data into the bitstream. For decode, the ECD3 decodes the bitstream and recovers the macroblock information and residual data.

6.1.2.1.10 SL2 Interface

The shared L2 interface (SL2IF) is an arbitrator that lets 18 initiators access an interleaved set of eight memory banks.

The SL2IF has two sets of interfaces:

- Eighteen 128-bit interfaces for accesses from modules to shared L2 memories
- Eight 128-bit memory interfaces for direct accesses to the memory bank

6.1.2.1.11 Message Bus

The message bus is an arbitrator that allows eight initiators to access eight targets. It is used to dispatch messages generated by the SYNCBOX of the different IPs.

6.1.2.1.12 IVA Local Interconnect (L4_IVA)

The IVA local interconnect provides connectivity between:

- One external host interconnect (L3_MAIN)
- Two local sequencers (ICONT1 and ICONT2)
- Video hardware accelerators (IME3, ILF3, ECD3, CALC3, MC3, IPE3)
- Video DMA engine (DMA_IVA)
- Local modules (mailbox and sysctrl)

6.1.2.1.13 MailBox

The mailbox supports 2-way communication between two hosts through an interrupt. It allows software to establish a communication channel between processors through a set of registers and associated interrupt signals by sending and receiving messages.

The mailbox embedded inside the IVA subsystem implements a 2-way communication between three external users and one internal user. This communication is ensured through three pairs of mailboxes and a 4-message deep FIFO for each message queue.

NOTE: The internal user is one of the two ICONTs. ICONT1 and ICONT2 are connected on a shared interrupt line. The choice between ICONT1 and ICONT2 is done by masking a mailbox interrupt on ICONT1 or ICONT2. ICONT1 and ICONT2 can access the mailbox through the IVA local interconnect.

6.1.2.1.14 IVA System Control

The SYSCTRL module of the IVA:

- Controls clocks to modules, upon software control and power handshaking state
- Controls power handshaking in the power, reset, and clock management (PRCM) module
- Provides the status of the previously mentioned operation
- Supports synchronization through external event

6.1.2.2 IVA Power Management

Table 6-4 lists the power-management features available for the IVA module.

NOTE: For descriptions of the IdleMode and StandbyMode features, see Module-Level Clock Management, in *Power, Reset, and Clock Management* chapter.

Table 6-4. Local Power-Management Features

Feature	Registers	Description
Slave- idle modes	IVAHD_SYSCONFIG[3:2] IDLEMODE	No-idle and smart-idle modes are available.
Master standby modes	IVAHD_SYSCONFIG[5:4] STANDBYMODE	No-standby and smart-standby modes are available.

6.1.2.3 IVA Memory Mapping

ARM968E-S (of each ICONT) can address a 4-GiB memory space. The lower address range (8 MiB) is allocated to its level 1 (L1) memories (ITCM and DTCM). The higher address range is allocated to L2 memories. Access to L2 memories can be buffered or nonbuffered, depending on the selected address range. For more information, see the *ARM968E-STM Technical Reference Manual*.

In Table 6-5, the address spaces of buffered regions are shown as EXT_BUF, and the address spaces of nonbuffered regions are listed as EXT_NBUF.

Table 6-5. ICONT Memory Mapping Regions

Region Name	Address		Size	Description
	Start	Stop	(KiB)	
ITCM	0x0000 0000	0x0000 FFFF	64	ITCM memory aliased 64 times
	...	...	...	
ITCM (alias 63)	0x003F 0000	0x003F FFFF	64	
DTCM	0x0040 0000	0x0040 7FFF	32	DTCM memory aliased 128 times
	...	...	...	
DTCM (alias 127)	0x007F 8000	0x007F FFFF	32	
EXT_BUF	0x0080 0000	0x008F FFFF	1024	External buffered region
	...	...	...	
EXT_BUF (alias 247)	0x0FF0 0000	0x0FFF FFFF	1024	External buffered region
EXT_NBUF (alias)	0x1000 0000	0x100F 0000	1024	External nonbuffered region
	...	...	...	
EXT_NBUF (alias)	0x1FF0 00000	0x1FFF FFFF	1024	External nonbuffered region

	...	...	...	
EXT_NBUF (alias)	0xFFF0 0000	0xFFFF FFFF	1024	External nonbuffered region

Each of these regions (EXT_BUF and EXT_NBUF) has the same memory map, aliased throughout the address range of the region. Table 6-6 lists ICONT1 memory mapping, and Table 6-7 lists ICONT2 memory mapping. Offsets shown are from the start of the region.

(1) ICONT2 private access to its own registers
(2) ICONT2 self-access to its own registers

NOTE: Definitions of ICONT self-access and private access:

- Self-access: Direct access of ICONT to its own memory-mapped registers (MMRs) (reduced latency); that is, without using the IVA local interconnect. Internal ICONT configuration (CFG) registers are not visible. Only IRQ, DM, and SBH registers can be accessed.
- Private access: Access through IVA local interconnect. By default, all ICONT accesses described in Table 6-6 and Table 6-7 are private, except for corresponding self-access. In case of ICONT private access to its own registers, internal ICONT CFG registers are visible (on top of IRQ, DM, and SBH).

NOTE: Examples of start address:

- Buffered region: 0x0080 0000, 0x0090 0000, 0x00A0 0000, 0x0FF0 0000, 0x2000 0000, and so forth.
- Nonbuffered region: 0x1000 0000, 0x1010 0000, 0x1020 0000, 0x1FF0 0000, 0x3000 0000, and so forth.

Table 6-8 lists the IVA modules and memory addresses for the L3_MAIN access.

6.1.3 IVA Register Manual

CAUTION

This section provides information about ICONT memory mapping (private access). This information represents only the address offsets from the start of relevant buffered (EXT_BUF) or nonbuffered (EXT_NBUF) regions. For more information, see Section 6.1.2.3, *IVA Memory Mapping*.

6.1.3.1 IVA Instance Summary

Table 6-9 shows the IVA instance summary.

Table 6-9. IVA Instance Summary

Module Name	Base Address (L3_MAIN Interconnect)	Base Address (ICONT Private Access)	Size
SYSCTRL	0x5A05 A400	0x000D A400	1 KiB

NOTE: Private access is an access through the IVA local interconnect without using the L3_MAIN interconnect.

6.1.3.2 SYSCTRL Registers

6.1.3.2.1 SYSCTRL Register Summary

Table 6-10 lists the mapping summary for the SYSCTRL registers.

CAUTION

SYSCTRL registers are limited to 32-bit access; 16- and 8-bit accesses are not allowed and can corrupt register content.

Table 6-10. SYSCTRL Registers Mapping Summary

Dual Cortex-M4 IPU Subsystem

This chapter describes the dual Cortex-M4 image processor unit (IPU) subsystem.

Topic **Page**

7.1 Dual Cortex-M4 IPU Subsystem Overview

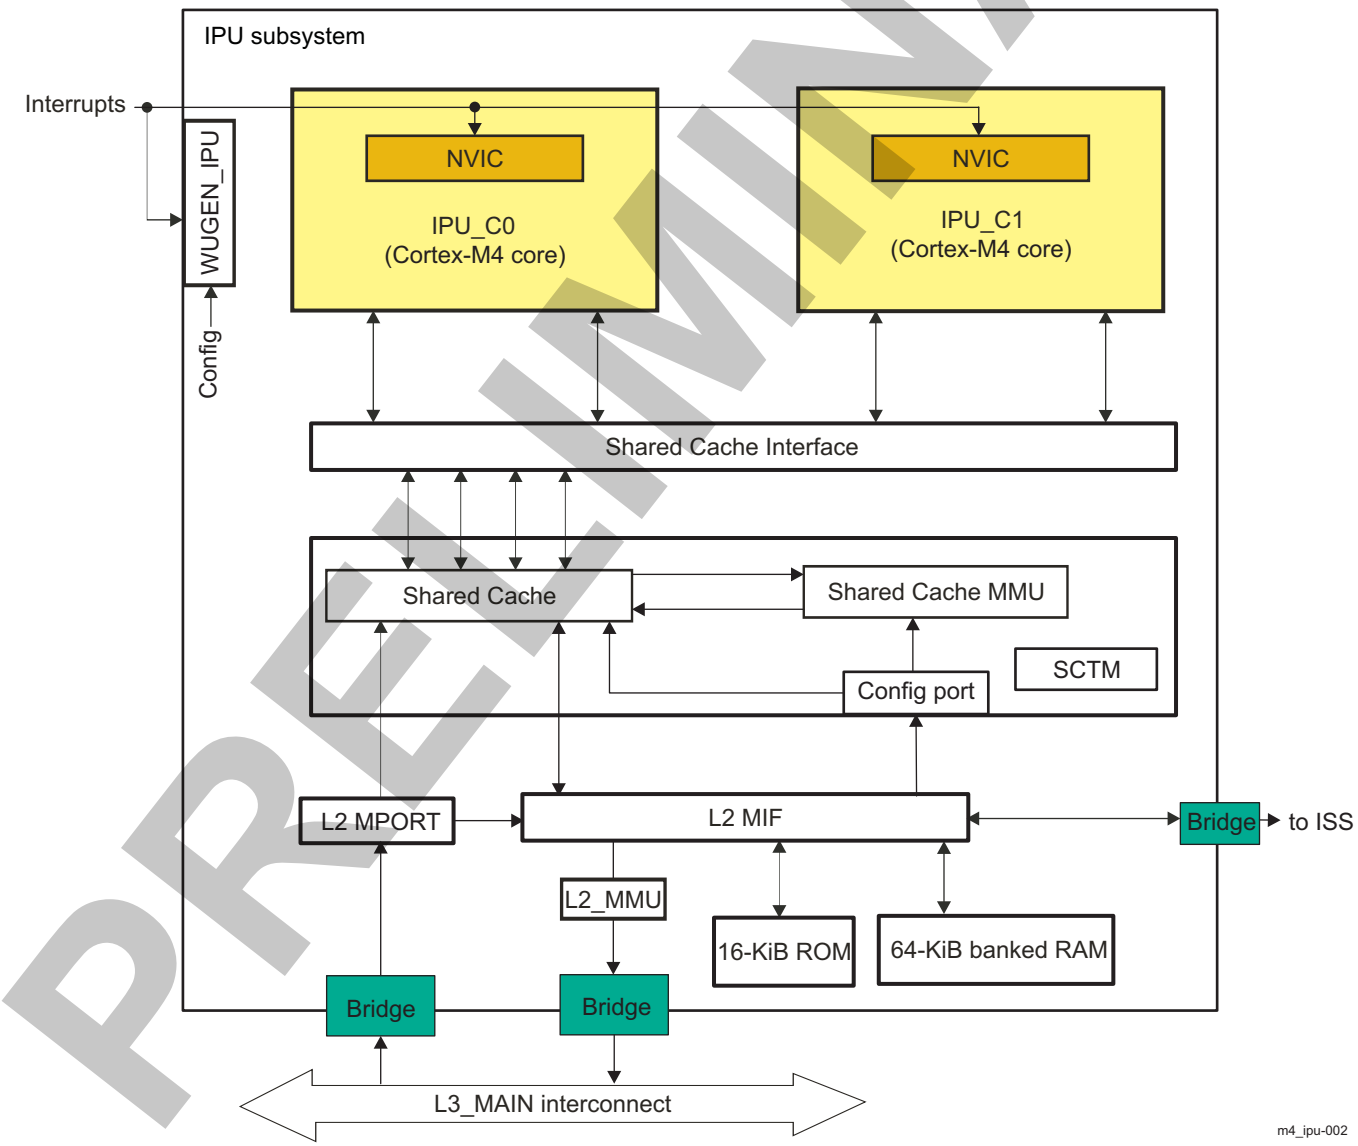
7.1.1 Introduction

The dual Cortex™-M4 image processor unit (IPU) subsystem is used primarily to configure and control the imaging subsystem (ISS), but it can also manage other tasks. It contains two ARM® Cortex-M4 processors (IPUC0 and IPU_C1) that share a common level 1 (L1) cache (called shared cache [SCACHE_IPU]). The integrated interrupt handling of the IPU subsystem allows it to function as an efficient control unit.

NOTE: The two Cortex-M4 cores are completely homogeneous to one another. Any task possible using one Cortex-M4 core is also possible using the other Cortex-M4 core. Both Cortex-M4 cores can be used to run RTOS and control ISP, SIMCOP, DSS, IVA, etc., as well as other tasks. It is software responsibility to distribute these tasks between each Cortex-M4 core for optimal performance.

Figure 7-1 is a high-level block diagram of the IPU subsystem.

Figure 7-1. IPU Subsystem Overview



7.1.2 Features

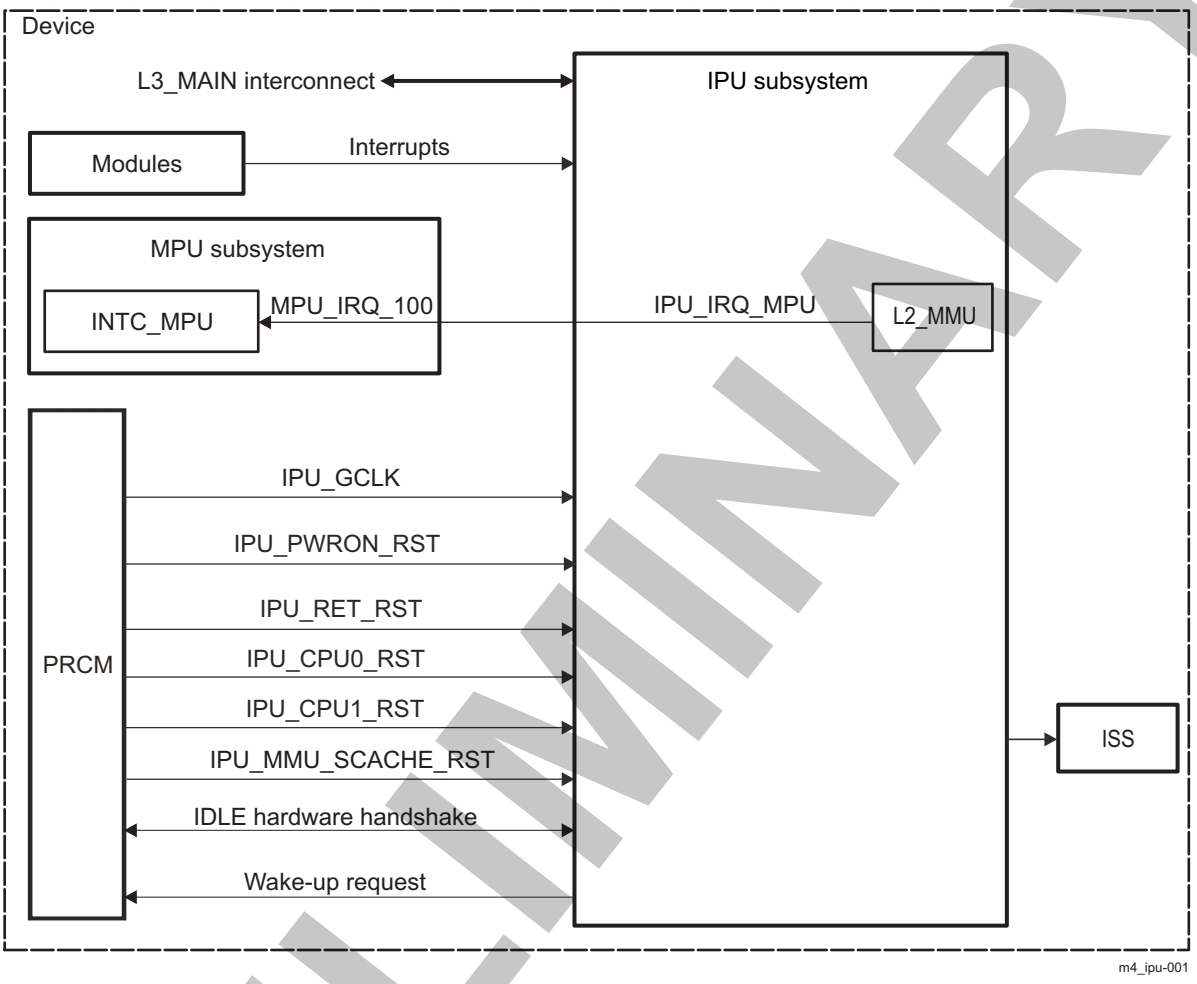
The IPU subsystem integrates the following:

- Two ARM Cortex-M4 microprocessors (IPU_C0 and IPU_C1):
  - ARMv7-M and Thumb®-2 instruction set architecture (ISA)
  - ARMv6 SIMD and digital signal processor (DSP) extensions
  - Single-cycle MAC
  - Integrated nested vector interrupt controller (NVIC) (also called INTC_IPU)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Shared cache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- Level 2 (L2) master interface (MIF) splitter for access to memory or configuration port
- Configuration port: Used for shared cache maintenance and shared cache memory management unit (SCACHE_MMU_IPU) configuration
- Shared cache:
  - 32 KiB divided into 16 banks
  - 4-way
  - Cache configuration lock/freeze/preload
  - Internal MMU:
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- Subsystem counter timer module (SCTM)
- On-chip ROM (ROM_IPU) and banked RAM (RAM_IPU) memory
- Emulation/debug: Emulation feature embedded in Cortex-M4
- L2_MMU: 32 entries with table walking logic
- Wake-up generator (WUGEN_IPU): Generates wake-up request from external interrupts
- Power management:
  - Local power-management control: Configurable through the WUGEN_IPU registers.
  - Three sleep modes supported, controlled by the local power-management module.
  - IPU is clock-gated in all sleep modes.
  - INTC_IPU interrupt interface stays awake.

7.2 Dual Cortex-M4 IPU Subsystem Integration

Figure 7-2 shows the signals that interface with other modules.

Figure 7-2. IPU Subsystem Integration Overview



NOTE: Some debug, trace, and emulation features are implemented in the IPU subsystem. This chapter includes only the clock/reset inputs and power-management aspects for these features.

Table 7-1 through Table 7-3 summarize the integration of the module in the device.

Table 7-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IPU	PD_CORE	L3_MAIN

Table 7-2. Hardware Requests

	Interrupt Requests			
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
L2_MMU	IPU_IRQ_MPU	MPU_IRQ_100	INTC_MPU	L2_MMU fault interrupt

Table 7-3. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
IPU	IPU_GCLK	IPU_GCLK	PRCM module	Interface and functional clock
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
IPU	IPU_PWRON_RST	IPU_PWRON_RST	PRCM module	Power-on reset, used to reset the whole IPU subsystem
	IPU_RET_RST	IPU_RET_RST	PRCM module	Retention reset to few retention logic inside the SCACHE_IPU
	IPU_CPU0_RST	IPU_CPU0_RST	PRCM module	Reset signal to IPU_C0
	IPU_CPU1_RST	IPU_CPU1_RST	PRCM module	Reset signal to IPU_C1
	IPU_MMU_SCACHE_RST	IPU_MMU_SCACHE_RST	PRCM module	Reset signal to the SCACHE_IPU and the L2_MMU

For more information about clocks, resets, and power domains, see Chapter 3, *Power, Reset, and Clock Management*.

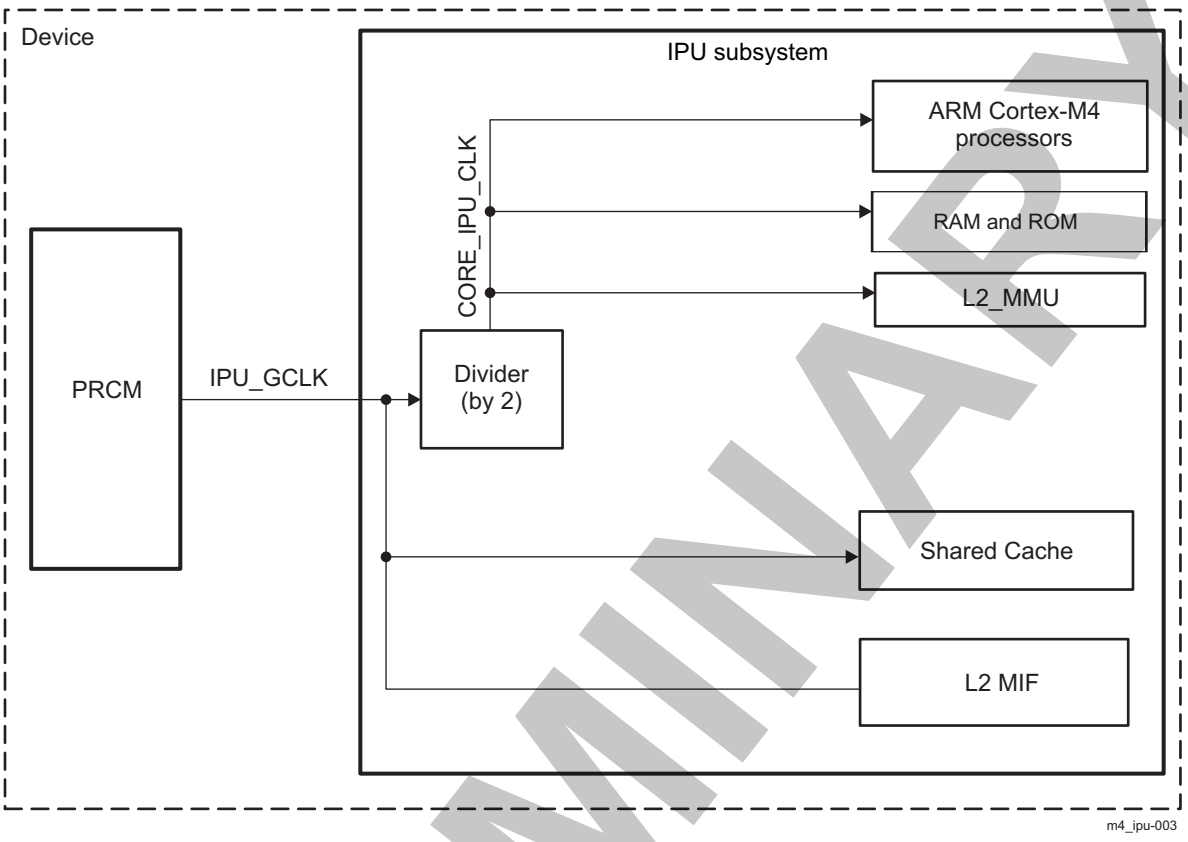
7.2.1 Dual Cortex-M4 IPU Subsystem Clock and Reset Distribution

7.2.1.1 Clock Distribution

The IPU subsystem receives only one clock, IPU_GCLK, which is divided by 2 (CORE_IPU_CLK) for each ARM Cortex-M4 processor, the ROM_IPU and RAM_IPU memory, and the L2_MMU. The SCACHE_IPU and the L2 MIF are directly clocked by the IPU_GCLK, without any division. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

Figure 7-3 shows the clocking scheme of the IPU subsystem.

Figure 7-3. IPU Subsystem Clocking Scheme



7.2.1.2 Reset Distribution

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two ARM Cortex-M4 processors and the rest of the IPU subsystem be reset independently. These three reset signals are: IPU_CPU0_RST, IPU_CPU1_RST, and IPU_MMU_SCACHE_RST. The ARM Cortex-M4 processors must come out of reset one at a time:

- At IPU_CPU0_RST, IPU_C0 comes out of reset, but IPU_C1 is held in reset.
- IPU_C0 controls the reset for IPU_C1 (through the PRCM RM_IPU_RSTCTRL[1] RST2 bit).

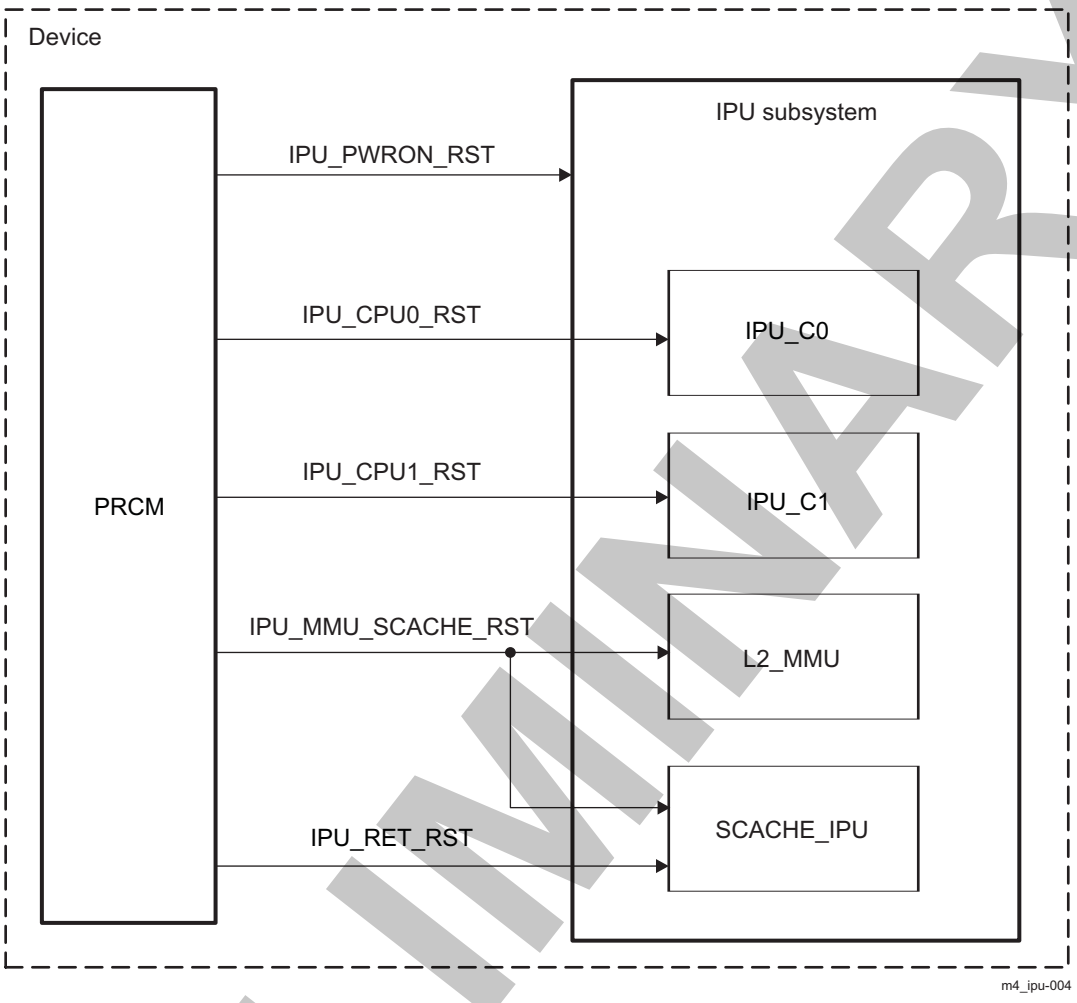
Because IPU_C0 controls the reset for IPU_C1 (through the PRCM registers), the code running on IPU_C0 decides the mode of operation, whether it is:

- Mode 1: One ARM Cortex-M4 processor is running, and the other processor is held on reset.
- Mode 2: The two ARM Cortex-M4 processors are running.

This decision of which mode to use is driven by the use case. If the software partitioning and performance requirement for a use case requires two Cortex-M4 processors to run simultaneously, the user must go to mode 2. If IPU_C1 is not required for a particular use case, the user can remain in mode 1.

Figure 7-4 shows the reset scheme of the IPU subsystem.

Figure 7-4. IPU Subsystem Reset Scheme



7.3 Dual Cortex-M4 IPU Subsystem Functional Description

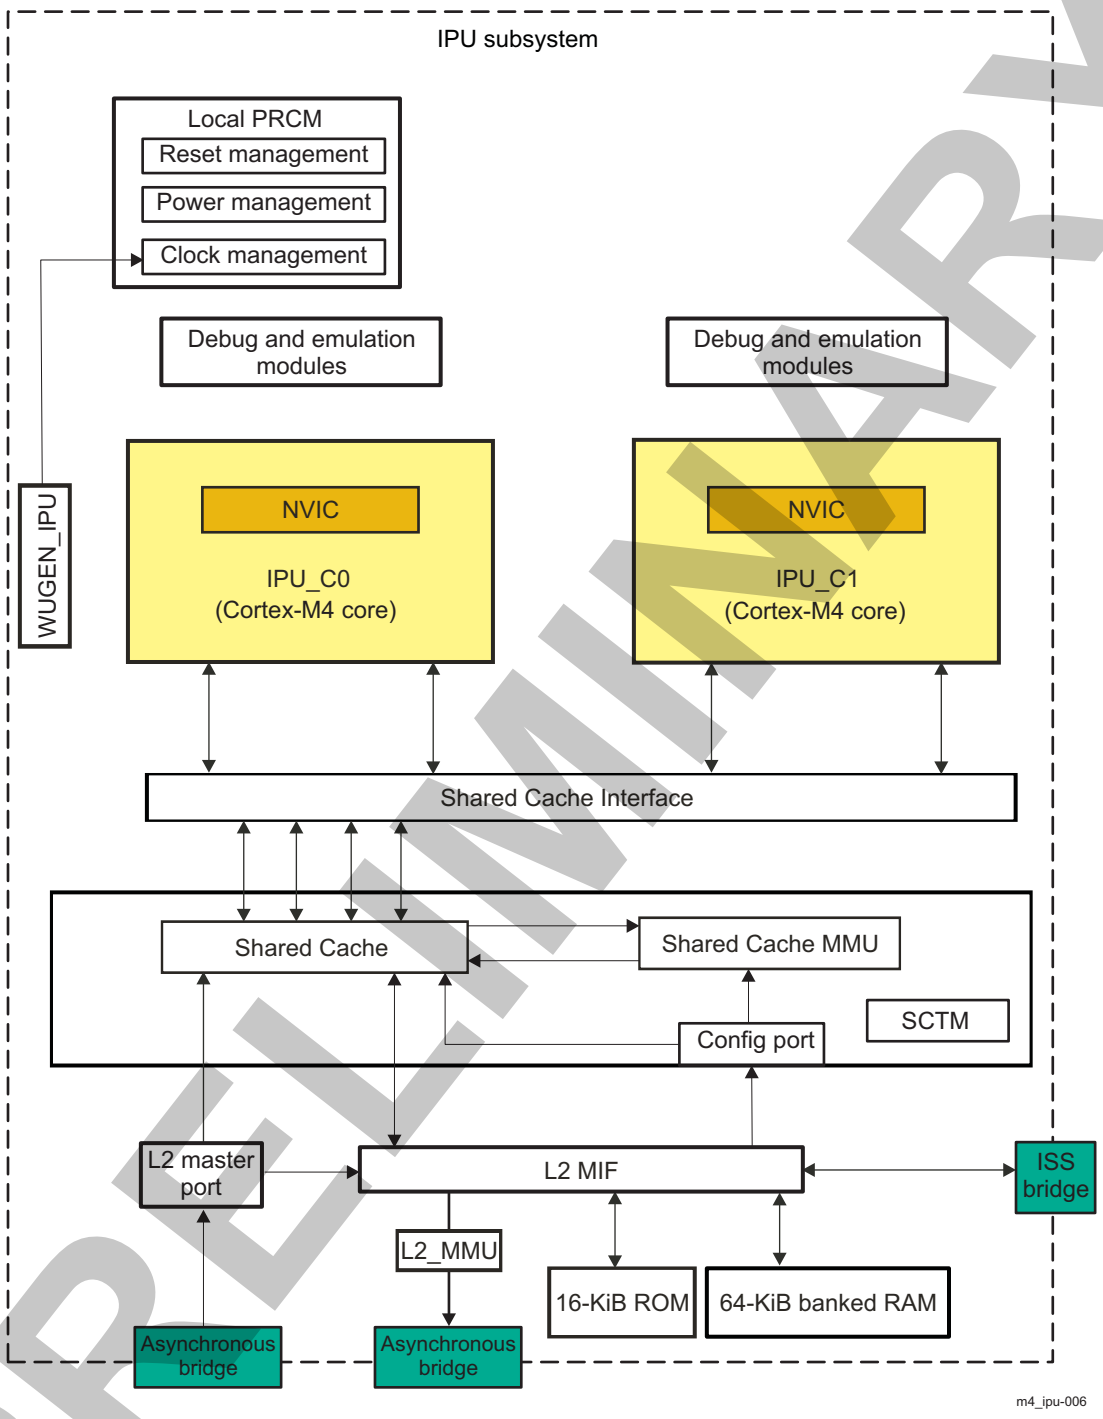
7.3.1 IPU Subsystem Block Diagram

The IPU subsystem integrates the following group of submodules:

- Two ARM Cortex-M4 processors: Two cores (r0p1 revision), IPU_C0 and IPU_C1. For a description of the ARM Cortex-M4 processor, see the *ARMCortex-M4 Technical Reference Manual*, available at infocenter.arm.com/help/index.jsp.
- Interrupt controller (INTC_IPU): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M4 processor receives the same interrupts, except for a few internal interrupts. Every IRQ line is shared between the two ARM processors. By properly configuring the INTC_IPU registers inside each ARM processor, it can be ensured that the shared IRQ is taken by only one of the ARM processors (for more information, see Chapter 17, *Interrupt Controllers*).
- SCACHE_IPU interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the ARM Cortex-M4 processors (two for each processor).The instruction and data connections from each ARM Cortex-M4 are multiplexed, but the ARM Cortex-M4 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cacheability is provided through the MMU inside the cache.
- SCACHE_IPU: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- SCACHE_MMU_IPU: Provides the multiple access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the SCACHE_MMU_IPU is done only under privilege mode. The SCACHE_MMU_IPU can be programmed by the dual Cortex-A15 microprocessor unit (MPU) subsystem through the IPU subsystem slave port.
- SCTM: Embedded in the SCACHE_IPU
- Interconnect configuration port: Cache maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the SCACHE_MMU_IPU. Interconnect accesses are generated from the L2 MIF.
- L2_MMU: Provides address translation for all the accesses done from the IPU subsystem to the level 3 (L3_MAIN) interconnect. The L2_MMU can be programmed by the MPU subsystem through the IPU subsystem slave port.
- L3_MAIN interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the IPU subsystem, see Chapter 2, *Memory Mapping*.
- On-chip ROM_IPU and banked RAM_IPU memory. The ROM_IPU memory is used for boot/initialization purposes. For more information about the initialization of the device, see Chapter 28, *Initialization*. The address range of the ROM_IPU memory is from 0x5500_0000 to 0x5500_3FFF. The address range of the on-chip banked RAM_IPU memory is from 0x5502_0000 to 0x5502_FFFF.

Figure 7-5 is a block diagram of the IPU subsystem.

Figure 7-5. IPU Subsystem Block Diagram



7.3.2 Power Management

NOTE: For information about source clock gating and for a description of the sleep/wake-up transitions, see Module-Level Clock Management in Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.1 Local Power Management

The user can configure the local power management through the STANDBY_CORE_SYSCONFIG, IDLE_CORE_SYSCONFIG, and WUGEN_IRQ_EN registers. The user can:

- Configure the different standby modes (the default is smart wake-up standby mode) through the STANDBY_CORE_SYSCONFIG[1:0] STANDBYMODE bit field
- Configure the different idle modes (the default is smart wake-up idle mode) through the IDLE_CORE_SYSCONFIG[1:0] IDLEMODE bit field
- Control which interrupts will cause a wakeup by appropriately configuring the WUGEN_MEVT0 and WUGEN_MEVT1 registers (the default is ALL_MASKED)

The IPU subsystem provides three sleep modes:

- On mode: Sleep on exit (wait for the interrupt service routine [ISR] to complete)
- Sleep mode: Wait for interrupt to wake up the processor
- Deep-sleep mode: Long duration sleep; phase-locked loop (PLL) can be stopped

During sleep mode, the system clock can be stopped, but the free-running clock input must still be running to allow the processor to be wakened by an interrupt or an event. The sleep modes are invoked by wait for interrupt (WFI) or wait for event (WFE) instructions. The processor clock is automatically stopped, waiting for an interrupt or an event. Deep-sleep mode also stops the processor clock, but this can also be supported by the PRCM module. A combined signal is generated from the two Cortex-M4 processors in deep-sleep mode to initiate another power state and let the PRCM module handle the next power states. At this time, software must ensure that all SCACHE_IPU background operations (for example, maintenance) are complete.

Table 7-4 describes local clock gating.

Table 7-4. Local Clock Gating

Cortex-M4 CPU Mode	IPU_C1 On	IPU_C1 Sleep	IPU_C1 Deep Sleep
IPU_C0 On	On	Functional clock 2 stopped locally	Functional clock 2 stopped locally
IPU_C0 Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Functional clock 1 and clock 2 stopped locally
IPU_C0 Deep Sleep	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Standby request to power-management module

7.3.2.2 Power Domains

The IPU subsystem is divided into two power domains (PD_CORE and PD_WKUP), which are controlled by the PRCM module (see Section 7.3.2.3, *Voltage Domain*).

The PD_CORE power domain is the main power domain and includes all the IPU subsystem components (two ARM Cortex-M4 processors, SCACHE_IPU, ROM_IPU and RAM_IPU memories, and emulation\debug modules) except the WUGEN_IPU.

The PD_COREAON power domain is an always-on power domain. The PD_COREAON power domain contains the WUGEN_IPU, which generates a wake-up request from external interrupts. By this separate PD_COREAON power domain, the wake-up request can be generated even when the PD_CORE power domain is in OFF or RET state.

For information about the PD_CORE and PD_COREAON power domains, see Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.3 Voltage Domain

The IPU subsystem is composed of two voltage domains. Each voltage domain can control individual voltage levels:

- VDD1: Cortex-M4 cores, SCACHE_IPU/MMU, WUGEN_IPU
- VDD_array: All memories array

The PD_COREAON and PD_CORE power domains are in the same voltage domain, the CORE voltage domain (CORE_VD).

For information about the physical power domains, see Chapter 3, *Power, Reset, and Clock Management*.

7.3.2.4 Power States and Modes

Table 7-5 lists the different power modes and the expected states for each power domain.

Table 7-5. IPU Subsystem Power Modes

		Activity			Power Status	
	Functional Domain	Core		IPU subsystem	PD_DSP Power Domain	PD_WKUPAON Power Domain
	Modules included	IPU_C0	IPU_C1	WUGEN_IPU		
Power modes	Active	Active	Active	Active	ON	ON
	IPU_C0 idle	Idle	Active	Active	ON	ON
	IPU_C1 idle	Active	Idle	Active	ON	ON
	Core standby	Idle	Idle	Active	ON	ON
	Full idle	Idle	Idle	Idle	ON	ON
	CSWR	Idle	Idle	Idle	ON/LOWV	ON/LOWV
	OSWR	Idle	Idle	Idle	RET	ON
	Power off	Idle	Idle	Idle	OFF	OFF

Table 7-6 lists the power mode transitions in the IPU subsystem.

Table 7-6. Power Mode Transitions

	Active	IPU_C0 Idle	IPU_C1 Idle	Standby	Full-Idle	Retention	Power Off
Active		WFE/WFI instruction	WFE/WFI instruction				
IPU_C0 idle	Events/ interrupts			Deep sleep			
IPU_C1 idle	Events/ interrupts			Deep sleep			
Standby	Wake-up IRQ				L1/L2/ WUGEN_IPU functional domain idle		
Full idle	Wake-up IRQ			Wake-up (through interconnect)		PRCM module	PRCM module
CSWR/OSWR					PRCM module or wakeup		PRCM module
Power off					PRCM module or wakeup	PRCM module	

The different power modes and their features are:

- Active mode: All function domains are operable.
- IPU_C0 and IPU_C1 idle mode:
  - Only the CPU core is idled (when running WFE/WFI instructions).
  - Only one Cortex-M4 core can be in this mode. Interrupts or events can waken the core.
  - Can go into sleep or deep-sleep mode. Potentially, both cores can be in sleep mode.
  - When both cores are in deep-sleep mode, a standby request is sent to the PRCM module.
  - Software must ensure that all SCACHE_IPU background operations (for example, maintenance) are complete before the PRCM module asserts an IdleReq. For more information, see Chapter 5, *DSP*, Section 5.4.2.2.3.1, *Direct Maintenance of Caches*.

- Core standby mode
  - Both cores in the CORE functional domain are in idle mode (an interrupt cannot wake up either of the cores).
  - The PRCM module must have acknowledged its acceptance by an MWait signal.
  - After this handshake, all power management is under the control of the PRCM module.
- Full-idle mode:
  - The IPU subsystem functional domain is also idled.
  - After coming to this mode, power states can be moved deeper.
- Retention mode:
  - The voltage of the logic supply is lowered to reduce static power consumption by leakage current. The logic power switch in the PD_CORE power domain is still closed (ON); thus, all logic states are retained.
  - L1 and/or L2 memories can go independently into retention depending on the settings done at the PRCM level.
- Power off mode:
  - The voltage source is shut down. The logic states, including the retention logic, are lost.
  - The WUGEN_IPU is not operating and only the PRCM module can trigger the IPU subsystem wakeup.
  - Reset must be applied to the IPU subsystem to restart the two ARM Cortex-M4 processors and the memory subsystem.

7.3.2.5 Wake-Up Generator (WUGEN_IPU)

The WUGEN_IPU in the IPU subsystem enables efficient power management. The WUGEN_IPU generates a wake-up signal to the PRCM module to enable the IPU subsystem to recover its functional clocks, which are gated by the PRCM module when at least one request is active. The WUGEN_IPU can be configured in standby mode or idle mode through the STANDBY_CORE_SYSCONFIG[1:0] STANDBYMODE and IDLE_CORE_SYSCONFIG[1:0] IDLEMODE bit fields.

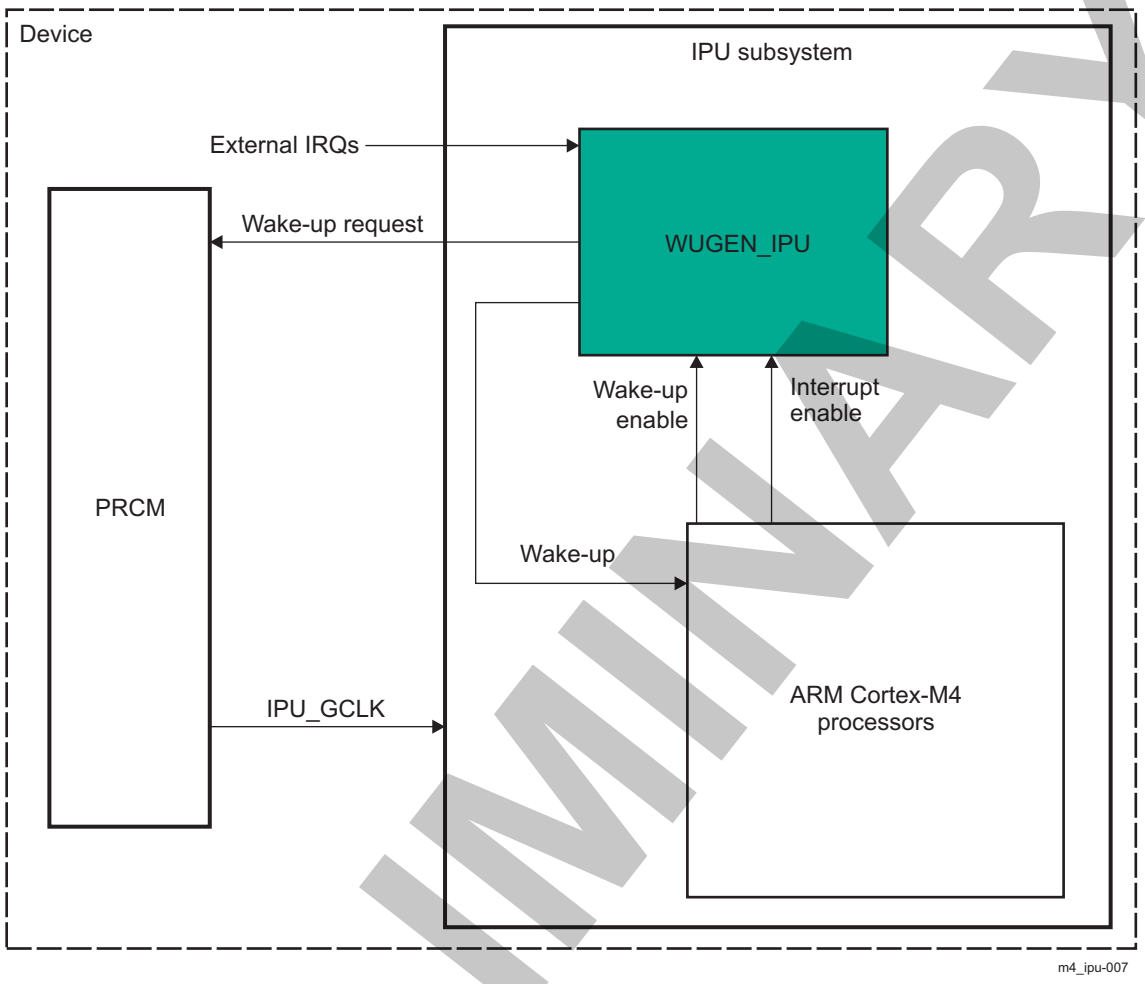
7.3.2.5.1 WUGEN_IPU Main Features

The WUGEN_IPU allows:

- Gating of the IPU subsystem clock dynamically, thus reducing power consumption
- Simplifying of dependencies in the PRCM module

Figure 7-6 is an overview of the WUGEN_IPU.

Figure 7-6. WUGEN_IPU Overview



The wake-up signal to the PRCM module requests the IPU subsystem functional clock (IPU_GCLK). The wake-up signal to the ARM Cortex-M4 processors indicates to them that at least one enabled request is active.

Two retention registers WUGEN_MEVT0 (for IPU_C0) and WUGEN_MEVT1 (for IPU_C1), enable the WUGEN_IPU requests to the INTC_IPUs.

7.3.3 SCACHE_IPU

Table 7-7 describes the SCACHE_IPU configuration in the IPU subsystem platform.

Table 7-7. SCACHE_IPU Configuration

Parameter	Value
Way	4
Size	32 KiB
Bank elements	32 bits
Bank number	16
Slave interface data size	32 bits
Master interface data size	64 bits
Line size	256 bits
MMU lookup	Included
Number of slaves	4

Table 7-7. SCACHE_IPU Configuration (continued)

Parameter	Value
Number of masters	1
Number of fill/prefetch buffers	Four prefetch buffers
Slave types	SCACHE_IPU interface

SCACHE_IPU allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

The SCACHE_IPU is the same as the one in the DSP subsystem. For more information about the SCACHE_IPU, see DSP Subsystem chapter.

7.3.4 SCACHE_MMU_IPU

The MMU for the SCACHE_IPU provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Table 7-8 describes the MMU configuration in the IPU subsystem.

Table 7-8. SCACHE_MMU_IPU Configuration

Parameter	Values
Number of large pages	Four entries
Size of large pages	512 MiB or 32 MiB (configurable)
Number of medium pages	Two entries
Size of medium pages	256 KiB or 128 MiB (configurable)
Number of small pages	10 entries
Size of small pages	16 KiB or 4 KiB (configurable)
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of SCACHE_IPU maintenance interfaces	3
Size of entry address	32-bit

The size of the pages is configurable in the SCACHE_MMU_IPU registers. The different MMU page sizes can be used to create smaller policies within a larger region. The SCACHE_MMU_IPU is the same as the one in the DSP subsystem. For more information, see Chapter 5, *DSP Subsystem*.

7.3.5 L2_MMU

An additional MMU provides address translation for the accesses done from the IPU subsystem to the L3_MAIN interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with ARMv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion

- Two-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16 MiB, 1 MiB, 64 KiB, 4 KiB)
- Page table alignment on 128-byte boundary for ARM11® compatibility

The configuration of the MMU can be done from one of the Cortex-M4 cores or from the L3_MAIN interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access.

For more information about the L2_MMU, see Memory Management Units chapter.

7.3.5.1 L2_MMU Behavior on Page-Fault in IPU Subsystem

Table 7-9. L2_MMU Behavior on Page-Fault

Application		Debug	
Table-Walker Enabled	**Table-Walker Disabled**	**Table-Walker Enabled**	**Table-Walker Disabled**
Use Table-Walker to find translation. Update TLB cache if successful, set TRANSLATIONFAULT bit and interrupt if not. The following bits are used for the purpose: MMU_IRQENABLE[1] TRANSLATIONFAULT and MMU_IRQSTATUS[1] TRANSLATIONFAULT.	Set TLBMISS bit and interrupt and stall. The following registers are used for the purpose: MMU_IRQENABLE[0] TLBMISS and MMU_IRQSTATUS[0] TLBMISS.	Use Table-Walker to find translation. Update TLB cache if successful (only if the MMU_CNTL[3] EMUTLBUPDATE bit is set), generate in-band bus error if not.	Set EMUMISS bit and interrupt and stall. The following bits are used for the purpose: MMU_IRQENABLE[2] EMUMISS and MMU_IRQSTATUS[2] EMUMISS.

The MMU fault interrupt line is connected to both Cortex-M4 cores and is also propagated outside of the IPU subsystem and connected to the Cortex-A15 MPU (MA_IRQ_100). The Cortex-A15 MPU receives the MMU fault and must clean up the fault to resume the execution of the code (or reset IPU subsystem). It is not possible for one of the Cortex-M4 CPUs to clean up the fault caused by the other Cortex-M4 CPU. This is because both the slave port of the L2_MMU (which is stalled) and the configuration port of L2_MMU are connected (through a splitter) to the same SCACHE_IPU master port.

The default behavior of the L2_MMU previously described can be overridden by setting the MMU_GP_REG[0] BUS_ERR_BACK_EN bit to 1. Once this bit is set, all MMU faults (including TLB miss) return a bus error to the IPU subsystem (interrupt event XLATE_MMU_FAULT). This allows the end user to quickly establish the cause of the MMU fault by having appropriate code in the ISR.

7.3.6 Interprocessor Communication (IPC)

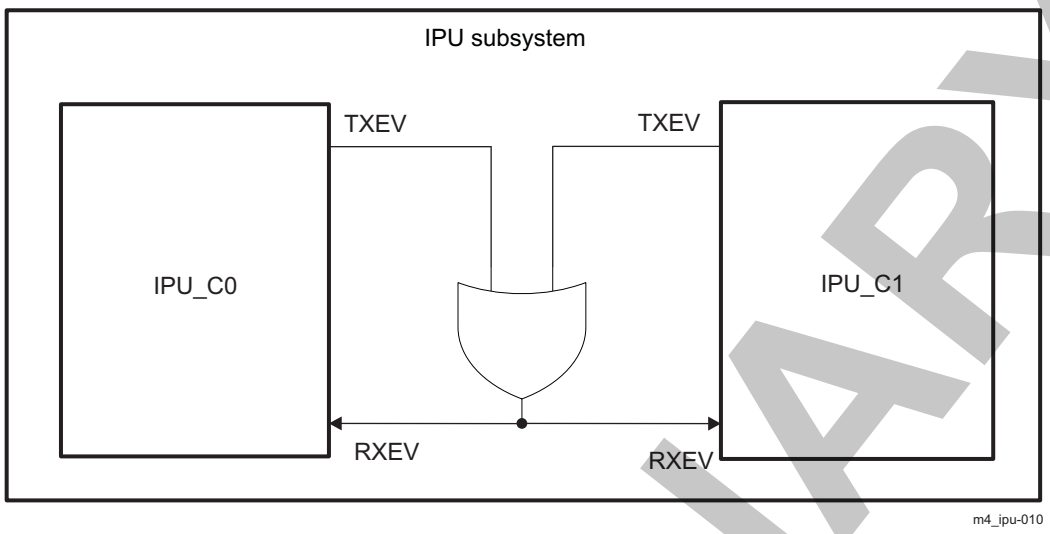
7.3.6.1 Use of WFE and SEV

The IPU subsystem provides a multiprocessor communication interface for synchronizing tasks. The ARM processors have one output signal, TXEV (transmit event), for sending events and one input signal, RXEV (receive event), for receiving events. Figure 7-7 shows how TXEV and RXEV are connected in the IPU subsystem.

When a WFE instruction is executed, the processor enters into sleep mode waiting for an event and continues instruction execution when an external event is received. With an SEV (send event) instruction, one processor can wake up the other processor, which is in sleep mode.

The WFE and SEV instructions can help reduce the number of iterations around a lock acquire loop (a spinlock), and thereby reduce power consumption. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction, which suspends execution on that observer until an asynchronous exception or an explicit event (sent by an observer using the SEV instruction) is seen by that observer. The observer that holds the lock uses the SEV instruction to send an event after a lock is released.

Figure 7-7. Event Communication Connection in IPU Subsystem



7.3.6.2 Use of Interrupt for IPC

Each Cortex-M4 core can interrupt the other Cortex-M4 core by setting up an interrupt register (CORTEXM4_CTRL_REG). Because the priority level for that interrupt can be defined, it is possible to choose the task level at which the interrupt will run. For example, if IPU_C0 was active and IPU_C1 was idle (WFI state), when IPU_C0 completes its task it sets the bit for IPU_C1 in the control register (CORTEXM4_CTRL_REG[16] INT_CORTEX_2) and goes into sleep mode. IPU_C1 wakes up seeing this interrupt, and starts running its task. After the completion of its task, IPU_C1 sets the interrupt for IPU_C0 (CORTEXM4_CTRL_REG[0] INT_CORTEX_1), and then goes into WFI state. This kind of handshake ensures that if IPU_C0 and IPU_C1 are accessing the same resources (memory, registers etc.), only one of the CPUs at a time is active.

7.3.6.3 Use of the Bit-Band Feature for Semaphore Operations

The two Cortex-M4 cores share the same memory system, and it is possible to use the bit-band feature to carry semaphore operations. Because the bit-band alias writes are locked read-modify-write transfers, provided that all tasks changed only the lock bit representing themselves, the lock bits of other tasks are not lost, even if two tasks try to write to the same memory location at the same time.

Each Cortex-M4 core supports two bit-band regions.

Bit-band 1 applies to the virtual address space 0x2000 0000–0x200F FFFF (1 MiB). This virtual address space can be mapped to any physical address and bit-banding will apply to that region. It is recommended that the user map the L2 RAM_IPU (64 KiB) to this virtual space and use it only for bit-banding operations. If required, the user can define other available small and medium pages over and above the L2 RAM_IPU virtual space and further extend the use of the bit-band feature.

Bit-band 2 applies to the virtual address space 0x4000 0000–0x400F FFFF (1 MiB). The first 16 KiB of this space (0x4000 0000–0x4000 3FFF) are already reserved for small (one page) pages and cannot be remapped by software. The bit-band alias that corresponds to this 16-KiB region (0x4200 0000–0x4207 FFFF) must also be treated as reserved and no access should be made. The rest of bit-band 2 can be used by appropriately defining the available small and medium pages. In this device, because it is likely that during normal AMMU programming all of L3_MAIN is mapped to this region, it is highly recommended that the user use only bit-band 1 for all purposes and bit-band 2 only if it is necessary.

7.3.6.4 Private Memory Space

Each ARM Cortex-M4 processor has its own memory space, inaccessible by the other processor. In the private memory space are the INTC_IPUs and RW table registers: CORTEXM4_RW_PID1 and CORTEXM4_RW_PID2. CORTEXM4_RW_PID1 and CORTEXM4_RW_PID2 are accessible only by the respective Cortex-M4 cores (CORTEXM4_RW_PID1 is accessible only by IPU_C0, while CORTEXM4_RW_PID2 is accessible only by IPU_C1) . These registers are not accessible from the Cortex-A15 MPU. Because they are not shared, they do not require the bit-band feature (semaphore) to read and write to them.

7.4 Dual Cortex-M4 IPU Subsystem Register Manual

7.4.1 IPU Subsystem Instance Summary

Table 7-10 summarizes the IPU subsystem instances.

Table 7-10. IPU subsystem Instance Summary

Module Name	Base Address	Size
SCACHE_CFG_IPU	0x5508 0000	4 KiB
SCACHE_SCTM_IPU	0x5508 0400	4 KiB
SCACHE_MMU_IPU	0x5508 0800	4 KiB
WUGEN_IPU	0x5508 1000	4 KiB
IPU_L2_MMU	0x5508 2000	4 KiB
INTC_IPU_C0(1)	0xE000 E000	4 KiB
INTC_IPU_C1(2)	0xE000 E000	4 KiB
IPU_RW_TABLE(3)	0xE00F E000	4 KiB

(1) Private memory space for IPU_C0
(2) Private memory space for IPU_C1
(3) Private memory space for each CPU

7.4.2 SCACHE_CFG_IPU Registers

For information about the SCACHE_CFG_IPU registers and their description, see DSP Subsystem chapter.

7.4.3 SCACHE_SCTM_IPU Registers

For information about the SCACHE_SCTM_IPU registers and their description, see DSP Subsystem chapter.

The SCTM registers in the IPU subsystem differ from the registers listed in Chapter 5, *DSP Subsystem*, in the following ways:

- Counters with indexes from i = 2 to 5 can be chained and shadowing is enabled.
- The reset value of the SCACHE_SCTM_CTCR_WOT_j[7] CHNSDW bit is 1.
- The option to write 1 in the SCACHE_SCTM_CTCR_WOT_j[4] CHAIN bit is not reserved and when the bit is write 1, the counter is chained.

7.4.4 SCACHE_MMU_IPU Registers

For information about the SCACHE_MMU_IPU registers and their description, see DSP Subsystem chapter.

The SCACHE_MMU_IPU in the IPU subsystem has four large pages, two medium pages, and ten small pages. Because of the different page sizes, there are differences with the registers described in - Chapter 5, *DSP Subsystem*, in the enumerated indexes below the register mapping, which are the following: (i = 0 to 3), (j = 0 to 1), (k = 0 to 9). There are also differences in the reset value of the following registers:

- SCACHE_MMU_SMALL_ADDR_0 with reset value 0x00000000
- SCACHE_MMU_SMALL_ADDR_1 with reset value 0x40000000
- SCACHE_MMU_SMALL_POLICY_k with reset value 0x0000000 (k = 0 to 9)
- SCACHE_MMU_SMALL_XLTE_0 with reset value 0x55020000
- SCACHE_MMU_SMALL_XLTE_1 with reset value 0x55080000
- SCACHE_MMU_SMALL_XLTE_k with reset value 0x00000000 (k = 2 to 9)

The page sizes for the 16 entries are:

- Large pages (four): The page sizes supported are 32 MiB and 512 MiB.

- Medium pages (two): The page sizes supported are 128 KiB and 256 KiB.
- Small pages (ten): The page sizes supported are 4 KiB and 16 KiB.

7.4.5 IPU_L2_MMU Registers

For information about the IPU_L2_MMU registers and their description, see Memory Management Units chapter.

7.4.6 INTC_IPU_C0/1 Registers

For information about the INTC_IPU_C0/1 (NVICs) registers and their description, see the *ARM Cortex-M4 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

7.4.7 WUGEN_IPU Registers

7.4.7.1 WUGEN_IPU Register Summary

Table 7-11 summarizes the WUGEN_IPU register mapping.

7.4.8.2 IPU_RW_TABLE Register Description

Table 7-23. CORTEXM4_RW_PID1

Address Offset	0x0000 0000		
Physical Address	0xE00F E000	**Instance**	IPU_RW_TABLE
Description	Peripheral Identification register– allows the user software to differentiate between the two ARM Cortex-M4 processors (two CPUs). The same piece of code running on the two CPUs can result in different execution (for example, branch to different location) depending on the address stored in the register. The address is stored by the BIOS code. The register cannot be accessed when the BIOS code is running (used).		
Type	RW

Imaging Subsystem

This chapter gives a top-level overview of the imaging subsystem (ISS) in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

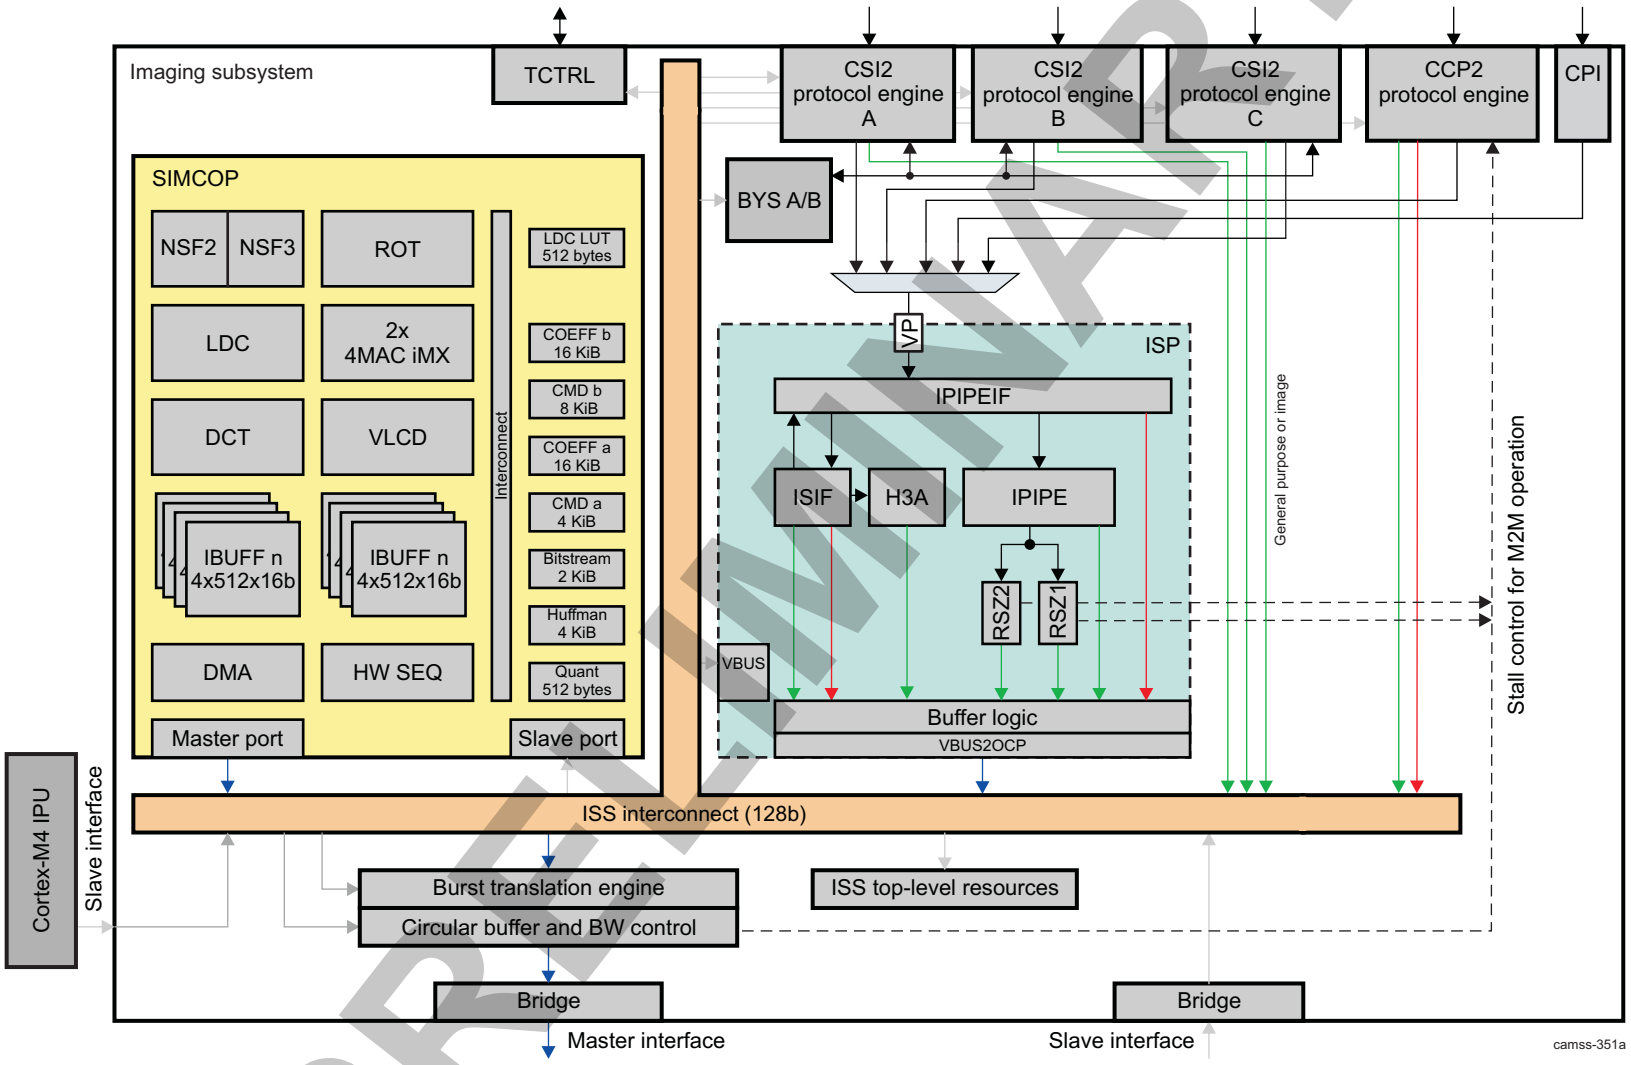
For the availability of device modules, see , *OMAP543x Family and Device Identification*, in Chapter 1, *Introduction*, and the corresponding TRM appendix and device data manual.

Topic **Page**

8.1 ISS Overview

The imaging subsystem (ISS) deals with the processing of the pixel data coming from an external image sensor, data from memory (image format encoding and decoding can be done to and from memory), or data from SL2 in IVA-HD for hardware encoding. With its subparts, such as interfaces and interconnects, image signal processor (ISP), and still image coprocessor (SIMCOP), the ISS is a key component for the following multimedia applications: camera viewfinder, video record, and still image capture. Figure 8-1 shows an overview of the ISS.

Figure 8-1. ISS Overview



The direction of the arrows shows the command flow direction from the master (initiator) to the slave (target). The following color conventions are used for the connections:

- Blue: Bidirectional, 128-bit-wide interface data connection
- Green: Write (ISS → system memory) data connection. Either 64-bit interface, 128-bit interface, or 32-bit MTC (inside ISP).
- Red: Read (system memory to ISS) data connection. 128-bit interface port or 32-bit MTC (inside ISP).
- Gray: 32-bit interface configuration connection
- Solid black: Video port and camera interface related signals
- Dotted black: Data flow stall control signal. Used to slow down ISP for memory-to-memory operation.

The ISS is mainly composed of CCP2, CSI2_A, CSI2_B, CSI2_C camera interfaces, a parallel interface (CPI), two bayer scalers (BYS_A and BYS_B), an ISP, and a block-based imaging accelerator (SIMCOP).

The ISS is designed to reach high throughput and low latency with large image sensors. In high-performance mode, the ISP supports a pixel throughput of 304 MPix/s.

Two programmable image processors (iMX4) are included in the SIMCOP subsystem to add further flexibility to implement new algorithms or where new issues are encountered with the image sensors. The iMX4 processors are also open to third-party algorithms.

The ISS is tightly coupled with a low-interrupt latency microprocessor subsystem (Cortex™-M4 IPU) that runs a real-time operating system (OS) to reach optimal performance. Mainly, the Cortex-M4 IPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks. It can also be configured using the main MPU subsystem (Cortex™-A15 MPU) or the system DMA controller (DMA_SYSTEM). Typically, Cortex-A15 MPU can run some less latency-sensitive tasks, and the DMA_SYSTEM can be used to transfer large configuration tables used by the ISS (for example, Gamma tables and iMX software).

The ISS targets the following major use cases:

- Viewfinder with digital zoom, video stabilization, and rotations
- Up to 1080p video record at 60 fps with digital zoom, video stabilization, and rotation
- Up to 1080p stereo video record at 30 fps with digital zoom, video stabilization, rotation and auto-convergence
- Up to 24 MPix still image capture with digital zoom and rotation
  - High performance mode: Up to 304 MPix/s throughput
  - High quality and low light modes: Up to 75 MPix/s throughput
- Still image capture during video record

NOTE: The ISS is not limited to 24 Mpix. Higher resolution can be achieved through multiple passes.

NOTE: For a detailed list of features of a certain submodule, see the related subsection.

The ISS offers the following features:

- SIMCOP:
  - Memory-to-memory operation
  - JPEG encode and decode hardware acceleration
  - High-ISO noise filtering
    - NSF 2.0 providing the following throughput:
      - Up to 127 MPix/s for YUV420 format
      - Up to 85 MPix/s for YUV422 format
    - NSF 3.0 with up to 190 MPix/s throughput at 426Mhz clock speed
  - Rotation accelerator

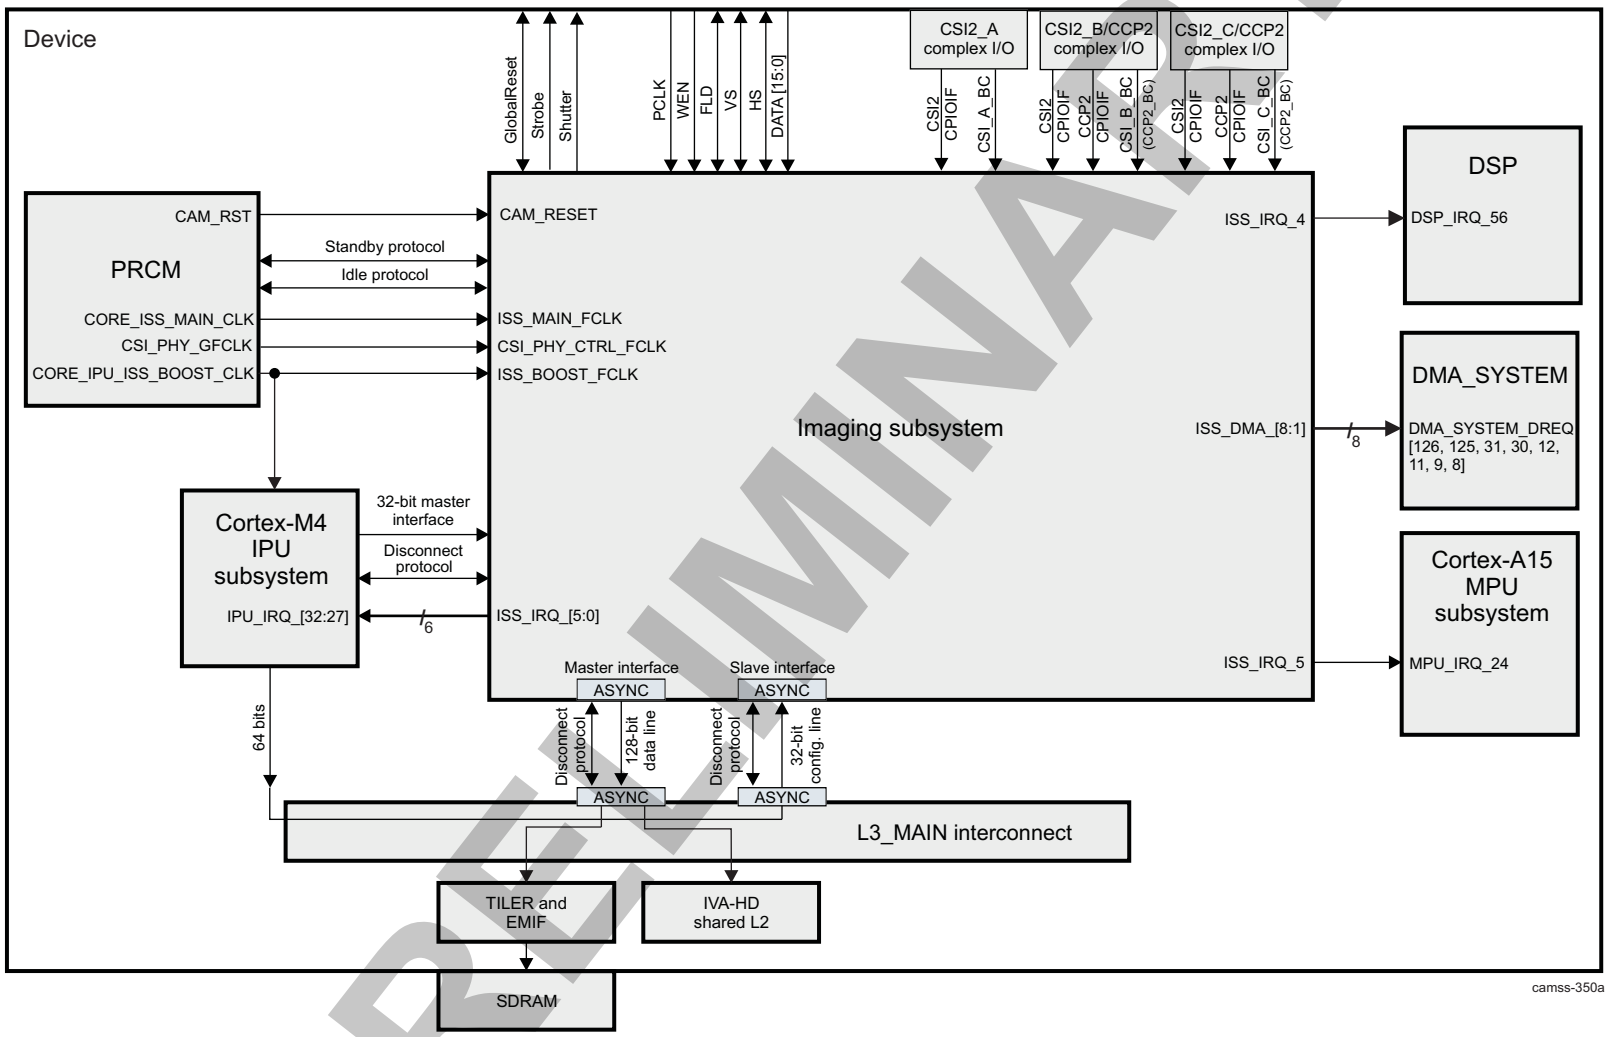
  - Warping accelerator
  - Lens distortion correction (YUV space) with up to 213 MPix/s throughput
  - General-purpose (GP) imaging accelerator (2x iMX4) with up to 426MHz clock speed
  - Direct memory access (DMA) controller
  - Hardware sequencer
- ISP:
  - On-the-fly or memory-to-memory processing
  - Up to 304MHz pixel throughput
  - Statistic data collection
  - Image pipe interface front-end raw data processing
  - RGB and YUV data processing through ISIF and IPIPE
  - Hardware 3A (H3A) statistics block for real-time auto focus (AF), auto exposure (AE), and auto white balance (AWB)
  - Two image continuous real-time resizers
  - Video port (VP) for interfacing with the receivers and directing data to the ISP
- ISS interfaces:
  - 128-bit-wide data interface to the level 3 (L3_MAIN) interconnect
  - Burst translation engine (BTE) tightly coupled with the TILER to support efficient rotation
  - Circular buffer for linear space, physically located in memory
  - The ISS relies on the centralized memory management unit (MMU). See Chapter 20, *Memory Management Unit*.
  - Three CSI2 camera interfaces: CSI2_A (primary), CSI2_B (secondary)and CSI2_C
  - CCP2 camera interface (secondary)
  - Parallel interface (CPI) (16 bit wide, with up to 148.5 MPix/s throughput, and supporting BT656, SYNC modes)
  - System memory data read-back port (supported by the CCP2 protocol engine module)
- BYS:
  - Two instances, BYS_A and BYS_B (connection to CSI2/3 interfaces)
  - Up to 5 MPix output image size
  - Down scaler and stabilization statistics collection

8.1.1 ISS Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 8-2 shows the ISS integration.

Figure 8-2. ISS Integration



NOTE: For more information about the IDLE hardware handshake and wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

This section gives an overview of typical uses of the module. For more information about the relationship of the power, reset, and clock management (PRCM) module to the ISS clocks and the reset settings, see the detailed functional description in Chapter 3, *Power, Reset, and Clock Management*.

The ISS is part of ISS-IPU hardware and power management, which comprises the Cortex-M4 IPU, ISS, and a clock generator. These are all independent power domains. The ISS is part of the CAM power domain.

The PRCM module provides two clocks to the ISS-IPU power management (CORE_IPU_ISS_BOOST_CLK and CORE_ISS_MAIN_CLK). The ISS-IPU clock generator generates from CORE_IPU_ISS_BOOST_CLK the clocks for the Cortex-M4 IPU and ISS. The CORE_ISS_MAIN_CLK is used by ISS only.

When enabled, CORE_IPU_ISS_BOOST_CLK is gated to provide CAM_BOOST_GCLK, which, after entering the ISS boundary, is named ISS_BOOST_FCLK. The CORE_IPU_ISS_BOOST_CLK is provided as long as the Cortex-M4 IPU or ISS sub-modules require it. The gating control is handled by the PRCM module.

When enabled, CORE_ISS_MAIN_CLK is gated to provide CAM_MAIN_GCLK, which, after entering the ISS boundary, is named ISS_MAIN_FCLK. The gating control is handled by the PRCM module.

CSI_PHY_GFCLK is gated from FUNC_96M_FCLK, which comes from the PRCM module. When enabled and inside the ISS boundary, it is called CSI_PHY_CTRL_FCLK.

NOTE: For more information about the device clocks and how they are handled by the PRCM module before going into the ISS, see Section 3.6.3.5, *DPLL_CORE Description*, and Section 3.6.22, *CD_CAM Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management.*

The ISS also supports software reset. A software reset has the same function as a hardware reset, except that it does not reset the power-management protocols.

Table 8-1 through Table 8-3 summarize the integration of the module in the device.

Table 8-1. ISS Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ISS	PD_CAM	No	L3_MAIN

Table 8-2. ISS Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	ISS_MAIN_FLCK	CORE_ISS_MAIN_CLK	PRCM	ISS main functional clock from the PRCM module. Up to 304 MHz for OPP_NOM.
	ISS_BOOST_FCLK	CORE_IPU_ISS_BOOST_CLK	PRCM	Functional clock for LDC, iMX, NSF2 and NSF3 modules in SIMCOP, as well as for attached memories. Up to 425,6 MHz for OPP_NOM.
	CSI_PHY_CTRL_FCLK	CSI_PHY_GFCLK	PRCM	Physical layer functional clock from the PRCM module. Up to 96 MHz for OPP_NOM.
Resets

Table 8-3. ISS Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ISS	ISS_IRQ_4	DSP_IRQ_56	DSP INTC	Interrupt generated by ISS to DSP
	ISS_IRQ_5	MPU_IRQ_24	Cortex-A15 INTC	Interrupt generated by ISS to Cortex-A15
	ISS_IRQ_0	IPU_IRQ_27	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
	ISS_IRQ_1	IPU_IRQ_28	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
	ISS_IRQ_2	IPU_IRQ_29	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
	ISS_IRQ_3	IPU_IRQ_30	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
	ISS_IRQ_4	IPU_IRQ_31	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
	ISS_IRQ_5	IPU_IRQ_32	Cortex-M4 INTC	Interrupt generated by ISS to Cortex-M4
DMA Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
ISS	ISS_DREQ_1	DMA_SYSTEM_DREQ_8	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by ISP.
	ISS_DREQ_2	DMA_SYSTEM_DREQ_9	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by ISP
	ISS_DREQ_3	DMA_SYSTEM_DREQ_11	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by ISP
	ISS_DREQ_4	DMA_SYSTEM_DREQ_12	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by ISP
	ISS_DREQ_5	DMA_SYSTEM_DREQ_30	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by BYS_A
	ISS_DREQ_6	DMA_SYSTEM_DREQ_31	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by BYS_A
	ISS_DREQ_7	DMA_SYSTEM_DREQ_125	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by BYS_B
	ISS_DREQ_8	DMA_SYSTEM_DREQ_126	DMA_SYSTEM	Signal connected to the DMA_SYSTEM directly provided by BYS_B

8.1.1.1 ISS PRCM Interface Integration

8.1.1.1.1 ISS Clock Domains

The ISS has five asynchronous clock domains. Most of the logic uses ISS_MAIN_FLCK; the other clock domains are used for interfaces.

Table 8-4 provides a high-level view of clocks. The frequencies provided are maximum values.

Table 8-4. ISS Local Clock Domains

Name	Description
PCLK	Parallel interface (CPI) pixel clock provided by the camera external sensor. The CSI2_A, CSI2_B, CSI2_C and CCP2 modules also have video port outputs, each having its own pixel clock. These pixel clocks are generated from the functional clock (ISS_MAIN_FCLK). Then all five pixel clock sources are multiplexed into one clock provided to the ISP. Up to 304 MHz for OPP_NOM.
CSI_A_BC	Byte clock sourced from the CSI2_A complex I/O (CSI_PHY_A) clock RXBYTECLKHS_A. Used by the CSI2_A protocol engine. Up to 187.5 MHz for OPP_NOM.

Table 8-4. ISS Local Clock Domains (continued)

Name	Description
CSI_B_BC	Byte clock sourced from the CSI2_B complex I/O (CSI_PHY_B) clock RXBYTECLKHS_B. Used by the CSI2_B protocol engine. Up to 187.5 MHz for OPP_NOM.
CSI_C_BC	Byte clock sourced from the CSI2_C complex I/O (CSI_PHY_C) clock RXBYTECLKHS_C. Used by the CSI2_C protocol engine. Up to 187.5 MHz for OPP_NOM.
CCP2_BC	Clock provided by the CCP2 complex I/O (CSI_PHY_B or CSI_PHY_C, depending on configuration). Used by the CCP2 protocol engine. Up to 21 MHz for OPP_NOM.
ISS_MAIN_FLCK	Functional clock provided by the PRCM module. It is used by all ISS submodules and ISS top-level resources. Up to 304 MHz for OPP_NOM.
CSI_PHY_CTRL_FCLK	Functional clock provided by the PRCM module. It is used by the CSI2_A, CSI2_B/CCP2 and CSI2_C/CCP2 complex I/Os. Up to 96 MHz for OPP_NOM.

To save power, the ISS can divide the received functional clock (ISS_MAIN_FLCK) by 2 or 4 using the ISS_CTRL[5:4] ISS_CLK_DIV register bit-field. The PCLK must always be less or equal to the ISS_MAIN_FLCK. The internal configuration clock (CFGCLK, used for the internal ISS configuration network) is always half the ISS_MAIN_FLCK. The ISS_BOOST_FCLK is not affected by the ISS_CLK_DIV bit-field.

The functional clock of some submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the ISS_CLKCTRL register. Also, the pixel clocks sent by submodules to ISP can be cut off from the corresponding ISS_CLKCTRL[] VPORT*x*_CLK bit-fields.

8.1.2 ISS Functional Description

This section provides only a top-level overview of the ISS. The ISS submodules are described in: Section 8.2.1, *ISS:interfaces*, Section 8.3.1, *ISS:ISP*, and Section 8.4, *ISS:SIMCOP*.

8.1.2.1 ISS Interrupts

Table 8-5 lists the events generated by the submodules and the top level of the ISS.

Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the ISS_HL_IRQENABLE_SET_i register. The interrupt is disabled by setting the appropriate bit in the ISS_HL_IRQENABLE_CLR_i register.

When an event occurs, the corresponding bit in the ISS_HL_IRQSTATUS_RAW_i register is set regardless of whether or not the event is enabled. Bits in the ISS_HL_IRQSTATUS_i registers are set only when an enabled event occurs.

Software can clear a pending HS_VS_IRQ event by setting the ISS_HL_IRQSTATUS_i[17] HS_VS_IRQ bit. Events generated by submodules are automatically cleared at the ISS level when they are cleared at the submodule level.

8.1.2.1.1 ISS Interrupt Merger

The ISS merges the following eleven interrupt sources into six physical interrupt lines. All six lines support level and pulse modes.

Table 8-5. ISS Interrupts

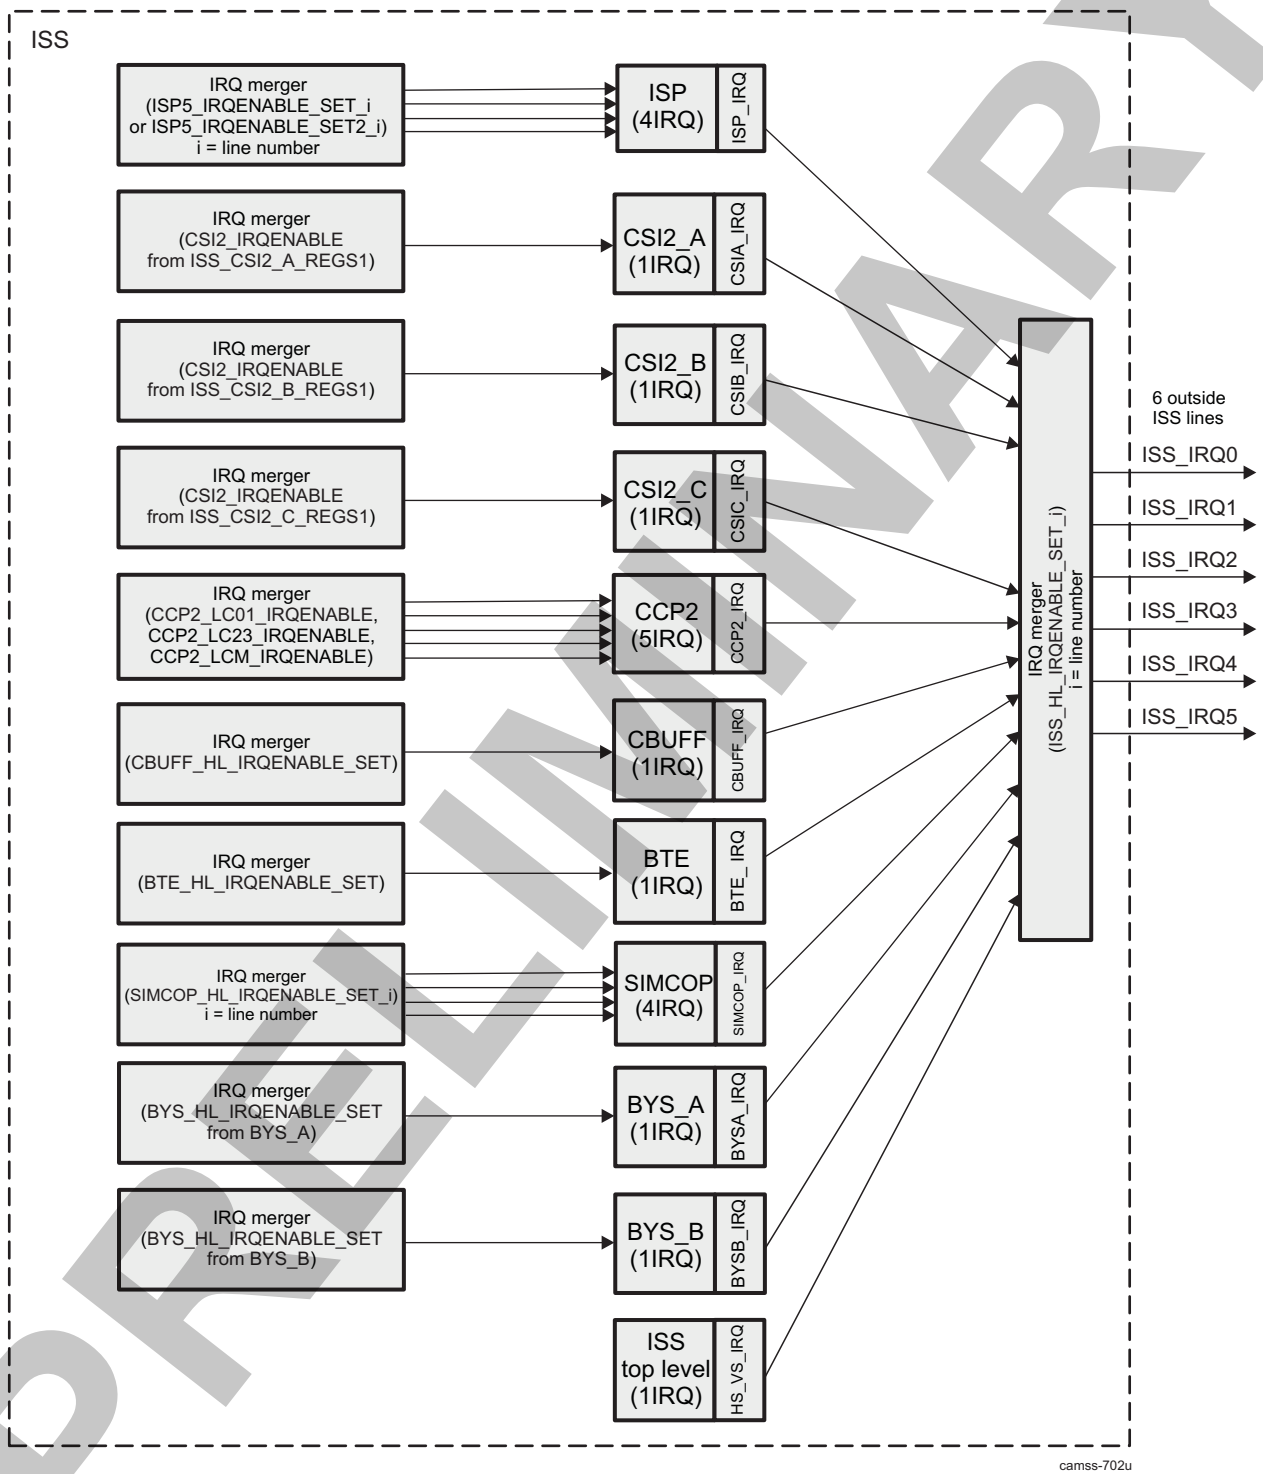
Interrupt	Source	Description
ISP_IRQ[3:0]	ISP	Interrupt generated by the ISP (1)
CSIA_IRQ	CSI2_A	Interrupt generated by the CSI2_A receiver(1)
CSIB_IRQ	CSI2_B	Interrupt generated by the CSI2_B receiver (1)
CSIC_IRQ	CSI2_C	Interrupt generated by the CSI2_C receiver (1)
CCP2_IRQ[3:0]	CCP2	Interrupt generated by the CCP2 receiver(1)
CCP2_IRQ[8]	CCP2	Interrupt generated by the CCP2 receiver(1)
CBUFF_IRQ	CBUFF	Interrupt generated by the circular buffer(1)
BTE_IRQ	BTE	Interrupt generated by the BTE (1)
SIMCOP_IRQ[3:0]	SIMCOP	Interrupt generated by SIMCOP
HS_VS_IRQ	ISS	HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen using the ISP_CTRL[0:1] SYNC_DETECT bit field.
BYSA_IRQ	BYS_A	Interrupt generated by the BYS_A module (1)
BYSB_IRQ	BYS_B	Interrupt generated by the BYS_B module (1)

(1) For more information, see Section 8.1.2.1.2, *ISS Submodule Interrupts*.

Software can select which interrupt sources are routed to each output line (ISS_IRQ_[0:5]). All six physical interrupt outputs have equivalent functions. Software can use different interrupt lines to group events together by type and therefore reduce interrupt latencies. Typically, one interrupt line is used for low-priority events (errors), and the other interrupt lines are used for high-priority events (for example, SIMCOP sequencing and end-of-frame events to trigger configuration load). The ISS internal interrupt request (IRQ) merger (see Figure 8-3) relies only on level interrupts provided by submodules. Pulse interrupts provided by submodules are ignored. Typically, all of the interrupts are routed to the Cortex-M4 IPU running the camera driver. In addition, one interrupt is routed to Cortex-A15 MPU, which may run the imaging software. Software does not need to clear events from submodules at the ISS level: it clears only the events at the submodule level. The IRQ merger automatically clears the IRQ at ISS level (events generated by sub-modules are automatically cleared at ISS level when they are cleared at sub-module level).

NOTE: Only the HS_VS_IRQ top-level event is cleared at the ISS level.

Figure 8-3. ISS Interrupt Merger



NOTE: For more information about mapping the six lines to the device modules outside ISS, see Table 8-3.

Only the ISP, SIMCOP, and HL ISS merger IRQ lines are configurable. Each interrupt can be mapped to the required line. This is not the case with CCP2 where, for example, LC01 is hardwired to line0 and line1.

8.1.2.1.2 ISS Submodule Interrupts

The ISS shown in Figure 8-3 and listed in Table 8-3 can generate six interrupts.

8.1.2.1.2.1 ISS ISP Interrupts

Table 8-6 summarizes events that cause ISP interrupts.

Table 8-6. ISS ISP Interrupts

Event and Register[1]	Description
ISP5_IRQENABLE_SET_i[[31] OCP_ERR_IRQ	An interface port error has been received on the ISP master port.
ISP5_IRQENABLE_SET_i[29] IPIPE_INT_DPC_RNEW1	HD interrupt signal to indicate the need to renew the defect pixel correction (DPC) table with new entries. The second 128 entries in the DPC table must be updated when this event triggers. This event is triggered when the 255th entry in the look-up table (LUT) is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_i[28] IPIPE_INT_DPC_RNEW0	VD interrupt signal to indicate the need to renew the DPC table with new entries. The first 128 entries in the DPC table must be updated when the event triggers. This event is triggered when the 127th entry in the LUT is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_i[27] IPIPE_INT_DPC_INI	Interrupt to signal the need to initialize the DPC table. The DPC table contains two tables of 128 entries. When this signal is used, software must ensure that the 256 table entries are updated with the DPC information.
ISP5_IRQENABLE_SET_i[25] IPIPE_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_i[24] H3A_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_i[22] RSZ_INT_EOF1	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[23] RSZ_INT_EOF0	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[19] RSZ_FIFO_IN_BLK_ERR	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[18] RSZ_FIFO_IN_OVF	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[17] RSZ_INT_CYC_RZB	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[16] RSZ_INT_CYC_RZA	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[15] RSZ_INT_DMA	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[14] RSZ_INT_LAST_PIX	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[13] RSZ_INT_REG	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[12] H3A_INT	Interrupt generated by the AF and AE/AWB blocks inside the H3A module. It indicates the end of processing a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_i[11] AF_INT	AF inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_i[10] AEW_INT	AEW inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.

(1) i = 0 to 3

Table 8-6. ISS ISP Interrupts (continued)

Event and Register[(1)]	Description
ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ	IPIPEIF module interrupt is generated at the start position of a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_i[8] IPIPE_INT_HST	IPIPE module interrupt is generated when histogram is done.
ISP5_IRQENABLE_SET_i[7] IPIPE_INT_BSC	IPIPE module interrupt is generated when boundary signal calculation is done.
ISP5_IRQENABLE_SET_i[6] IPIPE_INT_DMA	IPIPE module interrupt is issued when the SDRAM transfer of boxcar is done. At this time, IPIPE EOF is sent to buffer logic.
ISP5_IRQENABLE_SET_i[5] IPIPE_INT_LAST_PIX	IPIPE module interrupt is issued when the last pixel of a frame comes into IPIPE.
ISP5_IRQENABLE_SET_i[4] IPIPE_INT_REG	IPIPE module interrupt is issued when the register update of the module is allowed.
ISP5_IRQENABLE_SET_i[3] ISIF_INT_3	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[2] ISIF_INT_2	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[1] ISIF_INT_1	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET_i[0] ISIF_INT_0	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET2_i[0] H3A_OVF	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET2_i[1] IPIPEIF_UDF	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET2_i[2] IPIPE_BOXCAR_OVF	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET2_i[3] ISIF_OVF	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.
ISP5_IRQENABLE_SET2_i[4] IPIPE_HST_ERR	See Section 8.1.3, *ISS Register Manual*, and Section 8.3.5, *ISS ISP Register Manual*.

8.1.2.1.2.2 ISS CSI2_A, CSI2_B and CSI2_C Complex I/O Interrupts

Table 8-7 lists the event generation of the CSI2_A, CSI2_B and CSI2_C receivers through the CSI2 interrupt status and interrupt enable registers. The events are checked for status using the CSI2_IRQSTATUS and CSI2_IRQENABLE registers.

Table 8-7. ISS CSI2_A, CSI2_B and CSI2_C Interrupts

Event and Register	Description
CSI2_IRQENABLE[14] OCP_ERR_IRQ	Interface port error
CSI2_IRQENABLE[13] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types from 0x8 to 0xF are considered)
CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (short packet only).
CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CSI2_IRQENABLE[9] COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: This interrupt is triggered when any error is received from the complex I/O (events are defined in CSI2_COMPLEXIO_IRQSTATUS [see Table 8-8]).
CSI2_IRQENABLE[8] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered when a FIFO overflow is detected. An overflow can occur if there is a mismatch between the data input and output rates. In case of an overflow the module properly finishes the burst that has been started and does not issue any new OCP transactions on the master port. A reset of the module is required to restart correctly.
CSI2_IRQENABLE[7] CONTEXT7	At least one interrupt event enabled from Context 7 occurred (see Table 8-9).

Table 8-7. ISS CSI2_A, CSI2_B and CSI2_C Interrupts (continued)

Event and Register	Description
CSI2_IRQENABLE[6] CONTEXT6	At least one interrupt event enabled from Context 6 occurred (see Table 8-9).
CSI2_IRQENABLE[5] CONTEXT5	At least one interrupt event enabled from Context 5 occurred (see Table 8-9).
CSI2_IRQENABLE[4] CONTEXT4	At least one interrupt event enabled from Context 4 occurred (see Table 8-9).
CSI2_IRQENABLE[3] CONTEXT3	At least one interrupt event enabled from Context 3 occurred (see Table 8-9).
CSI2_IRQENABLE[2] CONTEXT2	At least one interrupt event enabled from Context 2 occurred (see Table 8-9).
CSI2_IRQENABLE[1] CONTEXT1	At least one interrupt event enabled from Context 1 occurred (see Table 8-9).
CSI2_IRQENABLE[0] CONTEXT0	At least one interrupt event enabled from Context 0 occurred (see Table 8-9).

Table 8-8 lists CSI2 receiver event generation through the CSI2_A/CSI2_B/CSI2_C complex I/O interrupt status and interrupt enable registers. The events are checked and controlled from the CSI2_COMPLEXIO_IRQSTATUS and CSI2_COMPLEXIO_IRQENABLE registers.

Table 8-8. ISS CSI2_A, CSI2_B and CSI2_C Receivers Complex I/O Interrupts

Event and Register	Description
CSI2_COMPLEXIO_IRQENABLE[0] ERRSOTHS1	Start of transmission error for lane 1
CSI2_COMPLEXIO_IRQENABLE[1] ERRSOTHS2	Start of transmission error for lane 2
CSI2_COMPLEXIO_IRQENABLE[2] ERRSOTHS3	Start of transmission error for lane 3
CSI2_COMPLEXIO_IRQENABLE[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CSI2_COMPLEXIO_IRQENABLE[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CSI2_COMPLEXIO_IRQENABLE[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CSI2_COMPLEXIO_IRQENABLE[10] ERRESC1	Escape entry error for lane 1
CSI2_COMPLEXIO_IRQENABLE[11] ERRESC2	Escape entry error for lane 2
CSI2_COMPLEXIO_IRQENABLE[12] ERRESC3	Escape entry error for lane 3
CSI2_COMPLEXIO_IRQENABLE[15] ERRCONTROL1	Control error for lane 1
CSI2_COMPLEXIO_IRQENABLE[16] ERRCONTROL2	Control error for lane 2
CSI2_COMPLEXIO_IRQENABLE[17] ERRCONTROL3	Control error for lane 3
CSI2_COMPLEXIO_IRQENABLE[20] STATEULPM1	Lane 1 in ULPM
CSI2_COMPLEXIO_IRQENABLE[21] STATEULPM2	Lane 2 in ULPM
CSI2_COMPLEXIO_IRQENABLE[22] STATEULPM3	Lane 3 in ULPM
CSI2_COMPLEXIO_IRQENABLE[25] STATEALLULPMENTER	All active lanes are entering the ULPM.
CSI2_COMPLEXIO_IRQENABLE[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

Because the CSI2_A/CSI2_B/CSI2_C receivers support eight contexts, the CSI2_CTX_IRQSTATUS_i and CSI2_CTX_IRQENABLE_i registers are present eight times (one time per context).

The events are generated only for the enabled context(s). Table 8-9 describes the generation of the CSI2 receiver event through the CSI2_CTX_IRQSTATUS_i and CSI2_CTX_IRQENABLE_i registers.

Table 8-9. ISS CSI2_A/CSI2_B/CSI2_C Receivers CONTEXT Interrupts

Event[(1)]	Description
CSI2_CTX_IRQENABLE_i[0] FS_IRQ	Frame start: This interrupt is triggered when a frame-start synchronization code is detected in the CSI2 data stream.

(1) i = 0 to 7

Table 8-9. ISS CSI2_A/CSI2_B/CSI2_C Receivers CONTEXT Interrupts (continued)

Event[1]	Description
CSI2_CTX_IRQENABLE_i[1] FE_IRQ	Frame end: This interrupt is triggered when a frame-end synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE_i[2] LS_IRQ	Line start: This interrupt is triggered when a line-start synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE_i[3] LE_IRQ	Line end: This interrupt is triggered when a line-end synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE_i[5] CS_IRQ	CS error: This interrupt is triggered when a mismatch between the transmitter and receiver checksums (payload) is detected.
CSI2_CTX_IRQENABLE_i[6] FRAME_NUMBER_IRQ	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
CSI2_CTX_IRQENABLE_i[7] LINE_NUMBER_IRQ	Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTX_CTRL1_i.LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTX_CTRL3_i.LINE_NUMBER); otherwise, the interrupt is generated only for the line number.
CSI2_CTX_IRQENABLE_i[8] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (long packets only).

8.1.2.1.2.3 ISS CCP2 Interrupts

Table 8-10 summarizes the CCP2 receiver interrupts.

Table 8-10. ISS CCP2 Receiver Interrupts

Event and Register	Description
CCP2_LC01_IRQENABLE[31] LC1_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 1
CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 1. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 1. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 1. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 1. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ	CCP2 frame counter reached on logical channel 1. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 1. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ	CCP2 CRC error for logical channel 1. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ	CCP2 false-synchronization protection code error for logical channel 1. This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bitstream.
CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ	CCP2 frame-width error for logical channel 1. This interrupt is generated if the frame width constraints associated with the current data type are not respected.
CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ	CCP2 false-synchronization code error for logical channel 1. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine (FSM).
CCP2_LC01_IRQENABLE[15] LC0_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 1
CCP2_LC01_IRQENABLE[11] LC0_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 0. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.

Table 8-10. ISS CCP2 Receiver Interrupts (continued)

Event and Register	Description
CCP2_LC01_IRQENABLE[10] LC0_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 0. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[9] LC0_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 0. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[8] LC0_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 0. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[7] LC0_COUNT_IRQ	CCP2 frame counter reached on logical channel 0. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC01_IRQENABLE[5] LC0_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 0. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQENABLE[4] LC0_CRC_IRQ	CCP2 CRC error for logical channel 0. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC01_IRQENABLE[3] LC0_FSP_IRQ	CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC01_IRQENABLE[2] LC0_FW_IRQ	CCP2 frame-width error for logical channel 0. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.
CCP2_LC01_IRQENABLE[1] LC0_FSC_IRQ	CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[31] LC3_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 3
CCP2_LC23_IRQENABLE[27] LC3_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 3. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[26] LC3_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 3. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[25] LC3_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 3. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[24] LC3_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 3. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[23] LC3_COUNT_IRQ	CCP2 frame counter reached on logical channel 3. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC23_IRQENABLE[21] LC3_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 3. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQENABLE[20] LC3_CRC_IRQ	CCP2 CRC error for logical channel 3. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC23_IRQENABLE[19] LC3_FSP_IRQ	CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[18] LC3_FW_IRQ	CCP2 frame-width error for logical channel 3. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.
CCP2_LC23_IRQENABLE[17] LC3_FSC_IRQ	CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[11] LC2_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQENABLE[10] LC2_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.

Table 8-10. ISS CCP2 Receiver Interrupts (continued)

Event and Register	Description
CCP2_LC23_IRQENABLE[9] LC2_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 2. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[8] LC2_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 2. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[7] LC2_COUNT_IRQ	CCP2 frame counter reached on logical channel 2. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC23_IRQENABLE[5] LC2_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 2. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQENABLE[4] LC2_CRC_IRQ	CCP2 CRC error for logical channel 2. This interrupt is triggered when a mismatch is detected between the transmitter and receiver checksums.
CCP2_LC23_IRQENABLE[3] LC2_FSP_IRQ	CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[2] LC2_FW_IRQ	CCP2 frame-width error for logical channel 2. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.
CCP2_LC23_IRQENABLE[1] LC2_FSC_IRQ	CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LCM_IRQENABLE[1] LCM_OCPERROR	CCP2 an interface error occurred on the master read port. This interrupt is triggered when an OCP error is detected on the master read port.
CCP2_LCM_IRQENABLE[0] LCM_EOF	Memory read channel – end of frame: This interrupt is triggered when a frame is read completely from memory.

8.1.2.1.2.4 ISS CBUFF Interrupts

Table 8-11 summarizes the CBUFF interrupts.

Table 8-11. ISS CBUFF Interrupts

Event and Register	Description
CBUFF_HL_IRQENABLE_SET[27] IRQ_CTX3_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[26] IRQ_CTX2_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[25] IRQ_CTX1_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[24] IRQ_CTX0_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[11] IRQ_CTX3_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[10] IRQ_CTX2_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[9] IRQ_CTX1_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[8] IRQ_CTX0_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[0] IRQ_OCP_ERR	CBUFF master interface port error

8.1.2.1.2.5 ISS BTE Interrupts

Table 8-12 summarizes the BTE interrupts.

Table 8-12. ISS BTE Interrupts

Event and Register	Description
BTE_HL_IRQENABLE_SET[27] IRQ_CTX3_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 3 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[26] IRQ_CTX2_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 2 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[25] IRQ_CTX1_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 1 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[24] IRQ_CTX0_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 0 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID	Writes enable invalid access to Context 3. Reads notify when access to an unexpected location in Context 3 is requested, or the start context location access is valid, but the burst length exceeds the Context 3 end. See Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
BTE_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID	Writes enable invalid access to Context 2. Reads notify when access to an unexpected location in Context 2 is requested, or the start context location access is valid, but the burst length exceeds the Context 2 end. See Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
BTE_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID	Writes enable invalid access to Context 1. Reads notify when access to an unexpected location in Context 1 is requested, or the start context location access is valid, but the burst length exceeds the Context 1 end. See Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
BTE_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID	Writes enable invalid access to Context 0. Reads notify when access to an unexpected location in Context 0 is requested, or the start context location access is valid, but the burst length exceeds the Context 0 end. See Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
BTE_HL_IRQENABLE_SET[11] IRQ_CTX3_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 3 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[10] IRQ_CTX2_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 2 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[9] IRQ_CTX1_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 1 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.

Table 8-12. ISS BTE Interrupts (continued)

Event and Register	Description
BTE_HL_IRQENABLE_SET[8] IRQ_CTX0_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 0 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.
BTE_HL_IRQENABLE_SET[1] IRQ_INVALID	Writes enable Invalid virtual space access notification. Reads notify when access falls into a translated from the BTE region, but it is 2D access or it does not map to an active context. See Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
BTE_HL_IRQENABLE_SET[1] IRQ_OCP_ERR	Writes enable notification for error on the master output interface. Reads notify when an error has occurred on the master output interface.

8.1.2.1.2.6 ISS SIMCOP Interrupts

Table 8-13 summarizes the SIMCOP high-level interrupts mapped to the outer boundaries of the SIMCOP. For more information about interrupts generated from inside the SIMCOP modules, see Section 8.4, *ISS Still Image Coprocessor*.

Table 8-13. ISS SIMCOP High-Level Interrupts

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[19] CPU_PROC_START_IRQ	Interrupt used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When the CPU finishes processing the data, it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit.
SIMCOP_HL_IRQENABLE_SET_i[18] SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
SIMCOP_HL_IRQENABLE_SET_i[16] OCP_ERR_IRQ	SIMCOP master port interface error
SIMCOP_HL_IRQENABLE_SET_i[15] VLCDJ_DECODE_ERR_IRQ	A decode error has been signaled by the VLCDJ module.
SIMCOP_HL_IRQENABLE_SET_i[14] DONE_IRQ	Event triggered when hardware sequencer finishes the sequence: • The sequence step counter has reached the limit. • All accelerator and DMA events for the last sequence step have been received.
SIMCOP_HL_IRQENABLE_SET_i[13] STEP3_IRQ	Event triggered when a SIMCOP Context 3 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[12] STEP2_IRQ	Event triggered when a SIMCOP Context 2 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[11] STEP1_IRQ	Event triggered when a SIMCOP Context 1 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[10] STEP0_IRQ	Event triggered when a SIMCOP Context 0 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ	A macroblock has been processed.
SIMCOP_HL_IRQENABLE_SET_i[8] NSF3_IRQ	Event triggered by the NSF3 imaging accelerator when processing of a block is complete
SIMCOP_HL_IRQENABLE_SET_i[7] ROT_A	Rotational engine interrupt
SIMCOP_HL_IRQENABLE_SET_i[6] IMX_B_IRQ	Event triggered when iMX has executed a SLEEP instruction
SIMCOP_HL_IRQENABLE_SET_i[5] IMX_A_IRQ	Event triggered when iMX has executed a SLEEP instruction
SIMCOP_HL_IRQENABLE_SET_i[4] NSF_IRQ	Event triggered by the NSD2 imaging accelerator when processing of a block is complete
SIMCOP_HL_IRQENABLE_SET_i[3] VLCDJ_BLOC_IRQ	A macroblock has been processed (that is, encode and decode).
SIMCOP_HL_IRQENABLE_SET_i[2] DCT_IRQ	DCT operating is complete (configured number of MCUs for YUV4:2:0/4:2:2 mode, or number of blocks for sequential block mode).

Table 8-13. ISS SIMCOP High-Level Interrupts (continued)

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[1] LDC_FRAME_IRQ	A full frame has been processed.
SIMCOP_HL_IRQENABLE_SET_i[0] SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA

8.1.2.1.2.7 ISS BYS Interrupts

Table 8-14 lists the event generation of the BYS_A and BYS_B modules through the BYS interrupt enable register. The events are checked for status using the BYS_HL_IRQSTATUS and BYS_HL_IRQENABLE_SET registers. The interrupts can be disabled using BYS_HL_IRQENABLE_CLR register.

Table 8-14. ISS BYS Interrupts

Event and Register	Description
BYS_HL_IRQENABLE_SET[8] VPO_EOF	Video port end of frame event. Triggered when the last pixel of a frame has been sent to the output video port.
BYS_HL_IRQENABLE_SET[5] EOF1	End of frame event of BSC pipe #1. Triggered when the last active bin had been updated.
BYS_HL_IRQENABLE_SET[4] EOF0	End of frame event of BSC pipe #0. Triggered when the last active bin had been updated.
BYS_HL_IRQENABLE_SET[3] H2V_OVR	H2V FIFO overflow event. This event occurs when data written by the horizontal stage arrives at a higher rate than what the vertical stage can process. This error is due to wrong configuration.
BYS_HL_IRQENABLE_SET[2] OB_OVR	Output buffer overflow event. This event occurs when the chosen buffer readout rate is too low for the incoming pixel rate. The pixels and BSC statistics for the frame are corrupted and must be discarded when this event has occurred. Software must reset the module and configure it properly (this overflow will be systematic failure and occur on every frame, if the configuration is not fixed).
BYS_HL_IRQENABLE_SET[1] LINE	Line event. Triggered when the input line number before the cropping stage matches the BYS_LINE[12:0] LINE register bit-field value. The input line number is reset when a VS pulse is received and incremented by one on every HS pulse. The event is triggered at the beginning of the line (i.e. when the first pixel of the line is received). This feature is typically used to synchronize BYS with other downstream processing. NOTE: LINE and VPI_SOF events will by triggered in the same time when BYS_LINE[12:0] LINE = 0.
BYS_HL_IRQENABLE_SET[0] VPI_SOF	Start of frame event. Triggered when the first pixel is received on the input video port. Matches the moment where shadow registers are swapped.

8.1.2.2 ISS Clocks

The clocks of ISS submodules can be cut individually using the ISS_CLKCTRL register. Software can poll the module status reading the appropriate bit in the ISS_CLKSTAT register.

When software wants to enable a submodule:

- Software sets the appropriate bit in the ISS_CLKCTRL register.
- Hardware enables the submodule functional and interface clocks (expected to take a few cycles).
- Hardware sets the appropriate bit in the ISS_CLKSTAT register.

Software must enable the modules in the correct order. The hardware imposes no particular constraint. For example, when data must be provided by the CSI2_A/CSI2_B receiver and processed by the ISP, both modules must be enabled and correctly configured before data arrives. An example of configuration order is: enabling the CSI2_A receiver powers up the complex I/O connected to the external sensor. Additionally, the ISP must be configured and the source interface must be selected. For details and the order of configuration, see the programming module of the particular submodule.

When software wants to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
  - The submodule must not generate new events.
  - The submodule must not have any pending events.
  - For initiators: The submodule must stop the generation of an interface bridge transaction.
- Software clears the appropriate bit in the ISS_CLKCTRL register.
- For modules having only a master port: Hardware waits until the submodule to be disconnected asserts the MStandBy signal on its master port. It asserts MWait of the submodule.

NOTE: The ISS does not assert the MWait signal when a shutdown of the module is not requested by software.

- Hardware cuts the submodule clocks.
- Hardware clears the appropriate bit in the ISS_CLKSTAT register.

Table 8-15 describes the clock gating of the ISS submodule.

Table 8-15. ISS Submodule Clock Gating

ISS Resource	Feature On/Off Control
ISS top-level resources	Not applicable. ISS top-level resources cannot be cut. However, top-level resources support the autogating feature.
SIMCOP	ISS_CLKCTRL[0] SIMCOP
ISP	ISS_CLKCTRL[1] ISP
CSI2_A	ISS_CLKCTRL[2] CSI2_A
CSI2_B	ISS_CLKCTRL[3] CSI2_B
CSI2_C	ISS_CLKCTRL[6] CSI2_C
CCP2	ISS_CLKCTRL[4] CCP2
BYS_A	ISS_CLKCTRL[5] BYS_A
BYS_B	ISS_CLKCTRL[7] BYS_B
ISS interconnect BTE CBUFF TCTRL	These modules cannot be switched off individually. They are required for any processing performed by SIMCOP because they are on the main data path. However, they support autogating to reduce power consumption when activity is low.

When the clock of a submodule is cut and an interface bridge request for this module is received from the ISS configuration interconnect, the ISS clock manager temporarily enables the module clock to handle the access properly.

All ISS submodules are off after reset; software must enable them before they can be used.

8.1.2.3 ISS Reset

The ISS can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the ISS_HL_SYSCONFIG[0] SOFTRESET bit to 1.
2. Read the ISS_HL_SYSCONFIG[0] SOFTRESET bit to check whether it equals 0, which means the reset occurred.

If after five reads, ISS_HL_SYSCONFIG[0] SOFTRESET still returns 1, it can be assumed that an error occurred during the reset stage.

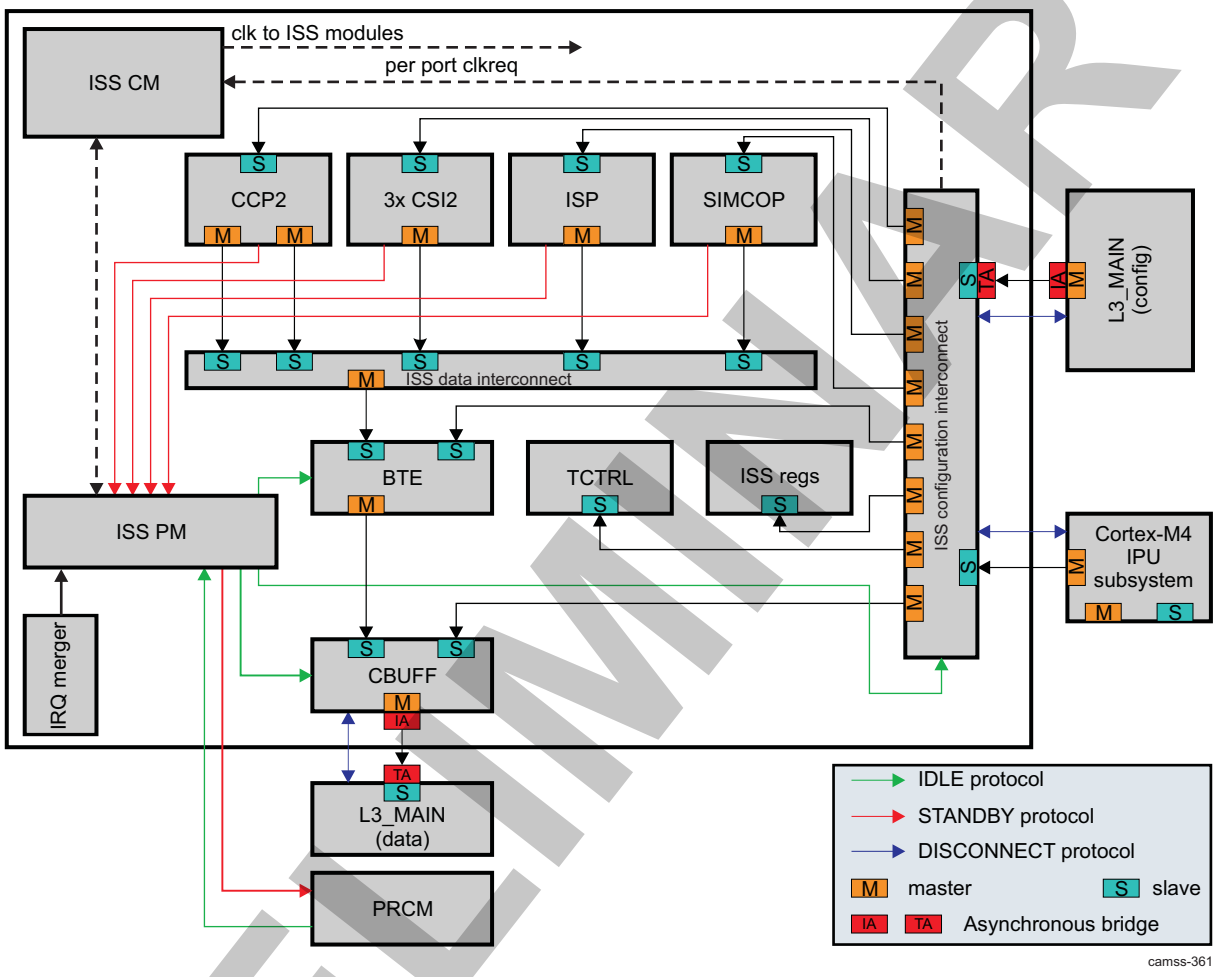
A software reset must not reset the power manager protocols (must not reset the IDLE and STANDBY generic IPs).

8.1.2.4 ISS Power Management

8.1.2.4.1 ISS Power-Management Infrastructure Overview

Figure 8-4 is an overview of the ISS power management.

Figure 8-4. ISS Power Management



NOTE: For power savings, the PRCM module can request idle mode from the ISS. When the ISS is not functional, software must decide when the PRCM module can send the request. For more information, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management.*

8.1.2.4.2 ISS STANDBY Mechanism

The power manager receives STANDBY information from the CCP2, CSI2_A, CSI2_B, CSI2_C, ISP, and SIMCOP modules. These modules assert a standby signal when they have no more transactions to perform. The ISS power manager acknowledges by asserting a wait signal.

When those five modules are in standby mode, the ISS power manager initiates a STANDBY sequence for the ISS:

1. The ISS waits while the CCP2, CSI2_A, CSI2_B, CSI2_C, ISP, and SIMCOP MStandby is asserted.
2. The ISS power manager acknowledges by asserting the CCP2, CSI2_A, CSI2_B, CSI2_C, ISP, and SIMCOP MWait signal.
3. The ISS initiators assert only the MStandBy signal when they receive responses to all sent requests.

Therefore, when all initiators have asserted MStandBy, the ISS interconnect has no more pending traffic (although configurable, only nonposted writes must be used for error reporting).

4. The ISS power manager sends an IDLE request to the BTE. This IDLE request is used to drain BTE data. It does not affect the configuration port.
5. The BTE drains all transactions.
6. The BTE acknowledges the IDLE request.
7. The ISS power manager sends an IDLE request to the CBUFF. This IDLE request is used to drain CBUFF data. It does not affect the configuration port.
8. CBUFF drains all transactions.
9. CBUFF disconnects the interface master port connected to the L3 interconnect.
10. CBUFF acknowledges the IDLE request.
11. The ISS power manager asserts the MStandBy signals connected to the system PRCM module.
12. The PRCM module acknowledges by asserting the MWait signal.

A functional standby transition can be aborted when one of the CCP2, CSI2_A, CSI2_B, CSI2_C, ISP, or SIMCOP modules deasserts the MStandBy signal. The corresponding MWait signal is deasserted only when the ISS interconnect, BTE, CBUFF, and ISS interface master port are ready to receive requests.

When one of the CCP2, CSI2_A, CSI2_B, CSI2_C, ISP, or SIMCOP modules must perform accesses to the ISS interface master port, it deasserts the MStandBy signal. The ISS power manager executes the following sequence to leave the STANDBY state:

1. The ISS power manager deasserts the MStandby signal.
2. The ISS waits until the PRCM module deasserts the MWait signal.
3. The ISS power manager requests CBUFF to go into functional mode.
4. CBUFF connects the interface port.
5. The ISS power manager requests the BTE to go into functional mode.
6. The ISS power manager waits until CBUFF and BTE acknowledge functional mode.
7. The ISS deasserts the MWait signal of the module requesting access.

Abort of the standby-to-functional mode transition is not supported. The ISS power manager completes the standby-to-functional transition and then allows a new functional-to-standby transition.

Typically, the MStandby signal is used for two purposes. Software chooses one of the following behaviors through PRCM configuration:

- During blanking periods: The ISS asserts the MStandBy signal between frames when it has no more data to send. The PRCM module can use this information to switch off the L3 interconnect and save some dynamic power. However, the PRCM module is not allowed to cut the ISS functional clock in that case, because it is needed to receive the next frame.
- For ISS shutdown: The ISS asserts MStandBy when it has no more transactions to perform. The PRCM module then initiates an IDLE sequence. Once the ISS acknowledges the transition into idle mode, the PRCM module can cut the ISS clock and power.

The internal standby mode can be reached only when CCP2, CSI2_A, CSI2_B, CSI2_C, SIMCOP, ISP, ISS data interconnect, BTE, and CBUFF are in IDLE or STANDBY state. Choosing no-idle or no-standby mode for any of these modules prevents the ISS from going into STANDBY state.

Four modes for standby control are supported, configured through the ISS_HL_SYSCONFIG [5:4] STANDBYMODE register bit-field:

- Smart-standby-wakeup mode [STANDBYMODE = 0x3]: This is the mode normally used. When in this mode, the ISS asserts the MStandBy signal when the MStandBy of all ISS internal initiators is asserted and the ISS data interconnect, BTE, and CBUFF are in IDLE state.
- Smart-standby mode (default) [STANDBYMODE = 0x2]: The ISS has no wake-up event. This mode is equivalent to smart-standby-wakeup mode.
- Force-standby mode [STANDBYMODE = 0x0]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS asserts MStandBy unconditionally. Software must ensure that the ISS is in a correct quiet state before programming this mode.

- No-standby mode [STANDBYMODE = 0x1]: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS never asserts the MStandBy signal.

8.1.2.4.3 ISS IDLE Mechanism

The PRCM module can request the ISS to go into IDLE state when the ISS has asserted its MStandBy output.

In a normal case, software must ensure that the ISS is in a quiet state before allowing the PRCM module to send an IDLE request to the ISS:

- The ISS has no more traffic to generate.
- The ISS cannot generate any new interrupts.
- The ISS has no pending interrupts.

When an IDLE request is received from the PRCM module, the ISS power manager verifies that the ISS MWait input has been asserted and that all ISS interrupt outputs are deasserted. It then starts the STANDBY-to-IDLE transition:

1. Send IDLE request to the ISS configuration interconnect.
2. The ISS configuration interconnect requests disconnection of both ISS interface slave ports. Disconnection is done by the master:
   - It stops accepting new requests and drains currently ongoing ones.
   - It waits for completion of all ongoing transactions.
3. The ISS configuration interconnect acknowledges the IDLE transition.
4. The ISS power manager acknowledges the IDLE request from the PRCM module.
5. The PRCM module can cut the ISS clock and power.

The PRCM module first enables the ISS power and clock before requesting the ISS to go into functional state by deasserting the SIdleReq signal. The ISS power manager then executes the wake-up sequence:

1. Request the ISS interconnect to go into functional state.
2. The ISS interconnect connects the ISS slave ports.
3. The ISS interconnect acknowledges transition into functional mode.
4. The ISS power manager acknowledges transition into functional mode (ISS output SIdleAck = 00).

Four modes for IDLE control are supported, controlled through the ISS_HL_SYSCONFIG[3:2] IDLEMODE register bit-field:

- Smart-idle-wakeup mode [IDLEMODE = 0x3]: This is the mode normally used. When in this mode, the ISS acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state.
- Smart-idle mode (default) [IDLEMODE = 0x2]: This is equivalent to smart-idle-wakeup mode.
- Force-idle mode [IDLEMODE = 0x0]: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the ISS acknowledges a request to go idle from the power manager with no hardware condition. Software must ensure that the ISS is in a correct quiet state before requesting a force-idle transition.
- No-idle mode [IDLEMODE = 0x1]: When in this mode, the ISS disregards any request to go idle from the power manager.

8.1.3 ISS Register Manual

8.1.3.1 ISS Instance Summary

Table 8-16 is the ISS instance.

ISS Overview
• ISS TOP Register Summary: [0]

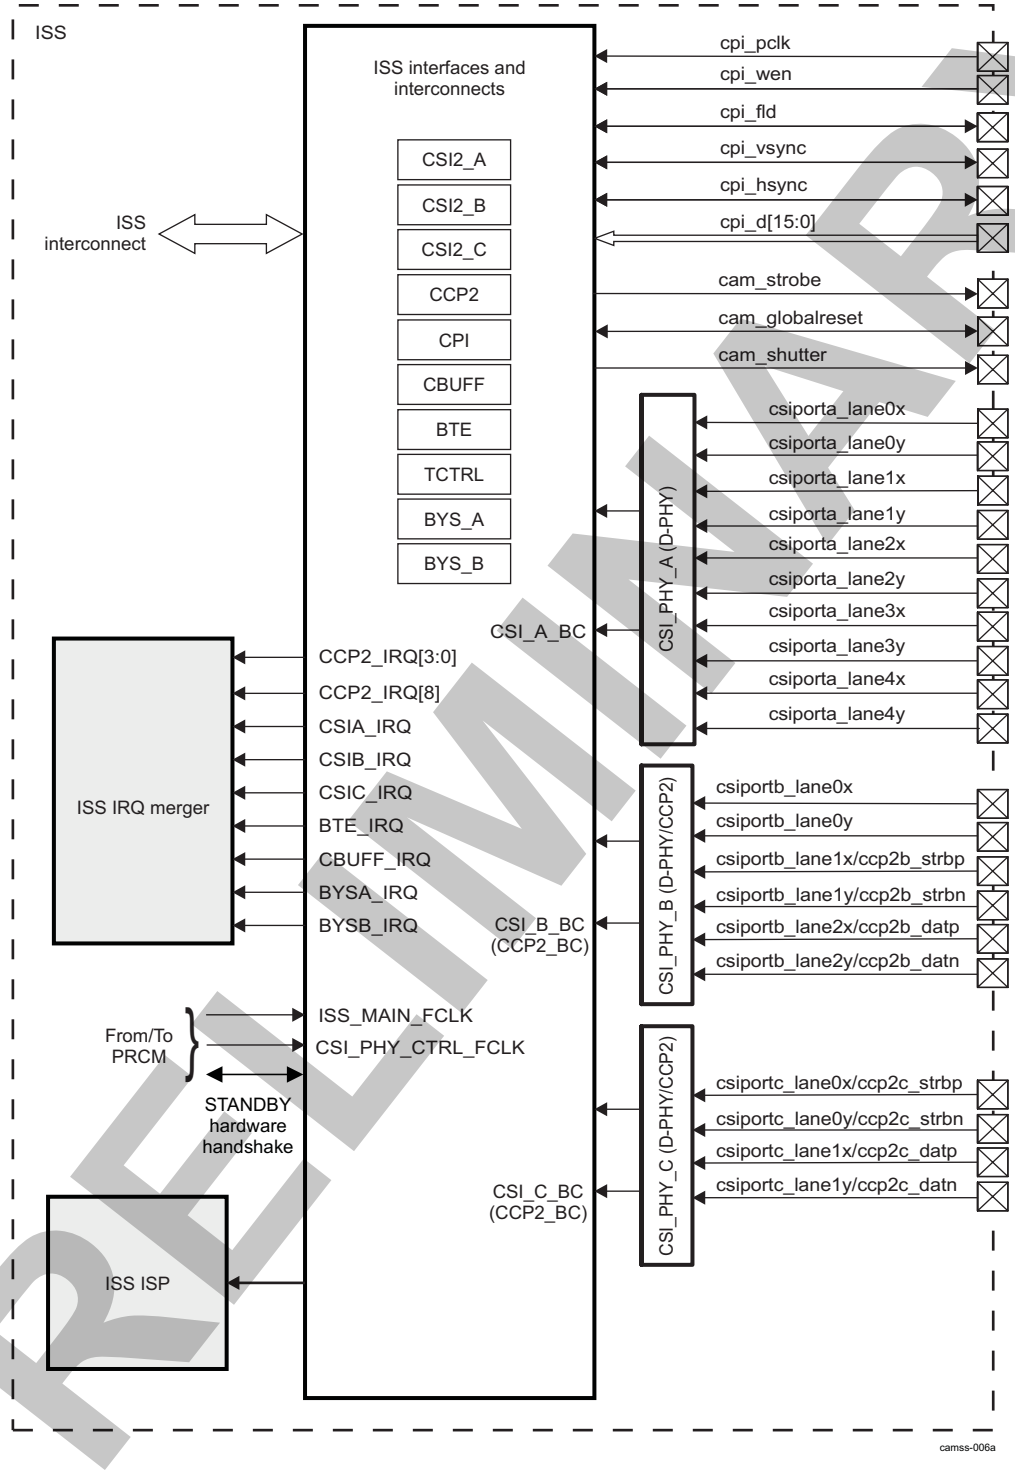
8.2 ISS Interfaces

8.2.1 ISS Interfaces Overview

Along with the submodules, the ISS has three serial camera interfaces (primary, secondary and tertiary) and a parallel interface within the ISS boundary. The primary serial interface (CSI2_A) supports MIPI® CSI2 protocol with four data lanes, the secondary serial interface (CSI2_B/CCP2) supports CSI2 protocol with two data lanes or CCP2 protocol, and the third serial interface (CSI2_C/CCP2) supports CSI2 protocol with one data lane or CCP2 protocol. The parallel interface (CPI) supports up to 16 data lanes. All interfaces can use the image signal processor (ISP), but not concurrently. When one interface uses the ISP, the other must send data to memory. However, the ISP can still be used to process this data in memory-to-memory. Time multiplex processing is also possible.

Figure 8-5 shows the ISS interfaces and interconnects.

Figure 8-5. ISS Interfaces and Interconnects Highlight



8.2.1.1 ISS Interface Features

The camera subsystem supports the following features:

- System interfaces and interconnects:
  - Two 32-bit-wide configuration interfaces:
    - Interface to Cortex™-M4 microprocessor unit (IPU): Synchronous to the functional clock

- Interface to Cortex™-A15 MPU and system direct memory access (DMA_SYSTEM): Asynchronous from the functional clock

– 128-bit-wide data interface to level 3 (L3_MAIN) interconnect: Asynchronous from the functional clock
  - Shared interface level 2 (L2) in IVA-HD module for hardware encoding
  - Outside connection using the L3_MAIN interconnect through the TILER to the synchronous dynamic random access memory (SDRAM) controller (SDRC), which acts as the primary interface between the SDRAM and the ISS functional block
– The ISS has a local interconnect that connects all modules inside the ISS
– BTE:
  - Tightly coupled with the TILER to support efficient rotation
– CBUFF:
  - Maps a linear space into a circular buffer
  - The buffer is physically located in system memory.
– TCTRL:
  - Camera global reset control
  - Control signal generation for flash prestrobe and strobe
– Two BYS modules:
  - Stabilization statistics collection (piece wise interpolated gamma correction, polynomial lens shading correction)
  - Down scaler (horizontal and vertical cropping, defect pixel correction)

- Camera interfaces:

– Three CSI2 camera interfaces: CSI2_A (primary), CSI2_B (secondary) and CSI2_C (tertiary)
  - Transfer pixels and data received by the three digital physical layer receivers (CSI_PHY_A/B/C in D-PHY mode) to the system memory or to the ISP
  - Use unidirectional data link
  - CSI2_A supports four configurable data links in addition to the clock signaling
  - CSI2_B supports two configurable data links in addition to the clock signaling

NOTE: The cameras on the CSI2_A and CSI2_B interfaces must be of the same type to form a dual camera set supporting half-resolution stereoscopic applications.

  - CSI2_C supports one configurable data link in addition to the clock signaling
  - Maximum data rate of 1.5 Gbps per data lane
  - Data merger for 2-, 3-, or 4-data lane configuration
  - Error detection and correction by the protocol engine
  - Direct memory access (DMA) engine integrated with dedicated first in first out (FIFO)
  - One-dimensional (1D) and two-dimensional (2D) addressing mode
  - Burst support
  - Streaming burst support (64- or 32-bit)
  - Eight contexts to support eight dedicated configurations of virtual channel ID and data types
  - Ping-pong mechanism for double-buffering
  - All primary and secondary MIPI-defined formats are supported.
  - Conversion of the RGB formats
  - On-the-fly differential pulse code modulation (DPCM) decompression
  - On-the-fly image cropping and A-law/DPCM compression
  - Configuration of the complex input/output (I/O) physical layers (CSI_PHY_A/B/C):
    - MIPI D-PHY compliant receiver PHY solution (D-PHY mode)

- SMIA CCP2 compatible receiver PHY solution (CCP2 mode)

– One CCP2 camera interface
  - Four logical channels
  - Transfer pixels and data received by two complex I/O physical layers (CSI_PHY_B/C in CCP2 mode) to the system memory or the ISP
  - Use unidirectional data link
  - Maximum data rate of 650 Mbps
  - DMA engine integrated with dedicated FIFO
  - 1D and 2D addressing mode
  - False synchronization code protection
  - Ping-pong mechanism for double-buffering
  - RGB, RAW, YUV, and JPEG formats supported
  - On-the-fly DPCM decompression
  - On-the-fly image cropping and A-Law/DPCM compression
– One Parallel interface (CPI)
  - 8/12/16 bits wide
  - Up to 148.5 MPix/s
  - BT656 and SYNC mode (HS, VS, FIELD, WEN)
– System memory data read back port (supported by the CCP2 protocol engine)
  - RAW 6, 7, 8, 10, 12, 14, 16 formats supported
  - DPCM and A-law decompression
  - Supports image cropping for compressed or uncompressed data

NOTE: Rotated DPCM data is not supported.

8.2.2 ISS Interfaces Environment

8.2.2.1 ISS Interfaces Signal Descriptions

Table 8-40 summarizes the ISS I/O signals and corresponding interface modes.

Table 8-40. ISS I/O Description

Signal Name	I/O[1]	Description	Serial Mode CCP2	Serial Mode CSI2	Parallel Mode CPI

ccp2c_datn	I	Serial CCP2 mode: Differential data negative input	x		
cpi_pclk	I	Parallel mode pixel clock input			x
cpi_wen	I	Parallel mode write enable signal input			x
cpi_fld	I/O	Parallel mode pixel clock field signal			x
cpi_vsync	I/O	Parallel mode vertical frame synchronization			x
cpi_hsync	I/O	Parallel mode horizontal frame synchronization			x
cpi_data[15:0]	I	Parallel mode data lanes (16 signals)			x

NOTE: Lane polarity can be changed in complex I/O. For more information, see Section 8.2.2.2, *ISS Interface Modes*.

NOTE: At least one data lane must be configured for using the CSI2_A and CSI2_B interfaces. The CSI2_C provides only one data lane. The signals are also configurable from the device Control Module. Thus, they are not required to be at a certain location to act as clock or data; this can be configured.

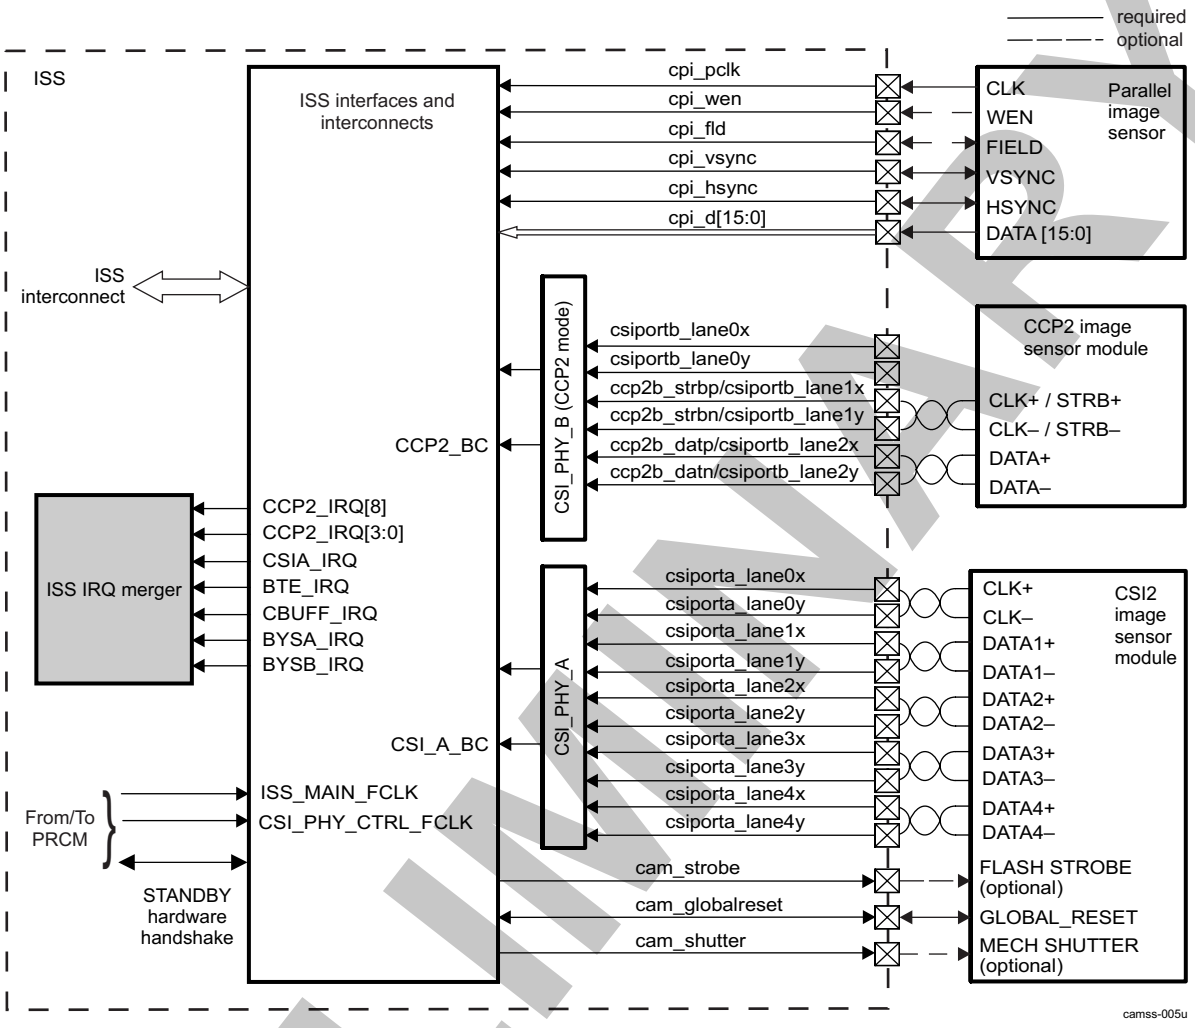
NOTE: The Parallel interface (CPI), CCP2, and CSI2_A/B/C interfaces share pins. Their modes are not supported as a pin configuration mux option. The modes are configured from the CSI_PHYs configured from the device Control Module (see Chapter 18, *Control Module*).

NOTE: The TCTRL cam_strobe and cam_shutter signals are available on a second pair of alternative device pads. See Chapter 18, *Control Module*, for more details.

8.2.2.2 ISS Interfaces Modes

The camera subsystem can manage a parallel interface and up to four serial image sensors. Depending on the configuration of the shared pins, four of the interfaces can be active at the same time. However, only one data flow can use the ISP. Moreover, if the parallel interface is used, the data from it goes to ISP and the other used interfaces must send it to memory. Figure 8-6 shows an example block diagram of the interface configuration (CSI2_C is not shown). Each serial port clock lane is configurable. The MIPI CSI2 protocol requires only a clock lane setup. The data lane configuration is optional. For more information, see Section 8.2.5.1.1, *ISS CSI2 Protocol and Data Format*.

Figure 8-6. ISS CSI2_A, CSI2_B/CCP2 Serial Interface Configuration



NOTE: Depending on the needs, cam_strobe, cam_globalreset, and cam_shutter can be connected to the image sensor module rather than the CSI2 image sensor module.

NOTE: Dedicated Power, Reset, and Clock Management (PRCM) module pins for power and ground are provided for external sensors: vdda_csiporta, vdda_csiportb, vdda_csiportc, vssa_csiporta, vssa_csiportb and vssa_csiportc.

A graphical representation of the pins for connecting external sensors to the ISS shows a variety of connectivity configurations that are possible by setting the CSI_PHYs immediately before the receivers, and a variety of output paths, including some sensor data through the receivers to memory or the ISP. Table 8-41 lists some of the connectivity possibilities; the ISP can take only one input lane at a time. For more information about the operating properties and configuration of the CSI_PHY modules, see Section 8.2.3, *ISS CSI PHY*.

	Serial Cameras Only			Serial + Parallel Cameras			
cpi_hsync				x	x	x	x
cpi_d[15:0]				x	x	x	x

NOTE: The ISP can take only one input at a time. The other inputs must go to memory and then be processed after the ISP processes the input that was received first.

NOTE: The cameras on the CSI2_A and CSI2_B interfaces must be of the same type to form a dual camera set supporting half-resolution stereoscopic applications.

In looking at the sample connections between the ISS through the receivers and external sensors, it is apparent that the lanes of the input can be adjusted for certain needs. For example, it is not necessary that the CSI2_A has four data lanes connected at the same time. The restriction is that CSI2_B is limited to two data lanes and CSI2_C to one data lane. Because CSI2_B/C and CCP2 share CSI_PHYs pins, they cannot be used simultaneously. CSI2_A, CSI2_B/CCP2 and CSI2_C/CCP2 can function at the same time by sending data to memory. In this manner, external sensors can be connected any way possible for best performance and results.

8.2.2.3 ISS Interfaces CPI Data Formats

8.2.2.3.1 ISS Interfaces CPI Generic Configuration Protocol and Data Format (8, 10, 12, 16 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8- to 16-bit-wide data signals.

In this configuration, no assumptions are made about the data format of pixels, but the dynamic range is limited to 8, 10, 12, and 16 bits (data can be pure Luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on cpi_data[15:0], where 1 pixel is sampled for every cpi_pclk rising edge (or falling edge, depending on the configuration of cpi_pclk polarity).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (cpi_hsync) and vertical synchronization (cpi_vsync). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

NOTE: For correct operation, the clock cpi_pclk must run during blanking periods (cpi_hsync and cpi_vsync inactive). The cpi_pclk must start before sending cpi_data[15:0] and start cpi_vsync and cpi_hsync.

Figure 8-7 and Figure 8-8 show the frame and data timing, based on synchronization signals in the parallel No BT configuration.

Figure 8-7. ISS Interfaces CPI Synchronization Signals and Frame Timing in SYNC Mode

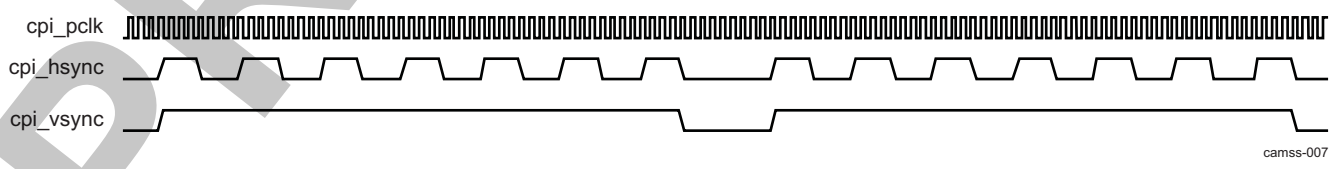

Figure 8-8. ISS Interfaces CPI Synchronization Signals and Data Timing in SYNC Mode

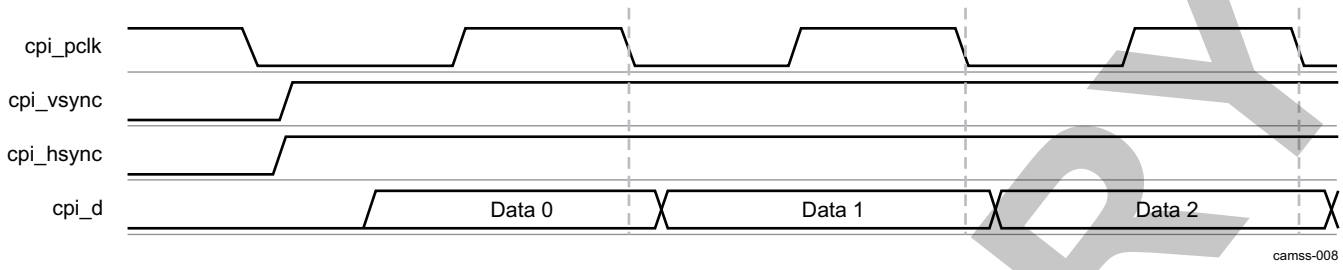
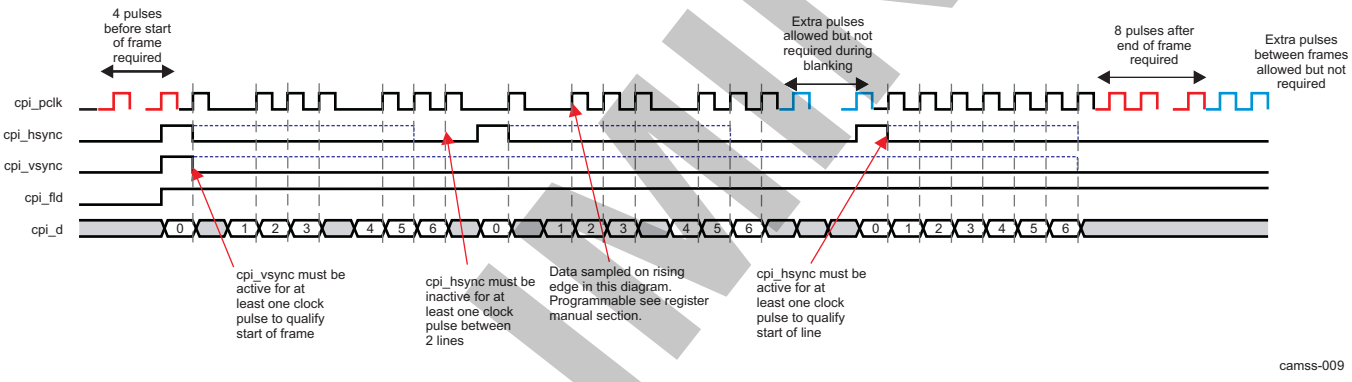


NOTE: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least four clock pulses are required before sending active image data and synchronization information; eight clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 8-9 shows the timing diagram of the SYNC move clock gating.

Figure 8-9. ISS Interfaces CPI SYNC Mode Clock Gating

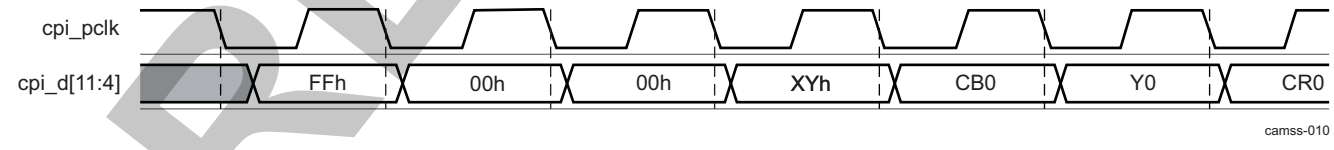


8.2.2.3.2 ISS Interfaces CPI ITU-R BT.656/1120 422 Protocol and Data Formats (8, 10 Bits)

The ISS CPI supports data in ITU-R BT.656 format. The ITU-R BT.656 standard specifies a method of transferring YUV4:2:2 data over an 8- or 10-bit video interface.

Figure 8-10 shows the data timing diagram with embedded synchronization signals.

Figure 8-10. ISS Interfaces CPI Data Timing With Embedded Synchronization Signals (8-Bit Case)



In BT.656, the data words (8- or 10-bit) in which the 8 most-significant bits (MSBs) are all set to 1, or all set to 0, are reserved.

NOTE: The ITU-R BT.656 specification is for 525-line and 625-line, digital component video signals in compliance with ITU-R BT.601. See the CCIR document Rec. 656-1 for detailed information about the interface.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved Luminance and Chroma samples and the following byte Y2n + 1 corresponds to the next Luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cpi_hsync and cpi_vsync are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: FF 00 00 XY. The first 3 bytes are a fixed preamble (see the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 8-42 lists the video timing reference codes for SAV and EAV.

Table 8-42. ISS Interfaces CPI Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 8-43 describes the F, V, and H signals.

Table 8-43. ISS Interfaces CPI F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the ISIF_REC656IF[0] ECCFVH bit.

NOTE: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

Table 8-44 lists the F, V, and H protection (error-correction) bits.

Table 8-44. ISS Interfaces CPI F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1

Table 8-44. ISS Interfaces CPI F, V, H Protection (Error-Correction) Bits (continued)

F	V	H	P3	P2	P1	P0
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in ITU-R BT.656 mode, data is stored in SDRAM according to the format listed in Table 8-45 when the ISIF_REC656IF[1] R656ON bit is enabled.

Table 8-45. ISS Interfaces CPI ITU-R BT.656 Mode Data Format in SDRAM

Pixel3 (Y1)	Pixel2 (Cr0)	Pixel1 (Y0)	Pixel0 (Cb0)

8.2.3 ISS CSI PHY

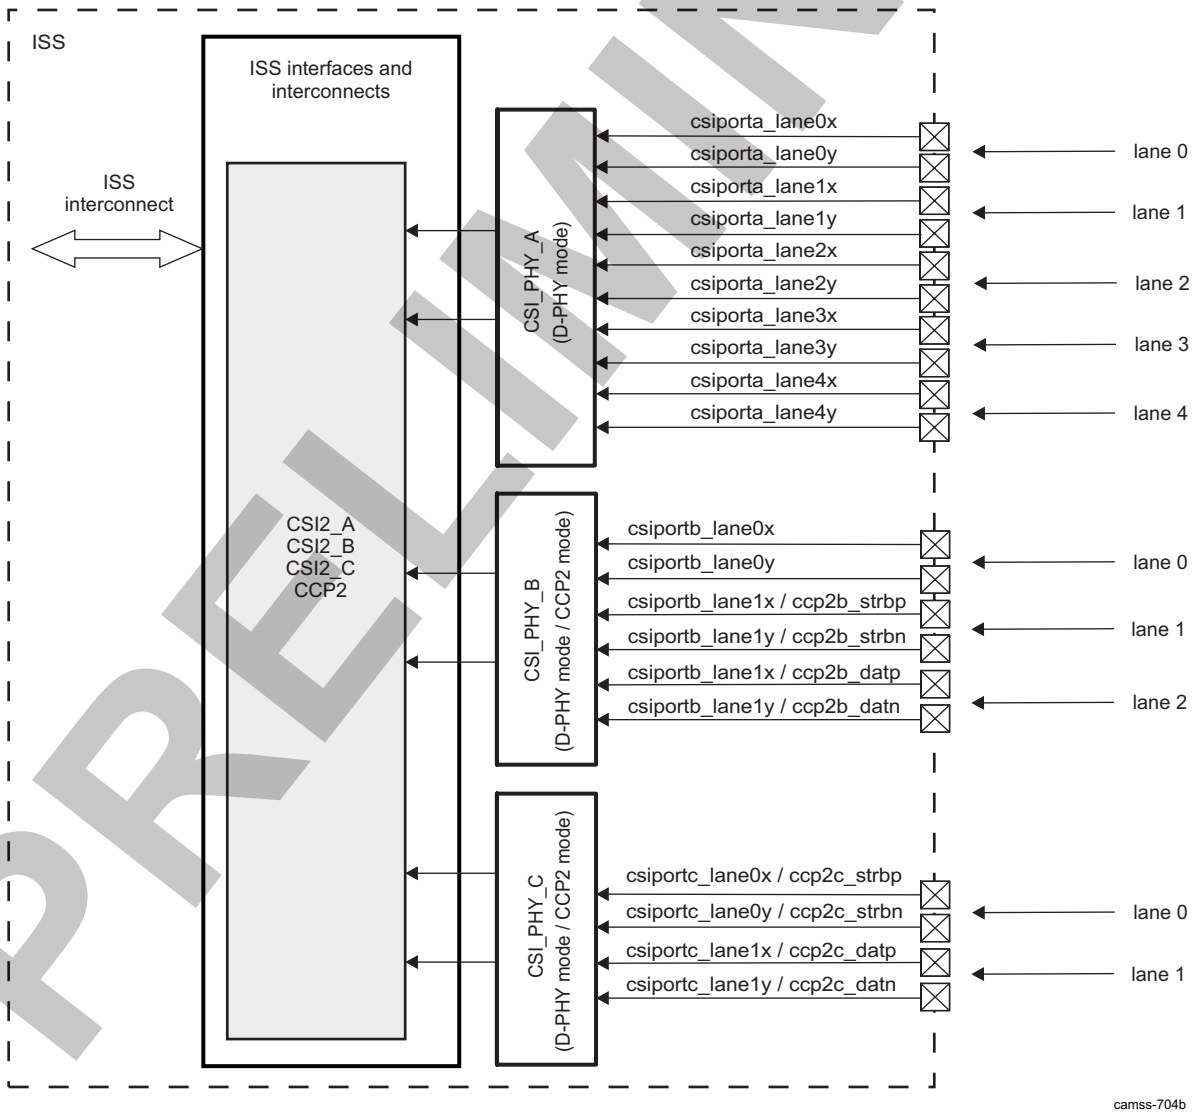
8.2.3.1 ISS CSI PHY Overview

Three MIPI D-PHY / SMIA CCP2 compliant PHY receivers (CSI_PHY_A, CSI_PHY_B and CSI_PHY_C, or generally referenced to as CSI_PHY) immediately before the ISS interfaces (CSI2_A, CSI2_B, CSI2_C and CCP2) act as a physical connection and configuration of clock/data lanes with external sensors. A CSI_PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receivers are compatible with the *MIPI D-PHY Specification v1.00.00*. The selection of a CSI_PHY in D-PHY mode, parallel mode, or CCP2 mode must be done before reset and not on the fly.

The CSI_PHY is controlled and must be configured first from the device Control Module for pad configuration. The differential data/clock lanes coming into the CSI2_A, CSI2_B and CSI2_C CSI_PHYs are configured from registers explained in (see register CONTROL_CAMERA_RX).

There are three CSI_PHYs integrated in the device. As shown in Figure 8-11, the CSI_PHY_A contains four data lane; CSI_PHY_B is the same, except that it has two data lanes plus a clock/strobe lane; CSI_PHY_C has one data lanes plus a clock/strobe lane. The figure below shows the three CSI_PHY cases, with their signals listed in Table 8-41.

Figure 8-11. ISS Interfaces CSI_PHYs Diagram



NOTE: If CCP2 mode is chosen for use in the CSI2_B/CCP2 CSI_PHY_B, then only LANE 1 and LANE 2 are used, as strbp/strbn and datp/datn respectively.

NOTE: LANE 4 of CSI2_A CSI_PHY_A can be used only as a data lane, never as a clock lane. All other configurations are possible.

NOTE: Depending on the selected mux mode from the Control Module, the Parallel Interface (CPI) signals can also be going through one of the CSI_PHYs.

CSI2_A, CSI2_B/CCP2 and CSI2_C/CCP2 CSI_PHYs represent the overall PHY solution for connecting external sensors to feed the ISS. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module, and the DX/DY data pad for each lane module can be configured as DP or DN pins defined. The configuration and the selection of D-PHY mode, data/clock, or data/strobes are done through the device Control Module (see Chapter 18, *Control Module*). The only exception is the four-data-lane use case, in which one corner lane is allowed to be only a data lane. For the CCP2 function, the CSI_PHY solution support two data/strobe or data/clock lane modules. The data lane module and strobe lane modules must be physically adjacent. CSI_PHY supports serial configuration protocol for the configuration interface.

8.2.3.2 ISS CSI PHY Functional Description

8.2.3.2.1 ISS CSI PHY Functional Configuration

The CSI_PHY converts the bitstream, divided into 1 up to 4 serial data lanes, and one clock lane, into a bitstream compatible with the CSI2/CCP2 receivers.

The CSI2_COMPLEXIO_IRQSTATUS register logs complex I/O events of the following types:

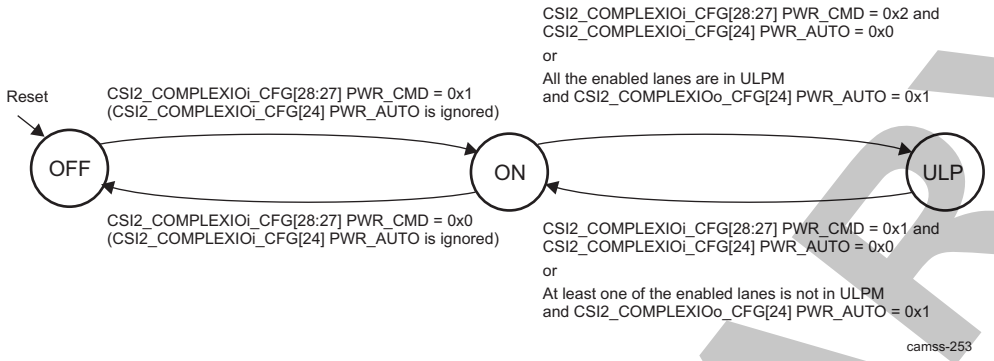
- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

The CSI2 receiver embeds two registers to configure/read some complex I/O parameters:

- The REG0 register detects clock miss with respect to the *MIPI D-PHY Specification v1.00.00* and control timing.
- The REG0 register reports completion of reset on the different parts of the module and configures the timing parameters.
- The CSI2_COMPLEXIO_CFG registers contain the PWR_AUTO and PWR_CMD bit fields, which affect the power management of the three complex I/Os.

The complex I/O has three power modes: on, off, and ultralow power (ULP). These modes can reflect the ON or ULP states of the five differential lines if the CSI2_COMPLEXIO_CFG[24] PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the complex I/O power state is controlled by the CSI2_COMPLEXIO_CFG[28:27] PWR_CMD bit field, which directly defines the power state. Figure 8-12 shows the complex I/O power finite state-machine (FSM).

Figure 8-12. ISS CSI Complex I/O Power FSM



Another register, CSI2_TIMING, is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the three complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The CSI2_TIMING[15] FORCE_RX_MODE_IO1 bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The FORCE_RX_MODE_IO bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bits (CSI2_TIMING[14] STOP_STATE_X16_IO1, CSI2_TIMING[13] STOP_STATE_X4_IO1, and the CSI2_TIMING[12:0] STOP_STATE_COUNTER_IO1 bit field) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock (ISS_MAIN_FCLK) cycles and can be calculated as follows:

Total delay in ISS_MAIN_FCLK cycle = CSI2_TIMING.STOP_STATE_COUNTER_IO x (1+CSI2_TIMING.STOP_STATE_X16_IO x 15) x (1+CSI2_TIMING.STOP_STATE_X4_IO x 3).

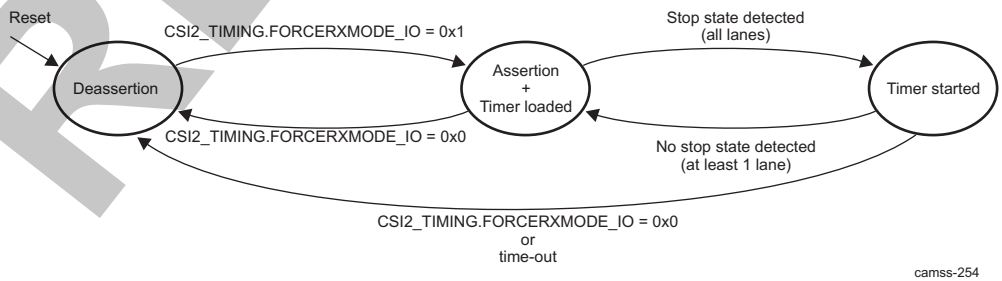
Table 8-46 lists the possible values of the delay, in terms of the ISS_MAIN_FCLK cycles, depending on the values of the STOP_STATE_X16_IO and STOP_STATE_X4_IO bits.

Table 8-46. ISS CSI2 Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO	STOP_STATE_X4_IO	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The FORCERXMODE signal is used at initialization time (complex I/O). Figure 8-13 describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

Figure 8-13. ISS CSI2 RxMode and StopState FSM



8.2.3.2.2 ISS CSI PHY (D-PHY Mode) and Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CSI_PHY. The CSI2_A/B/C receiver is expected to coordinate the PHY initialization. The controller must ensure that the CSI_PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CSI_PHY for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state." One possible initialization sequence is:

To fully initialize the CSI_PHY, perform the following steps:

1. Configure all CSI2 receiver registers to be ready to receive signals/data from the CSI_PHY:
   (a) Configure all needed CSI2 registers:
      (i) Set CSI2_COMPLEXIO_CFG[18:16] DATA4_POSITION.
      (ii) Set CSI2_COMPLEXIO_CFG[14:12] DATA3_POSITION.
      (iii) Set CSI2_COMPLEXIO_CFG[10:8] DATA2_POSITION.
      (iv) Set CSI2_COMPLEXIO_CFG[6:4] DATA1_POSITION.
      (v) Set CSI2_COMPLEXIO_CFG[2:0] CLOCK_POSITION.
      (vi) Set the CONTROL_CAMERA_RX[23:22] CSIPORTC_CAMMODE, CONTROL_CAMERA_RX[12:11] CSIPORTB_CAMMODE or CONTROL_CAMERA_RX[2:1] CSIPORTA_CAMMODE.

> **CAUTION**
>
> This must be done before the CSIPHY is active.

      (vii) A dedicated internal clock gate control is present for each PHY. Enable/disable the internal CTRLCLK from the CONTROL_CAMERA_RX register by setting the following bits:
         - [21] CSIPORTC_CTRLCLKEN for CSI_PHY_C
         - [10] CSIPORTB_CTRLCLKEN for CSI_PHY_B
         - [0] CSIPORTA_CTRLCLKEN for CSI_PHY_A
2. CSI_PHY and link initialization sequence:
   (a) Deassert the CSI_PHY reset.
      (i) Set CSI2_COMPLEXIO_CFG[30] RESET_CTRL to 0x1.

> **CAUTION**
>
> For the CSI2_COMPLEXIO_CFG[29] RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must to be active and sending the MIPI HS BYTECLK.

   The following registers can be set only after deasserting the CSI_PHY reset and before asserting the FORCERXMODE signal:
   - REG0
   - REG1
   - REG2

   (b) Assert the FORCERXMODE signal:
      (i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x1.
   (c) Connect pulldown on link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):
   For CSI2_PHY_A pulldown on signals through padconf registers:
   - csiporta_lane4x:
     – CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[8]

CSIPORTA_LANE4X_INPUTENABLE = 0x1

- CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[4] CSIPORTA_LANE4X_PULLTYPESELECT = 0x0
- CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[3] CSIPORTA_LANE4X_PULLUDENABLE = 0x1

- csiporta_lane4y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[24] CSIPORTA_LANE4Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[20] CSIPORTA_LANE4Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[19] CSIPORTA_LANE4Y_PULLUDENABLE = 0x1
- csiporta_lane3x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE3X_PAD1_CSIPORTA_LANE3Y[8] CSIPORTA_LANE3X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTA_LANE3X_PAD1_CSIPORTA_LANE3Y[4] CSIPORTA_LANE3X_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTA_LANE3X_PAD1_CSIPORTA_LANE3Y[3] CSIPORTA_LANE3X_PULLUDENABLE = 0x1
- csiporta_lane3y:

  - CONTROL_CORE_PAD0_CSIPORTA_LANE0X_PAD1_CSIPORTA_LANE0Y[19] CSIPORTA_LANE0Y_PULLUDENABLE = 0x1

For CSI_PHY_B pulldown on signals through padconf registers:

- csiportb_lane2x:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[8] CSIPORTB_LANE2X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[4] CSIPORTB_LANE2X_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[3] CSIPORTB_LANE2X_PULLUDENABLE = 0x1
- csiportb_lane2y:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[24] CSIPORTB_LANE2Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[20] CSIPORTB_LANE2Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTB_LANE2X_PAD1_CSIPORTB_LANE2Y[19] CSIPORTB_LANE2Y_PULLUDENABLE = 0x1
- csiportb_lane1x:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[8] CSIPORTB_LANE1X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[4] CSIPORTB_LANE1X_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[3] CSIPORTB_LANE1X_PULLUDENABLEE = 0x1
- csiportb_lane1y:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[24] CSIPORTB_LANE1Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[20] CSIPORTB_LANE1Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTB_LANE1X_PAD1_CSIPORTB_LANE1Y[19] CSIPORTB_LANE1Y_PULLUDENABLE = 0x1
- csiportb_lane0x:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[8] CSIPORTB_LANE0X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[4] CSIPORTB_LANE0X_PULLTYPESELECT = 0x0

– CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[3] CSIPORTB_LANE0X_PULLUDENABLE = 0x1

- csiportb_lane0y:
  - CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[24] CSIPORTB_LANE0Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[20] CSIPORTB_LANE0Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTB_LANE0X_PAD1_CSIPORTB_LANE0Y[19] CSIPORTB_LANE0Y_PULLUDENABLE = 0x1

For CSI_PHY_C pulldown on signals through padconf registers:

- csiportc_lane1x:
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[8] CSIPORTC_LANE1X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[4] CSIPORTC_LANE1X_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[3] CSIPORTC_LANE1X_PULLUDENABLE = 0x1
- csiportc_lane1y:
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[24] CSIPORTC_LANE1Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[20] CSIPORTC_LANE1Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTC_LANE1X_PAD1_CSIPORTC_LANE1Y[19] CSIPORTC_LANE1Y_PULLUDENABLE = 0x1
- csiportc_lane0x:
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[8] CSIPORTC_LANE0X_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[4] CSIPORTC_LANE0X_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[3] CSIPORTC_LANE0X_PULLUDENABLE = 0x1
- csiportc_lane0y:
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[24] CSIPORTC_LANE0Y_INPUTENABLE = 0x1
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[20] CSIPORTC_LANE0Y_PULLTYPESELECT = 0x0
  - CONTROL_CORE_PAD0_CSIPORTC_LANE0X_PAD1_CSIPORTC_LANE0Y[19] CSIPORTC_LANE0Y_PULLUDENABLE = 0x1

(d) Power up the CSI_PHY:

(i) Set CSI2_COMPLEXIO_CFG[28:27] PWR_CMD to 0x1.

(e) Check whether the state status reaches the ON state:

- CSI2_COMPLEXIO_CFG[26:25] PWR_STATUS = 0x1

(f) Wait for STOPSTATE = 1 (for all enabled lane modules):

(i) The timer is set through the CSI2_TIMING[14:0] bit field. The reset value can be kept.

(ii) Wait until CSI2_TIMING[15] FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.

(g) Release PIPD* (= 1).

For CSI_PHY_A pullup on signals through padconf registers:

- csiporta_lane4x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[4]

CSIPORTA_LANE4X_PULLTYPESELECT = 0x1

- csiporta_lane4y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE4X_PAD1_CSIPORTA_LANE4Y[20] CSIPORTA_LANE4Y_PULLTYPESELECT = 0x1
- csiporta_lane3x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE3X_PAD1_CSIPORTA_LANE3Y[4] CSIPORTA_LANE3X_PULLTYPESELECT = 0x1
- csiporta_lane3y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE3X_PAD1_CSIPORTA_LANE3Y[20] CSIPORTA_LANE3Y_PULLTYPESELECT = 0x1
- csiporta_lane2x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE2X_PAD1_CSIPORTA_LANE2Y[4] CSIPORTA_LANE2X_PULLTYPESELECT = 0x1
- csiporta_lane2y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE2X_PAD1_CSIPORTA_LANE2Y[20] CSIPORTA_LANE2Y_PULLTYPESELECT = 0x1
- csiporta_lane1x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE1X_PAD1_CSIPORTA_LANE1Y[4] CSIPORTA_LANE1X_PULLTYPESELECT = 0x1
- csiporta_lane1y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE1X_PAD1_CSIPORTA_LANE1Y[20] CSIPORTA_LANE1Y_PULLTYPESELECT = 0x1
- csiporta_lane0x:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE0X_PAD1_CSIPORTA_LANE0Y[4] CSIPORTA_LANE0X_PULLTYPESELECT = 0x1
- csiporta_lane0y:
  - CONTROL_CORE_PAD0_CSIPORTA_LANE0X_PAD1_CSIPORTA_LANE0Y[20] CSIPORTA_LANE0Y_PULLTYPESELECT = 0x1

3. The CSI_PHY is initialized and ready/active in CSI2 (D-PHY) mode.

8.2.3.2.3 ISS CSI PHY (CCP2 Mode) and Link Initialization Sequence

The CSI2_B/C receiver is expected to coordinate the CSI_PHY initialization in CCP2 mode. The controller must ensure that the PHY is held in RESET state until the CCP transmitter is powered up and the link comes to the defined state. The controller can use the FORCERXMODE signals of CSI_PHY for this purpose. FORCERXMODE forces the receiver state-machine into RESET state, while the rest of common logic is powered up and functional. One possible initialization sequence is:

To fully initialize the CSI_PHY, perform the following steps:

1. Configure all CSI2_B/C receiver registers to be ready to receive signals/data from the CSI_PHY:

   (a) Configure all CCP2 registers:

   (i) Set CSI2_COMPLEXIO_CFG[10:8] DATA2_POSITION.

   (ii) Set CSI2_COMPLEXIO_CFG[6:4] DATA1_POSITION.

   (b) Set CONTROL_CAMERA_RX[12:11] CSIPORTB_CAMMODE or CONTROL_CAMERA_RX[23:22] CSIPORTC_CAMMODE.

CAUTION

This must be done before the CSI_PHY is active.

(c) A dedicated internal clock gate control is present for each PHY. Enable/disable the internal

CTRLCLK from the CONTROL_CAMERA_RX register by setting the following bits:

- [21] CSIPORTC_CTRLCLKEN for CSI_PHY_C
- [10] CSIPORTB_CTRLCLKEN for CSI_PHY_B
- [0] CSIPORTA_CTRLCLKEN for CSI_PHY_A

2. CSI_PHY and link initialization sequence:
   (a) Deassert the CSI_PHY reset:
      (i) Set CSI2_COMPLEXIO_CFG[30] RESET_CTRL to 0x1.
   (b) Assert the FORCERXMODE signal:
      (i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x1.
   (c) Power up the CSI_PHY:
      (i) Set CSI2_COMPLEXIO_CFG[28:27] PWR_CMD to 0x1.
   (d) Check that the state status reaches the ON state:
      - CSI2_COMPLEXIO_CFG[26:25] PWR_STATUS = 0x1
   (e) Release the FORCERXMODE signal:
      (i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x0.
3. The CSI_PHY is initialized and ready/active in CSI1/CCP2B mode.

8.2.3.2.4 ISS CSI PHY Error Signals

In D-PHY mode, the CSI_PHY supports the following error detection and signaling to the associated receiver:

- ERRSOTHS: Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSI_PHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS: Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSI_PHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL: Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC: Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRSYNCESC: Flags the low-power data transmission synchronization error. This error is flagged if the number of bits received during a low-power data transmission is not a multiple of 8 bits. This signal, if asserted, is high until the next change in the state of the LP line. In case the number of received bits is 1 less than a multiple of 8, RXVALIDESC is also asserted together with ERRSYNCESC, and an erroneous data byte is output on RXDATAESC. In other cases of this error, RXVALIDESC is not asserted and an erroneous data byte is not sent out.

In CCP2 mode, the CSI_PHY supports the following error detection and signaling to the associated receiver:

- CCPERRRESYNC output is an error indicator to the receiver to flag the shifted synchronization error, if the new synchronization sequence is not aligned with a 32-bit word boundary compared to the previously received synchronization sequence. This error flag is asserted for 32 cycles (4 bytes/32 bits).

8.2.3.3 ISS CSI PHY Register Manual

8.2.3.3.1 ISS CSI PHY Instance Summary

Table 8-47 lists the ISS CSI PHY instance.

Table 8-47. ISS CSI PHY Instance Summary

Module Name	L3_MAIN Base Address	Size
ISS_CAMERARX_CORE1	0x5200 1170	64 bytes
ISS_CAMERARX_CORE2	0x5200 1570	64 bytes
ISS_CAMERARX_CORE3	0x5200 2570	64 bytes

NOTE: ISS_CAMERARX_CORE1 is for CSI2_A CSI_PHY_A.

ISS_CAMERARX_CORE2 is for CSI2_B/CCP2 CSI_PHY_B.

ISS_CAMERARX_CORE3 is for CSI2_C/CCP2 CSI_PHY_C.

8.2.3.3.2 ISS CSI PHY Registers

8.2.3.3.2.1 ISS CSI PHY Register Summary

Table 8-48 summarizes the ISS CSI PHY register mapping.

Table 8-48. ISS CSI PHY Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	ISS_CAMERARX_CORE1 Base Address	ISS_CAMERARX_CORE2 Base Address	ISS_CAMERARX_CORE3 Base Address
REG0	RW	32	0x0000 0000	0x5200 1170	0x5200 1570	0x5200 2570

8.2.4 ISS CCP2

8.2.4.1 ISS CCP2 Environment

8.2.4.1.1 ISS CCP2 Protocol and Data Formats

This section describes the CCP2 protocol and data formats. The CCP2 receiver is compatible with the *SMIA CCP2 Specification v1.0* and the *MIPI CSI1 Specification*. Table 8-55 describes the I/O for serial interface CCP2.

Table 8-55. I/O Description for Serial Interface CCP2

Signal Name		I/O[1]	Description
ccp2b_datp / ccp2c_datp	CAM_S_DATA	I	Serial data input. Configurable.
ccp2b_datn / ccp2c_datn			
ccp2b_strbp / ccp2c_strbp	CAM_S_CLK	I	Serial clock or strobe input. Configurable.
ccp2b_strbn / ccp2c_strbn			

(1) I = Input; O = Output

From the device point of view, the CCP2 interface comprises four differential inputs representing two effective signals: the serial data and the clock.

The CCP2 receiver is a serial interface to an image sensor. Signals from the camera are serial input data (CAM_S_DATA) and a clock/strobe signal (CAM_S_CLK). For more details on signals connectivity to image sensors, see Section 8.2.4.3.2, *ISS CCP2 PHY*.

8.2.4.1.1.1 ISS CCP2 Synchronization Codes

Each frame is clearly identified by four unique 32-bit synchronization codes: frame start, frame end, line start, and line end, which are embedded in the serial bitstream. The logical channel identification number is also encoded in the synchronization codes.

- Frame-start code (FSC): Identifies the start of a new frame
- Line-start code (LSC): Identifies the start of a new line and is received for every line, except the first line, that starts with an FSC
- Line-end code (LEC): Identifies the end of a line and is received for every line, except the last line, that ends with an FEC
- Frame-end code (FEC): Identifies the end of the last line and the end of the current frame

8.2.4.1.1.2 ISS CCP2 False Synchronization Code Protection

CCP2 supports false synchronization protection (FSP). Additional bytes after the JPEG stream can be written to the SDRAM. They do not prevent JPEG encode and there is no need to preserve them.

8.2.4.1.1.3 ISS CCP2 Image Data Operating Modes and Alignment Constraints

The CCP2 receiver interface has several image data operating modes (see Table 8-56). The EXPx formats (where x = 8, 16, or 32) are used to expand data up to 8, 16, or 32 bits by padding data with zeros. The Data Size Increase in Memory column indicates memory overhead versus format without data expansion and/or DPCM compression.

Table 8-56. ISS CCP2 Image Data Operating Modes and Alignment Constraints

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP)	Data Size Increase in Memory. (When negative, data compression present)	2D Mode Availability[1]	Comments
0x0	YUV4:2:2 big endian	16	0%	Yes	
0x1	YUV4:2:2 little endian	16	0%	Yes	
0x2	YUV4:2:0	12	0%	Yes	
0x3	YUV4:2:2 + VP	N/A, data are sent to VP, YUV4:2:2 + VP = RAW8 + VP	N/A	Yes	
0x3	RAW8 + VP	N/A, data are sent to VP, YUV4:2:2 + VP must be used to output RAW8 + VP to memory	N/A	Yes	
0x4	RGB444 + EXP16	16	50%	Yes	
0x5	RGB565	16	0%	Yes	
0x6	RGB888	24	0%	Yes	
0x7	RGB888 + EXP32	32	33%	Yes	
0x8	RAW6 + EXP8	8	33%	Yes	
0x9	RAW6 + DPCM10 + EXP16	16	167%	Yes	DPCM decompression
0xA	RAW6 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xB	RAW10 -> RAW6 DPCM	6	–40%	Yes	DPCM compression
0xC	RAW7 + EXP8	8	14%	Yes	
0xD	RAW7 + DPCM10 + EXP16	16	128%	Yes	DPCM decompression
0xE	RAW7 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xF	RAW10 -> RAW6 DPCM + EXP8	8	–25%	Yes	DPCM compression
0x10	RAW8, this mode can be used to output RAW6 and RAW7	8	0%	Yes	
0x11	RAW8 + DPCM10 + EXP16	16	100%	Yes	DPCM decompression
0x12	RAW8 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0x13	RAW10 -> RAW7 DPCM	7	–30%	Yes	DPCM compression
0x14	RAW10	10	0%	Yes	
0x15	RAW10 + EXP16	16	60%	Yes	
0x16	RAW10 + VP	N/A, data are sent to VP	N/A	Yes	
0x17	RAW10 -> RAW7 DPCM + EXP8	8	–20%	Yes	
0x18	RAW12	12	0%	Yes	
0x19	RAW12 + EXP16	16	33%	Yes	
0x1A	RAW12 + VP	N/A, data are sent to VP	N/A	Yes	

(1) If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

Table 8-56. ISS CCP2 Image Data Operating Modes and Alignment Constraints (continued)

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP)	Data Size Increase in Memory. (When negative, data compression present)	2D Mode Availability(1)	Comments
0x1B	RAW10 -> RAW8 DPCM	8	–20%	Yes	DPCM decompression
0x1C	JPEG, 8-bit data	N/A	0%	Yes	
0x1D	JPEG, 8-bit data + FSP	N/A	0%	Yes	
0x1E	RAW10 -> RAW8 DPCM	8	–20%	Yes	Data right shift
0x1F	RAW8 DPCM12-> RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x20	RAW10 -> RAW8 ALAW	8	–20%	Yes	
0x21	RAW8 DPCM10 -> ALAW	8	–20%	Yes	

NOTE:

- Padding data of a 32-bit pixel data stream is handled the same way regardless of the programmed format. Therefore, there is no increase or decrease in storage because it is not compressed or decompressed.
- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros

  CCP2_LCx_CTRL[15:8] ALPHA can be used to set an alpha value.

  For RGB444 + EXP16:

  – data_out[31:28] = ALPHA [3:0]
  – data_out[15:12] = ALPHA [3:0]
- EXP32 = Data expansion to 32 bits, padding with alpha

  CCP2_LCx_CTRL[15:8] ALPHA can be used to set an alpha value.

  For RGB888 + EXP32: data_out[31:24] = ALPHA [7:0]
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video-preprocessing hardware is enabled. Programmers must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
- DPCM10 = Data decompression to 10 bits. Applies only to RAW6, RAW7, and RAW8 data formats; disabled if CCP2_CTRL[4] MODE = 0.
- Padding is handled the same way regardless of the programmed format.

NOTE: Data written by CSI2 can be read back by the CCP2 read channel. Some constrains apply (see Table 8-59).

8.2.4.1.1.4 ISS CCP2 Pixel Data Format

This section summarizes how the CCP2 pixel data formats are transmitted over the serial interface and how the pixels are reconstructed, stored in memory, or passed to the video port.

The CCP2 receiver can cope with all data formats if the data line length sent through the CS1/CCP2 physical protocol is a multiple of 32 bits. This condition is required for the CCP2 receiver to work correctly.

However, some data formats impose stronger line-length constraints to finish pixel reconstruction correctly at the end of the lines. This is imposed by CCP2 protocol-specific requirements, and not the CCP2 receiver. If CCP2 protocol constraints are not respected:

- Only the pixels reconstructed last in every line are erroneous. The missing bits are replaced with zeros to perform pixel reconstruction.
- The FW_IRQ interrupt is triggered.

8.2.4.1.1.4.1 ISS CCP2 YUV Operating Modes

NOTE: Although there are different possibilities of endianness in the bitstream, the device as a whole typically works in little-endian format. Therefore, the use of little-endian format is recommended.

8.2.4.1.1.4.1.1 ISS CCP2 YUV4:2:2

The YUV4:2:2 data format can be stored to memory in little- or big-endian format. The line length sent through the CCP2 receiver protocol must be a multiple of 32 bits.

YUV4:2:2 data format can also be sent to the video port.

YUV4:2:2 + VP is used to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP. Figure 8-14 and Figure 8-15 show big-endian and little-endian YUV4:2:2 format, respectively. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x0 to select YUV4:2:2 little-endian mode and to 0x1 for YUV4:2:2 big-endian mode.

Figure 8-14. ISS CCP2 YUV4:2:2 Big Endian

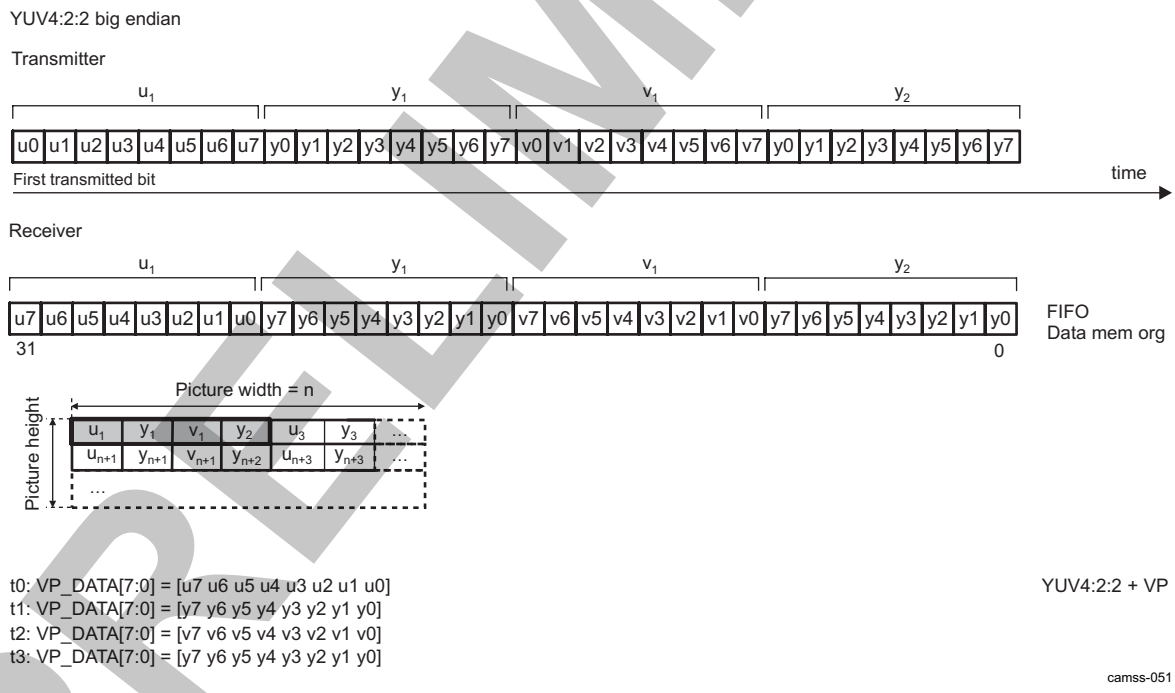

Figure 8-15. ISS CCP2 YUV4:2:2 Little Endian

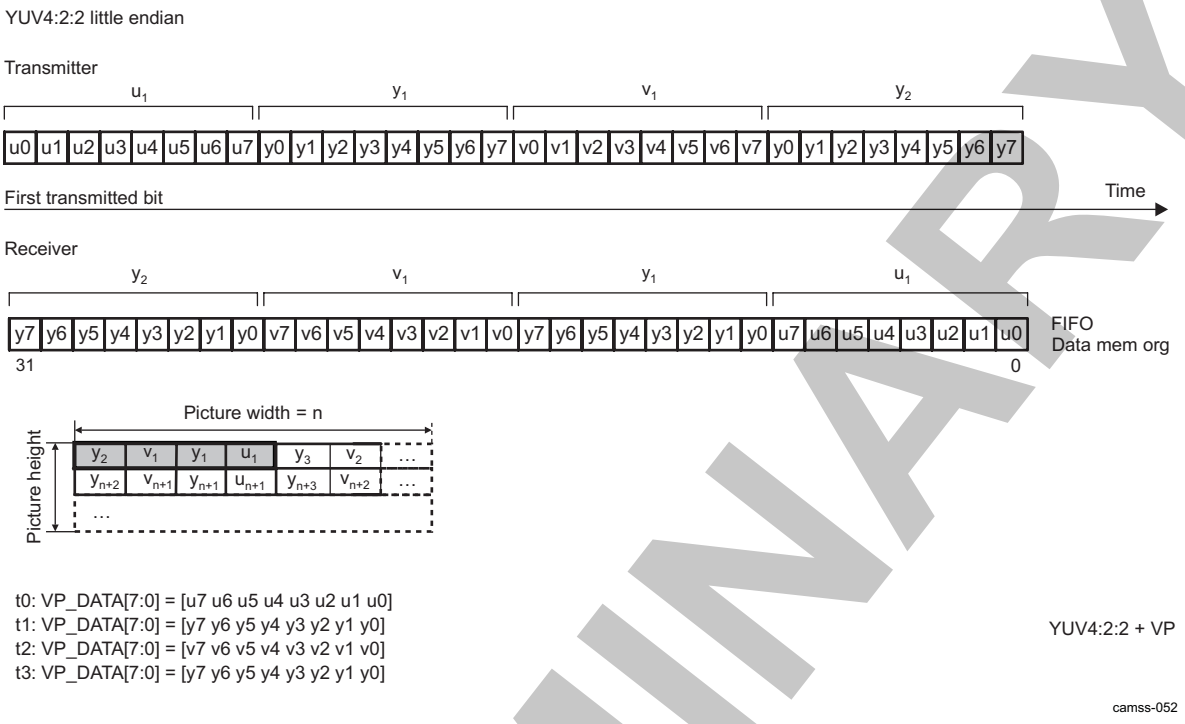
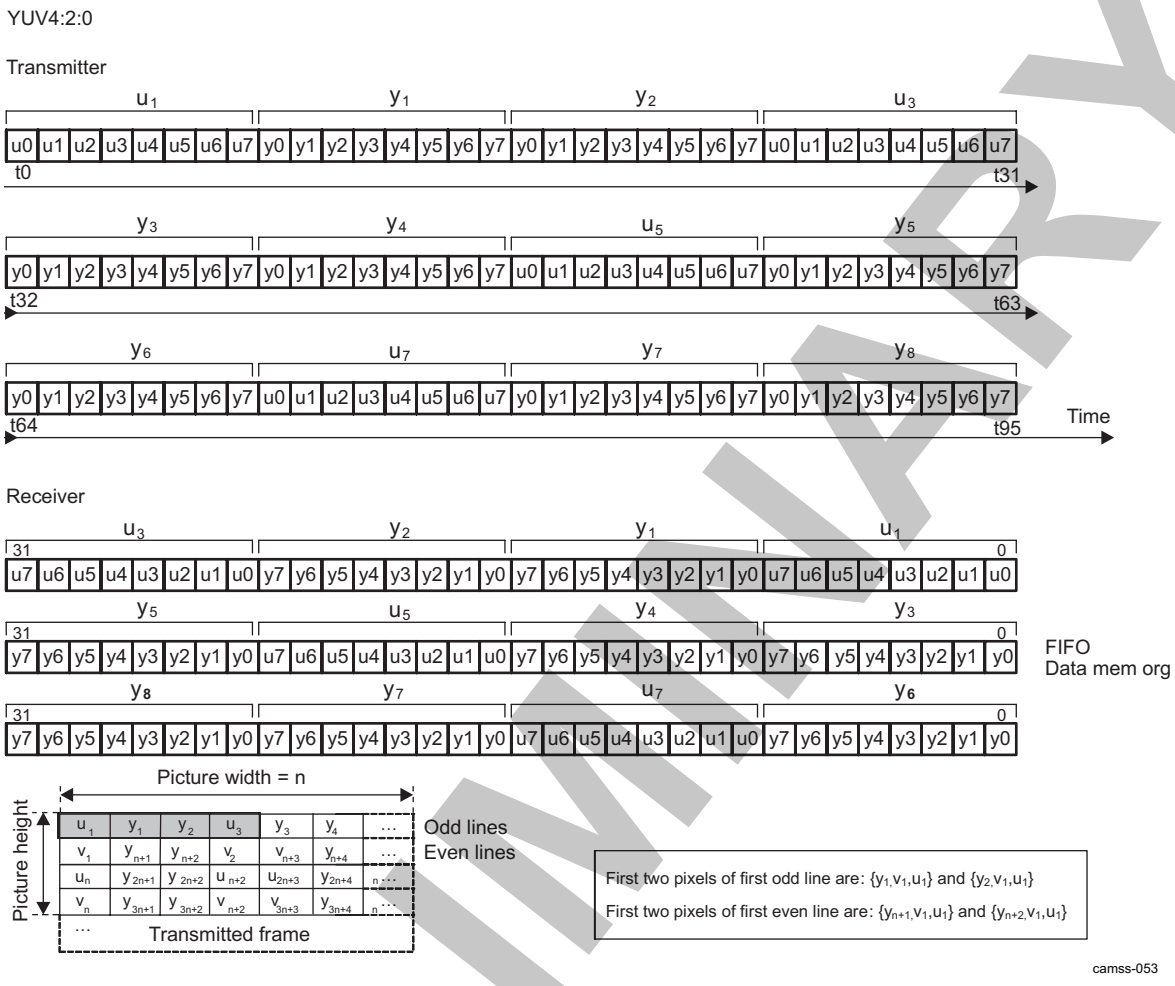


8.2.4.1.1.4.1.2 ISS CCP2 YUV4:2:0

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in Figure 8-16. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x3 to select YUV4:2:0 mode.

Figure 8-16. ISS CCP2 YUV4:2:0



8.2.4.1.1.4.2 ISS CCP2 RGB Operating Modes

8.2.4.1.1.4.2.1 ISS CCP2 RGB888

RGB888 data format can be output to memory in two formats: without data expansion and with data expansion.

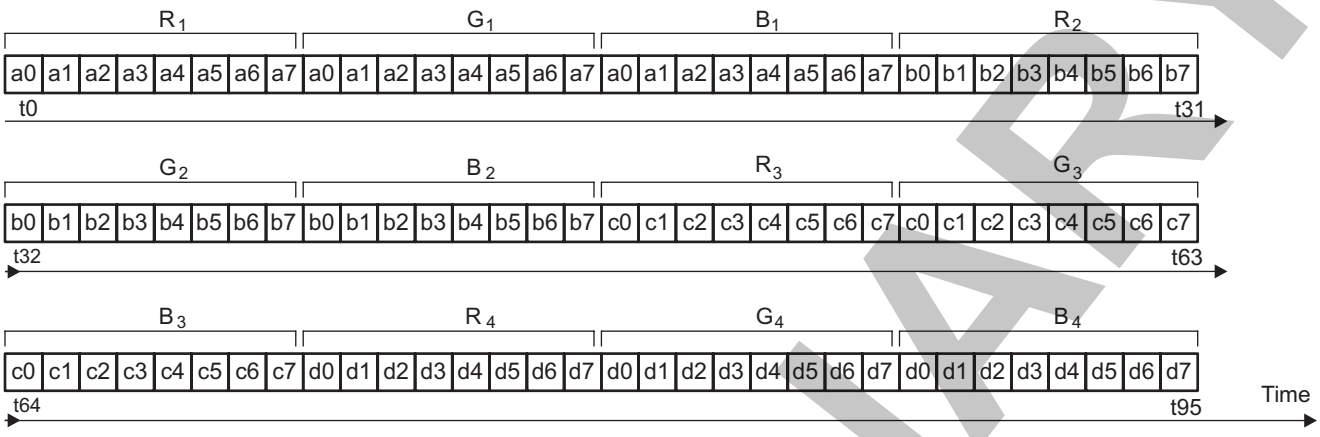
If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly.

Figure 8-17 is an example of RGB888 format. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x6 to select RGB888 mode (24 bits) or to 0x7 to expand RGB888 over 32 bits.

Figure 8-17. ISS CCP2 RGB888

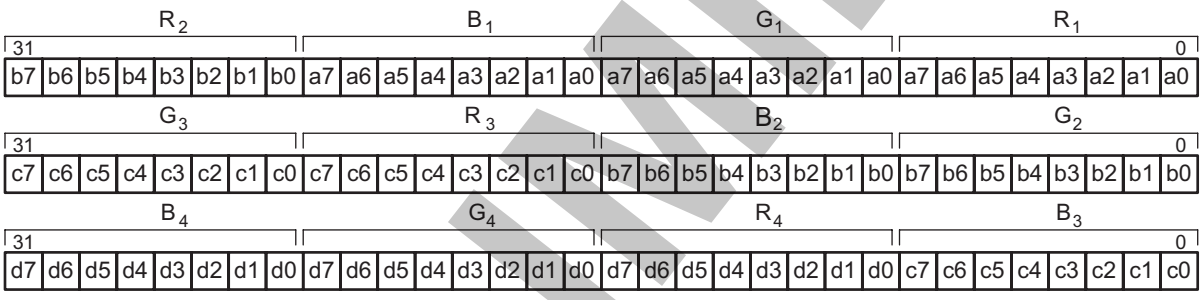
RGB888 Line width must be a multiple of three 32-bit words.

Transmitter

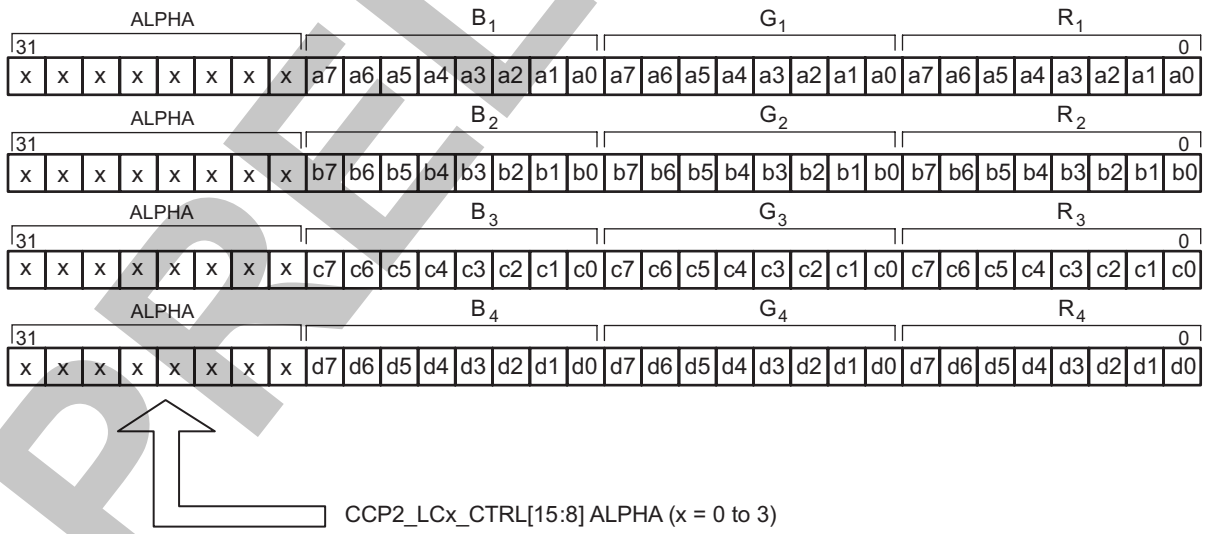


Receiver

Without data expansion



With data expansion

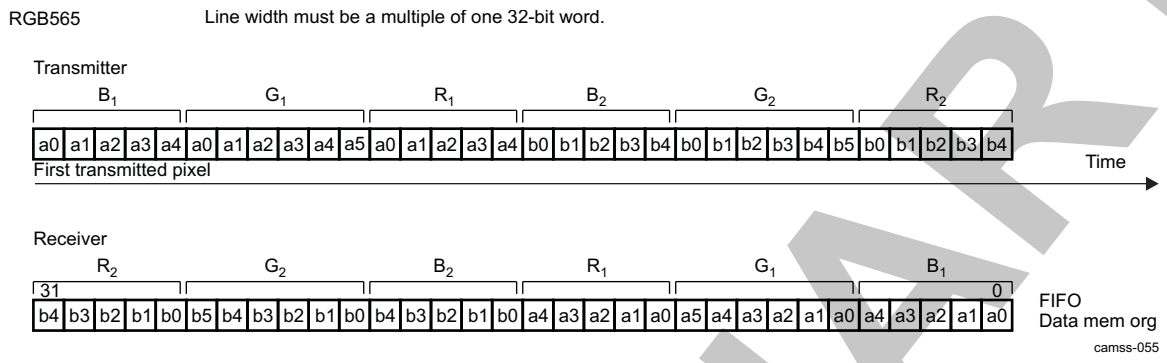


camss-054

8.2.4.1.1.4.2.2 ISS CCP2 RGB565

For RGB565, the line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see Figure 8-18). Set CCP2_LCx_CTRL[7:2] FORMAT to 0x6 to select RGB565 mode.

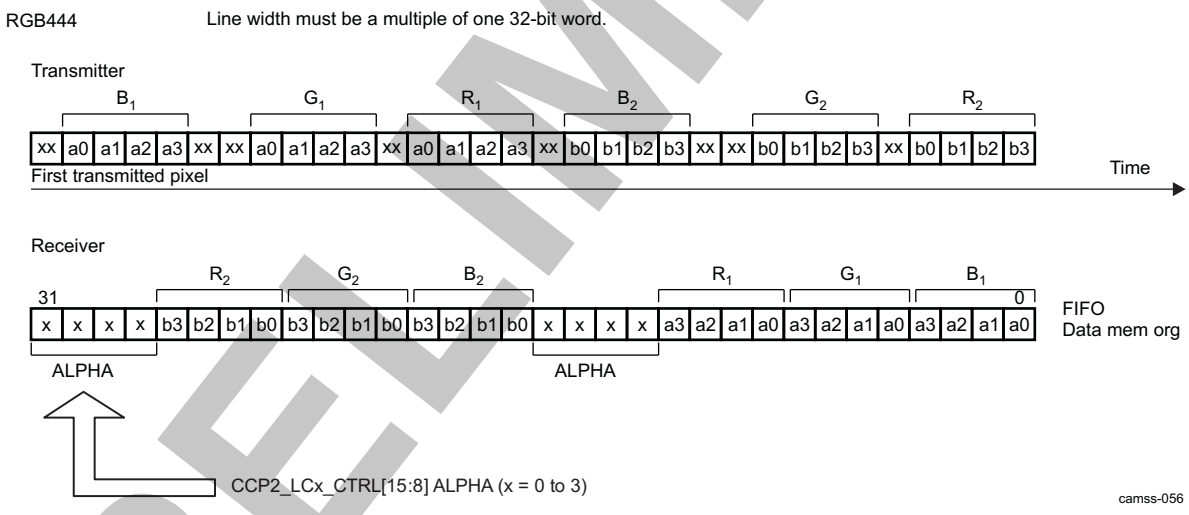
Figure 8-18. ISS CCP2 RGB565



8.2.4.1.1.4.2.3 ISS CCP2 RGB444

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see Figure 8-19). Set CCP2_LCx_CTRL[7:2] FORMAT to 0x4 to select RGB444 mode (12 bits expanded to 16).

Figure 8-19. ISS CCP2 RGB444



8.2.4.1.1.4.3 ISS CCP2 RAW Bayer Operating Modes

NOTE: For more information about packed RAW data, see Section 8.2.4.3.5.1, *ISS CCP2 Read Data From Memory*.

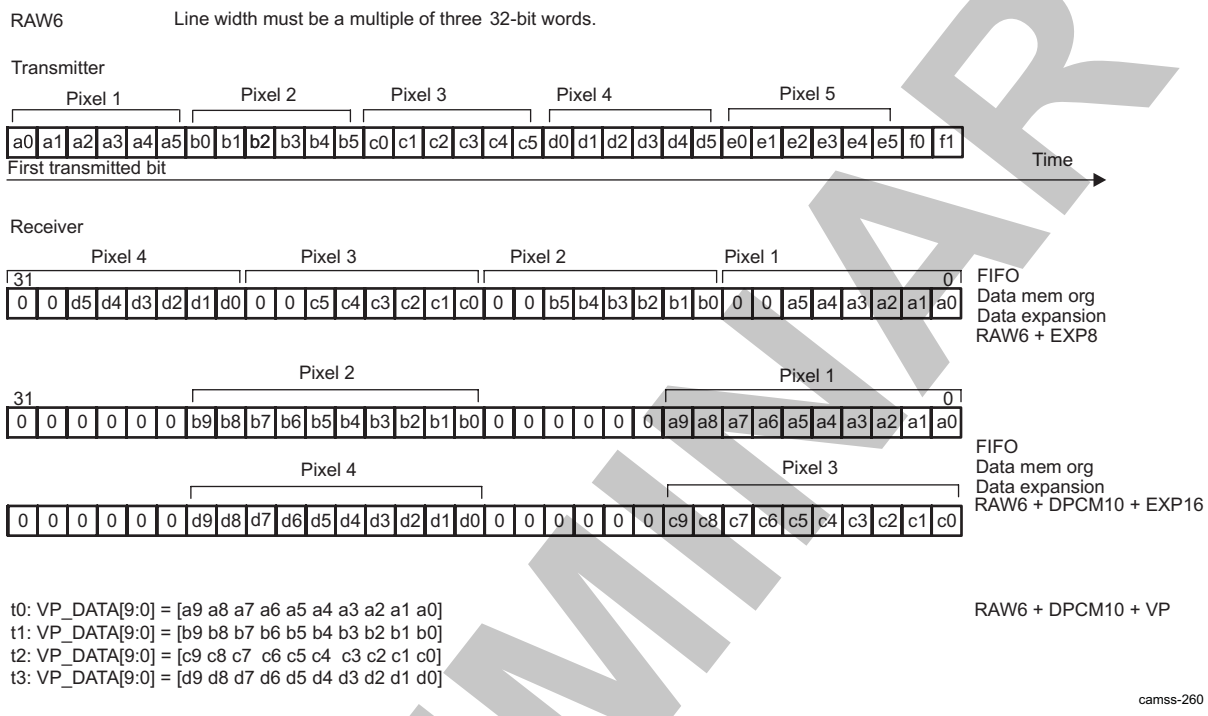
8.2.4.1.1.4.3.1 ISS CCP2 RAW6

RAW6 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CSI receiver protocol is a multiple of 32 bits. The line all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 6 is 96; that is, 3 x 32 bits).

Figure 8-20 shows the RAW6 format. Set CCP2_LCx_CTRL[7:2] FORMAT to:

- 0x8 to select RAW6 mode expanded to 8-bit
- 0x9 to select RAW6 mode with DPCM decompression
- 10-bit and expansion to 16-bit
- 0xA to select RAW6 mode with DPCM decompression to 10-bit to video port

Figure 8-20. ISS CCP2 RAW6



NOTE: Use RAW8 data format to output RAW6 data format to memory.

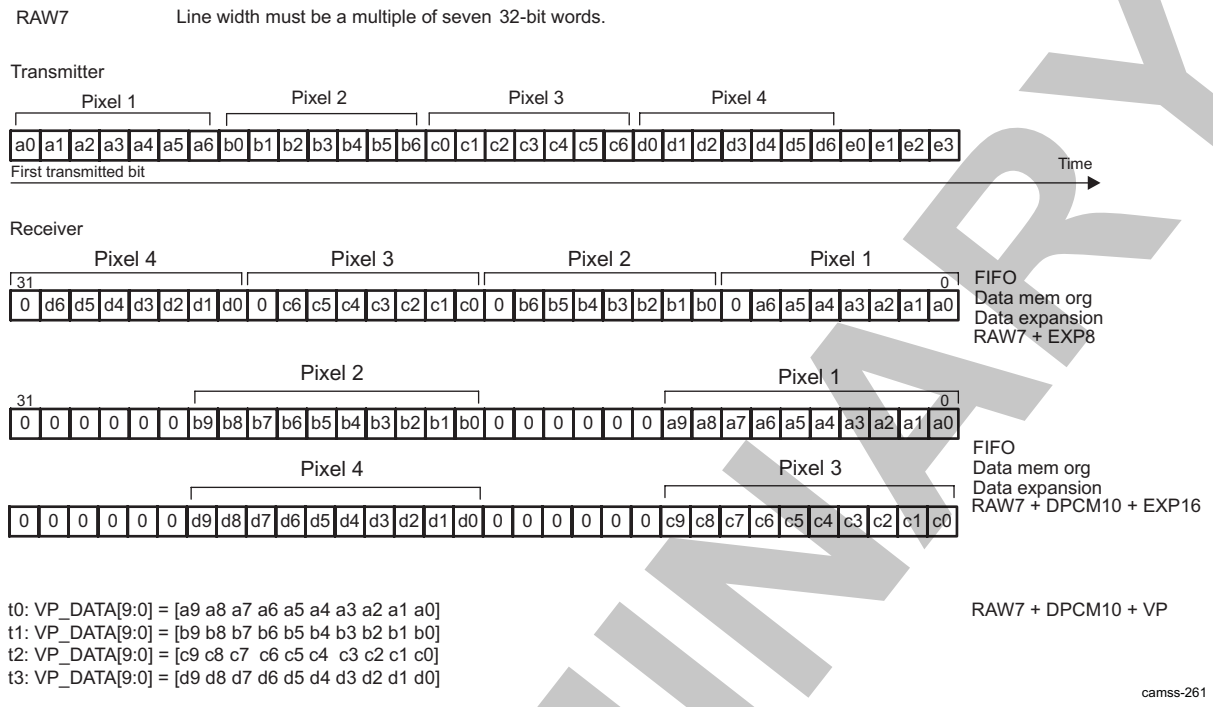
8.2.4.1.1.4.3.2 ISS CCP2 RAW7

RAW7 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 7 x 32 bits to finish the pixel reconstruction correctly (the lowest common multiple of 32 and 7 is 224; that is, 7 x 32 bits).

Figure 8-21 shows the RAW7 format. Set CCP2_LCx_CTRL[7:2] FORMAT to:

- 0xC to select RAW7 mode expanded to 8-bit
- 0xD to select RAW7 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0xE to select RAW7 mode with DPCM decompression to 10-bit to video port

Figure 8-21. ISS CCP2 RAW7



NOTE: Use RAW8 data format to output RAW7 data format to memory.

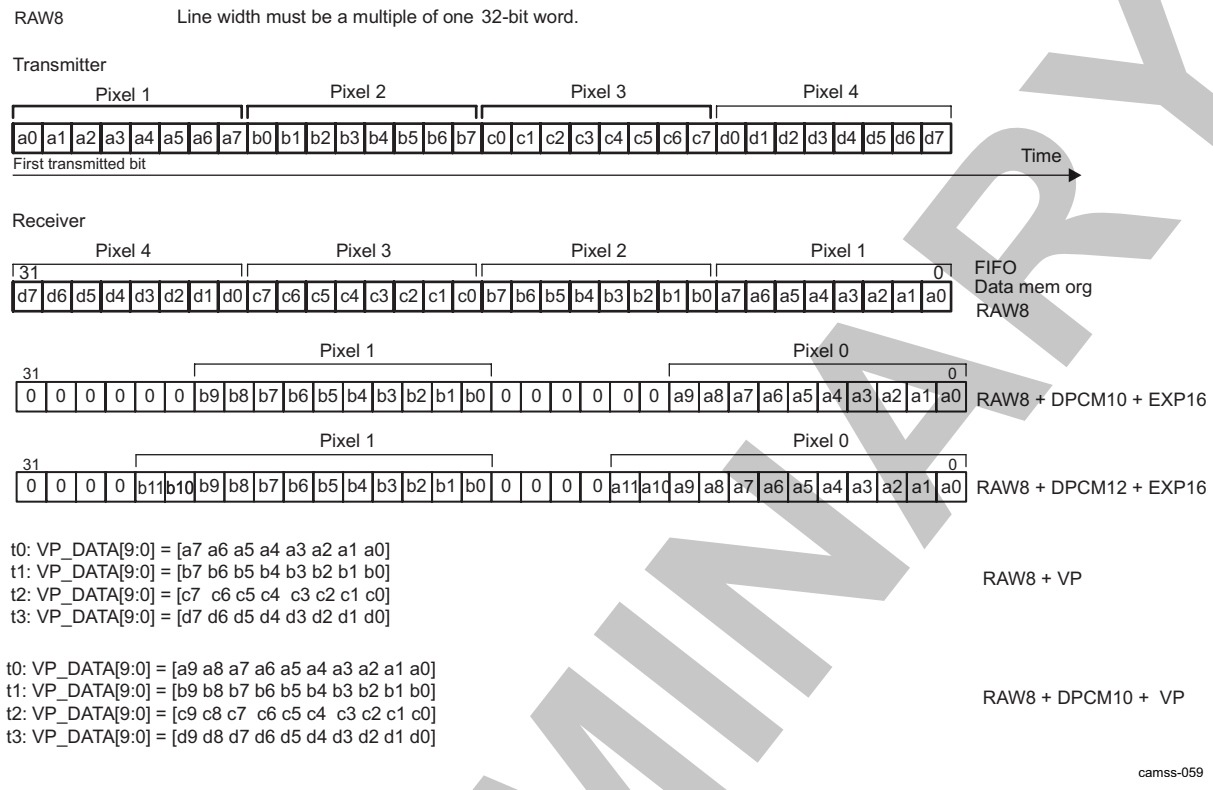
8.2.4.1.1.4.3.3 ISS CCP2 RAW8

RAW8 data format can be output to memory. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits.

Figure 8-22 shows RAW8 format. Set CCP2_LCx_CTRL[7:2] FORMAT to:

- 0x10 to select RAW8
- 0x11 to select RAW8 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0x12 to select RAW8 mode with DPCM decompression to 10-bit to video port
- 0x20 to select RAW8 with A-Law decompression to RAW10

Figure 8-22. ISS CCP2 RAW8



NOTE: Use YUV4:2:2 + VP to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP.

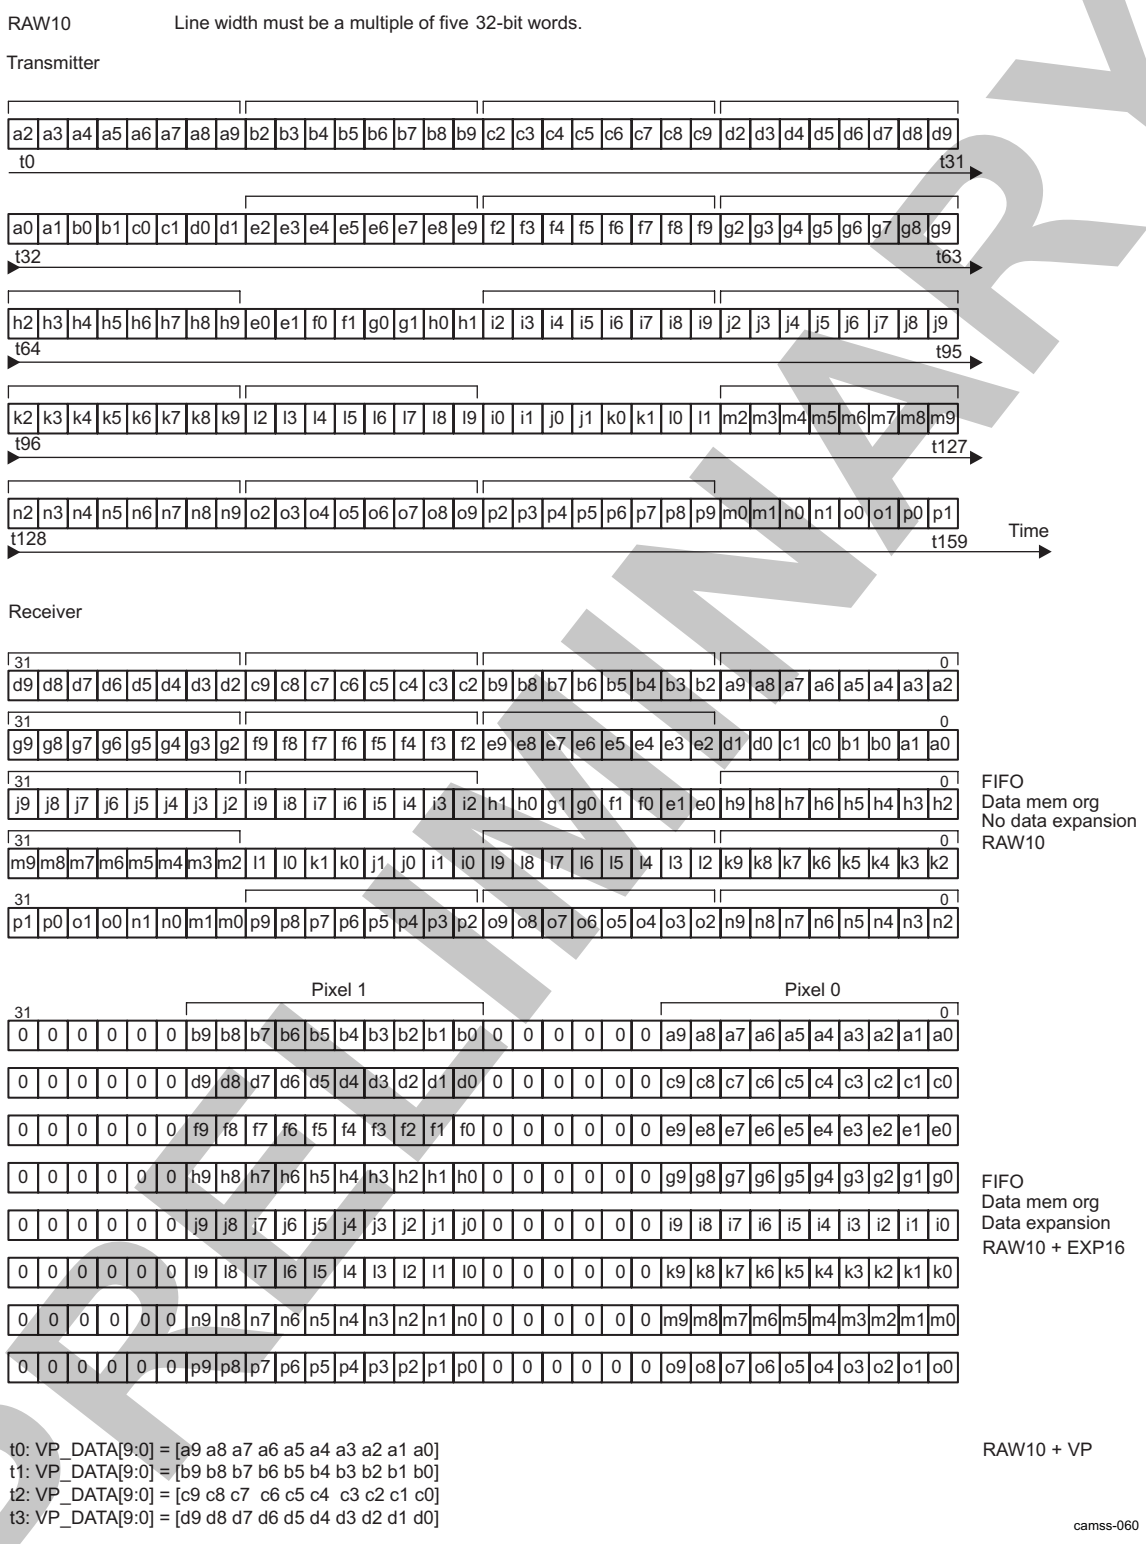
8.2.4.1.1.4.3.4 ISS CCP2 RAW10

RAW10 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 5 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 10 is 320; that is, 10 x 32 bits).

RAW10 data format can be sent to the video port. Figure 8-23 shows the RAW10 format. Set CCP2_LCx_CTRL[7:2] FORMAT to:

- 0x14 to select RAW10
- 0x13 to select RAW10 mode with DPCM compression to 7-bit
- 0x16 to select RAW10 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit
- 0x1B to select RAW10 compressed to 8-bit
- 0xB with DPCM compression to 6-bit
- 0xF to select RAW10 compressed to 6-bit with expansion to 8-bit
- 0x1E to select RAW10 compressed to 8-bit
- 0x20 to select RAW10 with A-Law compression to RAW8

Figure 8-23. ISS CCP2 RAW10



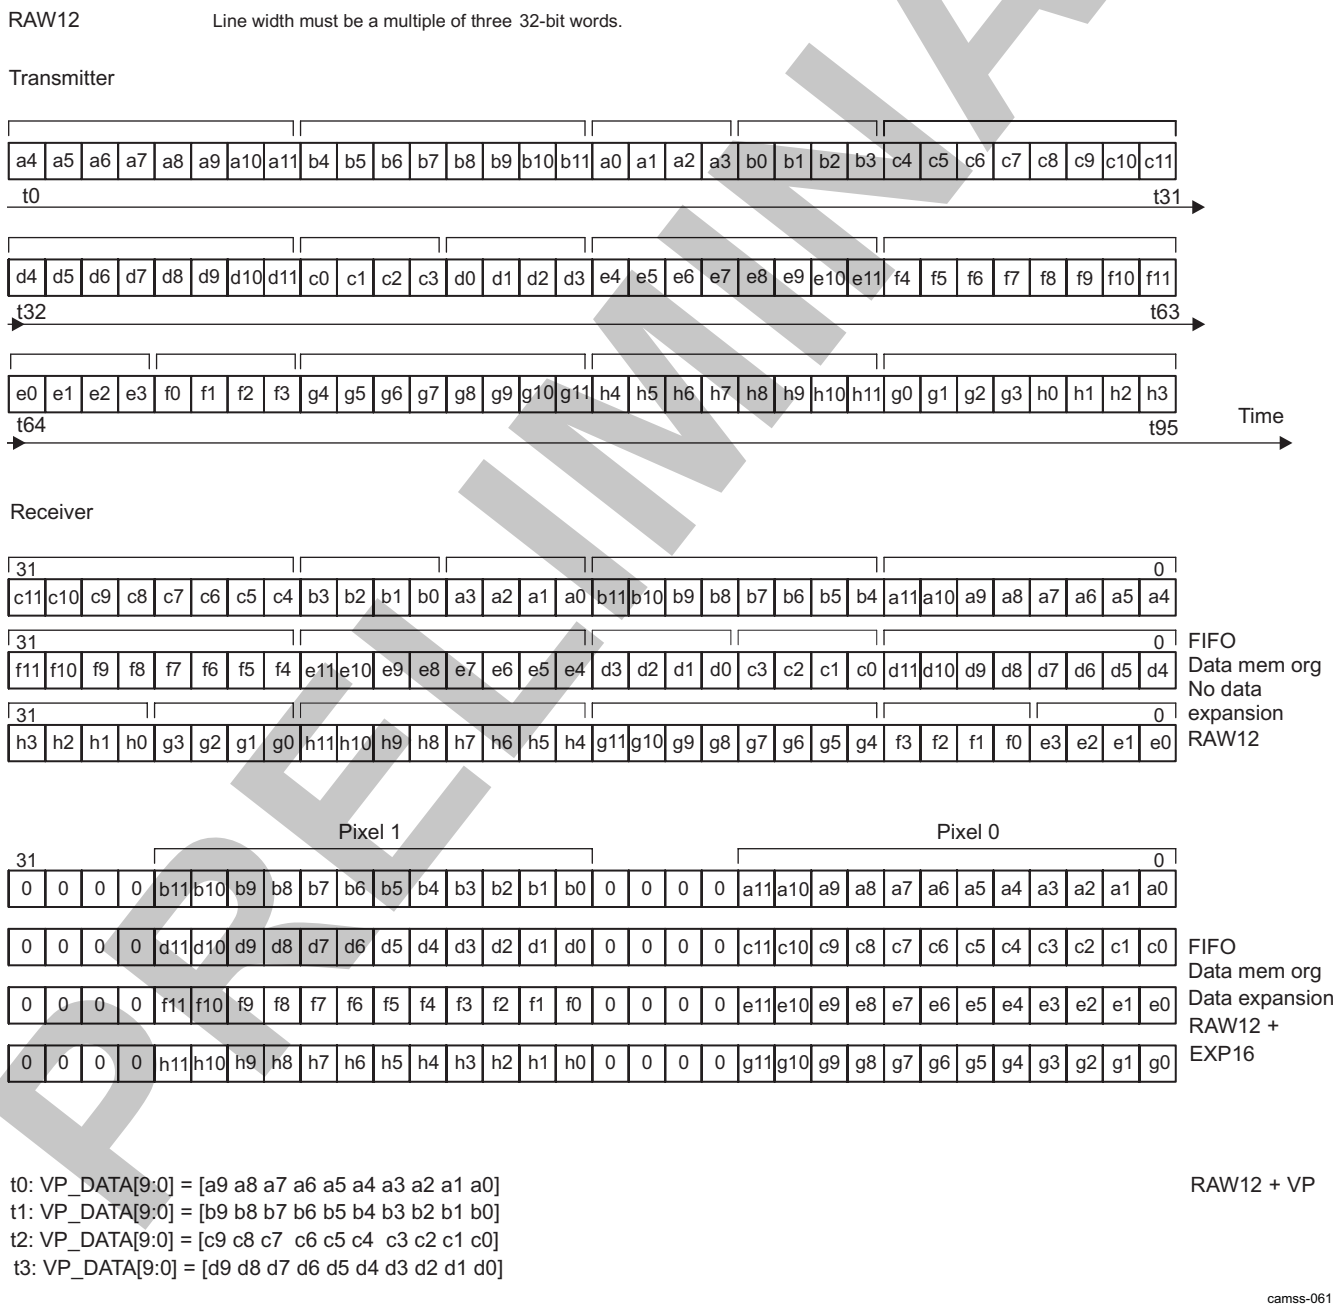
8.2.4.1.1.4.3.5 ISS CCP2 RAW12

RAW12 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 PHY is a multiple of 32 bits. The line length is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 12 is 96; that is, 3 x 32 bits).

RAW12 data format can be sent to the video port. Figure 8-24 shows RAW12 format. Set CCP2_LCx_CTRL[7:2] FORMAT to:

- 0x18 to select RAW12
- 0x19 to select RAW12 mode with expansion to 16-bit
- 0x1A to select RAW12 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit

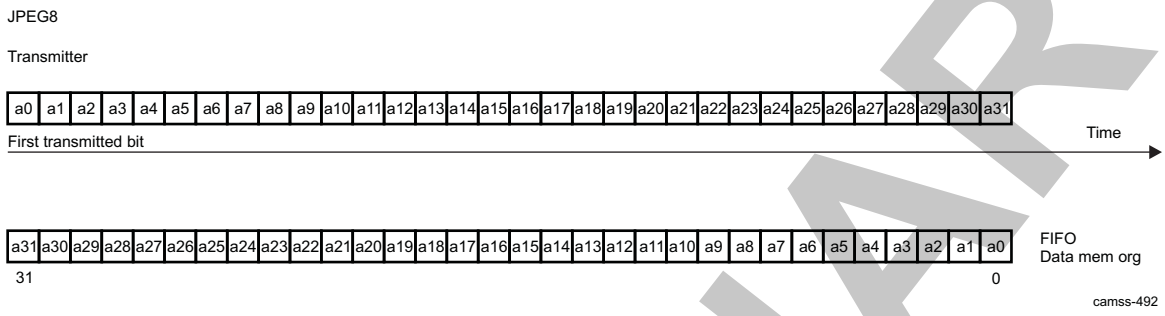
Figure 8-24. ISS CCP2 RAW12



8.2.4.1.1.4.4 ISS CCP2 JPEG8 Operating Modes

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The FSP code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. Figure 8-25 shows the JPEG8 and JPEG8 FSP format. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x1C to select JPEG8 format, or to 0x1D to select JPEG8 format with FSP.

Figure 8-25. ISS CCP2 JPEG8 and JPEG8 FSP



In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream for line-start and line-end before and after the transmitted data. For more information, see Section 8.2.4.1.1.2, *ISS CCP2 False Synchronization Protection Code*.

8.2.4.1.1.5 ISS CCP2 Data Transfer Through Write Master Port

The CCP2 receiver module uses its 64-bit master interface to transfer the data stored in the FIFO. The system can set the burst size to be used in the CCP2_CTRL BURST register. The recommended burst size is 128 bytes (0x4: 16 x 64-bit bursts are the most efficient for memory output); other sizes must be used only when issues are faced. The module tries to burst data whenever possible to increase system performance and save power. The module uses the appropriate register-selected burst size when the conditions (address is properly aligned, there is enough data in the FIFO to finish the line) are met; otherwise, it uses single requests.

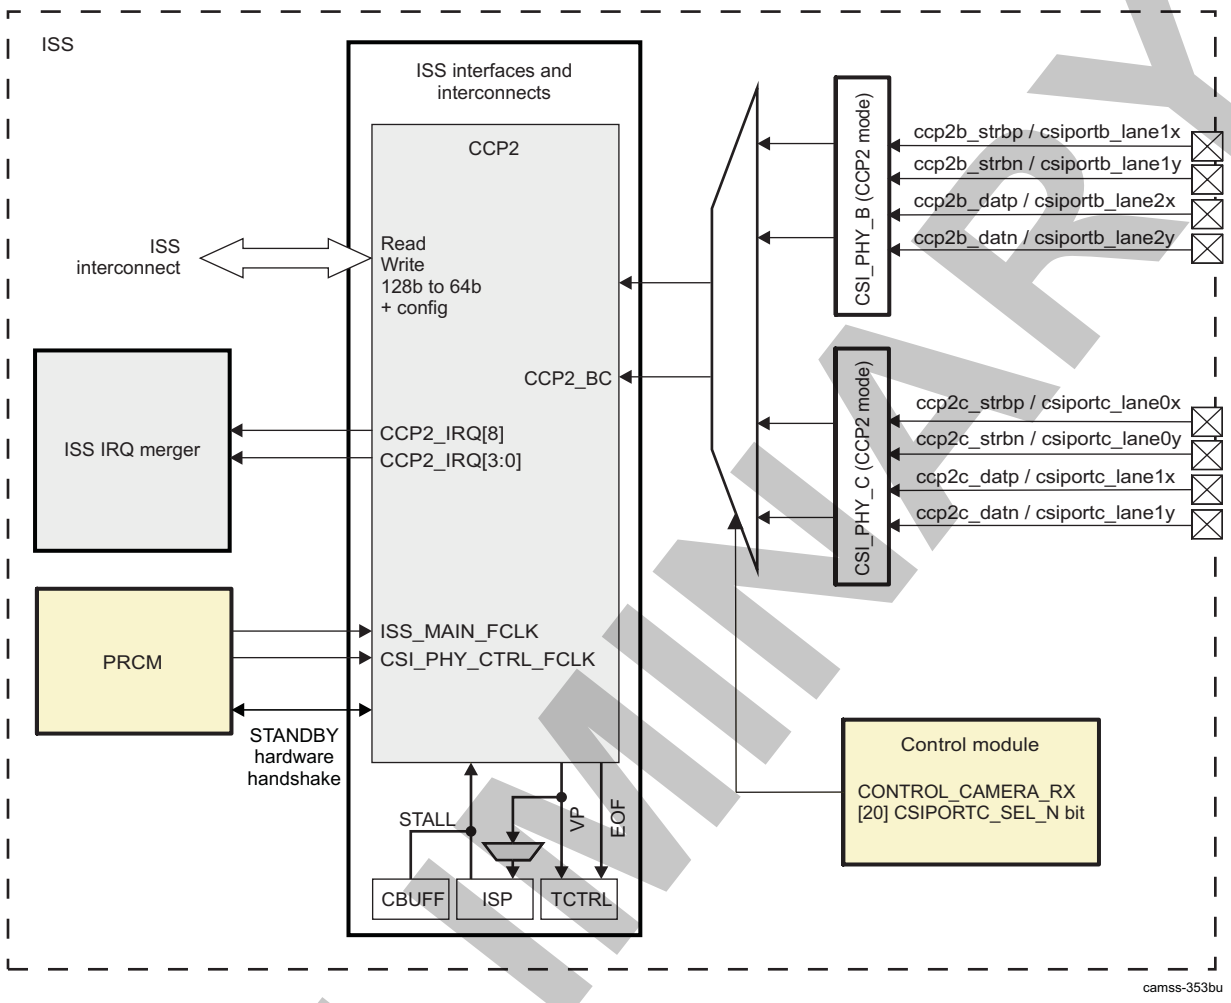
For example, if the line consists of 50 pixels of 64-bit data and BURST = 0x4 (16 × 64-bit bursts), the module generates four times 16 x 64-bit bursts to transmit the whole line. The FIFO can have information about only two different lines.

The CCP2 engine supports tag count. The count is configurable through a register at the top level of the ISS (see Section 8.1.3, *ISS Register Manual*).

8.2.4.2 ISS CCP2 Integration

Figure 8-26 is an overview of the integration of the CCP2 interface in the ISS and device.

Figure 8-26. ISS CCP2 Integration



NOTE: Because CSI2_B/C and CCP2 receivers share CSI_PHY_B/C pins for camera interconnection, they cannot be used simultaneously. That is, for example, when CSI_PHY_C is configured for CCP2 mode, the CSI2_C receiver cannot use it at the same time in D-PHY mode. For ISP source select, see Section 8.1.1, *ISS Integration*, for ISP registers input selection and for top-level input select settings.

For power domain, clocks, reset, and hardware requests, see Section 8.1.2.4, *ISS Power Management*.

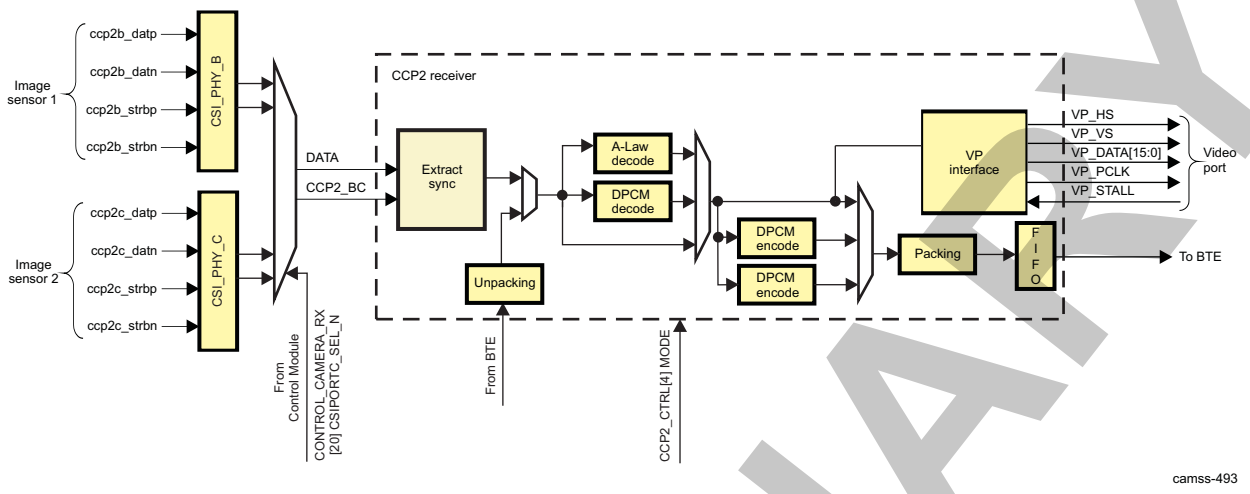
8.2.4.3 ISS CCP2 Functional Description

8.2.4.3.1 ISS CCP2 Overview

Figure 8-27 is the top-level block diagram of the CCP2 receiver. The CCP2 receiver receives serial data from a CCP2-compatible image sensor through one of the two CSI_PHYs (CSI_PHY_B or CSI_PHY_C), converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the VP interface (which is connected to the video preprocessing hardware [ISP]) or the ISS interconnect. The CCP2 can also read data from memory getting burst packets from the BTE when this feature has been enabled at compile time. For read data from memory, see Section 8.2.4.3.5, *ISS CCP2 Memory Read Channel*.

The CCP2 receiver video port interface is connected to the video preprocessing hardware (ISP).

Figure 8-27. ISS CCP2 Receiver Block Diagram



8.2.4.3.2 ISS CCP2 PHY

The CCP2 receiver does not connect directly to a sensor (see Section 8.2.3, *ISS CSI PHY*). It uses a complex I/O physical layer. There are two CCP2 complex I/Os. One complex I/O (CSI_PHY_B) is shared with the CSI2_B receiver. Second complex I/O (CSI_PHY_C) is shared with the CSI2_C receiver. The CCP2 receiver can handle only one complex I/O traffic at a time. The selection of the complex I/O routed to the CCP2 receiver is done through the CONTROL_CAMERA_RX[20] CSIPORTC_SEL_N bit at the device Control Module level (see Figure 8-27, *ISS CCP2 Receiver Block Diagram* for more details). The CSI_PHYs are powered up by configuring the CSI2 receiver configuration register. For more information about the configuration of the CSI_PHYs, see Section 8.2.3.2.1, *ISS CSI PHY Functional Configuration*. The CCP2 serial interface is a unidirectional differential serial interface with two options for the PHYs: data/clock or data/strobe signals. After the CSI_PHYs are configured and initialization is done, the CCP2 mode can be selected and controlled by the CCP2_CTRL[4] MODE bit.

8.2.4.3.2.1 ISS CCP2 Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and data clock.

- The data signal carries bit serial data. The CCP2 transmitter writes the data on each falling edge of the clock. The data are usually transmitted bytewise, least-significant bit (LSB) first.
- The data clock signal carries the clock signal. The CCP2 transmitter writes the data on each falling edge of the clock. The CCP2 receiver reads the data on the rising edge of the clock.

8.2.4.3.2.2 ISS CCP2 Data/Strobe Signaling (CCP2 Only)

Data/strobe signaling consists of two parallel signals: data and data strobe.

- The data signal carries bit serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state.

The data signal or the strobe signal changes between 2 data bits. The data and strobe signals must not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data. Set the CCP2_CTRL[4] MODE bit and see Section 8.2.3, *ISS CSI PHY*, to set the data/clock or data/strobe function.

8.2.4.3.3 ISS CCP2 VP Interface

Table 8-57 summarizes the video interface signals. The video interface connects the CCP2 receiver module to the video preprocessing hardware (ISP). The interface is connected to a 16-bit video port. On the other side of the video port is the ISIF inside the ISP. The ISIF also uses the signals listed in Table 8-57 to synchronize pixel data sent to it by the CCP2 receiver.

Table 8-57. ISS CCP2 Video interface Signals

Pin	Type[1]	Description
VP_HS	O	Line trigger output signal
VP_VS	O	Frame trigger output signal
VP_DATA[15:0]	O	Parallel output data: bits 0 to 15
VP_PCLK	O	Video port pixel clock. The frequency can be configured.
VP_STALL	I	Stalls data flow when data is read from memory

(1) I = Input; O = Output

When data is read from memory and sent to the video port, the data flow can be stalled by asserting the VP_STALL signal. Doing so does not overflow internal FIFOs: the CCP2 module adapts its read rate automatically.

The response time to the VP_STALL signal must not exceed two cycles: when VP_STALL is asserted, the CCP2 module can send 0, 1, or 2 pixels to the video port.

VP_STALL is asserted and deasserted synchronous to the functional clock.

NOTE: Stalling the video port for data received from the sensor may lead to internal overflows; VP_STALL must not be used for this purpose.

The pixel clock is generated from the functional clock. Clock pulses are gated based on the selected clock division factor and pixel availability. In other words, software must set the CCP2 receiver to ensure that the pixel clock:

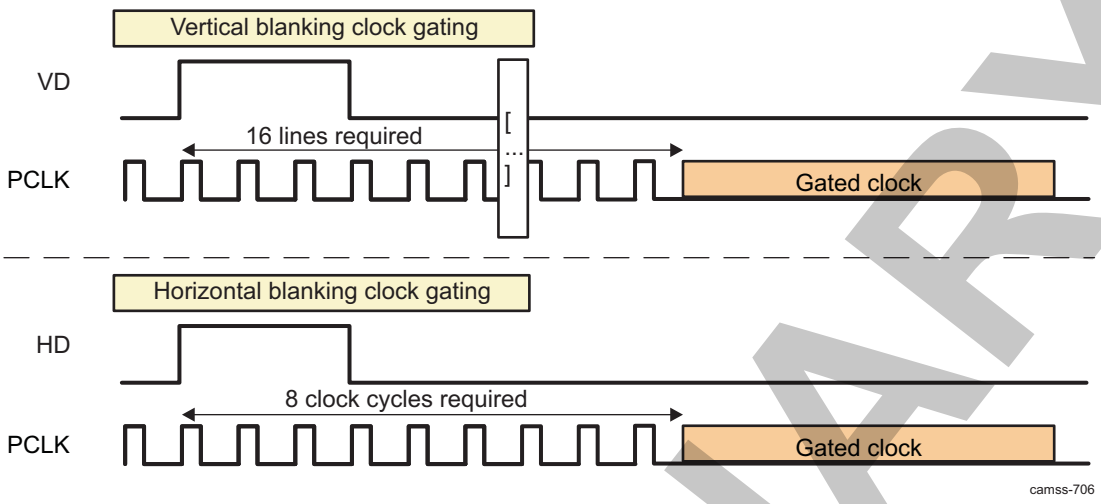
- Never exceeds what the ISP can support: the top value set in the CCP2_CTRL[31:15] FRACDIV bit field
- Is sent only when valid pixels or blanking data must be sent

Also, software must set the number of clock pulses during horizontal blanking periods using the CCP2_CTRL1[1:0] BLANKING bit field.

- The CCP2 receiver stops generating horizontal blanking clock pulses when the number of pulses defined in the CCP2_CTRL1[1:0] BLANKING bit field are generated or when data for the next line arrives from the sensor.
- Free-running horizontal blanking can be selected only when data comes from the sensor.
- When data comes from memory, the CCP2 receiver ensures that the number of horizontal blanking pulses defined in the CCP2_CTRL1[1:0] BLANKING bit field is received. The CCP2 receiver stops generating horizontal blanking clock pulses when then number of pulses defined in the CCP2_CTRL1[1:0] BLANKING bit field is generated or when data for the next line arrives from the sensor.

NOTE: To work properly, the ISP requires a minimum of eight clock cycles in the horizontal blanking period and a minimum of 16 lines in the vertical blanking period. The pixel clock can be gated only when these intervals are respected. This is required to flush the pipeline of the different ISP modules. Figure 8-28 shows VP_PCLK gating during blanking periods.

Figure 8-28. ISS CCP2 VP_PCLK Gating During Blanking Periods



Vertical blanking generation is controlled through the CCP2_CTRL[9] VP_CLK_FORCE_ON bit. The VP_PCLK clock is enabled during vertical blanking periods when this bit is set. This pushes pixels through the ISP processing pipe. It is needed, for example, when the ISP resizer uses the averager. Otherwise, hardware ensures only that at least four clock pulses are generated before the first pixel of each frame. It may be necessary for the clock to keep running after the frame end to flush internal pipelines. In that case, an interrupt request (IRQ) or status bit is typically present in the attached hardware that indicates when the VP_PCLK clock is no longer needed (for example, an end of processing interrupt). The module leaves the vertical blanking state when new data is received from the sensor or the memory read channel.

The configured pixel clock is used for active and blanking periods.

Table 8-58 shows how RAW and YUV data is sent over the video port. The data is sent to the ISIF if ISP is used. For the ISIF details about video port data, see Section 8.3.1 *ISS ISP*.

Table 8-58. ISS CCP2 Video Port Data Mapping

Format	Video Port DATA[15:0]

8.2.4.3.4 ISS CCP2 Data Compression

The data compression technique used is DPCM and pulse code modulation (PCM).

The CCP2 receiver performs on-the-fly compression and decompression. The compressed/decompressed data is passed to the video preprocessing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded and decoded separately.

Two different predictors are used:

- The simple predictor

  This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- The advanced predictor

  This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value is defined.

The preferable use is that the simple predictor is used with 10 bits to 8 bits or 12 bits to 8 bits conversion (10-8-10 or 12-8-12) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10-7-10 and 10-6-10). The advanced predictor gives slightly better prediction for pixel value; thus, the image quality can be improved with it. Because the simple predictor is very simple, the processing power and memory requirements are reduced with it, when the image quality is already high enough.

Select the predictor with the CCP2_LCx_CTRL[18] DPCM_PRED bit.

8.2.4.3.5 ISS CCP2 Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM or A-Law decompressed if necessary.
- Sends data to the video preprocessing hardware
- Sends data back to memory. It can be DPCM or A-Law compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

Table 8-59 summarizes supported modes for memory-to-memory operations.

NOTE: Video port and memory destinations are mutually exclusive.

Table 8-59. ISS CCP2 Memory-to-Memory Supported Operations

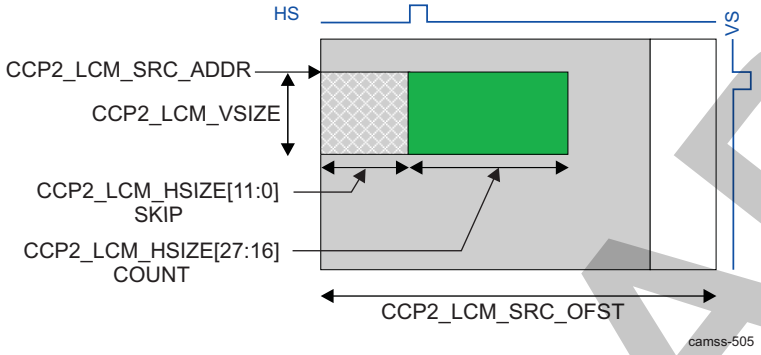
8.2.4.3.5.1 ISS CCP2 Read Data From Memory

Figure 8-29 shows the data organization in memory.

Figure 8-29. ISS CCP2 Data Organization in Memory



The user chooses the start address and the line length using the CCP2_LCM_SRC_ADDR and CCP2_LCM_SRC_OFST registers. The image start address normally must point to the beginning of a line because of packing constraints. However, it does not necessarily point to the first line of the frame in memory. The CCP2_LCM_VSIZE[27:16] COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count (CCP2_LCM_HSIZE[11:0] SKIP) from the start of the line. Thus, they are not sent to the video port or back to memory. The CCP2_LCM_HSIZE[27:16] COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

When data are sent to the video port, throughput is imposed by the selected VP_PCLK. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the CCP2_LCM_CTRL[4:3] READ_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the video preprocessing hardware.

The data storage format in memory is defined by the CCP2_LCM_CTRL[18:16] SRC_FORMAT and CCP2_LCM_CTRL[23] SRC_PACK bit fields.

Not all I/O format combinations are valid. For more information, see Table 8-59 and Table 8-60.

Figure 8-30 shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a, b, c). Therefore, data storage is little endian.

Figure 8-30. ISS CCP2 Data Organization Packing in Memory

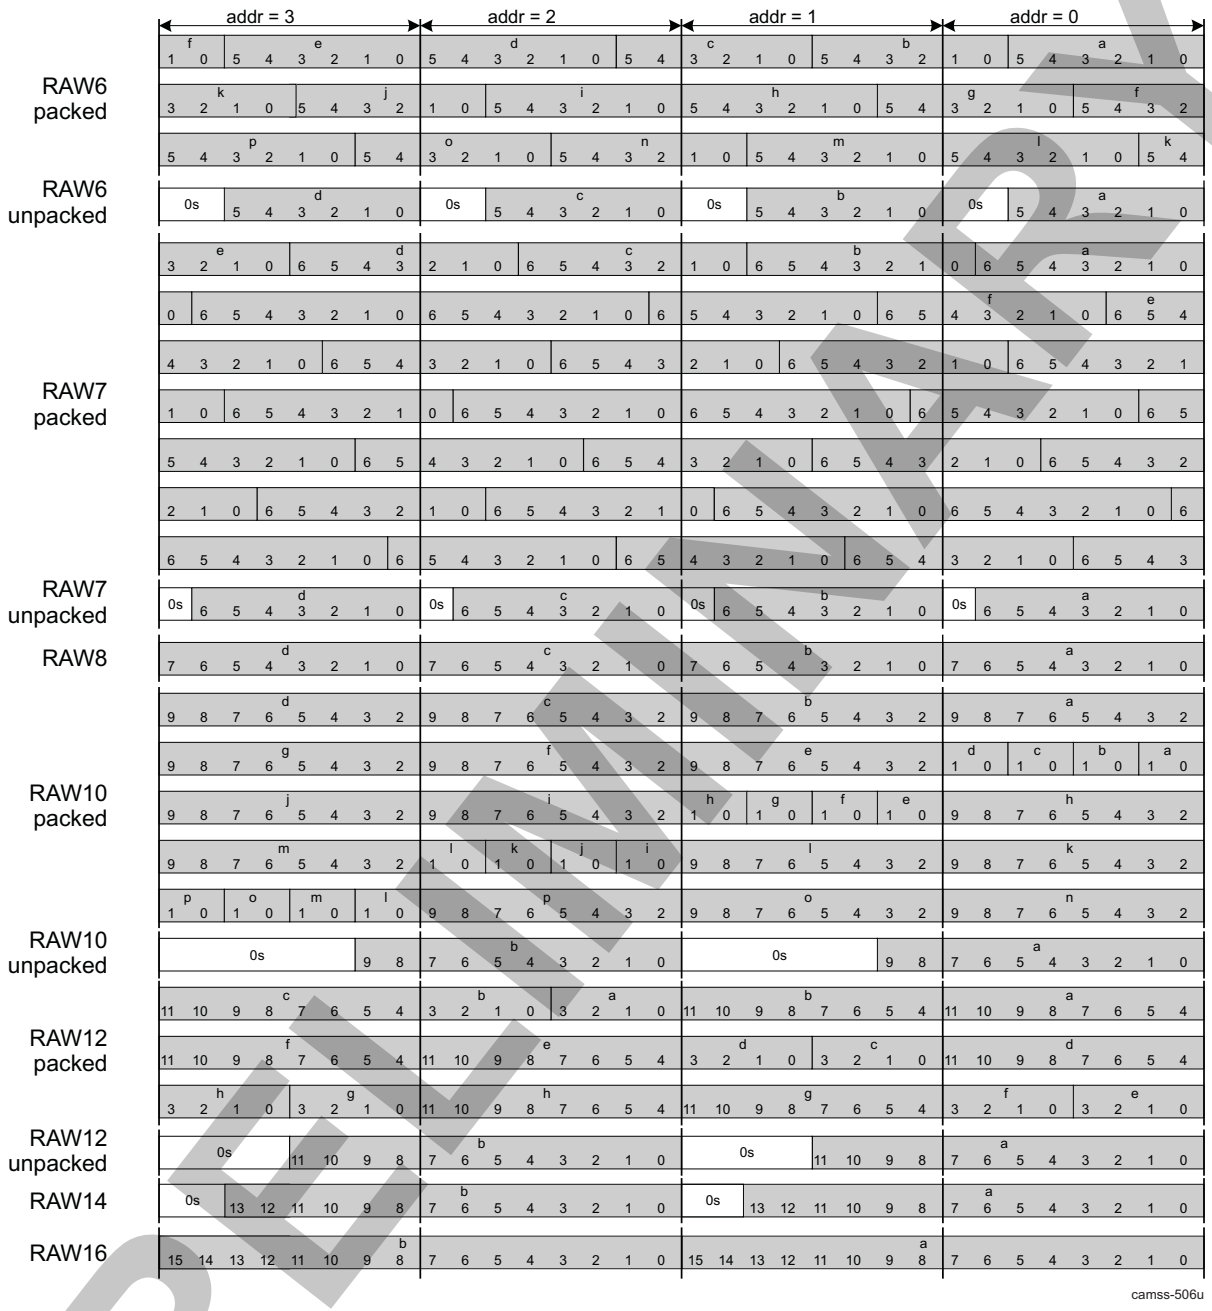


Table 8-61 summarizes the storage reduction versus unpacked format and image width restrictions when data packing is used. The image width applies to the data width multiple in pixels that must be stored to have storage reduction. Moreover, because each address is 8 bits long, the percentage shows how many bits out of 8 are to be packed in the empty space from another pixel address. A pixel is selected and split. One of the parts is put into another pixel address empty space. When unpacked, each pixel bit is stored continuously again.

Table 8-61. ISS CCP2 Data Packing Benefit and Constraints

	Bits Per Pixel		Storage Reduction	Width Multiple (Pixels)
	Packed	Unpacked		
RAW6	6	8	25%	16
RAW7	7	8	13%	3

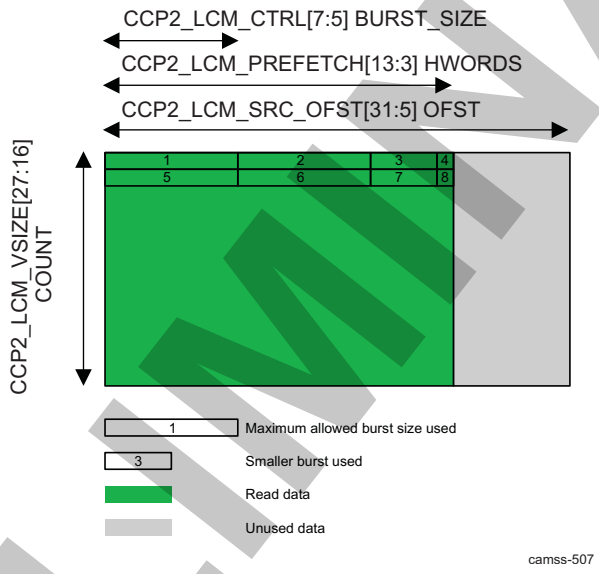
Table 8-61. ISS CCP2 Data Packing Benefit and Constraints (continued)

	Bits Per Pixel		Storage Reduction	Width Multiple (Pixels)
	Packed	Unpacked		
RAW8	8	8	0%	4
RAW10	10	16	38%	16
RAW12	12	16	25%	8

8.2.4.3.5.2 ISS CCP2 Memory Read Port Burst Generation

Hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2 receiver. Only full 64-bit burst words are read back from memory. Figure 8-31 shows the data organization and the relationship between the different parameters controlling the burst generation.

Figure 8-31. ISS CCP2 Data Organization in Memory



NOTE:

- A minimum burst size of 2 must be selected for correct operation.
- The HWORDS bit field must be even for correct operation.

The CCP2_LCM_SRC_ADDR register address of the first data to read is aligned to a 32-byte boundary. The read port fetches CCP2_LCM_PREFETCH[13:3] HWORDS of 64-bit words per line using the longest possible burst computed from the CCP2_LCM_CTRL[7:5] BURST_SIZE bit field and the remaining data to be fetched. Burst size of 128 bytes is preferred. When the CCP2 receiver is configured to fetch more data than required, extra data are dropped internally.

8.2.4.3.5.3 ISS CCP2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CCP2 real-time traffic, when required, based on the fullness of the CCP2 DMA read and write buffers. Programmable buffer thresholds are used to indicate when the local MFLAG signal is generated, which is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CCP2 MFLAG signal is asynchronous to any ongoing OCP transaction. The threshold corresponds to the fullness of DMA buffer, and is defined by the following threshold parameters:

- High threshold: When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the CCP2_CTRL1[30:24] LEVH register.

- Low threshold: When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the CCP2_CTRL1[22:16] LEVL register.

8.2.4.3.5.4 ISS CCP2 Video Port

The video port always receives unpacked data. It can be enabled using the CCP2_LCM_CTRL[2] DST_PORT bit. Its clock can be selected with the CCP2_CTRL[31:15] FRACDIV bit field and gated or not during frame blanking periods using the CCP2_CTRL[9] VP_CLK_FORCE_ON bit.

The data format used by the video port is defined by the CCP2_LCM_CTRL[26:24] DST_FORMAT bit field. For a list of supported modes, see Table 8-60.

8.2.4.3.5.5 ISS CCP2 Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the CCP2_LCM_CTRL[2] DST_PORT bit. The output data format is defined by the CCP2_LCM_CTRL[26:24] DST_FORMAT bit field and the CCP2_LCM_CTRL[31] DST_PACK bit. Not all possible combinations are supported; see Table 8-59 for details.

The destination address and offset for the output data of the memory channel are set by the CCP2_LCM_DST_ADDR and CCP2_LCM_DST_OFST registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in Table 8-62 apply.

Table 8-62. ISS CCP2 Output Width Restrictions in Memory-to-Memory Operation

Format	Bits per Pixel	Width Multiple of(1)	Note
RAW6	8	1	Full 32-bit words are written at the end of the line. This last word can eventually include 0s.
RAW6 packed	6	1	
RAW7	8	1	
RAW7 packed	7	1	
RAW8	8	1	
RAW10	16	1	
RAW10 packed	10	16	
RAW12	16	1	Same constraints as RAW8
RAW12 packed	12	8	

(1) In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see Figure 8-30).

When the DST_OFST bit is set to 0, start of lines are aligned on 4-byte boundaries. When DST_OFST is not set to 0, data are aligned on 32-byte boundaries.

NOTE: The RAW6, RAW7, and DPCM data formats do not apply to the MIPI CSI1-compatible mode.

8.2.4.3.5.6 ISS CCP2 DPCM Decompression History

The DPCM compression algorithm can encode the difference between consecutive samples in a line instead of the actual samples value to reduce the amount of data to store. The drawback is that lines must always be decoded from the beginning (the first samples of a line are always encoded as PCM).

The CCP2 receiver has a mechanism to preserve the DPCM decode history for each line to avoid decoding the same samples multiple times when vertical frame division mode is used.

The typical use case (also known as vertical frame division mode) is when an image is wider than the ISP can process on the fly, but the image must be processed. Therefore, the image is cut into multiple vertical slices that are processed sequentially by the ISP. The slices are stitched together in the SDRAM after ISP processing through proper address generation in the ISP. Because of various alignment constraints in the ISP, the slices sent to ISP must overlap. Without preserving the DPCM history, all lines from the beginning of the second (and other consecutive) vertical slice would have to be recoded, which would lead to performance degradation.

Writing DPCM history information into the system memory is enabled by setting the CCP2_LCM_HISTORY[16] EN_HIST_WR bit. The CCP2_LCM_HISTORY[15:0] HIST_EXPORT bit field defines the position at which history data is written to memory. The position is counted from the beginning line. The first decoded pixel has position 0. The last decoded pixel has position CCP2_LCM_HSIZE[14:0] SKIP + CCP2_LCM_HSIZE[30:16] COUNT - 1. The CCP2_LCM_HISTORY[15:0] HIST_EXPORT bit field is used to choose the resume position and allows support of overlapping vertical slices. The CCP2 receiver always writes 8 bytes of history data per line to the SDRAM regardless of the chosen DPCM format. The CCP2 receiver uses the interface bursts to send history data to memory.

DPCM history data holds the decoded value of four samples. The CCP2 receiver exports samples of positions:

- CCP2_LCM_HISTORY[15:0] HIST_EXPORT – 3
- CCP2_LCM_HISTORY[15:0] HIST_EXPORT – 2
- CCP2_LCM_HISTORY[15:0] HIST_EXPORT – 1
- CCP2_LCM_HISTORY[15:0] HIST_EXPORT

Every sample is coded on 16 bits, and several MSBs are unused. The valid range for CCP2_LCM_HISTORY[15:0] HIST_EXPORT is [3.. CCP2_LCM_HSIZE[14:0] SKIP + CCP2_LCM_HSIZE[30:16] COUNT – 1]. History data can be exported even when data is not sent to the video port or ISS interconnect port (i.e. the condition CCP2_LCM_HISTORY[15:0] HIST_EXPORT < CCP2_LCM_HSIZE[14:0] SKIP is valid).

The source and destination addresses for history and pixel data depend on the CCP2_LCM_HISTORY[18] HIST_DATA_DST bit:

- Memory to video port (CCP2_LCM_HISTORY[18] HIST_DATA_DST = 0)
  - Pixel data read: CCP2_LCM_SRC_ADDR + Y*CCP2_LCM_SRC_OFST
  - History data read: CCP2_LCM_DST_ADDR + Y*8
  - Pixel data write: (video port)
  - History data write: CCP2_LCM_DST_ADDR + Y*8
- Memory to memory (CCP2_LCM_HISTORY[18] HIST_DATA_DST = 1)
  - Pixel data read: CCP2_LCM_SRC_ADDR + Y*CCP2_LCM_SRC_OFST
  - History data read: CCP2_LCM_HIST_ADDR + Y*8
  - Pixel data write: CCP2_LCM_DST_ADDR + Y*CCP2_LCM_DST_OFST
  - History data write: CCP2_LCM_HIST_ADDR + Y*8,

where Y represents the line number in the image. It starts from 0 and is incremented by one for each line (i.e. Y = 0 for the 1st image line, Y = 1 for the 2nd image line, etc.).

Reading back history information is enabled by setting the CCP2_LCM_HISTORY[17] EN_HIST_RD register. The CCP2 receiver always reads 8 bytes of history data per line from SDRAM regardless of the chosen DPCM format. The CCP2 receiver uses single interface requests to read history data from memory. For each line, the DPCM decoder fetches 8 bytes of history data and CCP2_LCM_PREFETCH[15:3] HWORDS words of 64-bits of compressed pixel data from memory.

NOTE: In memory to memory mode, new histogram data overwrites the old one when CCP2_LCM_HISTORY[16] EN_HIST_WR = 1 and CCP2_LCM_HISTORY[17] EN_HIST_RD = 1. However, as reads are done before writes, there is no risk of data corruption. Software must copy the history date before enabling the processing, if the same history data needs to be used multiple times and CCP2_LCM_HISTORY[16] EN_HIST_WR = 1 and CCP2_LCM_HISTORY[17] EN_HIST_RD = 1.

The values of CCP2_LCM_HISTORY[15:0] HIST_EXPORT bit field of the write pass and CCP_LCM_SRC_ADDR register of the read pass must match, in order to avoid generation of corrupted data. The CCP2_LCM_HSIZE[14:0] SKIP and CCP2_LCM_HSIZE[30:16] COUNT bit fields can be used to define with pixel accuracy what is sent to the video port (if CCP2_LCM_HISTORY[18] HIST_DATA_DST = 0) or ISS interconnect port (if CCP2_LCM_HISTORY[18] HIST_DATA_DST = 1).

8.2.4.4 ISS CCP2 Programming Model

This section describes the programming model of the CCP2 receiver.

8.2.4.4.1 ISS CCP2 Programming Hardware Setup/Initialization

This section discusses the configuration of the CCP2 receiver required before image capture can begin. Before using the receiver, a CSI_PHY initialization in CCP2 mode must be made for CSI_PHY_B or CSI_PHY_C, whichever is associated with the CCP2 receiver. See Section 8.2.3.2.3, *ISS CSI PHY (CCP2 Mode) and Link Initialization Sequence.*

NOTE: The setup/initialization previously explained is valid only when the external sensor is used. If the user plans to use the logical memory channel (LCM) or debug mode (CCP2_CTRL[13] DBG_EN = 0x1) instead of the external sensor, this setup/initialization is not necessary.

8.2.4.4.1.1 ISS CCP2 Reset Behavior

On hardware or software reset of the ISS, all registers in the CCP2 receiver are reset to their reset values.

The two sources for CCP2 software reset are:

- Global reset for the whole ISS through the ISS_HL_SYSCONFIG[0] SOFTRESET bit
- Local reset, affecting only the CCP2 module. The reset is initiated by writing 0x1 in the CCP2_SYSCONFIG[1] SOFT_RESET bit. The reset done status can be check by reading the CCP2_SYSSTATUS[0] RESET_DONE bit.

8.2.4.4.2 ISS CCP2 Programming Event and Status Checking

When an event occurs, the corresponding bit in the CCP2_LC01_IRQSTATUS, CCP2_LC23_IRQSTATUS, or CCP2_LCM_IRQSTATUS register is set. Each event can be individually masked using the CCP2_LC01_IRQENABLE, CCP2_LC23_IRQENABLE, or CCP2_LCM_IRQENABLE register. Masked events are not transmitted to the interrupt line, but the CCP2_LC01_IRQSTATUS, CCP2_LC23_IRQSTATUS, or CCP2_LCM_IRQSTATUS register is updated.

Events transmitted to the ISS interrupt merger can be mapped to the Cortex-A15 MPU or Cortex-M4 IPU subsystems, or DSP, by unmasking ISS_HL_IRQENABLE_SET_i[] CCP2_IRQj (where i = 0 to 5, j = 0, 1, 2, 3, and 8). Only the ISS_HL_IRQENABLE_SET_5 output line is connected to the Cortex-A15 MPU SS interrupt controller (INTC), and only the ISS_HL_IRQENABLE_SET_4 output line is connected to the DSP INTC. The Cortex-M4 MPU SS INTC, however, is connected to all six output lines of ISS_HL_IRQENABLE_SET_i (where i = 0 to 5). To clear an event, the following actions are required:

- Clear the event at the CCP2 receiver level by writing 1 to the corresponding bit in the CCP2_LC01_IRQSTATUS, CCP2_LC23_IRQSTATUS or CCP2_LCM_IRQSTATUS register.
- Events generated by the submodules and ISS top level clear it. Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the ISS_HL_IRQENABLE_SET_i register. It is disabled by setting the appropriate bit in the ISS_HL_IRQENABLE_CLR_i register. When an event occurs, the corresponding bit in the ISS_HL_IRQSTATUS_i register is set, regardless of whether or not

the event is enabled. Bits in the ISS_HL_IRQSTATUS_i registers are set only when an enabled event occurs. Software can clear a pending HS_VS_IRQ event by setting the appropriate bit ISS_HL_IRQSTATUS[17] HS_VS_IRQ. Events generated by submodules are automatically cleared at ISS top level when they are cleared at submodule level.

8.2.4.4.3 ISS CCP2 Programming Register Accessibility During Frame Processing

There are two types of register accesses in the CCP2 receiver:

- Shadowed registers:
  - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most-recent write, even though the settings are not used until the next start of frame.
  - The shadowed registers are:
    - CCP2_LCx_CTRL
    - CCP2_LCx_CODE
    - CCP2_LCx_STAT_START
    - CCP2_LCx_STAT_SIZE
    - CCP2_LCx_SOF_ADDR
    - CCP2_LCx_EOF_ADDR
    - CCP2_LCx_DAT_SIZE
    - CCP2_LCx_DAT_PING_ADDR
    - CCP2_LCx_DAT_PONG_ADDR
    - CCP2_LCx_DAT_OFST
- Busy-locked registers:
  - These registers/fields must not be written if the module is busy.
  - All register fields not listed as shadowed are busy-writable registers.

8.2.4.4.4 ISS CCP2 Programming Enable/Disable the Hardware

The CCP2 receiver is globally controlled by the CCP2_CTRL register. The bit fields in this register must not be modified when the CCP2 interface is active (except CCP2_CTRL[0] IF_EN).

Table 8-63 and Table 8-64 list the procedures to enable and disable, respectively, the interface.

Table 8-63. ISS CCP2 Interface Enable

Step	Bit Field	Value
Clear the interface. Data acquisition starts on the following FSC synchronization code.	CCP2_CTRL[0] IF_EN	0x1
Reset the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.	CCP2_CTRL[0] IF_EN	0x1

Table 8-64. ISS CCP2 Interface Disable

Step	Bit Field	Value
Disable interface. • The interface is disabled immediately if CCP2_CTRL[3] FRAME = 0x0. • If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x0, the interface is disabled after the FEC synchronization code is received. • If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received. • Before disabling the interface (IF_EN = 0), it is advised to disable all active channels by writing CCP2_LCx_CTRL[0] CHAN_EN = 0x0. Otherwise, if IF_EN = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active channels.	CCP2_CTRL[0] IF_EN	0x0

8.2.4.4.5 ISS CCP2 Programming Select the Signaling Scheme

Table 8-65 lists the procedure to select the signaling scheme.

Table 8-65. ISS CCP2 Select the Signaling Scheme

Step	Bit Field	Value
Selects whether the data/strobe or data/clock signaling scheme is used. For the correct settings as a function of the image sensor class, see Section 8.2.3, *ISS CSI PHY*. Setting CCP2_CTRL[1] PHY_SEL = 0x1 has no effect if CCP2_CTRL[4] MODE = 0x0 (CSI1 mode). This setting must also be configured in the control module.	See Section 8.2.3, *ISS CSI PHY*. For the register and bit field, see Chapter 18, *Control Module*.	0x0: Data/clock 0x1: Data/strobe

8.2.4.4.6 ISS CCP2 Programming Select the Mode: MIPI CSI1 or CCP2

Table 8-66 lists the procedure to select MIPI CSI1 or CCP2 mode.

Table 8-66. ISS CCP2 Select MIPI CSI1 or CCP2 Mode

Step	Bit Field	Value
Selects whether the CCP2 module works in MIPI CSI1 or CCP2-compatible mode	CCP2_CTRL[4] MODE	0x0: Disables the CCP2-specific features (data/strobe, CRC, logical channels, RAW6, RAW7, and DPCM data formats) 0x1: CCP2 mode

8.2.4.4.7 ISS CCP2 Programming Burst Settings

Table 8-67 lists the procedure to configure the burst settings.

Table 8-67. ISS CCP2 Configure Burst Settings

Step	Bit Field	Value
The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, 8x, and 16 x 64 bits. The module must always use 16 x 64. The FIFO size is 64 x 64 bits.	CCP2_CTRL[6:5] BURST CSI2_CTRL[16] BURST_SIZE_EXPAND	0x0: Single request. 0x1: 2 x 64-bit bursts 0x2: 4 x 64-bit bursts 0x3: 8 x 64-bit bursts 0x4: 16 x 64-bit bursts (with burst expand)
Enable 128 bytes (recommended setting) of the DMA CSI2/CCP DMA engine to burst 128 bytes over the L3_MAIN interconnect.	CSI2_CTRL[16] BURST_SIZE_EXPAND	0x0: Use the burst size defined in the BURST_SIZE bit field. 0x1: Allow generation of 16 x 64-bit bursts.

8.2.4.4.8 ISS CCP2 Programming Debug Mode

Table 8-68 lists the procedure to enable debug mode.

Table 8-68. ISS CCP2 Enable Debug Mode

Step	Bit Field	Value
Enable debug mode.	CCP2_CTRL[13] DBG_EN	0x1

- During debug mode, the input comes from the CCP2_DBG register, not from the CCP2 physical interface. The full CCP2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the CCP2_DBG register.
- The following bit has no effect during debug mode:
  - CCP2_CTRL[0] IF_EN
- The following examples apply to the CCP2_DBG register:
  - Synchronization codes: CCP2_DBG = 0xFF000000 (LSC) or 0xFF00001 (LEC) or 0xFF00002 (FSC) or 0xFF000003 (FEC)
  - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write CCP2_DBG = 0x01234567 followed by CCP2_DBG = 0x89abcdef and CCP2_DBG = 0x76543210.

NOTE: Each write to the CCP2_DBG register sends a full 32-bit word through the CCP2 receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x0000 00FF the MPU subsystem informs that only 8 bits are written), the CCP2 receiver pipeline gets 0x01234567 followed by 0x012345FF.

8.2.4.4.9 ISS CCP2 Programming Video Port

Table 8-69 lists the procedure to configure the video port.

Table 8-69. ISS CCP2 Configure Video Port

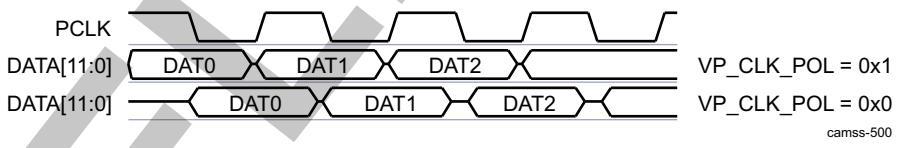
Step	Bit Field	Value
Set the video port output frequency. It varies from ISS_MAIN_FLCK down to ISS_MAIN_FLCK / 65,536 MHz.	CCP2_CTRL[31:15] FRACDIV	From 1 to 65,536
Enable video port clock during vertical blanking periods or not.	CCP2_CTRL[9] VP_CLK_FORCE_ON	0x0: The video port clock is gated during vertical blanking periods. 0x1: The video port clock is free-running during vertical blanking periods.

Table 8-69. ISS CCP2 Configure Video Port (continued)

Step	Bit Field	Value
Controls whether the video-port output is the only output interface enabled and applies for all channels. When CCP2_CTRL[11] VP_ONLY_EN = 0x1, the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to the video port and embedded data to the interconnect). • The video port outputs the embedded data defined by the CCP2_LCx_STAT_START and CCP2_LCx_STAT_SIZE registers without decompression. • The video port outputs the pixel data defined by the CCP2_LCx_DAT_START and CCP2_LCx_DAT_SIZE registers.	CCP2_CTRL[11] VP_ONLY_EN	
Control the video port pixel clock polarity: (Recommended setting: rising edge)	CCP2_CTRL[12] VP_CLK_POL	0x0: The CCP2 receiver writes the data on the video port on the pixel-clock falling edge. The module connected to the video port samples the data on the pixel clock rising edge. 0x1: The CCP2 receiver writes the data on the video port on the pixel-clock rising edge. The module connected to the video port samples the data on the pixel clock falling edge. Figure 8-32 shows the settings for CCP2_CTRL[12] VP_CLK_POL.

Figure 8-32 shows the settings for CCP2_CTRL[12] VP_CLK_POL.

Figure 8-32. CCP2_CTRL[12] VP_CLK_POL Settings



8.2.4.4.10 ISS CCP2 Programming Logical Channels

The CCP2 receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all four logical channels (LCx, where x = 0 to 3).

All the registers in Section 8.2.4.4.11, *ISS CCP2 Programming Controls* through Section 8.2.4.4.18, *ISS CCP2 Programming Pixel Data Region* can be modified at any time. However, the modifications apply only from the start of the following frame.

8.2.4.4.11 ISS CCP2 Programming Controls

Table 8-70 lists the procedure to enable the logical channels.

Table 8-70. ISS CCP2 Enable Logical Channels

Step	Bit Field	Value
Enable logical channels. It has no effect if CCP2_CTRL[4] MODE = 0x0. By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the video preprocessing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface.	CCP2_LCx_CTRL[0] CHAN_EN	0x1

8.2.4.4.12 ISS CCP2 Programming Region-of-Interest

Table 8-71 lists the procedure to enable the region-of-interest.

Table 8-71. ISS CCP2 Enable Region-of-Interest

Step	Bit Field	Value
Enables the region-of-interest feature (SOF lines, pixel data, and EOF lines): • If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored. • If disabled, all data in the frame are output. CCP2_LCx_CTRL[1] REGION_EN is set to 0x0 for a JPEG bitstream.	CCP2_LCx_CTRL[1] REGION_EN	0x1

8.2.4.4.13 ISS CCP2 Programming CRC

Table 8-72 lists the procedure to enable the CRC.

Table 8-72. ISS CCP2 Enable the CRC

Step	Bit Field	Value
Enable the CRC. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is LCx_CRC_IRQ. Setting CCP2_LCx_CTRL[2] CRC_EN = 0x1 has no effect, if CCP2_CTRL[4] MODE = 0x0.	CCP2_LCx_CTRL[2] CRC_EN	0x1

8.2.4.4.14 ISS CCP2 Programming Destination Format

Control the destination format:

- The CCP2 receiver reformats received data to store it in memory or to send it to the video preprocessing.
- The CCP2_LCx_CTRL[7:3] FORMAT bit field controls the destination-data format:
  - EXP8 = Data expansion to 8 bits, padding with zeros
  - EXP16 = Data expansion to 16 bits, padding with alpha or zeros. The CCP2_CTRL[15:8] ALPHA bit field can be used to set an alpha value. For RGB444 + EXP16:
    - data_out [31:28] = ALPHA [3:0]
    - data_out [15:12] = ALPHA [3:0]
  - EXP32 = Data expansion to 32 bits, padding with alpha. The CCP2_CTRL[15:8] ALPHA bit field can be used to set an alpha value. For RGB888 + EXP32: data_out [31:24] = ALPHA [7:0]
  - FSP = False synchronization protection code decoding. Applies only to JPEG8 data format.
  - VP = Output to video preprocessing is enabled.

8.2.4.4.15 ISS CCP2 Programming Frame Acquisition

Table 8-73 lists the procedure to acquire frames.

Table 8-73. ISS CCP2 Frame Acquisition

Step	Bit Field	Value
Program the number of frames that the CCP2 receiver acquires. The value of COUNT is decremented after each frame received.	CCP2_LCx_CTRL[31:24] COUNT	0: The counter is free-running (default value). 1255: Remaining frames to be acquired
Writes to the COUNT bit field are controlled by the COUNT_UNLOCK bit.	CCP2_LCx_CTRL[16] COUNT_UNLOCK	
Configures PING and PONG addresses	CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR	
Indicates whether the PING address or PONG address was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in CCP2_CTRL[0] IF_EN, the pixel data are written in the PING buffer and CCP2_LCx_CTRL[17] PING_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and CCP2_LCx_CTRL[17] PING_PONG = 0x0 (PING). CCP2_LCx_CTRL[17] PING_PONG toggles after every FEC synchronization code.	CCP2_LCx_CTRL[17] PING_PONG	

After the correct number of frames is received, acquisition is automatically disabled (CCP2_LCx_CTRL[0] CHAN_EN = 0x0) and the COUNT_IRQ interrupt is triggered. The programmer can re-enable the acquisition by resetting the CCP2_LCx_CTRL[0] CHAN_EN bit to 0x1.

8.2.4.4.16 ISS CCP2 Programming Synchronization Codes

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the *SMIA CCP2 Specification v1.0*. Also, each logical channel is identified by a default identifier.

The CCP2_LCx_CODE register enables overwriting of the default values: CCP2_LCx_CODE[11:8] FSC, CCP2_LCx_CODE[15:12] FEC, CCP2_LCx_CODE[3:0] LSC, and CCP2_LCx_CODE[7:4] LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values must not be modified.

8.2.4.4.17 ISS CCP2 Programming Status Data

The SOF and EOF status lines can be output to memory.

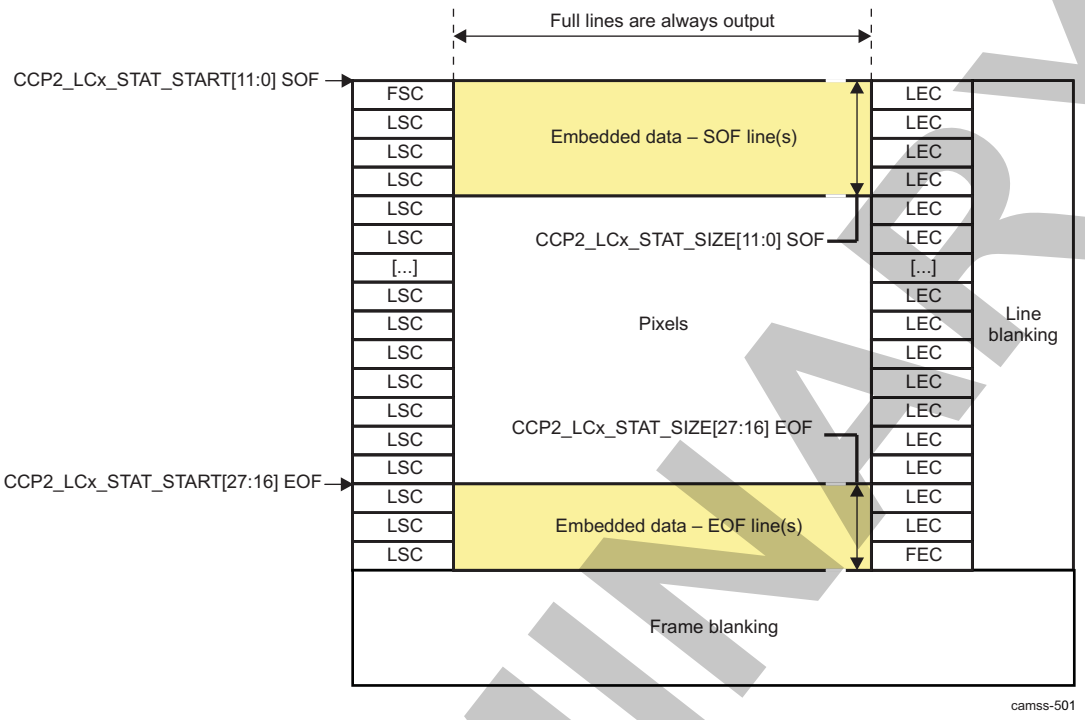
The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The CCP2_LCx_STAT_START register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CCP2 frame, CCP2_LCx_STAT_START[11:0] SOF = 0x0.

The CCP2_LCx_STAT_SIZE register enables the setting of the numbers of SOF and EOF status lines. If CCP2_LCx_STAT_SIZE[11:0] SOF = 0x0 and CCP2_LCx_STAT_SIZE[27:16] EOF = 0x0, no status data are output.

Figure 8-33 shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive.

Figure 8-33. ISS CCP2 SOF and EOF Region Settings



The 32-bit destination addresses of the SOF status lines are set by the CCP2_LCx_SOF_ADDR register.

NOTE: The destination addresses of the SOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the CCP2_LCx_EOF_ADDR register.

NOTE: The destination addresses of the EOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The EOF lines are packed together at the destination address.

NOTE: The CCP2 receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

8.2.4.4.18 ISS CCP2 Programming Pixel Data Region

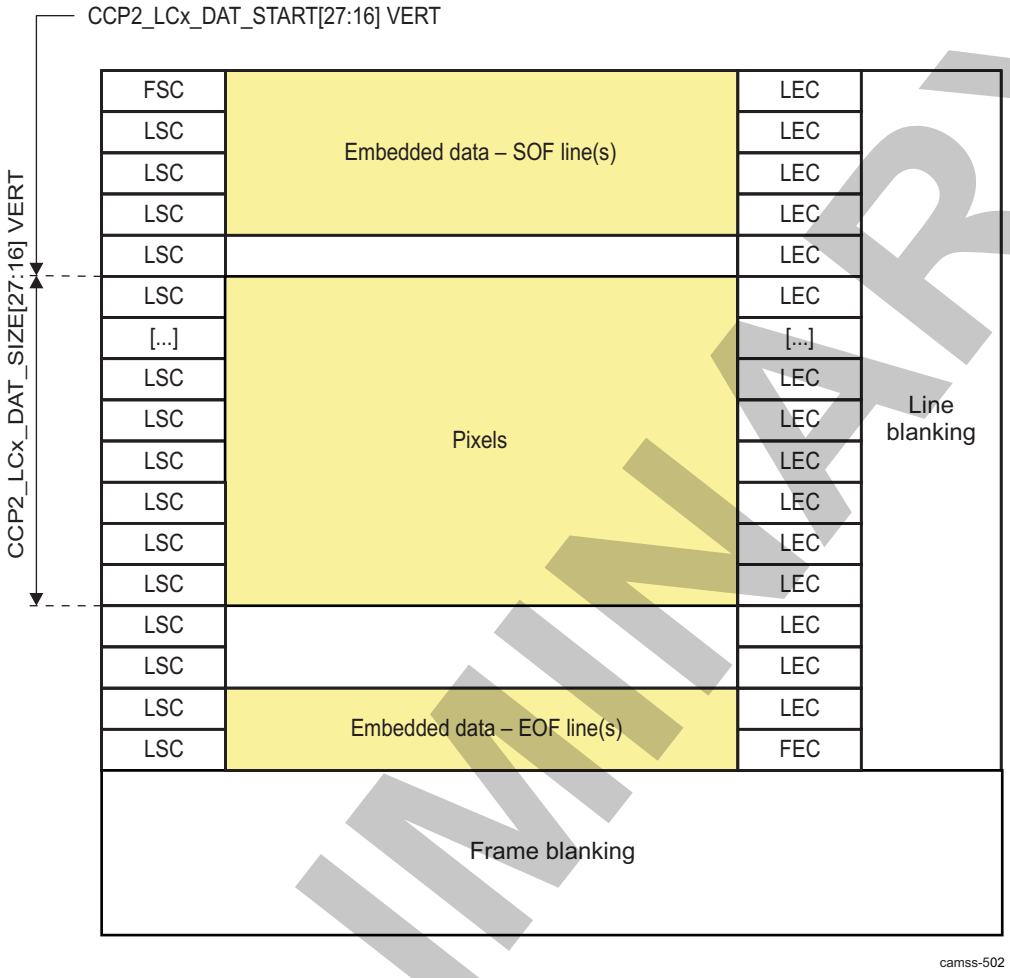
Pixel data can be output to memory or to the video-preprocessing hardware.

The pixel data region covers full lines. The CCP2_LCx_DAT_SIZE register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The CCP2_LCx_DAT_START register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

Figure 8-34 shows the pixel region settings.

Figure 8-34. ISS CCP2 Pixel Data Region Settings



The 32-bit destination addresses of the pixel data are set by the CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR registers.

NOTE: The destination address must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR registers. It is possible to disable double-buffering by setting up the same address in both registers. The CCP2_LCx_CTRL[17] PING_PONG bit must be used by software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the CCP2_LCx_DAT_OFST register. It applies for CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR.

NOTE: The destination pitch must be a multiple of 32 bytes; the 5 LSBs of the address are ignored.

The destination data format is set with the CCP2_LCx_CTRL[7:2] FORMAT bit field.

For the PING frame:

- @Line0 = CCP2_LCx_DAT_PING_ADDR
- @Line1 = @Line0 + CCP2_LCx_DAT_OFST

- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

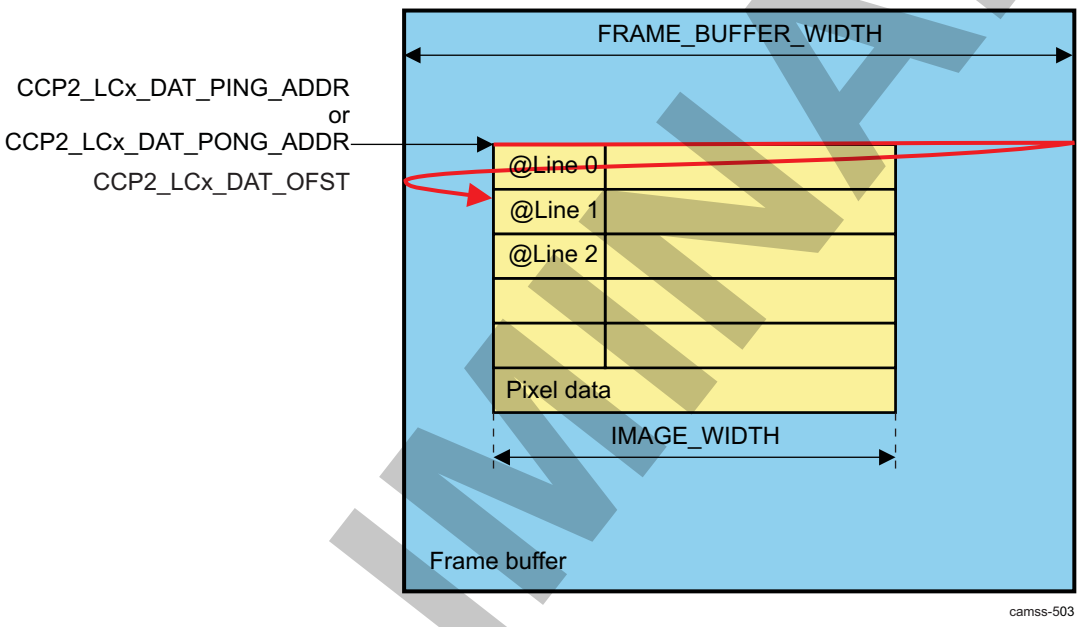
For the PONG frame:

- @Line0 = CCP2_LCx_DAT_PONG_ADDR
- @Line1 = @Line0 + CCP2_LCx_DAT_OFST
- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

When CCP2_LCx_DAT_OFST = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, CCP2_LCx_DAT_OFST = FRAME_BUFFER_WIDTH. Figure 8-35 shows the pixel data destination settings.

Figure 8-35. ISS CCP2 Pixel Data Destination Settings



8.2.4.4.19 ISS CCP2 Programming Memory Read Channel

8.2.4.4.19.1 ISS CCP2 Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV4:2:2 little-endian format.

8.2.4.4.19.2 ISS CCP2 Read Data From Memory

Table 8-74 lists the procedure to configure read data from memory.

Table 8-74. ISS CCP2 Configure Read Data From Memory

Step	Bit Field	Value
Disable all logical channels.	CCP2_CTRL[0] IF_EN	0x0
Wait until disabling of the physical interface is effective before enabling the memory read channel.	CCP2_CTRL[3] FRAME	0x1
Configure the burst siz .The recommended value for best performance is 0x4 (16 × 64-bit burst).	CCP2_LCM_CTRL[7:5] BURST_SIZE	–

Table 8-74. ISS CCP2 Configure Read Data From Memory (continued)

Step	Bit Field	Value
Configure the source data format, location, and framing. In addition to the CCP2_LCM_HSIZE[11:0] SKIP and CCP2_LCM_HSIZE[27:16] COUNT bit fields, firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula: HWORDS = 4 × ceil(((SKIP + COUNT) x bits_per_pixel)/(8 × 32)) (3) The CCP2_LCM_SRC_ADDR and CCP2_LCM_SRC_OFST registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries. See the example following this table.	CCP2_LCM_CTRL, CCP2_LCM_HSIZE, CCP2_LCM_VSIZE, CCP2_LCM_PREFETCH, CCP2_LCM_SRC_ADDR, CCP2_LCM_SRC_OFST	
Select destination.	CCP2_LCM_CTRL[2] DST_PORT	0x0: Video port 0x1: Memory
If destination = video port, configure clock frequency and its gating during frame blanking periods.	CCP2_CTRL[31:15] FRACDIV, CCP2_CTRL[9] VP_CLK_FORCE_ON	
If needed, configure READ_THROTTLE to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port (controlled by video port clock in this case).	CCP2_LCM_CTRL[4:3] READ_THROTTLE	
If the memory write port is used, the destination format and address must be configured.	CCP2_LCM_DST_ADDR, CCP2_LCM_DST_OFST	
Enable memory read channel. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered.	CCP2_LCM_CTRL[0] CHAN_EN	0x1

Example:

- CCP2_LCM_CTRL[7:5] BURST_SIZE is set to 16 × 64 bits
- CCP2_LCM_HSIZE[11:0] SKIP = 0
- CCP2_LCM_HSIZE[27:16] COUNT = 1000
- CCP2_LCM_CTRL[23] SRC_PACK = YES
- CCP2_LCM_CTRL[18:16] SRC_FORMAT = RAW6
- CCP2_LCM_PREFETCH[13:3] HWORDS = 96 (>=94)

  Setting the size to 94 produces the following burst sequence: 16, 16, 16, 16, 16, 8, and 4 (7 interconnect requests). However, when it is set to 96, the burst sequence is 6 × 16 (6 interconnect requests).

Table 8-75 summarizes the expected settings for all possible modes of the LCM feature, when data is sent to the video port (bit CCP2_LCM_CTRL[2] DST_PORT = 0x0).

Table 8-76 summarizes the expected settings for all possible modes of the LCM feature, when data is sent to memory through the interface port (bit CCP2_LCM_CTRL[2] DST_PORT = 0x1).

The following constraints on the register settings apply, when the writing of DPCM history information into system memory is enabled (see Section 8.2.4.3.5.6, *ISS CCP2 DPCM Decompression History*, for more details):

- CCP2_LCM_CTRL[26:24] DST_FORMAT = RAW10 or RAW12
- CCP2_LCM_CTRL[29:28] DST_COMPR = 0
- CCP2_LCM_CTRL[30] DST_DPCM_PRED = 0
- CCP2_LCM_CTRL[31] DST_PACK = 0
- CCP2_LCM_CTRL[23] SRC_PACK = 0 or 1
- CCP2_LCM_CTRL[22] SRC_DPCM_PRED = 0 or 1
- CCP2_LCM_CTRL[21:20] SRC_DECOMPR = 0x2 or 0x3
- CCP2_LCM_CTRL[19:16] SRC_FORMAT = RAW6, RAW7 or RAW8
- CCP2_LCM_CTRL[2] DST_PORT = 0 or 1
- CCP2_LCM_DST_OFST = OFST, when destination is OCP (CCP2_LCM_CTRL[2] DST_PORT = 1)
- CCP2_LCM_DST_ADDR = SDRAM address of:
  - Pixels, when CCP2_LCM_CTRL[2] DST_PORT = 1
  - History data, when CCP2_LCM_CTRL[2] DST_PORT = 0
- CCP2_LCM_HIST_ADDR = SDRAM address of history data when CCP2_LCM_CTRL[2] DST_PORT = 1

Table 8-97. CCP2_CTRL

Address Offset	0x0000 0040		
Physical Address	0x5200 1C40	**Instance**	ISS_CCP2
Description	GLOBAL CONTROL REGISTER This register controls the CCP2 receiver. This register must not be modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACDIV																POSTED	DBG_EN	VP_CLK_POL	VP_ONLY_EN	RESERVED	VP_CLK_FORCE_ON	RESERVED	BURST			MODE	FRAME	RESERVED	RESERVED	IF_EN	

Bits	Field Name	Description	Type	Reset
31:15	FRACDIV	Fractional clock divider control for the video port. The mean video port clock is VPBASECLOCK * FRACDIV/65536. Valid range: 1-65536	RW	0x10000
14	POSTED	Selects between posted and non posted writes. 0x0: Non posted 0x1: Posted	RW	0

Bits	Field Name	Description	Type	Reset
13	DBG_EN	Enables the debug mode. 0x0: Disable 0x1: Enable	RW	0
12	VP_CLK_POL	VP clock polarity 0x0: The CCP2 receiver writes the data on the VP on the L3 falling edge before the next falling PCLK edge. 0x1: The CCP2 receiver writes the data on the VP on the L3 rising edge before the next rising PCLK edge.	RW	0
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the OCP master port are enabled. 0x1: The VP is enabled and the OCP master port is disabled. The embedded data and pixel data are output on the VP.	RW	0
10	RESERVED	Read returns reset value	RW	0
9	VP_CLK_FORCE_ON	Controls VP_PCLK gating during frame blanking periods. 0x0: The VP_PCLK is gated during vertical blanking periods. 0x1: The VP_PCLK is free-running during vertical blanking periods.	RW	0
8	RESERVED		R	0
7:5	BURST	Forces the write burst size used by the module. The write burst size must never exceed the output FIFO size. The output FIFO size can be read with the CCP2_GNQ.FIFODEPTH bit field. 0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts.	RW	0x0
4	MODE	Selects the receiver operating mode. This bit is only writable when the CCP2MODE input is 1. 0x0: MIPI CSI1 compatible mode. When this bit is set all CCP2 settings are ignored. If the settings are not set correctly to MIPI CSI1 values, the behavior of the receiver is unpredictable. 0x1: CCP2 compatible mode	RW	0
3	FRAME	Set the modality in which IF_EN works. 0x0: When software writes IF_EN = 0 the interface is disabled immediately. 0x1: When software writes IF_EN = 0 the interface is disabled after the next FEC sync code.	RW	0
2	RESERVED	Read returns reset value	RW	0
1	RESERVED	Read returns reset value	RW	0
0	IF_EN	Enables the physical interface to the module. 0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC sync code. If FRAME=1, it is advised to disable the logical channels first (CCP2_LCx_CTRL.CHAN_EN=0) before writing IF_EN=0. 0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CCP2_LCx_CTRL.PING_PONG bits are reset to 1 as well.	RW	0

Table 8-99. CCP2_DBG

Address Offset	0x0000 0044		
Physical Address	0x5200 1C44	**Instance**	ISS_CCP2
Description	DEBUG REGISTER This register provides a way to debug the CCP2 receiver with no image sensor connected to the module. The debug mode is enabled by CCP2_CTRL.DBG_EN. Each write to this register provides a full 32bit word to the CCP2 receiver, even when only 8 or 16 bits are written. The newly written value is merged with the previous value (check the example in the programming model section).		
Type	W

Address Offset	0x0000 0078 + (x * 0x30)	**Index**	x = 0 to 3
Physical Address	0x5200 1C78 + (x * 0x30)	**Instance**	ISS_CCP2
Description	DATA MEM ADDRESS OFFSET REGISTER - LOG CHAN 0 This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CCP2_LC0_DAT_PING_ADDR and CCP2_LC0_DAT_PONG_ADDR. For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data must have the same data format. The 5 LSBs are ignored: the offset must be a multiple of 32 bytes. Only full 64-bits words are written to memory at the end of lines. This register is shadowed: modifications are taken into account after the next FSC sync code.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFST																											RESERVED					

Bits	Field Name	Description	Type	Reset
31:5	OFST	Line offset programmed in bytes. If OFST = 0, the data is written contiguously in memory. Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line. NOTE: An OCP access (read/write) is required to properly update the CCP2_LCx_DAT_OFST register	RW	0x0000000

Bits	Field Name	Description	Type	Reset
31	DST_PACK	Data is packed before it is send to memory. Applies to RAW6, RAW7, RAW10, and RAW12 only. 0x0: Disabled 0x1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
30	DST_DPCM_PRED	Selects the DPCM predictor to be used for the RAW6+DPCM10 and RAW7+DPCM10 data formats. The RAW8+DPCM10 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used.	RW	0
29:28	DST_COMPR	Enables data compression of data sent to memory 0x0: No compression 0x1: A-Law compression RAW10 -> RAW8 A-Law when DST_FORMAT=RAW8 other destination formats are invalid. 0x2: DPCM compression RAW10 -> RAW6 DPCM when DST_FORMAT=RAW6 RAW10 -> RAW7 DPCM when DST_FORMAT=RAW7 RAW10 -> RAW8 DPCM when DST_FORMAT=RAW8 other destination formats are invalid.	RW	0x0
27	RESERVED		R	0
26:24	DST_FORMAT	Output format selection. Not every combination between input and output formats are possible. 0x6: RAW16 0x1: RAW7 0x0: RAW6 0x2: RAW8 0x4: RAW12 0x5: RAW14 0x3: RAW10	RW	0x0
23	SRC_PACK	Data stored in memory is packed and must be unpacked. 0x0: Disabled 0x1: Enabled	RW	0
22	SRC_DPCM_PRED	Selects the DPCM predictor to be used for the RAW6+DPCM10, RAW7+DPCM10 and RAW8+DPCM12 data formats. The RAW8+DPCM10 and RAW6 + DPCM12 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used.	RW	0
21:20	SRC_DECOMPR	Enable decompression of incoming data 0x0: No decompression 0x1: A-Law decompression RAW8 A-Law -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid. 0x3: DPCM decompression RAW6 DPCM -> RAW12 when SRC_FORMAT=RAW6 RAW8 DPCM -> RAW12 when SRC_FORMAT=RAW8 other source formats are invalid. 0x2: DPCM decompression RAW6 DPCM -> RAW10 when SRC_FORMAT=RAW6 RAW7 DPCM -> RAW10 when SRC_FORMAT=RAW7 RAW8 DPCM -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid.	RW	0x0

Bits	Field Name	Description	Type	Reset
19:16	SRC_FORMAT	Data format of the data stored in memory. As there is no header embedded in the data sent to memory the user is responsible of choosing the adequate format. 0x6: RAW16 0x1: RAW7 0xA: Reserved 0x7: Reserved 0xD: Reserved 0x0: RAW6 0x2: RAW8 0x8: Reserved 0x9: Reserved 0xB: Reserved 0x4: RAW12 0x5: RAW14 0xF: Reserved 0xC: Reserved 0x3: RAW10 0xE: Reserved	RW	0x0
15:8	RESERVED		R	0x00
7:5	BURST_SIZE	Defines the burst size of the master read port 0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts.	RW	0x0
4:3	READ_THROTTLE	Limit maximum data read speed for memory to memory operation 0x0: Full speed. Throughput is limited by internal processing capabilities. 0x1: 1/2 speed 0x3: 1/8 speed 0x2: 1/4 speed	RW	0x0
2	DST_PORT	Select the destination port 0x0: Data is send to video port, it is always send without compression or packing. The DST_COMPR, DST_DPCM_PRED, DST_PACK, CCP2_LCM_DST_WRITE, and CCP2_LCM_DST_OFST registers have no effect. 0x1: Data is send to memory.	RW	0
1	RESERVED		R	0
0	CHAN_EN	Enables the read from memory channel. Before enabling the memory read channel software must: - disable the physical interface using the IF_EN bit - wait until disabling of the physical interface is effective (depends on the FRAME bit) Read from memory starts as soon as this bit is set, therefore all CCP2_LCM_x registers must be configured correctly before. This bit is cleared by hardware at the end of the frame. 0x0: Disabled 0x1: Enabled	RW	0

8.2.5 ISS CSI2

8.2.5.1 ISS CSI2 Environment

8.2.5.1.1 ISS CSI2 Protocol and Data Format

The CSI2 supports MIPI CSI2 multiple data type formats. This section describes MIPI CSI2 protocol and data formats. The CSI2 is compatible with the *MIPI CSI2 Specification v1.0-01-00 r0.03*. Table 8-147 lists the MIPI CSI2 supported by CSI2 formats in addition to JPEG8. Shading in the primary and secondary MIPI CSI2_defined formats indicates special format extensions of the CSI2 receiver.

Table 8-147 summarizes the pixel formats supported by the CSI2 receiver interface.

Table 8-147. ISS CSI2 Pixel Format Modes

CSI2_CTX_CTRL2_i[9:0] Format	CSI2 Data Format	Bits per Pixel (BPP)	Data Size Increases in Memory	2D Mode Availability[1]	Comments

0x12	JPEG8	8	0%		

(1) If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

For more information about how the data formats are transmitted and how the data are stored in memory, see Section 8.2.5.1.1.4, *CSI2 Operating Modes*.

NOTE: The VP formats are not included in Table 8-147, because they are not sent to memory; instead they are sent to the ISP for further processing.

NOTE: Data written by CSI2 can be read back by the CCP2 read channel. CCP2 can get data from a sensor or memory. For more information about supported memory operations, see Table 8-59.

8.2.5.1.1.1 ISS CSI2 Physical Layer

The CSI2_A/CSI2_B/CSI2_C receivers (also generally referenced to as CSI2_RECEIVER) are tightly connected to a PHY layer (for more information about the PHY, see Section 8.2.3, *ISS CSI PHY*). Table 8-148 lists the CSI2_A receiver I/O signals, Table 8-149 lists the CSI2_B receiver I/O and Table 8-150 lists the CSI2_C receiver I/O. The CSI2_RECEIVER provides access to the complex I/O configuration through a serial configuration port (SCP) interface from the CSI2_COMPLEXIO_CFG register. The CSI2_RECEIVER can access up to 2x8 32-bit registers in the complex I/O. The 16 registers in the complex I/O are handled as two banks of 8 registers each. Software must select a bank, prior to doing registers accesses, using the CSI2_COMPLEXIO_CFG[31] PHY_REG_BANK register bit.

Table 8-148. ISS CSI2_A I/O Description

Signal Name		I/O[1]	Description
csiporta_lane0x	lane 0 (position 1)	I	Serial data/clock input
csiporta_lane0y			
csiporta_lane1x	lane 1 (position 2)	I	Serial data/clock input
csiporta_lane1y			
csiporta_lane2x	lane 2 (position 3)	I	Serial data/clock input
csiporta_lane2y			
csiporta_lane3x	lane 3 (position 4)	I	Serial data/clock input
csiporta_lane3y			
csiporta_lane4x	lane 4 (position 5)	I	Serial data input only
csiporta_lane4y			

(1) I = Input

Table 8-149. ISS CSI2_B I/O Description

Signal Name		I/O[1]	Description
csiportb_lane0x	line 0 (position 1)	I	Serial data/clock input
csiportb_lane0y			
csiportb_lane1x	line 1 (position 2)	I	Serial data/clock input
csiportb_lane1y			
csiportb_lane2x	line 2 (position 3)	I	Serial data/clock input
csiportb_lane2y			

(1) I = Input

Table 8-150. ISS CSI2_C I/O Description

Signal Name		I/O[1]	Description
csiportc_lane0x	lane 0 (position 1)	I	Serial data/clock input
csiportc_lane0y			
csiportc_lane1x	lane 1 (position 2)	I	Serial data/clock input
csiportc_lane1y			

(1) I = Input

NOTE: The serial lane can be used as clock lane or data lane (excluding lane 4 on the CSI2_A I/O). The MIPI CSI2 protocol requires one clock lane (others are data lane or unused lane).

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

8.2.5.1.1.2 ISS CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The lane merger can merge up to four lanes (CSI2_A) into a single byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2_A and CSI2_B receiver cores depends on the lane configuration. The merger is not used for a single lane.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

Figure 8-36 to Figure 8-39 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 8-36. ISS CSI2 One Data-Lane Configuration

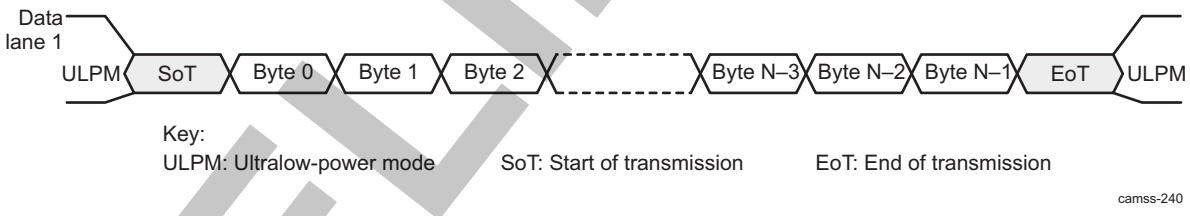

Figure 8-37. ISS CSI2 Two Data-Lane Merger Configuration

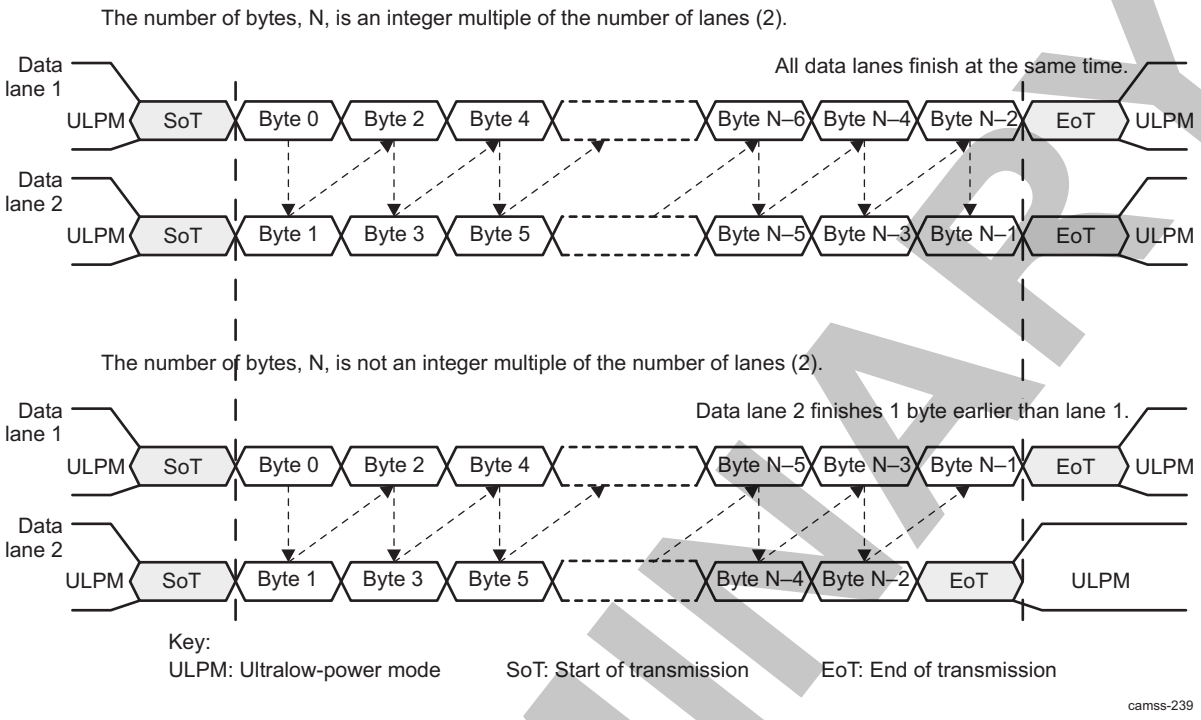

Figure 8-38. ISS CSI2 Three Data-Lane Merger Configuration

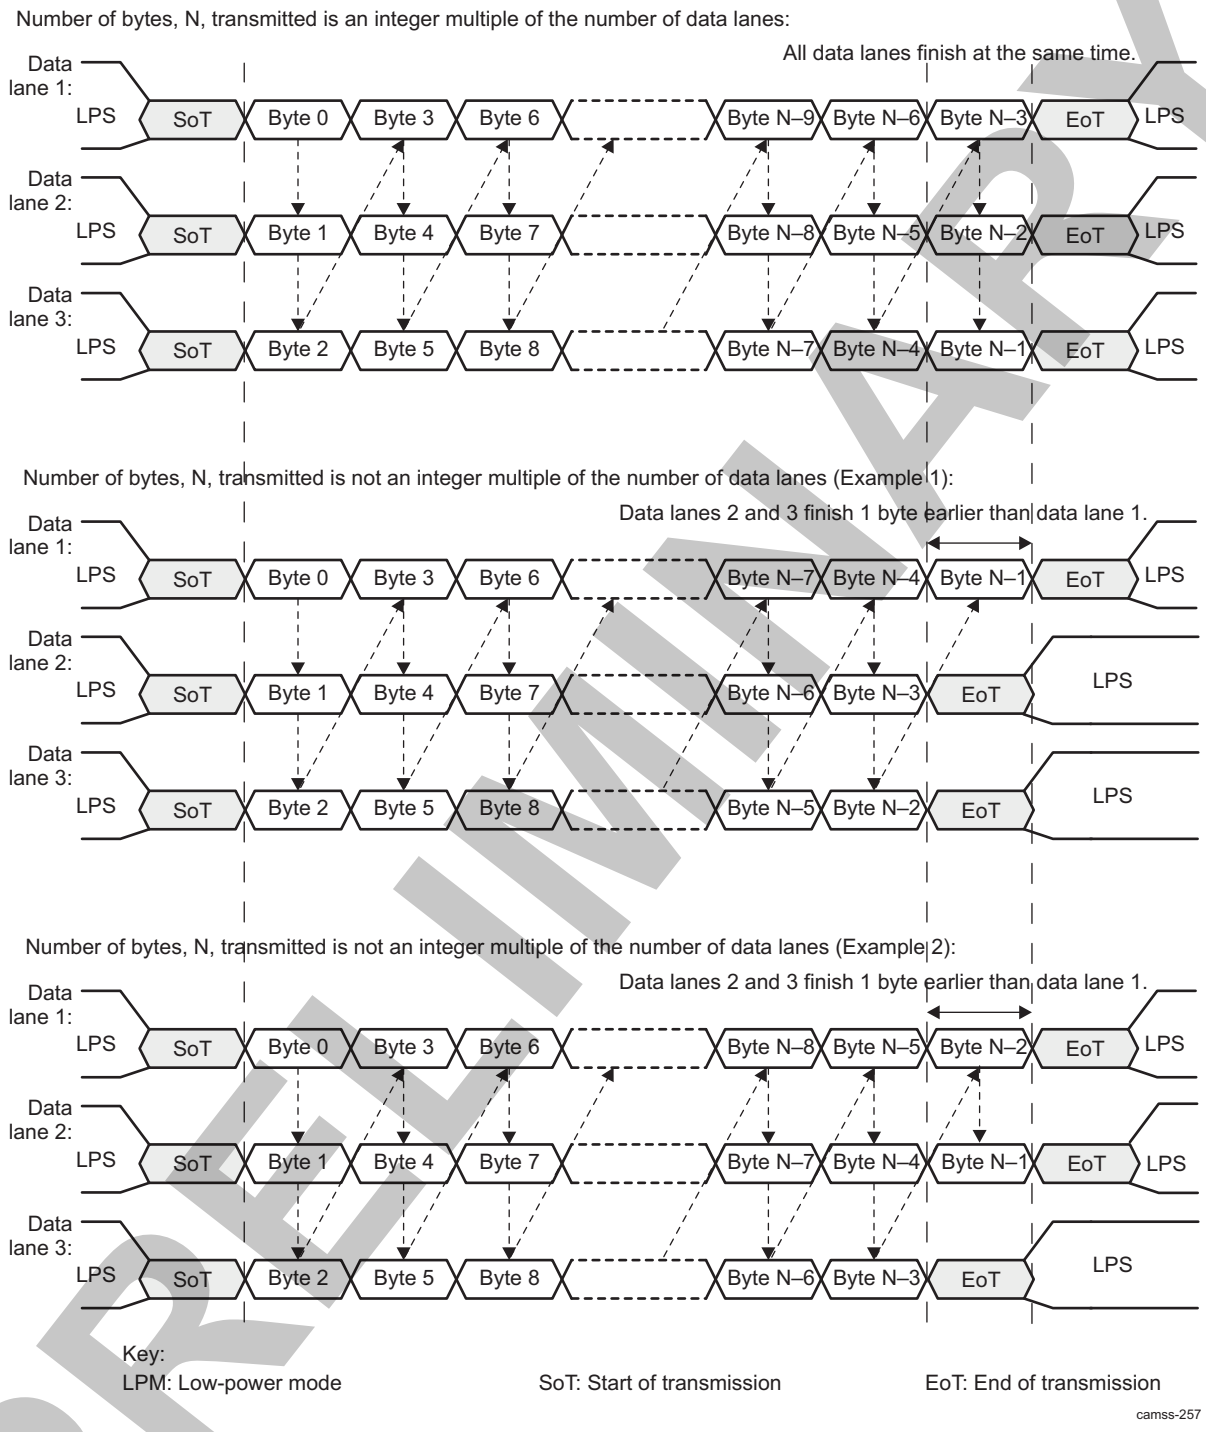

Figure 8-39. ISS CSI2 Four Data-Lane Merger Configuration

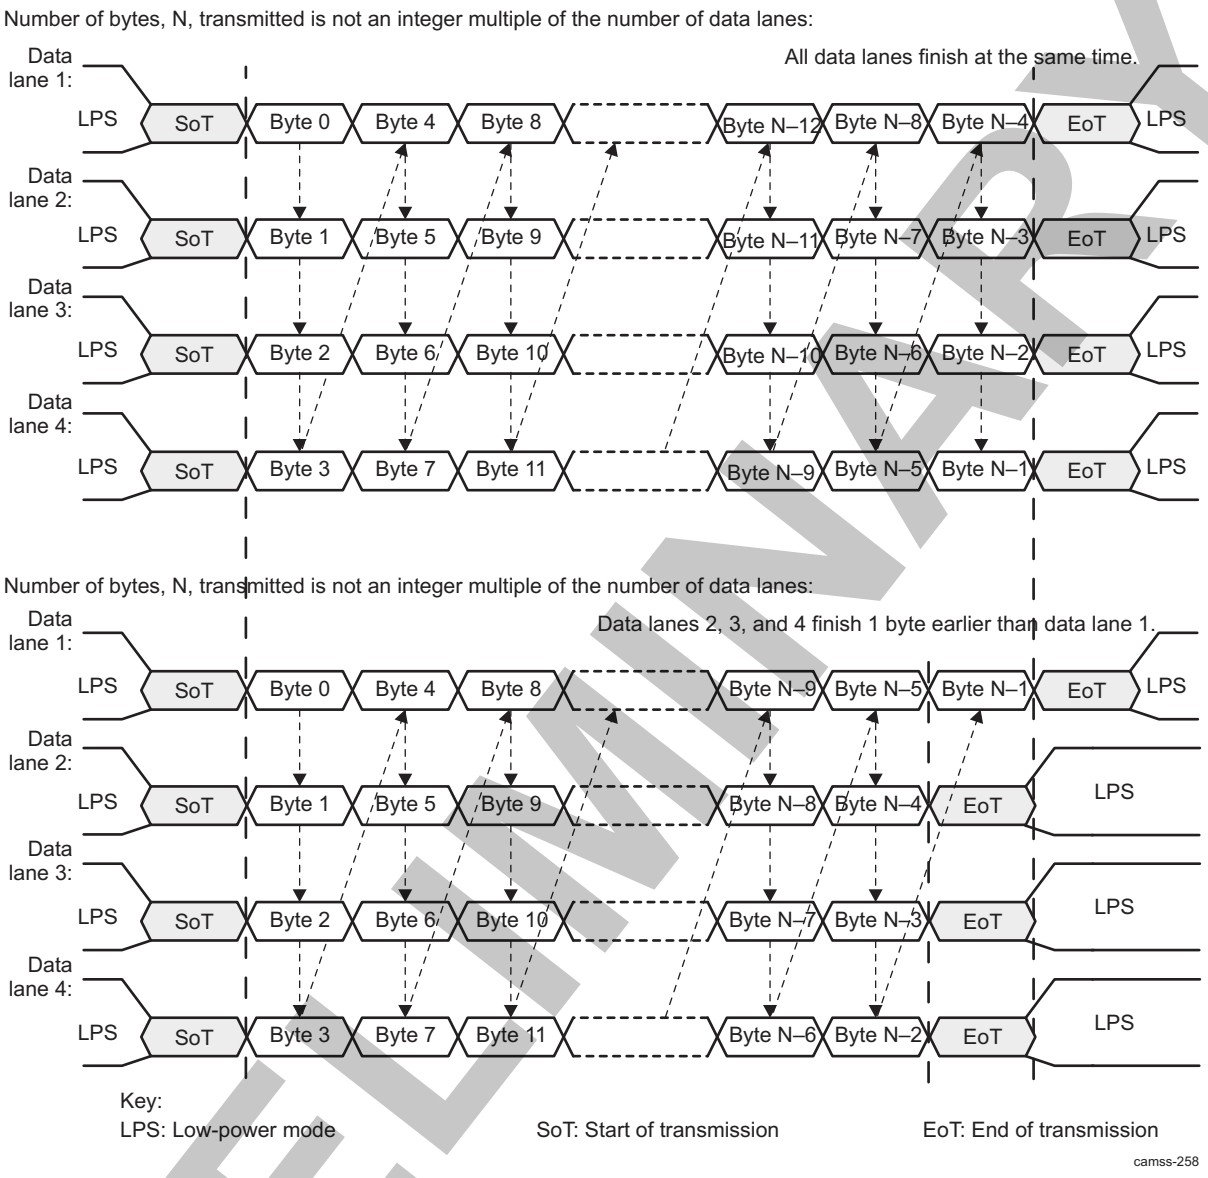


8.2.5.1.1.3 ISS CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

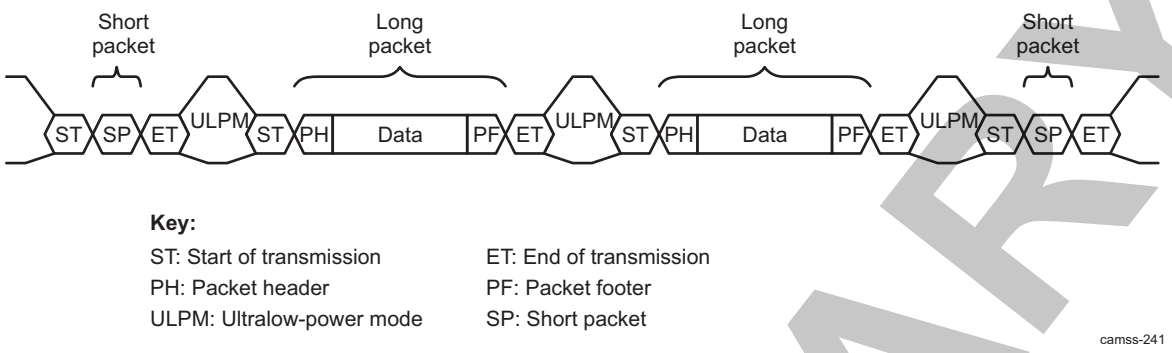
The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 8-40 shows the CSI2 protocol layer with short and long packets.

Figure 8-40. ISS CSI2 Protocol Layer With Short and Long Packets

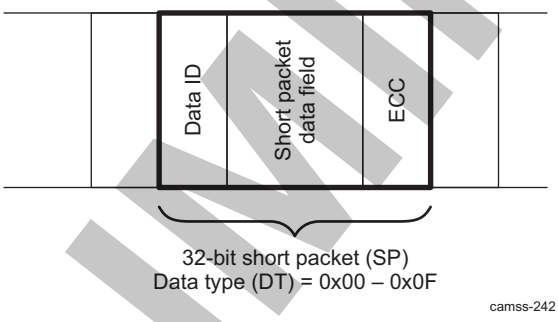


Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

8.2.5.1.1.3.1 ISS CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 8-41 shows the structure of a short packet.

Figure 8-41. ISS CSI2 Short Packet Structure



For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0 and is inoperative.
- The frame number increments by 1 for every FS packet within the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For LSC and LEC synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the use case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0 and is inoperative.
- The line number increments by 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended use is for progressive scan (noninterlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero

arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be different between successive frames. The intended use is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (up to eight contexts support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

8.2.5.1.1.3.2 ISS CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

The packet header is composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 8-42 and Table 8-151 show the structure of a long packet.

Figure 8-42. ISS CSI2 Long Packet Structure

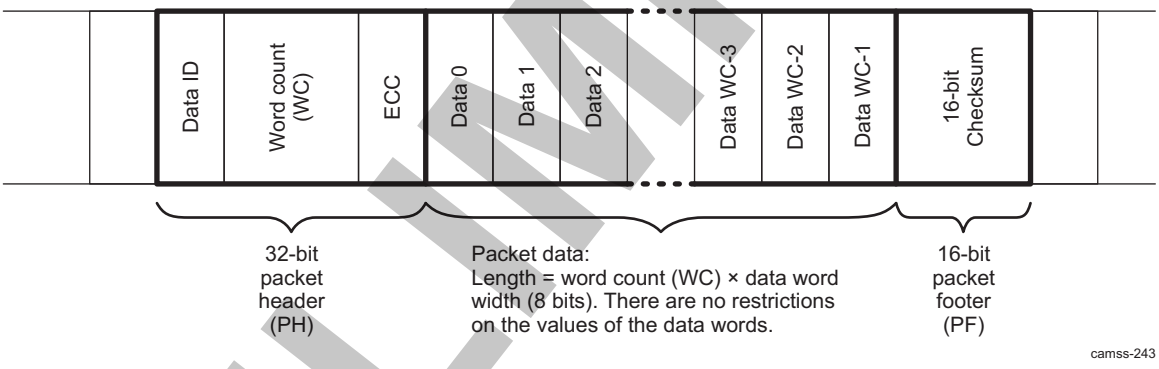


Table 8-151. ISS CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bits)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC-8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit CRC for packet data

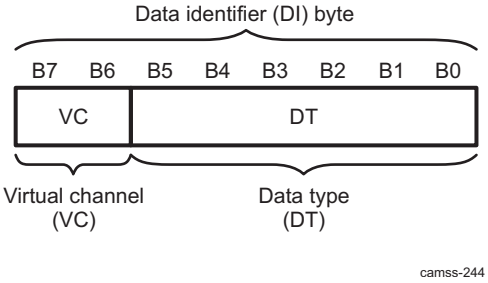
There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

8.2.5.1.1.3.3 ISS CSI2 Data Identifier

The data identifier byte contains the virtual channel (VC) value and the data-type (DT) value, as shown in Figure 8-43. The VC value is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 8-43 shows the data identifier structure.

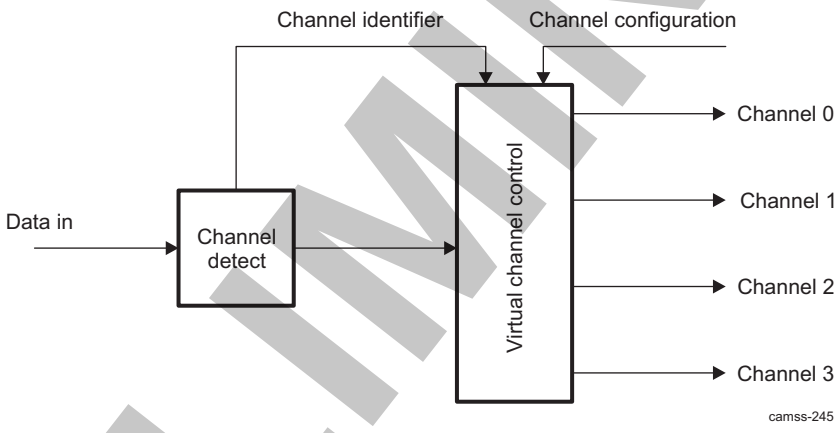
Figure 8-43. ISS CSI2 Data Identifier Structure



Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 8-44 shows a virtual channel.

Figure 8-44. ISS CSI2 Virtual Channel



Pixel Formats

8.2.5.1.1.3.4 ISS CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

Table 8-152 summarizes the synchronization code values.

Table 8-152. ISS CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

8.2.5.1.1.3.5 ISS CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

8.2.5.1.1.3.6 ISS CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit nonimage data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

8.2.5.1.1.3.7 ISS CSI2 Frame Structure

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as SOF and EOF information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame contains embedded data and image-sensor data. Figure 8-45 shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in Figure 8-45 and Figure 8-46. The following definitions for a frame apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image embedded data is carried using separate data types and virtual channels (see Section 8.2.4.1.1, *ISS CCP2 Protocol and Data Formats*, and Section 8.2.5.3.3.4, *ISS CSI2 Virtual Channel and Context*).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See Section 8.2.5.3.3.4, *ISS CSI2 Virtual Channel and Context*.

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 8-45. ISS CSI2 General Frame Structure (Informative)

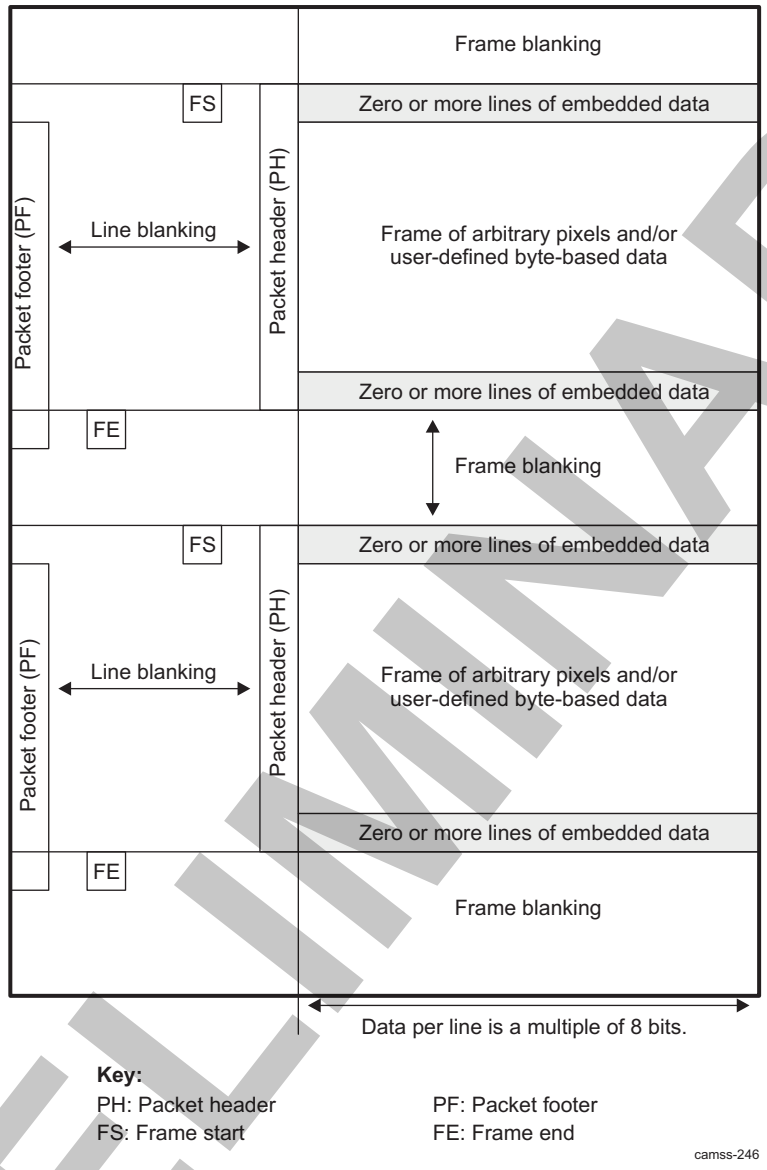


Figure 8-46 shows the frame structure of a YUV4:2:2 interlaced video frame without embedded data.

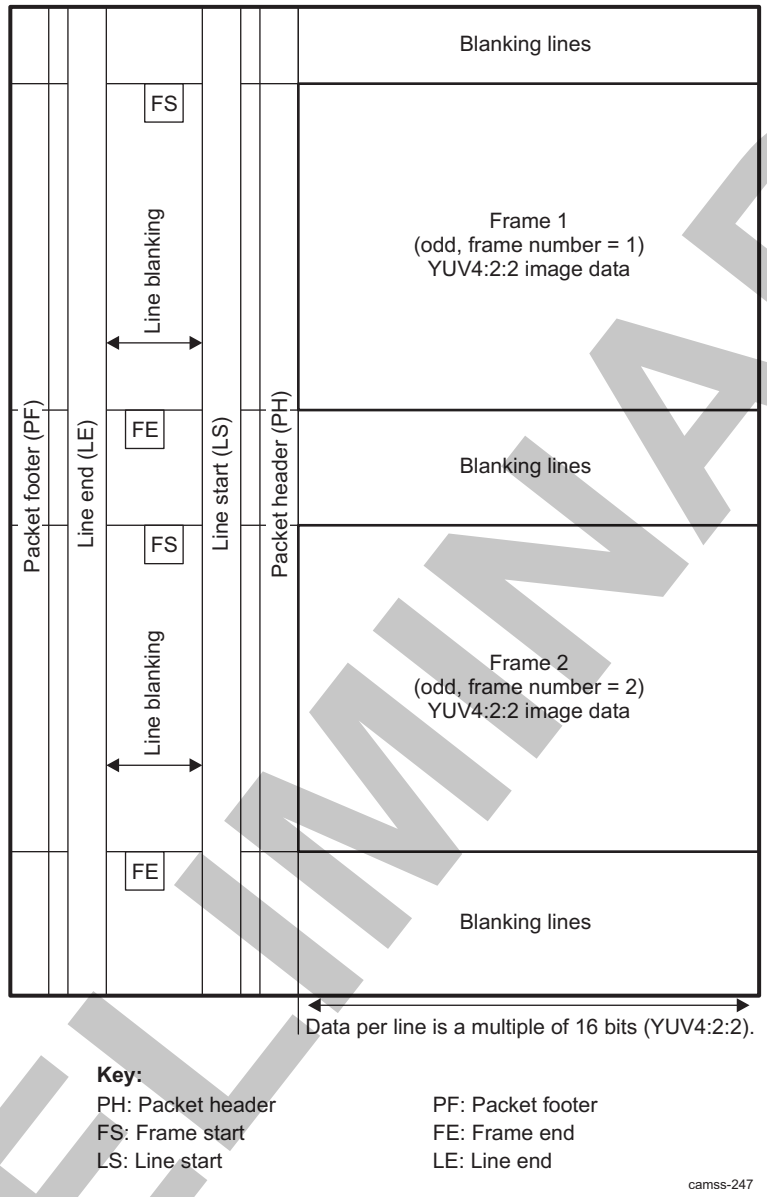
Figure 8-46. ISS CSI2 Digital Interlaced Video Frame (Informative)



The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0. The image data is stored in memory by selecting one of the various operating modes. Section 8.2.5.1.1.4, *ISS CSI2 Operating Modes*, explains storing image data frames into memory.

8.2.5.1.1.4 ISS CSI2 Operating Modes

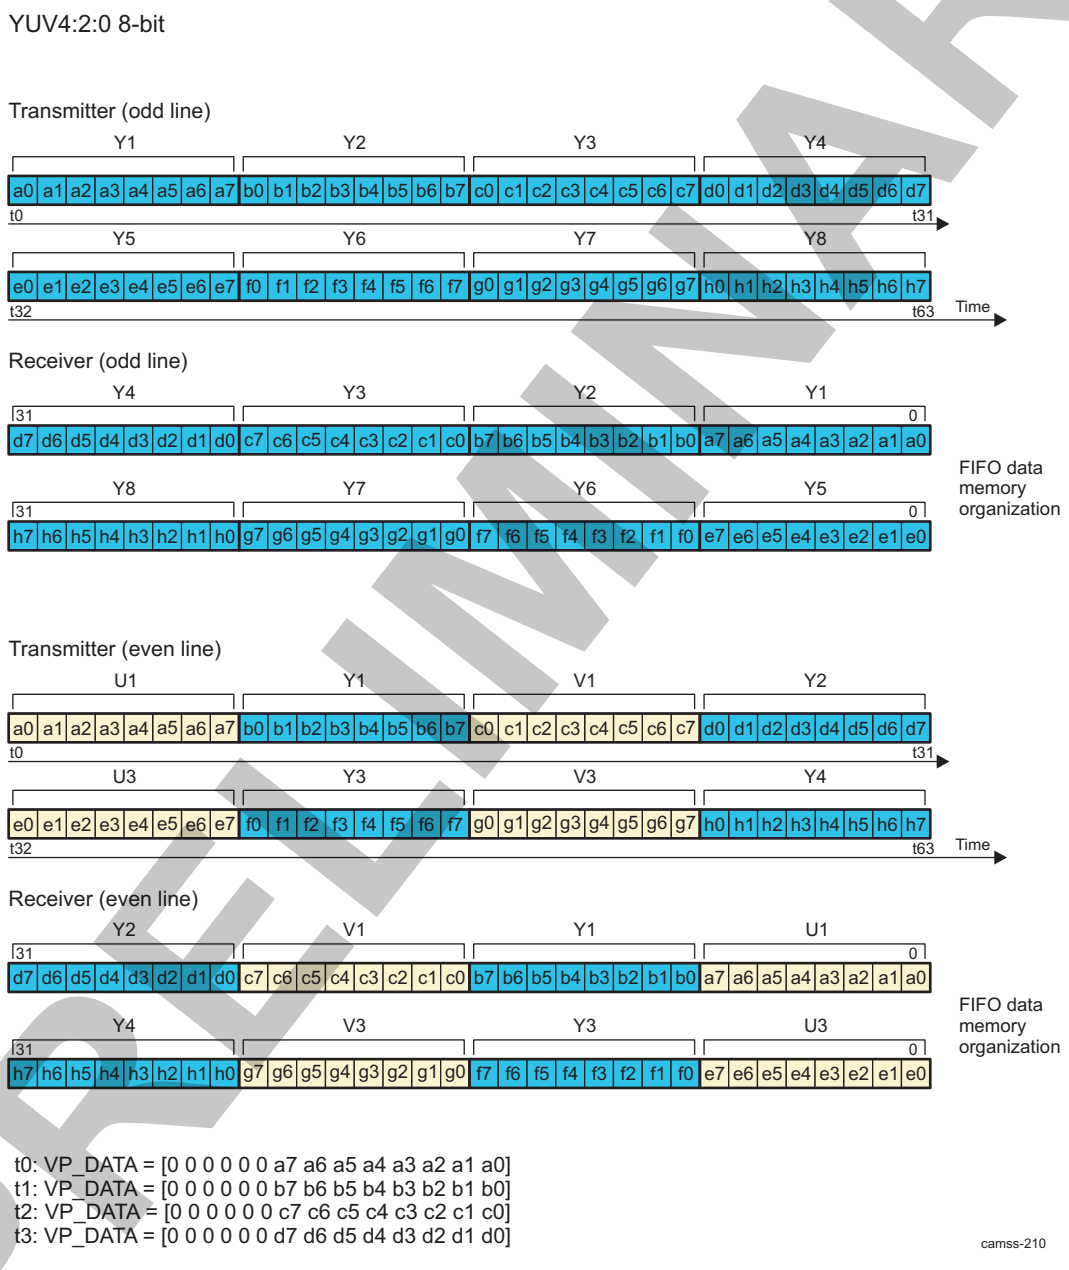
8.2.5.1.1.4.1 ISS CSI2 YUV Operating Modes

8.2.5.1.1.4.1.1 ISS CSI2 YUV4:2:0 8-Bit

YUV4:2:0 8-bit data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:0 use the CSI2_CTRL[4] ENDIANNESS bit. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 32 bits and the number of lines must be even. Figure 8-47 shows the storage format for YUV4:2:0 8-bit data. It is shown as little endian. If the data format is big endian, the figure changes accordingly. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x18 to select YUV4:2:0 8-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the CSI2_CTX_DAT_OFST_i[16:5] OFST bit field; for example, if the offset is 0, the data is written in a contiguous way (bit-to-bit of odd and even lines). If the data has an offset, set the destination offset between the first pixel of the previous line and the first pixel of the current line being written to memory.

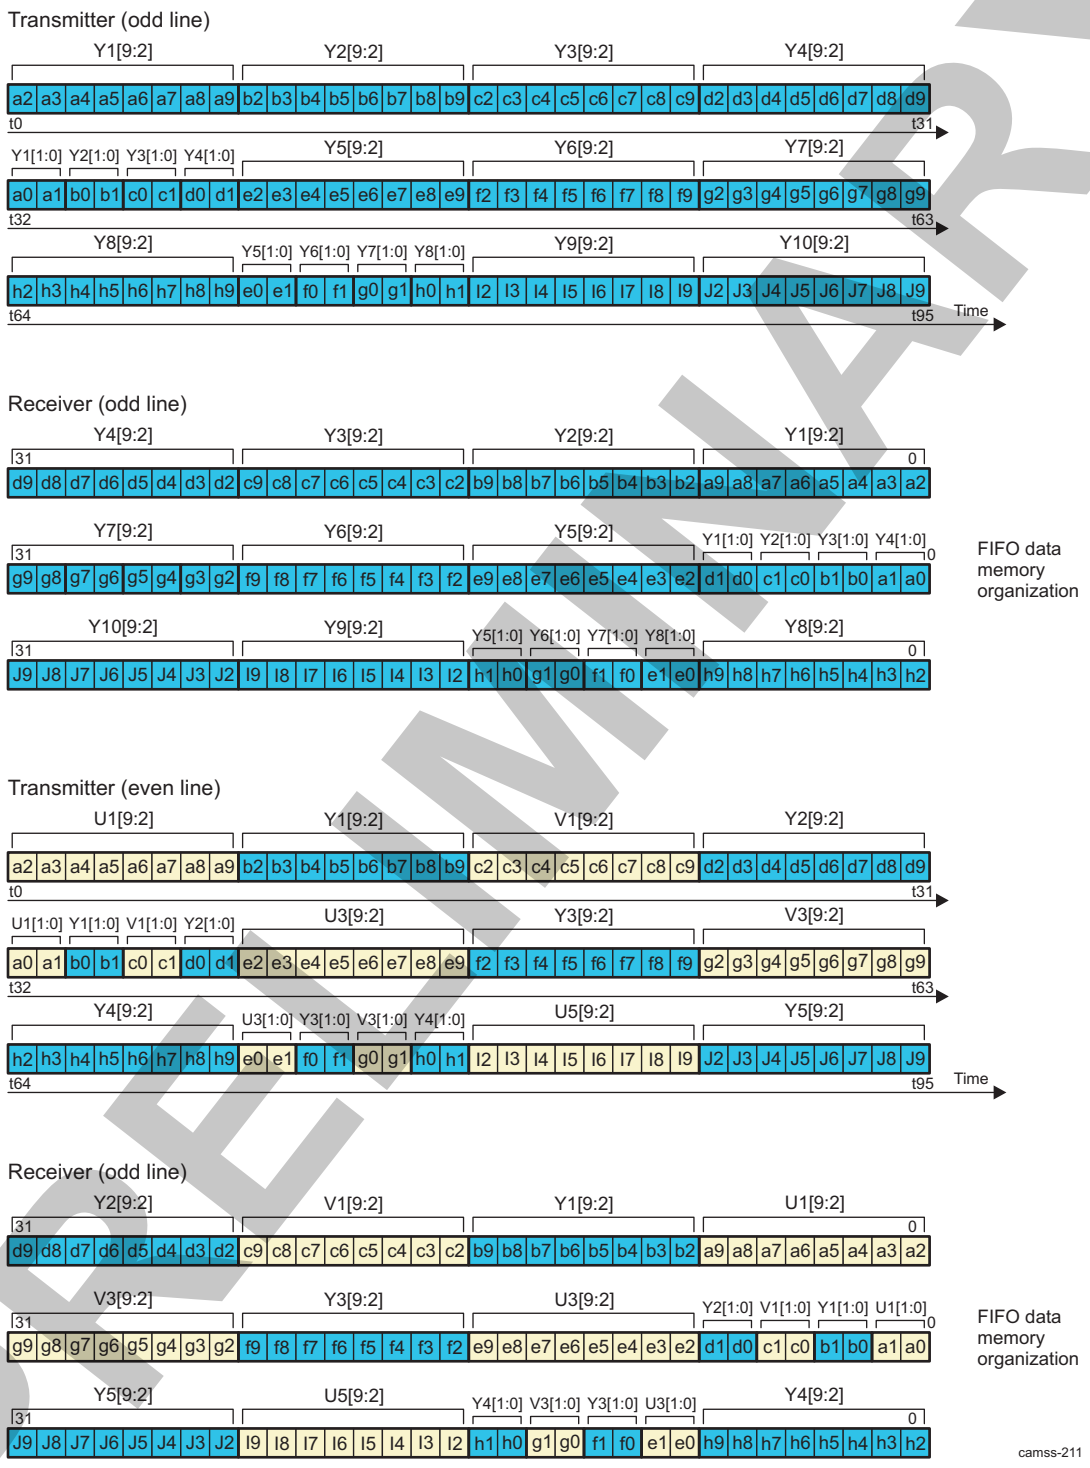
Figure 8-47. ISS CSI2 YUV4:2:0 8-Bit



8.2.5.1.1.4.1.2 ISS CSI2 YUV4:2:0 10-Bit

YUV4:2:0 10-bit data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. Figure 8-48 shows the storage format for YUV4:2:0 10-bit data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x19 to select YUV4:2:0 10-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the CSI2_CTX_DAT_OFST_i[16:5] OFST bit field.

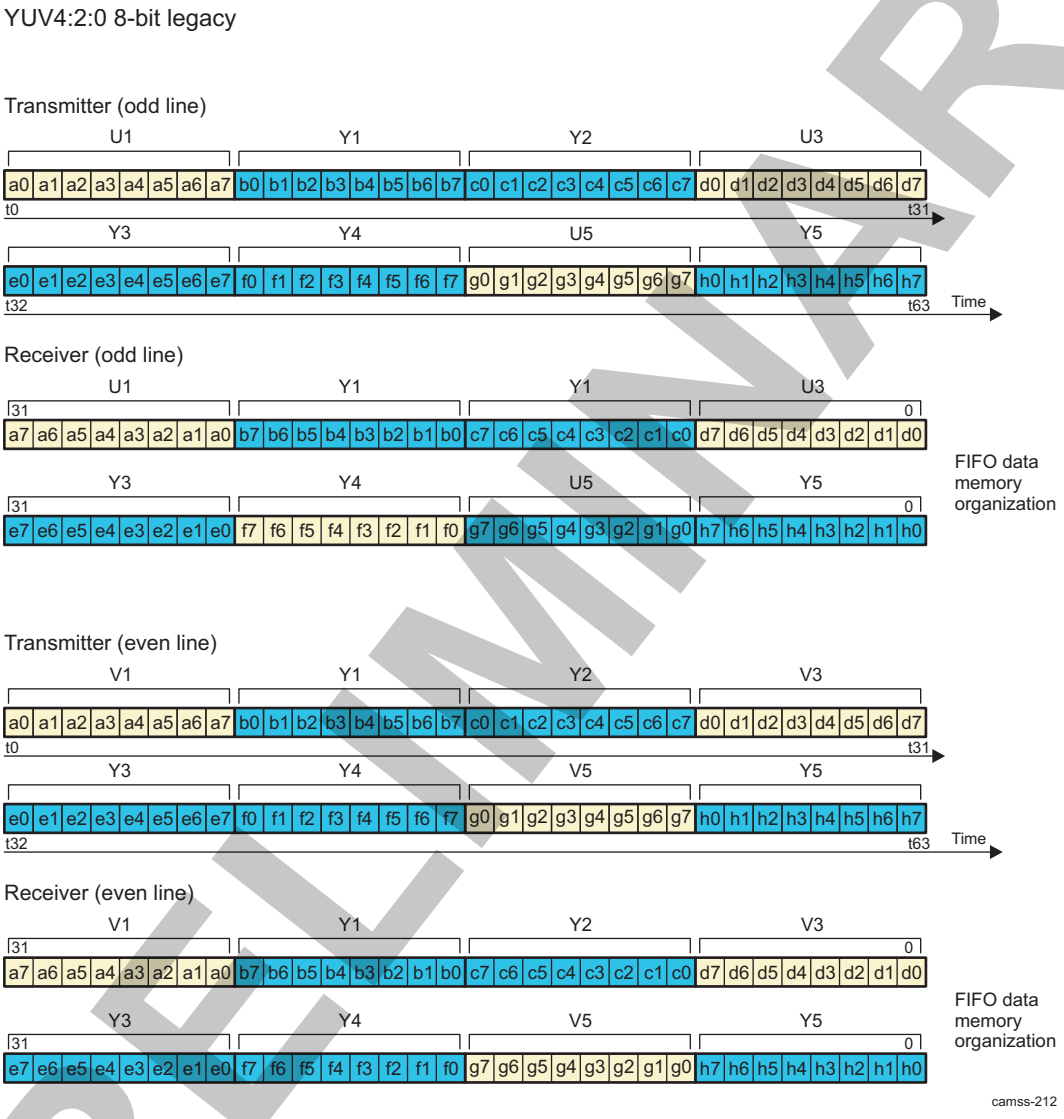
Figure 8-48. ISS CSI2 YUV4:2:0 10-Bit



8.2.5.1.1.4.1.3 CSI2 YUV4:2:0 8-Bit Legacy

YUV4:2:0 8-bit legacy data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 4 bytes. Figure 8-49 shows the storage format for YUV4:2:0 8-bit legacy data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x1A to select YUV4:2:0 8-bit legacy mode.

Figure 8-49. ISS CSI2 YUV4:2:0 8-Bit Legacy

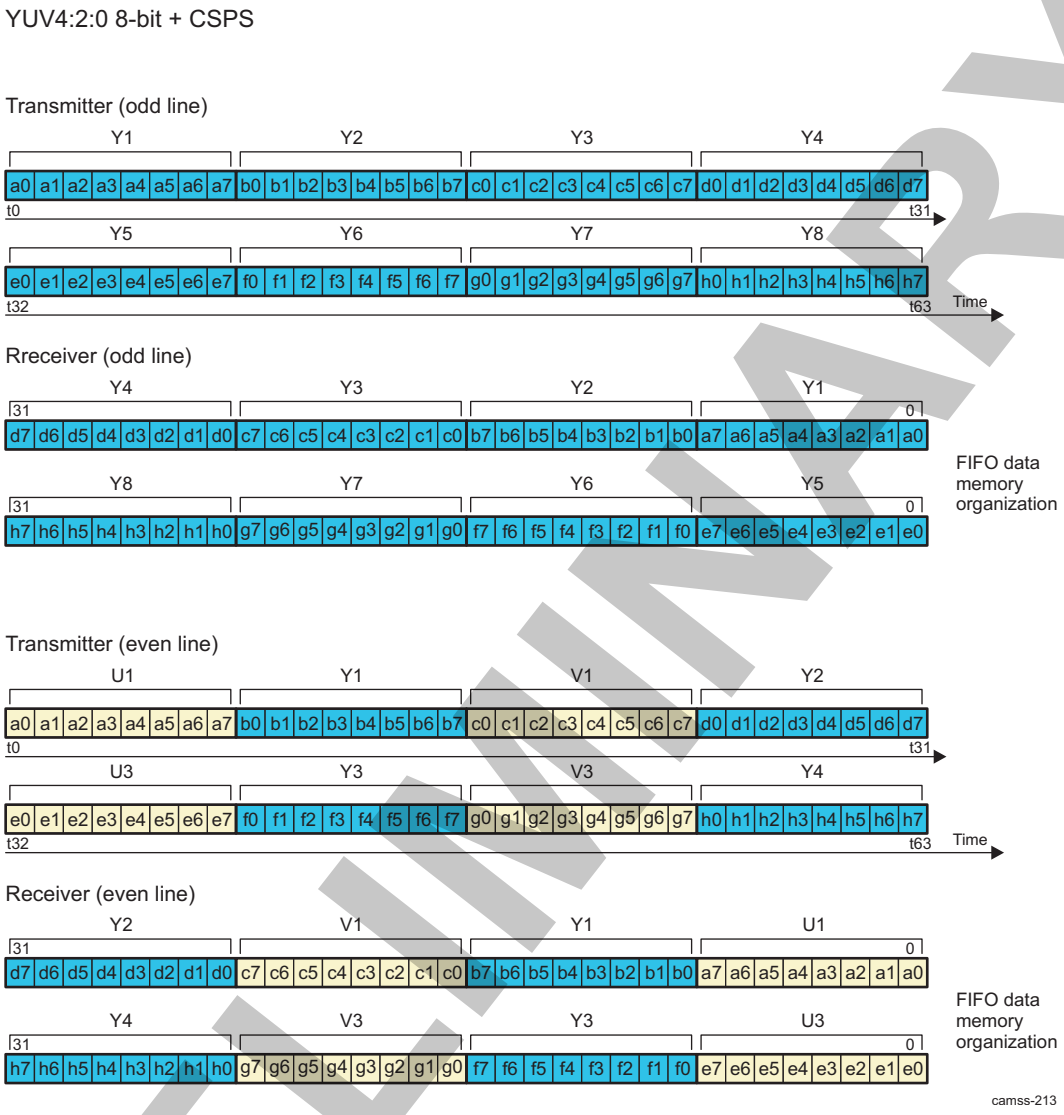


8.2.5.1.1.4.1.4 ISS CSI2 YUV4:2:0 8-Bit + CSPS

YUV4:2:0 8-bit CSPS data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3 32 bits and the number of lines must be even. Figure 8-50 shows the storage format for YUV4:2:0 8-bit + CSPS data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x1C to select YUV4:2:0 8-bit + CSPS mode.

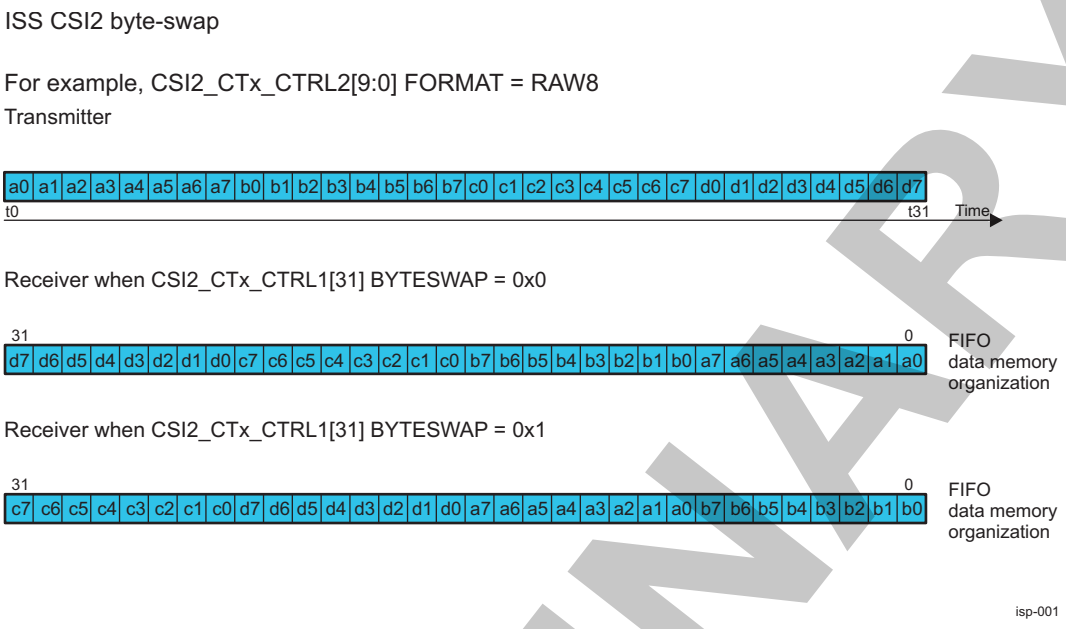
Figure 8-50. ISS CSI2 YUV4:2:0 8-Bit + CSPS



8.2.5.1.1.4.1.5 Camera ISP CSI2 Byte Swap

The CSI2 receiver incorporates a byte-swapping function. Software can optionally enable byte-swapping of the payload data by setting the CSI2_CTx_CTRL1[31] BYTESWAP bit. This feature must be used only when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

Figure 8-51. Camera ISP CSI2 Byte Swap



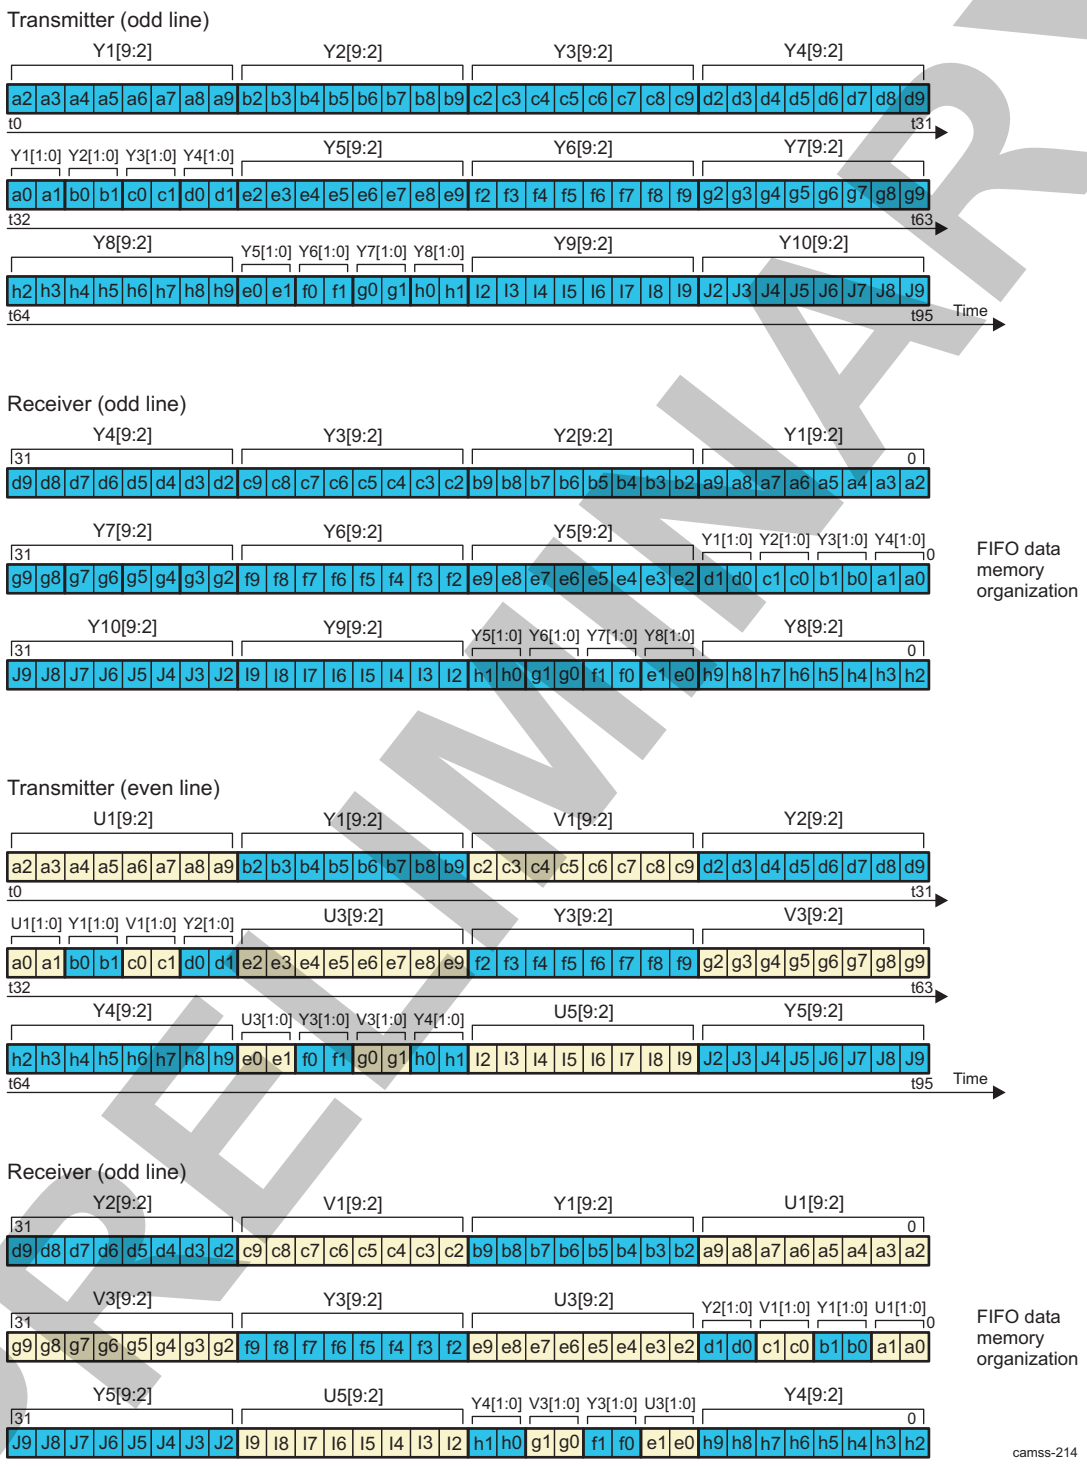
8.2.5.1.1.4.1.6 ISS CSI2 YUV4:2:0 10-Bit + CSPS

YUV4:2:0 10-bit CSPS data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3 32 bits and the number of lines must be even. Figure 8-52 shows the storage format for YUV4:2:0 10-bit + CSPS data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x1D to select YUV4:2:0 10-bit + CSPS mode.

Figure 8-52. ISS CSI2 YUV4:2:0 10-Bit + CSPS

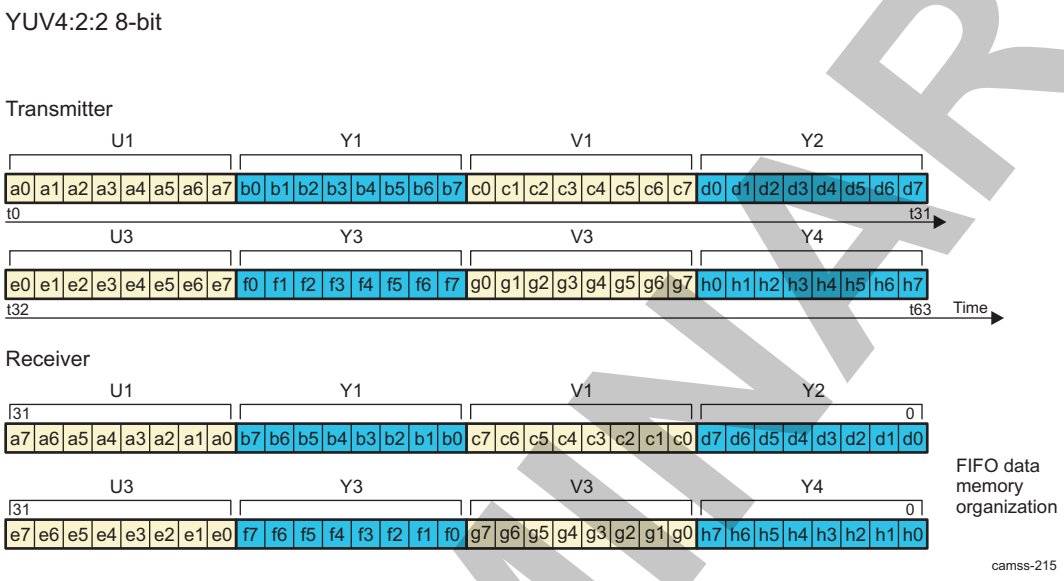
YUV4:2:0 10-bit + CSPS



8.2.5.1.1.4.1.7 ISS CSI2 YUV4:2:2 8-Bit

YUV4:2:2 data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:2 use the CSI2_CTRL[4] ENDIANNESS bit. The line length sent through the CSI2 physical protocol is a multiple of 32 bits. Figure 8-53 shows the storage format for YUV4:2:2 8-bit data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x1E to select YUV4:2:2 8-bit mode.

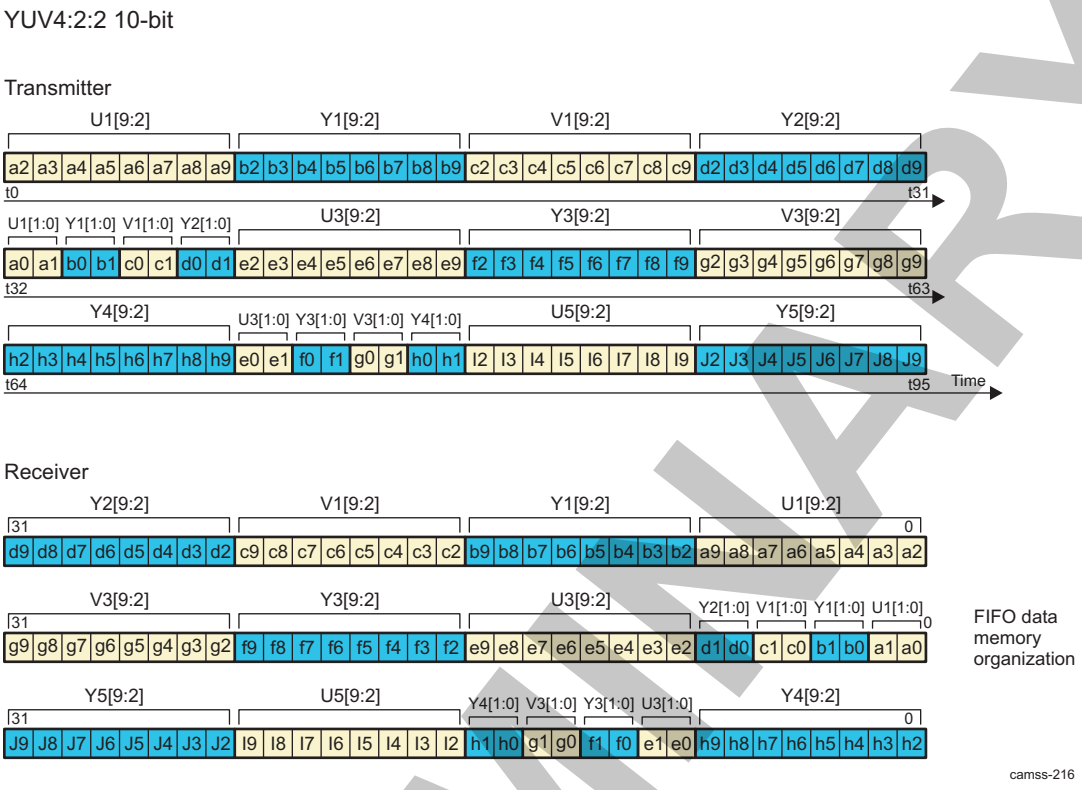
Figure 8-53. ISS CSI2 YUV4:2:2 8-Bit



8.2.5.1.1.4.1.8 CSI2 YUV4:2:2 10-Bit

YUV4:2:2 data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits. Figure 8-54 shows the storage format for YUV4:2:2 10-bit data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x1F to select YUV4:2:2 10-bit mode.

Figure 8-54. ISS CSI2 YUV4:2:2 10-Bit



8.2.5.1.1.4.2 ISS CSI2 RGB Operating Modes

8.2.5.1.1.4.2.1 ISS CSI2 RGB565

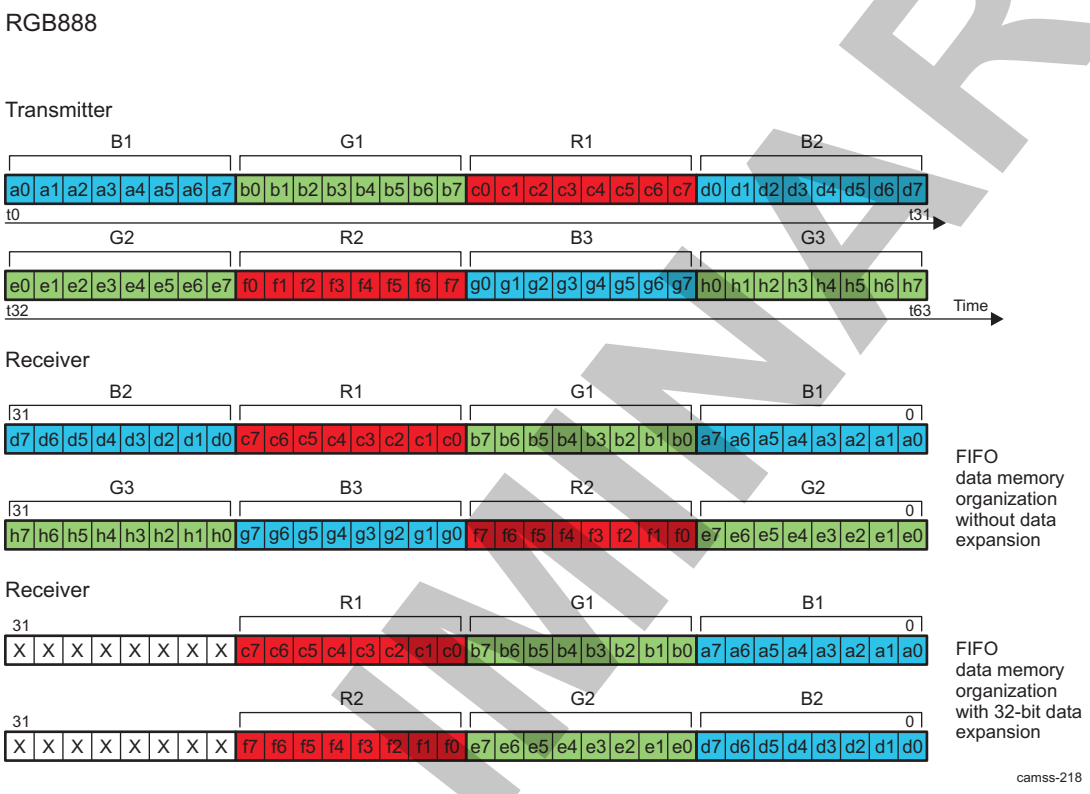
RGB565 data is output to memory without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 16 bits. Figure 8-55 shows the storage format for RGB565 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x22 to select RGB565 mode.

Figure 8-55. ISS CSI2 RGB565

8.2.5.1.1.4.2.2 ISS CSI2 RGB888

RGB888 data can be output to memory in two formats: with or without data expansion. If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). Figure 8-56 shows the storage format for RGB888 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x24 to select RGB888 mode.

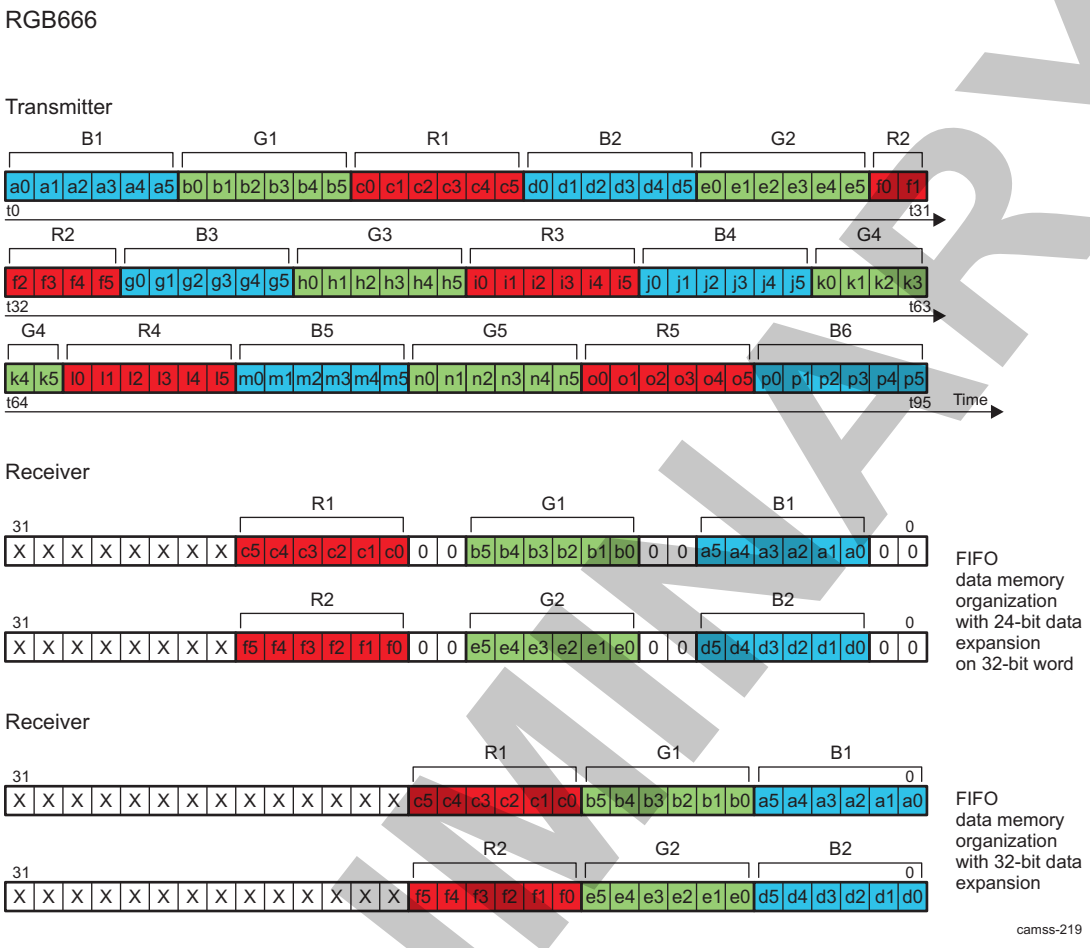
Figure 8-56. ISS CSI2 RGB888



8.2.5.1.1.4.2.3 ISS CSI2 RGB666

RGB666 data is always output to memory with data expansion. The value of the 14 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). The line length sent through the CSI2 physical protocol is a multiple of 8 bits. Furthermore, the line length is a multiple of 9 × 8 bits to finish the pixel reconstruction correctly. Figure 8-57 shows the storage format for RGB666 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0x33 to select RGB666 mode.

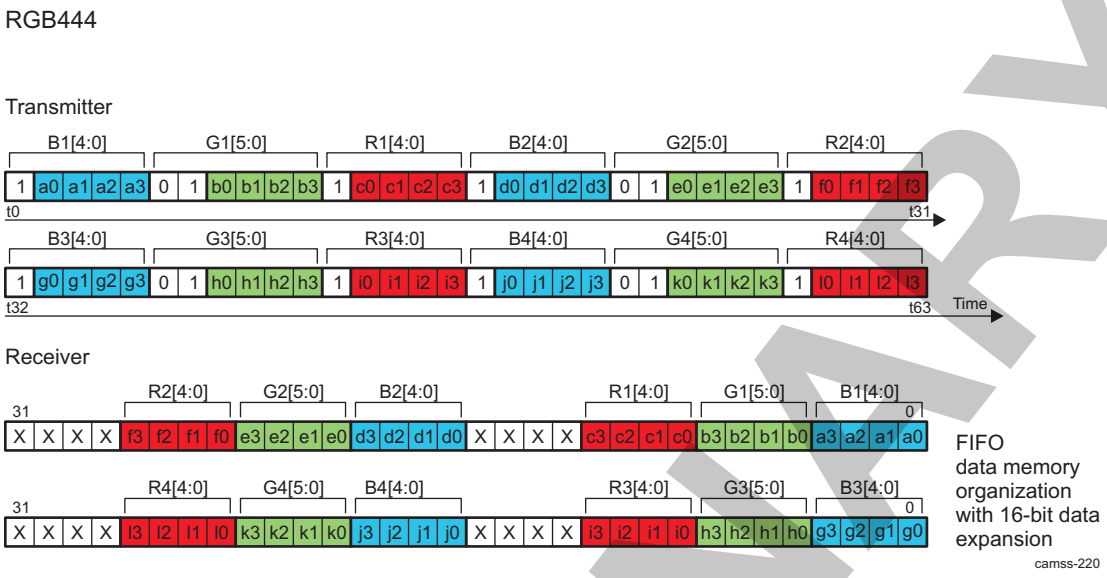
Figure 8-57. ISS CSI2 RGB666



8.2.5.1.1.4.2.4 ISS CSI2 RGB444

RGB444 data is output to memory with data expansion. When data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTX_CTRL3_i[29:16] ALPHA bit field). Figure 8-58 shows the storage format for RGB444 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0xA0 to select RGB444 mode.

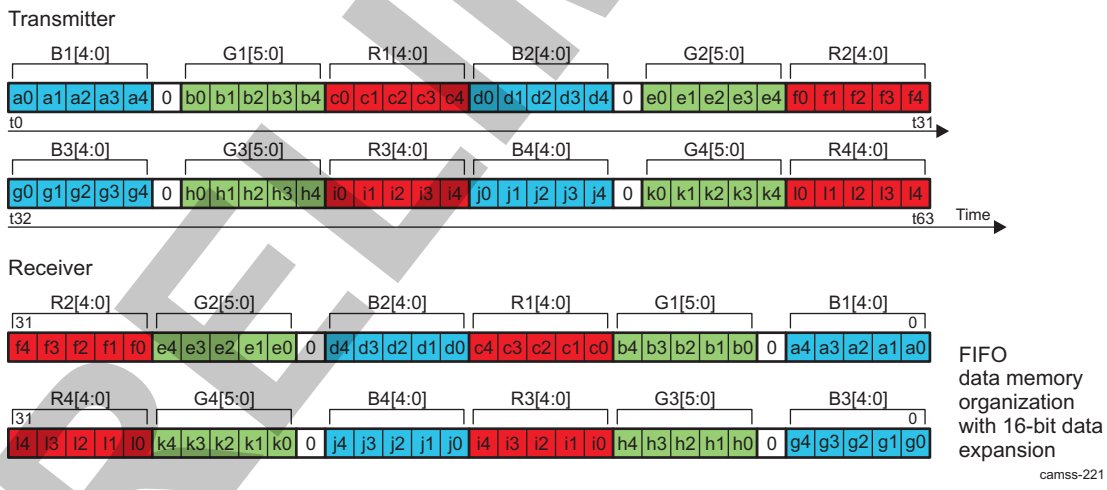
Figure 8-58. ISS CSI2 RGB444



8.2.5.1.1.4.2.5 ISS CSI2 RGB555

RGB555 data is output to memory with data expansion. Figure 8-59 shows the storage format for RGB555 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field to 0xA1 to select RGB555 mode.

Figure 8-59. ISS CSI2 RGB555



8.2.5.1.1.4.3 ISS CSI2 RAW Bayer RGB Operating Modes

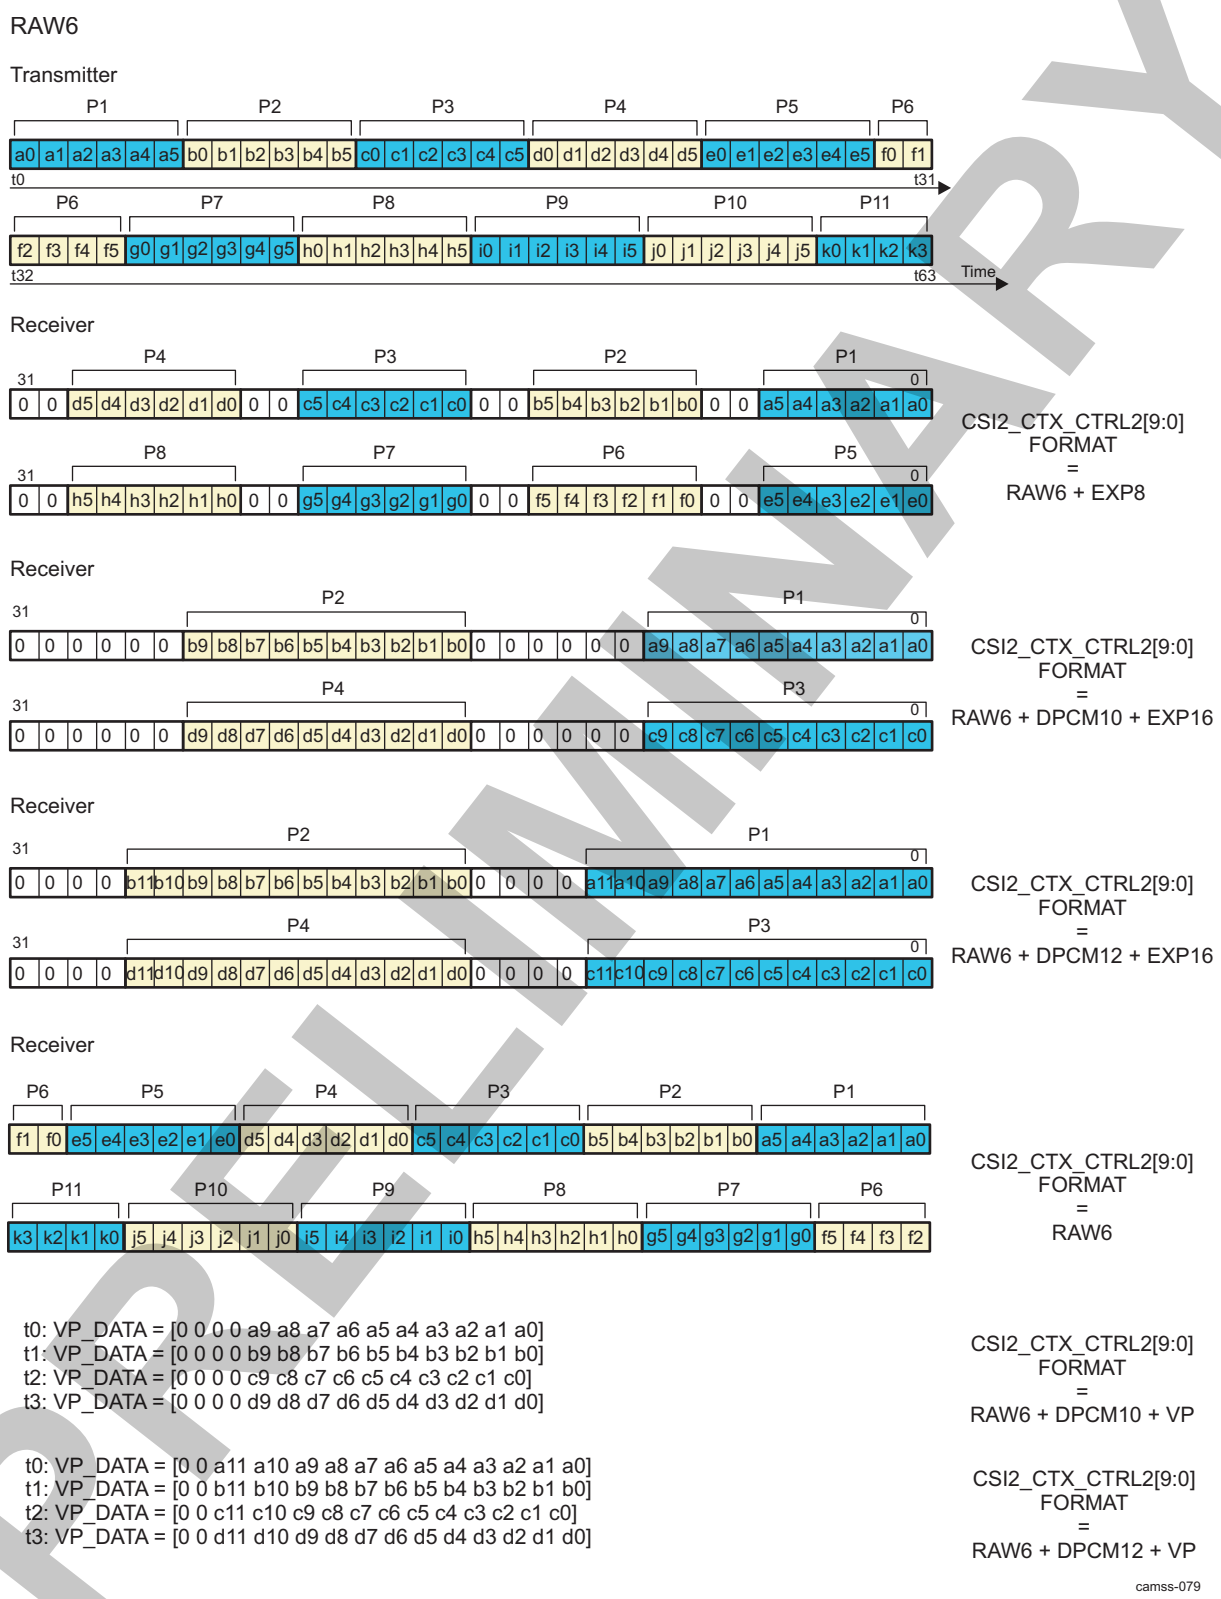
8.2.5.1.1.4.3.1 ISS CSI2 RAW6

RAW6 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits (6-bit image data + 2-bit expansion). Furthermore, the line length is a multiple of 3 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 6 is 24, so 3 × 8 bits). Figure 8-60 shows the storage format for RAW6 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x28 to select RAW6 mode

- To 0x68 for RAW6 + 8-bit expansion
- To 0xE8 for RAW6 + DPCM decompression to 10-bit to video port
- To 0x2A8 for RAW6 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x3A8 for RAW6 + DPCM decompression to 12-bit expanded to 16-bit
- To 0x368 for RAW6 + DPCM decompression to 12-bit to video port

Figure 8-60. ISS CSI2 RAW6

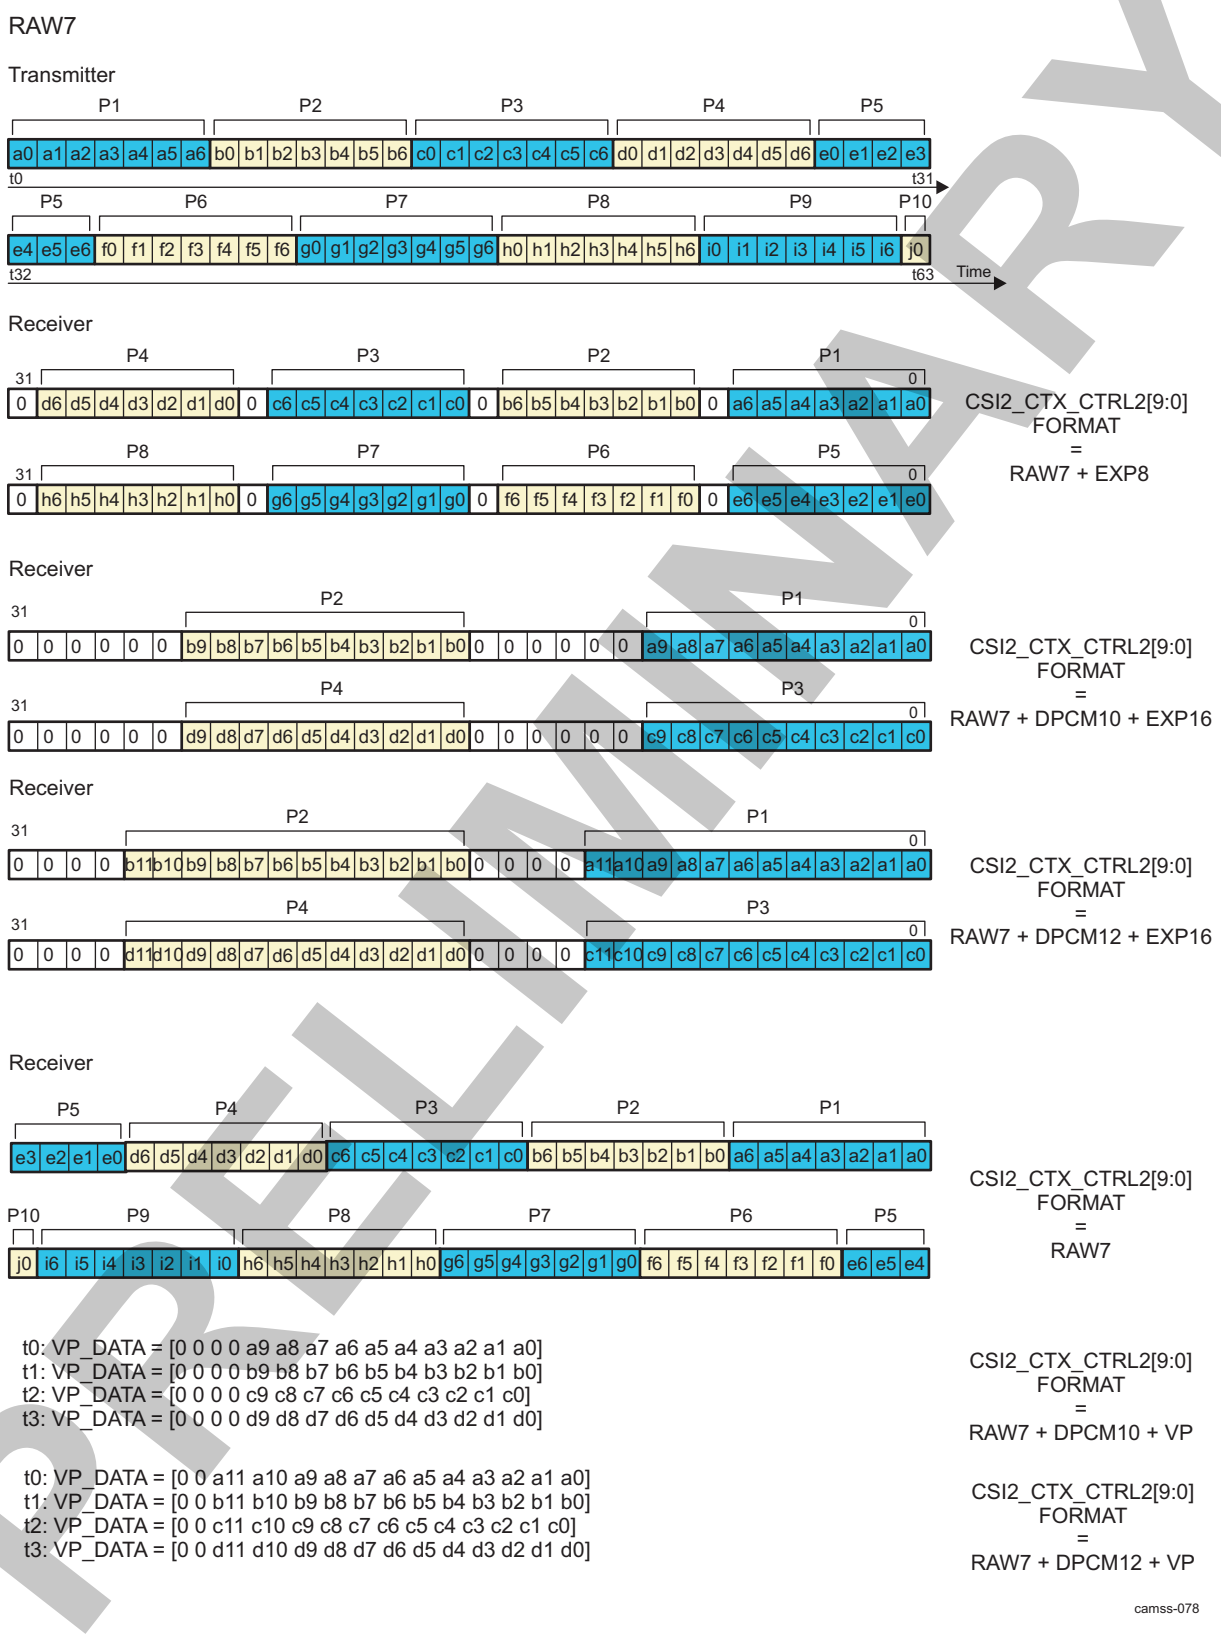


8.2.5.1.1.4.3.2 ISS CSI2 RAW7

RAW7 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 7 is 56, so 7 × 8 bits). Figure 8-61 shows the storage format for RAW7 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x29 to select RAW7 mode
- To 0x69 for RAW7 + 8-bit expansion
- To 0x329 for RAW7 + DPCM decompression to 10-bit to video port
- To 0x229 for RAW7 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x369 for RAW7 + DPCM decompression to 12-bit expanded to 16-bit
- To 0x3A9 for RAW7 + DPCM decompression to 12-bit to video port

Figure 8-61. ISS CSI2 RAW7

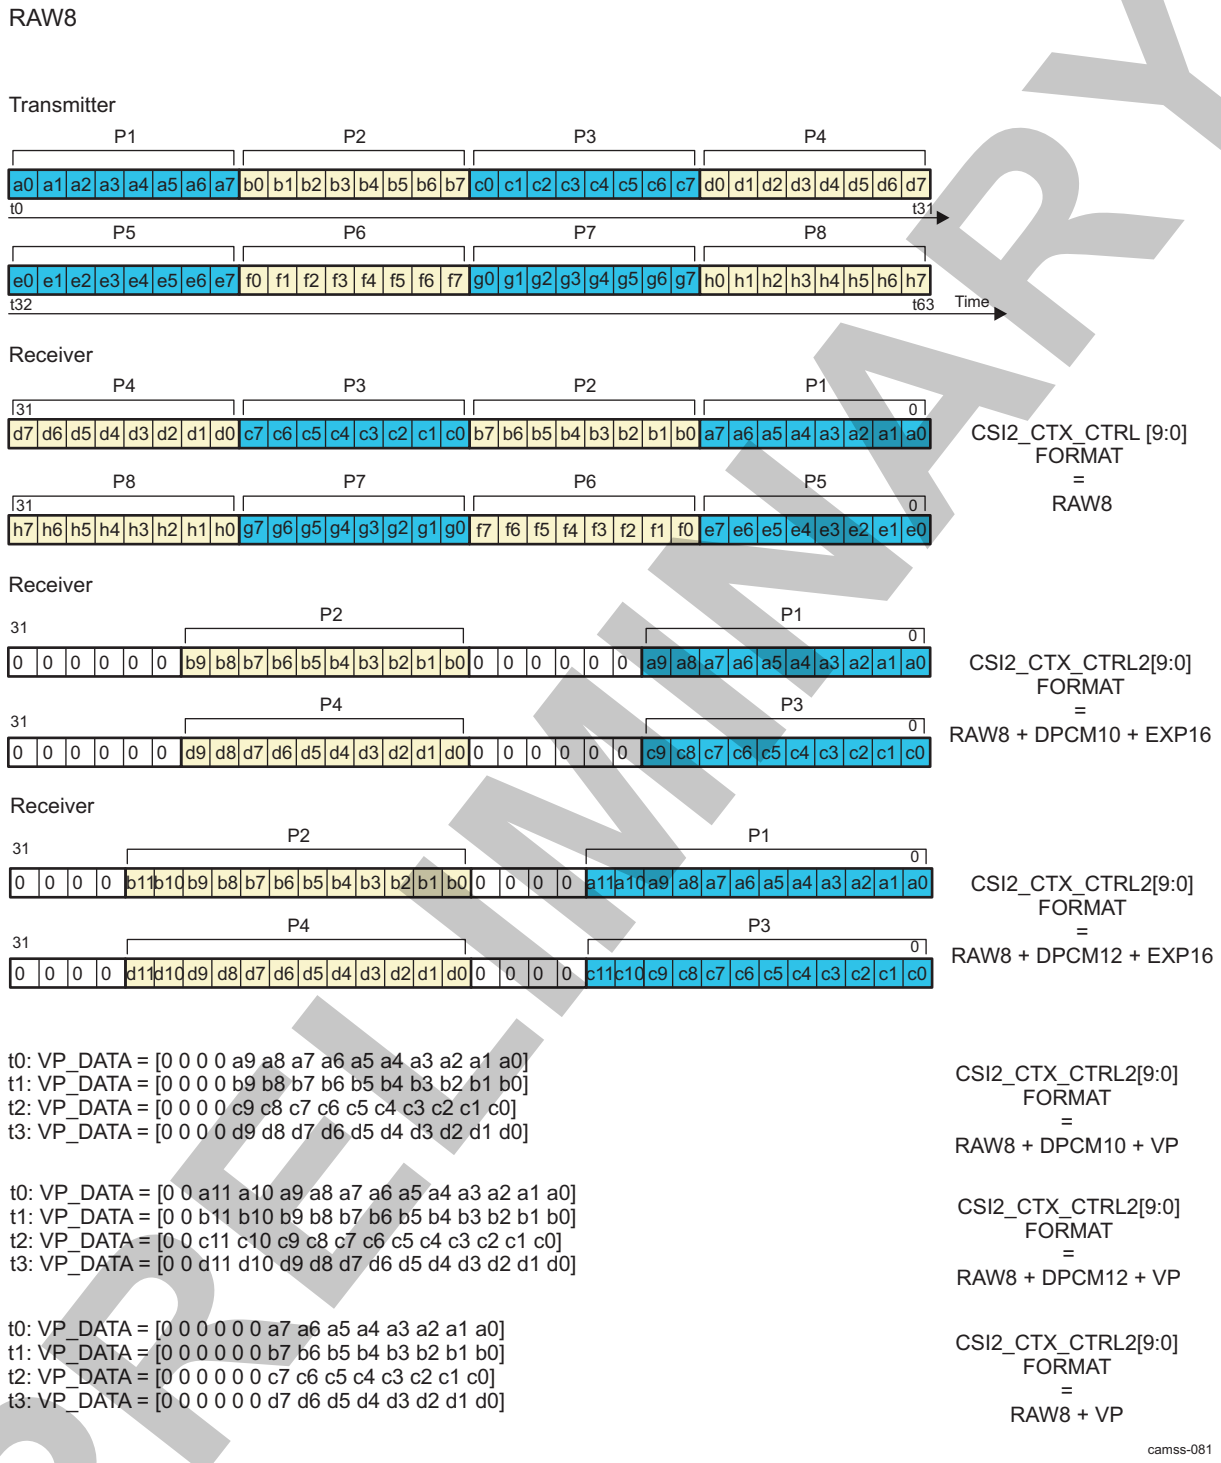


8.2.5.1.1.4.3.3 ISS CSI2 RAW8

RAW8 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 8 bits. Figure 8-62 shows the storage format for RAW8 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x2A to select RAW8 mode
- To 0x12A for RAW8 to video port
- To 0x32A for RAW8 + DPCM decompression to 10-bit to video port
- To 0x2AA for RAW8 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x36A for RAW8 + DPCM decompression to 12-bit expanded to 16-bit
- To 0x3AA for RAW8 + DPCM decompression to 12-bit to video port

Figure 8-62. ISS CSI2 RAW8

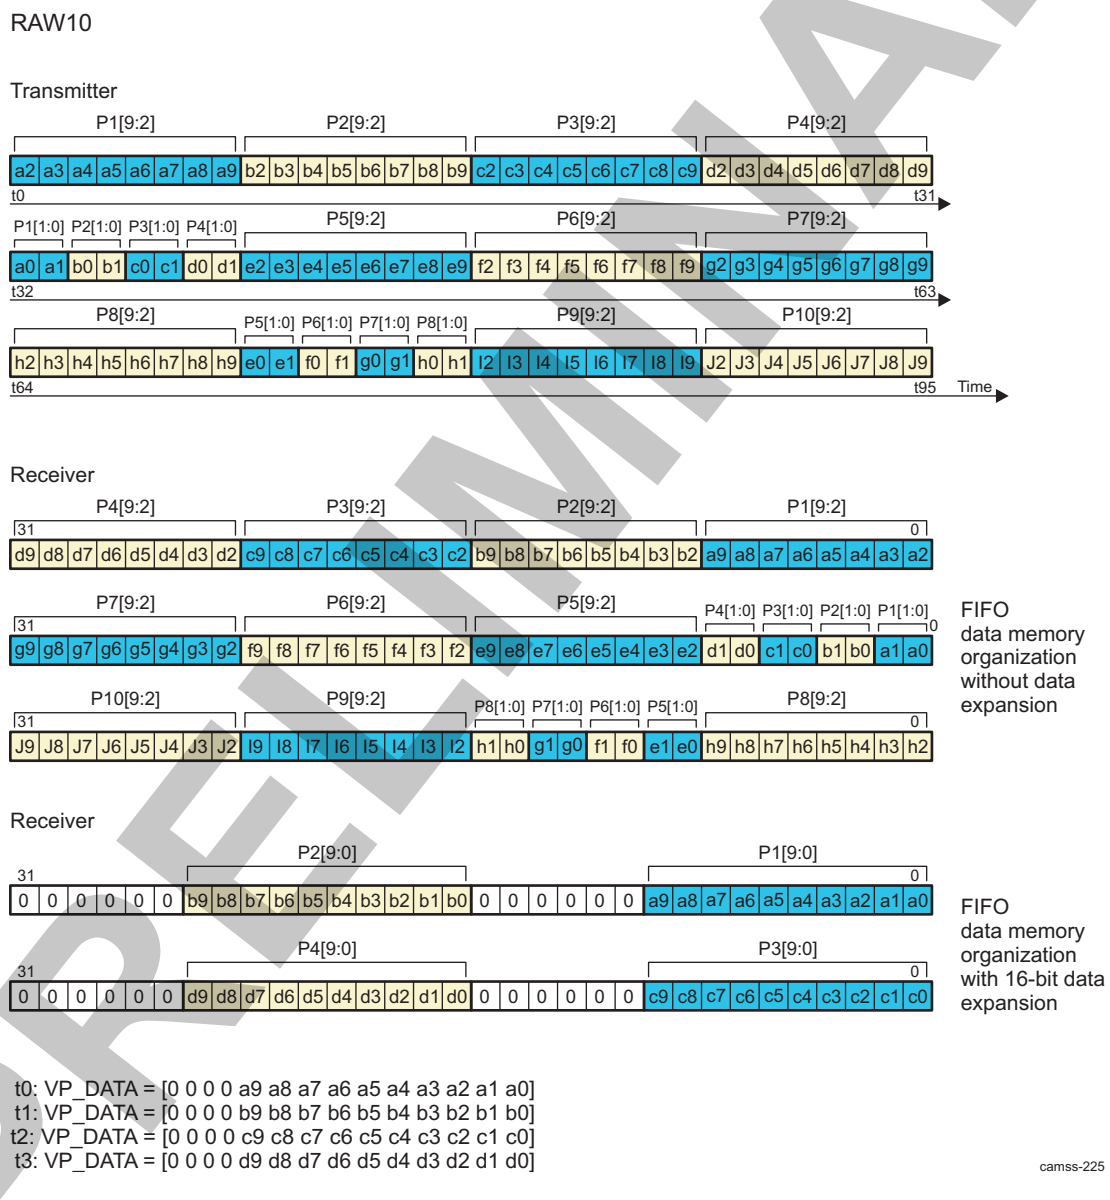


8.2.5.1.1.4.3.4 ISS CSI2 RAW10

RAW10 data can be output memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 5 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 10 is 40, so 5 × 8 bits). Figure 8-63 shows the storage format for RAW10 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x2B to select RAW10 mode
- To 0xAB for RAW10 + 16-bit expansion
- To 0x12F for RAW10 to video port

Figure 8-63. ISS CSI2 RAW10

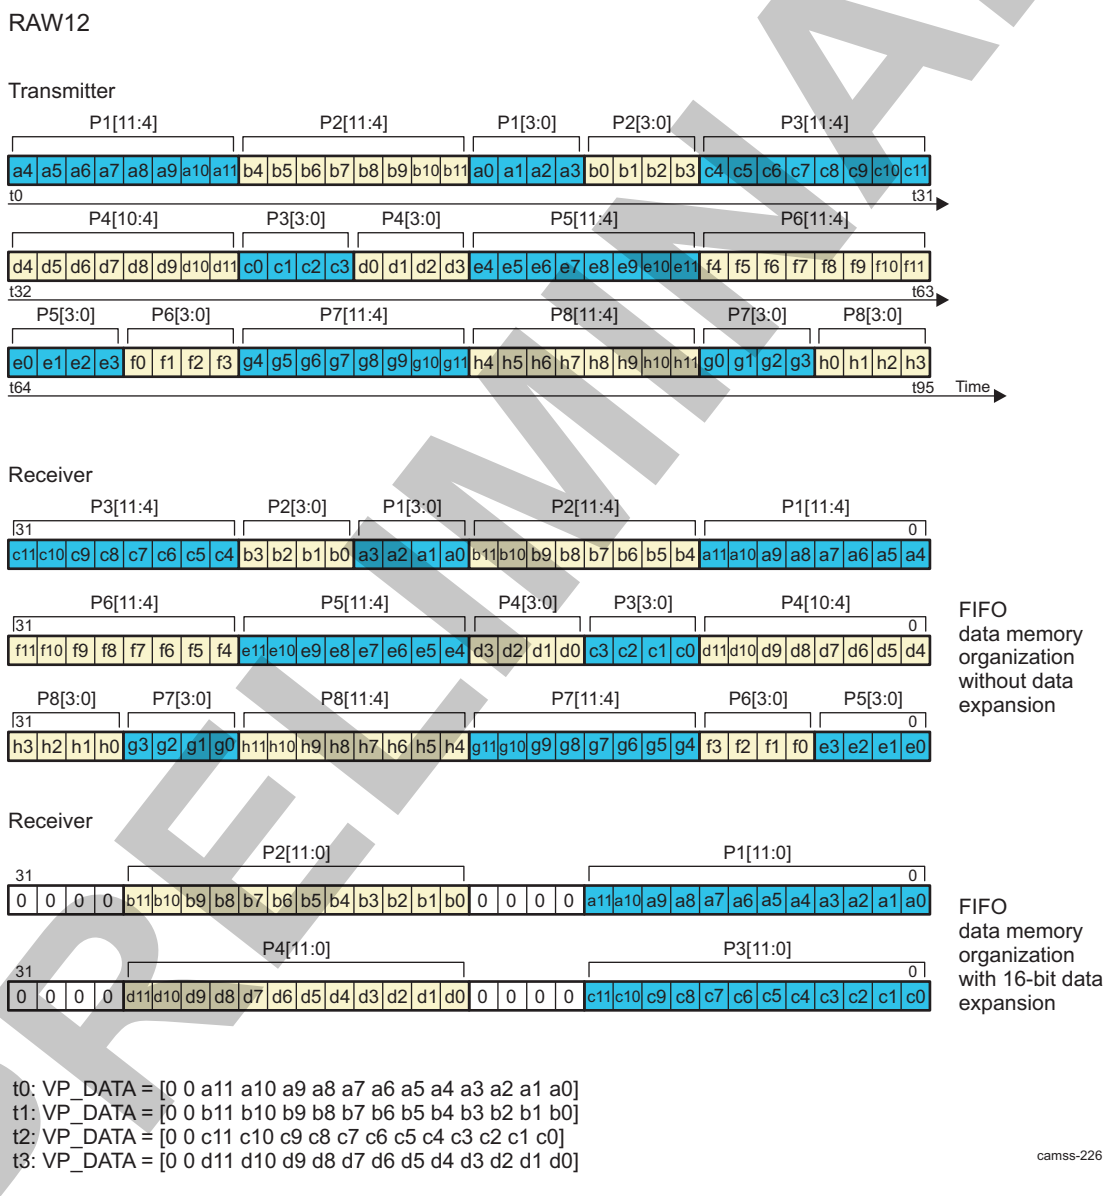


8.2.5.1.1.4.3.5 ISS CSI2 RAW12

RAW12 data can be output to memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 3 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 12 is 24, so 3 × 8 bits). Figure 8-64 shows the storage format for RAW12 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x2C to select RAW12 mode
- To 0xAC for RAW12 + 16-bit expansion
- To 0x12C for RAW12 to video port

Figure 8-64. ISS CSI2 RAW12

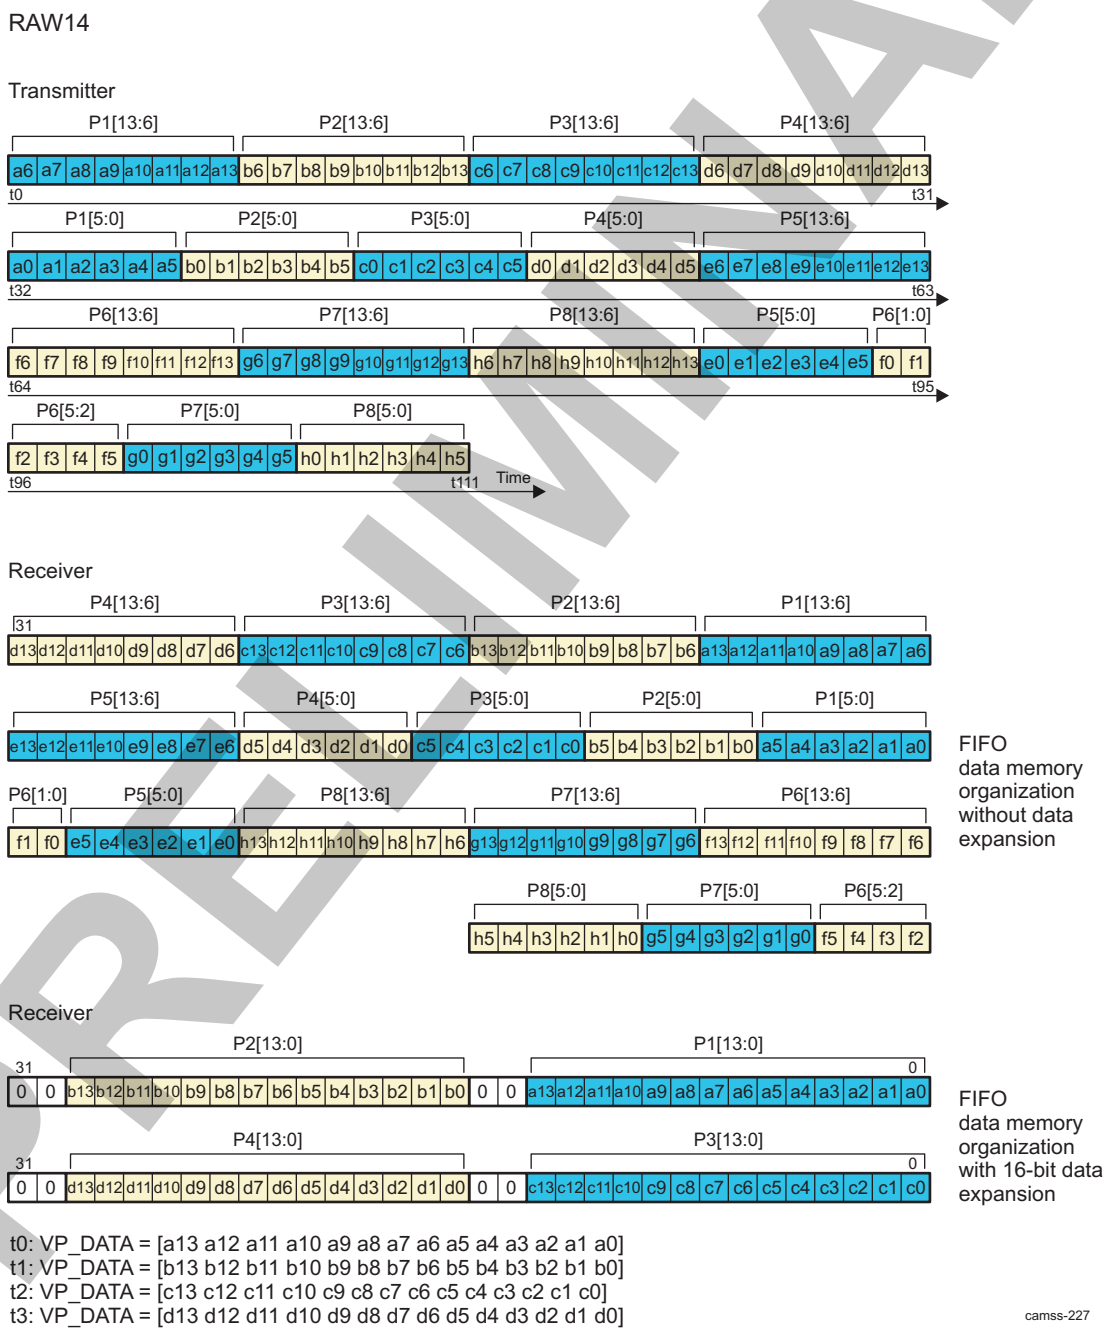


8.2.5.1.1.4.3.6 ISS CSI2 RAW14

RAW14 data can be output to memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 14-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 14 is 56, so 7 × 8 bits). Figure 8-65 shows the storage format for RAW14 data. Set the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field as follows:

- To 0x2D to select RAW14 mode
- To 0xAD for RAW14 + 16-bit expansion
- To 0x12D for RAW12 to video port

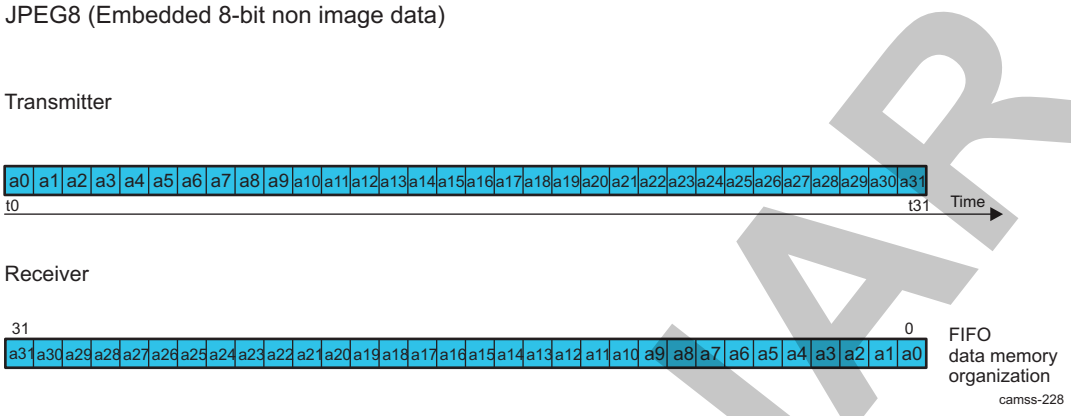
Figure 8-65. ISS CSI2 RAW14



8.2.5.1.1.4.4 ISS CSI2 JPEG8 Operating Modes

The size of a compressed stream can be known in advance. Figure 8-66 shows the format for storing JPEG8 data.

Figure 8-66. ISS CSI2 JPEG8

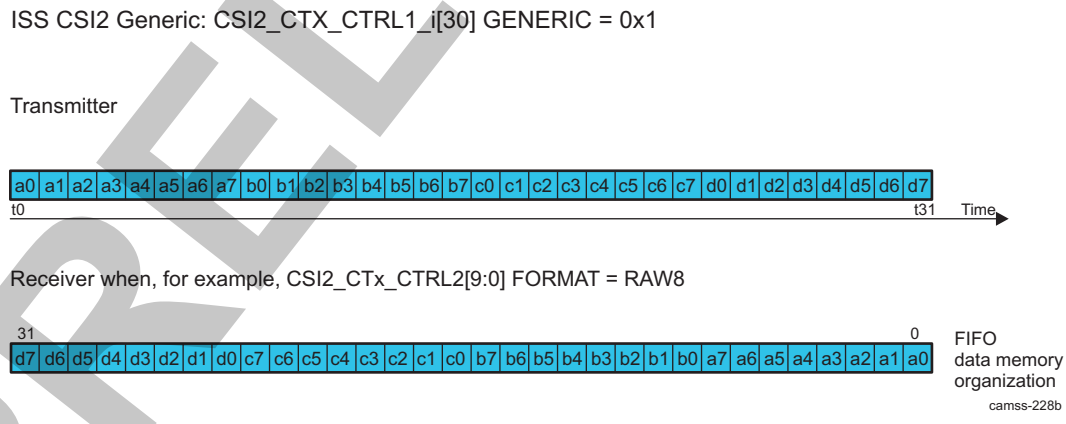


8.2.5.1.1.4.5 ISS CSI2 Generic Format

The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the CSI2_CTX_CTRL1_i[30] GENERIC bit. The CSI2_CTX_CTRL2_i[9:0] FORMAT bit field defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), the MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code.) When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If not matched, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is mapped only to a single context.

Figure 8-67 shows the ISS CSI2 generic format.

Figure 8-67. ISS CSI2 Generic Format



8.2.5.1.1.4.6 ISS CSI2 MIPI Format Supported Summary

Table 8-153 summarizes the CSI2 MIPI-supported formats and their output category. By setting the CSI2_CTX_CTRL2_i register format, the CSI2 outputs certain types of pixel packet data.

Table 8-153. ISS CSI2 MIPI Format Supported by the Protocol Engine

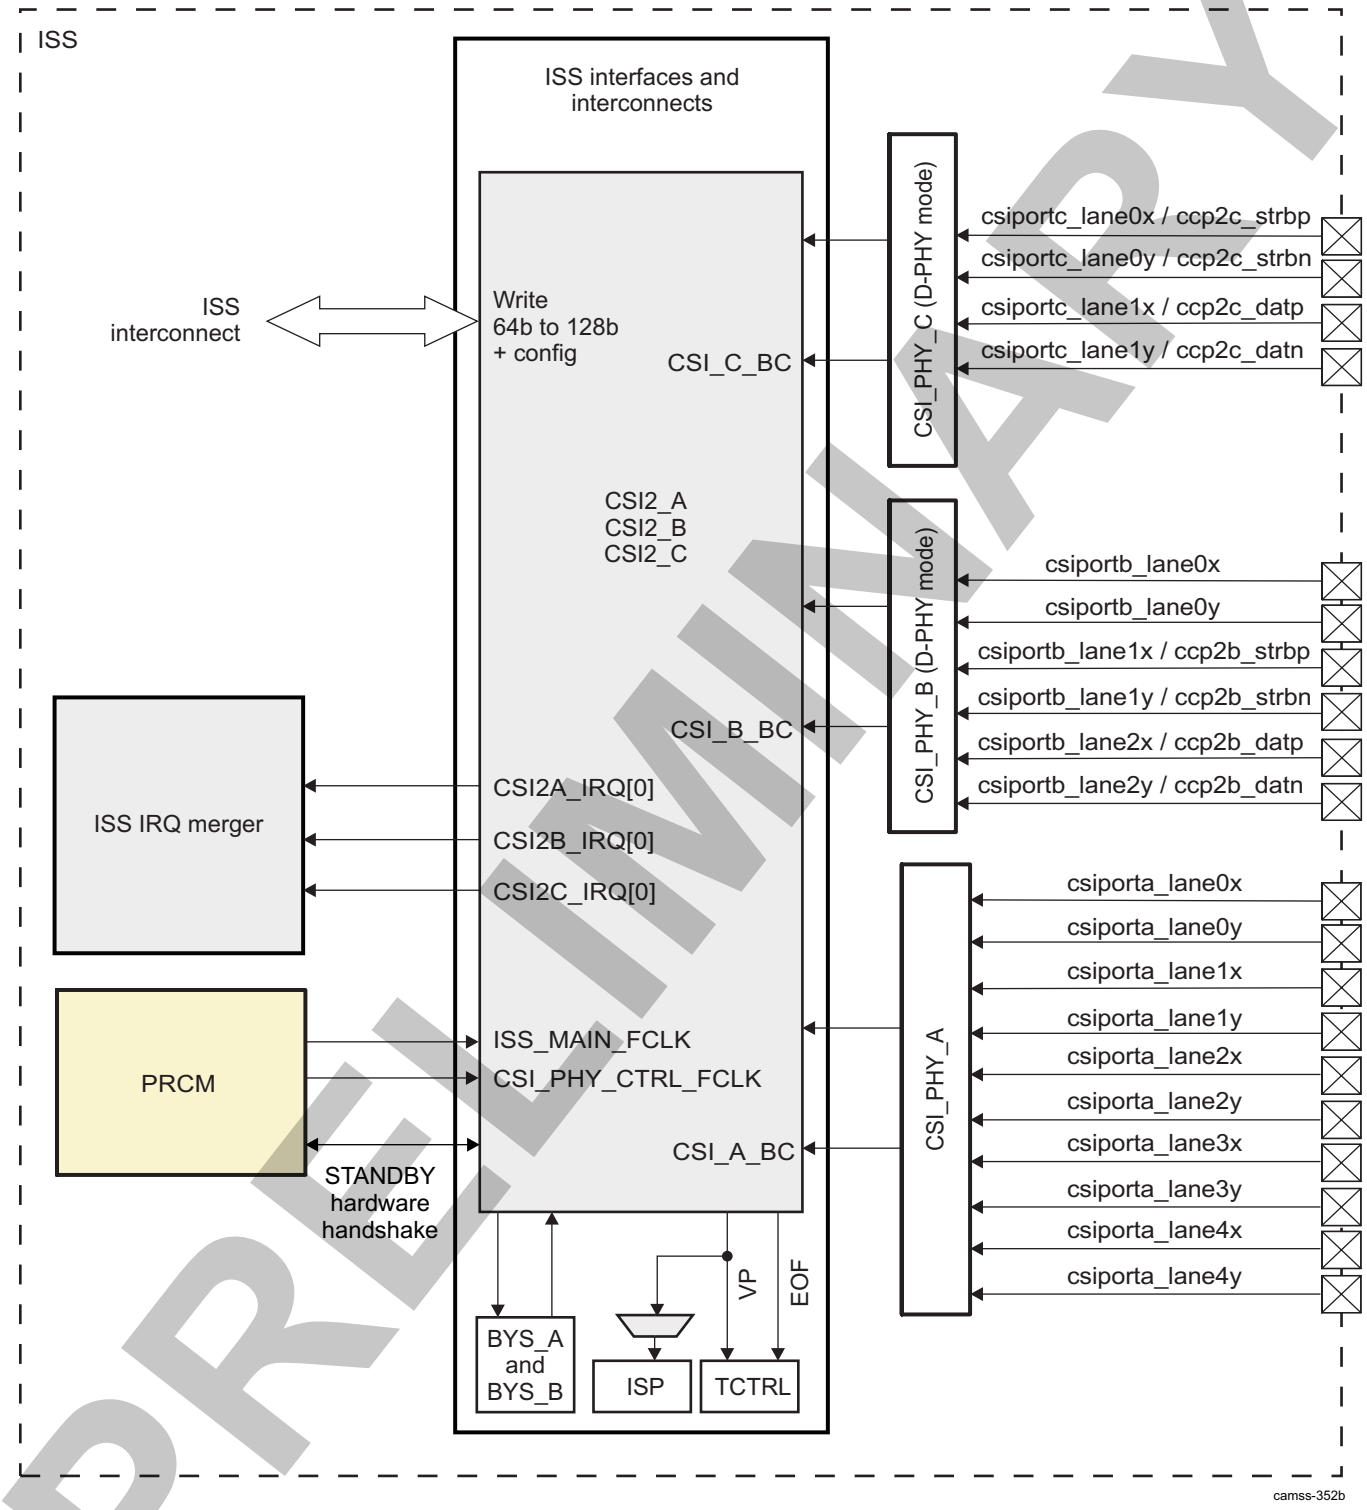
8.2.5.2 ISS CSI2 Integration

Figure 8-68 is an overview of the integration of the CSI2_A/CSI2_B/CSI2_C interface in the device. The figure is the top-level block diagram of the CSI2_A/CSI2_B/CSI2_C receiver. The CSI2_A/CSI2_B/CSI2_C receiver receives the serial data coming from a CSI2 compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface. A direct connection to both bayer scaler modules (BYS_A and BYS_B) is provided.

Figure 8-68. ISS CSI2_A/CSI2_B/CSI2_C Integration



The CSI2_A/CSI2_B/CSI2_C receiver can send data directly to system memory using the master port or send it to the camera ISP using the video port.

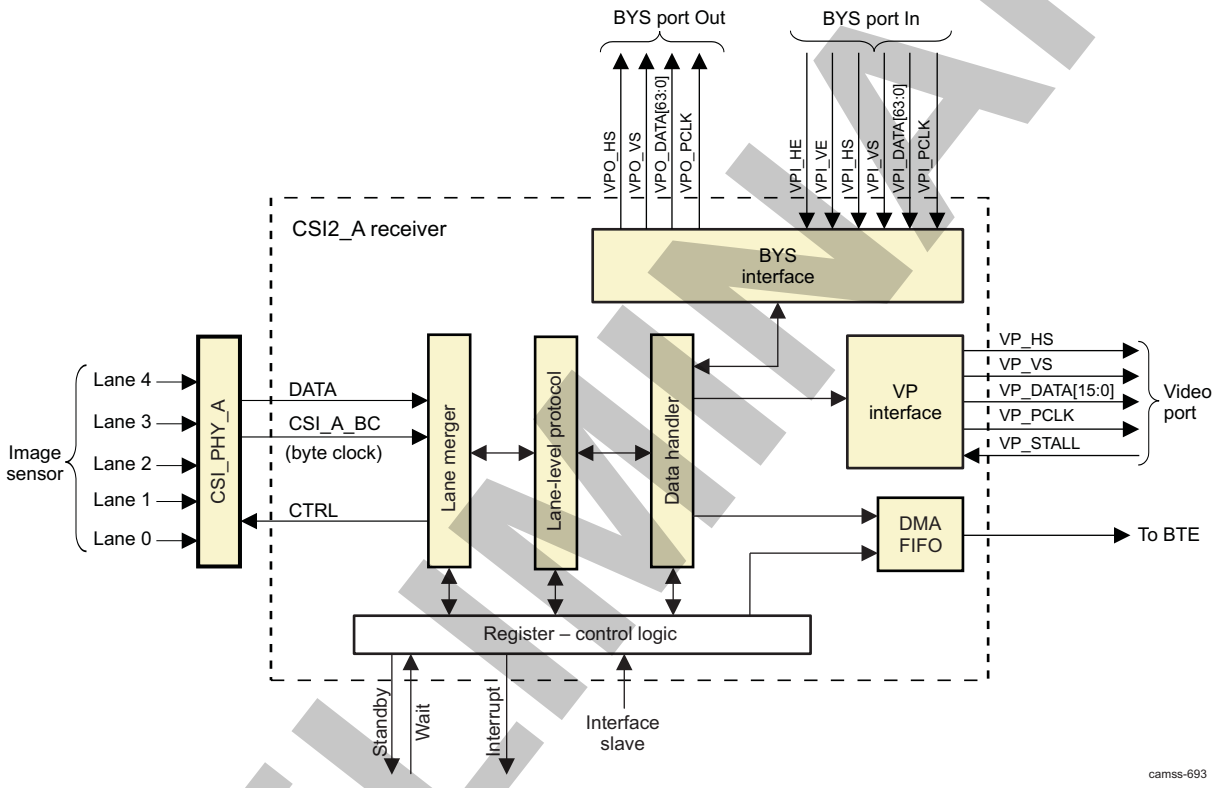
For power domain, clocks, reset, and hardware requests, see Section 8.1.2.4, *ISS Power Management*.

8.2.5.3 ISS CSI2 Functional Description

8.2.5.3.1 ISS CSI2 Overview

Figure 8-69 is the CSI2_A receiver block diagram (it assumes there are four CSI2 image sensor data lines). The only difference for CSI2_B and CSI2_C is the number of lanes coming into the complex I/O. The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver CSI_PHY_A (up to four data pairs), converts it to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface. Data communication between CSI2 and ISP is done through the video port.

Figure 8-69. ISS CSI2_A Receiver Block Diagram



8.2.5.3.2 ISS CSI2 Features

The CSI2 receiver is a master on the L3_MAIN interconnect for storing data in memory and a slave on the level 4 (L4) interconnect for register access.

The main features of the CSI2 receiver are:

- Transfer pixels and data received by the CSI2 PHY to the system memory or video processor
- Unidirectional data link
- Supports up to four data-configurable links in addition to the clock signaling (minimum of one data link and maximum of four depending on the speed)
- Data merger for two, three, or four data lane configurations
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)

- Supports all primary and secondary MIPI-defined formats (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion to the RGB formats
- Decompressions of the RAW formats
- RAW frame transcoding, including DPCM and A-Law compression
- Fully configurable interface of the complex PHY I/O: position of the clock and data and order of ± differential signals for each pair

8.2.5.3.3 ISS CSI2 Functional Description

8.2.5.3.3.1 ISS CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or clock lane with a restriction to the fourth line, which can only be data (see Section 8.2.3.1, *ISS CSI PHY Overview*). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the CSI2_COMPLEXIO_CFG registers. The CSI2_COMPLEXIO_CFG[2:0] CLOCK_POSITION bit field and the CSI2_COMPLEXIO_CFG[3] CLOCK_POL bit configure which lane transmits the clock and define its polarity. DATAl_POSITION and DATAl_POL configure the data lanes and their polarity, where l is the number of the data lane (l = 1 to 4). When the DATAl_POSITION field is set to 0, data lane l is not used.

CAUTION

Lane 4 (position 5) supports only data. The CLOCK_POSITION must not be set at position 5.

8.2.5.3.3.2 ISS CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

8.2.5.3.3.2.1 ISS CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered to the host central processing unit (CPU).

For long and short packets, the correction is always done if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. Table 8-154 describes the field in which events are logged. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_IRQENABLE and CSI2_CTX_IRQENABLE_i registers to prevent event generation at a higher level.

Table 8-154. ISS CSI2 ECC Event Logging

	Short Packet	Long Packet
With correction	Global CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	Context CSI2_CTX_IRQSTATUS_i[8] ECC_CORRECTION_IRQ
Without correction	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by setting the CSI2_CTRL[2] ECC_EN bit to 0. Setting the bit to 1 enables the ECC check.

8.2.5.3.3.2.2 ISS CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an interrupt is triggered to the host CPU.

CRC errors are logged in the CS_IRQ field of the corresponding context register, CSI2_CTX_IRQSTATUS_i. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_CTX_IRQENABLE_i register to prevent event generation at a higher level.

The CRC can be disabled for a specific context by setting the CSI2_CTRL[5] CS_EN bit to 0. Setting the bit to 1 enables the CRC.

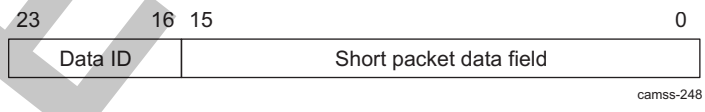
8.2.5.3.3.3 ISS CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled. Then, the short packet is written in the CSI2_SHORT_PACKET[23:0] SHORT_PACKET bit field. The ECC field is deleted from the short packet. Figure 8-70 shows the SHORT_PACKET bit field format.

Figure 8-70. ISS CSI2 SHORT_PACKET Bit Field Format



When a short packet is stored, an event is logged in the CSI2_IRQSTATUS[13] SHORT_PACKET_IRQ bit. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_IRQENABLE register to prevent event generation at a higher level.

The application reads the CSI2_SHORT_PACKET register before the next short packet with a code from 0x8 to 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

8.2.5.3.3.4 ISS CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

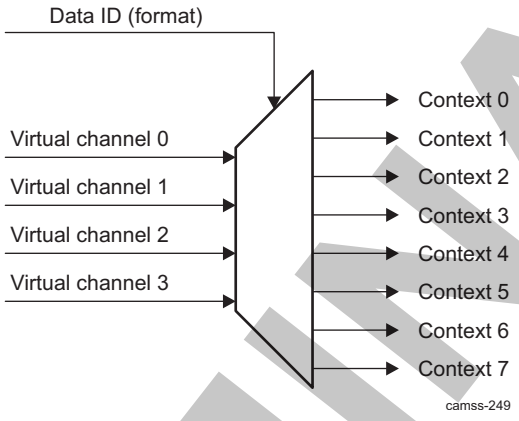
The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts with their events to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following bit fields permit configuration of a context:

- CSI2_CTX_CTRL2_i[12:11] VIRTUAL_ID: Configures the virtual ID linked to the current context
- CSI2_CTX_CTRL2_i[9:0] FORMAT: Configures the data format linked to the current context

Figure 8-71 shows the relationships between virtual channels and contexts.

Figure 8-71. ISS CSI2 Virtual Channel to Context



Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by setting the CSI2_CTX_CTRL1_i[0] CTX_EN bit to 1; setting this bit to 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the CSI2_CTX_CTRL1_i[15:8] COUNT bit field. Acceptable values are 0 to 255; 0 stands for infinite capture (no count). After each frame is acquired, the count value is decremented by 1. When the count value reaches 0, the CSI2_CTX_IRQSTATUS_i[6] FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK bit must be set to 1. If the value of the COUNT_UNLOCK bit is 0, a write in the COUNT bit field has no effect.

The CSI2_CTX_CTRL3_i[15:0] LINE_NUMBER bit field configures the generation of the CSI2_CTX_IRQSTATUS_i[7] LINE_NUMBER_IRQ event. The CSI2_CTX_CTRL1_i[1] LINE_MODULO bit configures how the LINE_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the CSI2_CTX_CTRL2_i[31:16] FRAME_NUMBER bit field shows the number that identifies the frame received.

8.2.5.3.3.5 ISS CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration is common to the eight channels and is defined in the CSI2_CTRL register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports:

- 1D addressing mode (no address line offset, CSI2_CTX_DAT_OFST_i = 0)
- 2D addressing mode (address line offset different than 0, CSI2_CTX_DAT_OFST_i = 0)

The burst size is defined in the CSI2_CTRL[6:5] BURST_SIZE bit field and the CSI2_CTRL[16] BURST_SIZE_EXPAND bit. The DMA uses the burst size or smaller sizes down to single open-core protocol (OCP) writes depending on the alignment at the end of lines. The DMA engine can handle burst requests. When the burst requests can be used, as soon as one burst of data is present in the FIFO, the DMA engine initiates a burst write. The burst size is defined in the CSI2_CTRL[6:5] BURST_SIZE bit field and the CSI2_CTRL[16] BURST_SIZE_EXPAND bit.

NOTE: Unless there are specific requirements, CSI2 (also applies to all other ISS initiators) must be configured to use only a burst size of 128 bytes and nonposted writes.

The CSI-2 receiver issues single request at the end of lines, when there is not enough data to generate the programmed burst size. Other burst sizes than a single request and the programmed burst size are not used.

When single requests must be used, as soon as one element (the size depends on the data type and the post-processing: DPCM, EXT, etc.) is present in the FIFO, the DMA engine initiates a single write.

Interleave mode is dedicated by the CSI2 receiver only when the line numbers are received (short packets). The line number is used to calculate the start address of the line.

The DMA starts to write in memory using the CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR bit field for the first frame to be transferred, and then uses the CSI2_CTX_DAT_PONG_ADDR_i[31:5] ADDR bit field and the ping address alternately. Thus, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The CSI2_CTX_CTRL1_i[3] PING_PONG status bit indicates whether the ping address (CSI2_CTX_DAT_PING_ADDR_i) or the pong address (CSI2_CTX_DAT_PONG_ADDR_i) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the CSI2_CTRL[0] IF_EN bit, the pixel data is written in the ping buffer and the CSI2_CTX_CTRL1_i[3] PING_PONG bit = PONG. When the number of FECs received equals the value programmed in the CSI2_CTX_CTRL1_i[23:16] FEC_NUMBER bit field, the pixel data are written in the pong buffer and CSI2_CTX_CTRL1_i[3] PING_PONG = PING. CSI2_CTX_CTRL1_i[3] PING_PONG toggles after the CSI2_CTX_CTRL1_i[23:16] FEC_NUMBER FEC sync code with the virtual channel ID defined is received in the CSI2_CTX_CTRL2_i[12:11] VIRTUAL_ID bit field.

The CSI2_CTX_CTRL1_i[23:16] FEC_NUMBER bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the PING_PONG buffer.

8.2.5.3.3.5.1 ISS CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the CSI2_CTX_DAT_OFST_i[31:5] OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the value of OFST sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTX_DAT_PING_ADDR_i@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i@Line2 = @Line1 +
CSI2_CTX_DAT_OFST_i
```

For the pong frame:

```
@Line0 = CSI2_CTX_DAT_PONG_ADDR_i@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i@Line2 = @Line1 +
CSI2_CTX_DAT_OFST_i
```

8.2.5.3.3.5.2 ISS CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

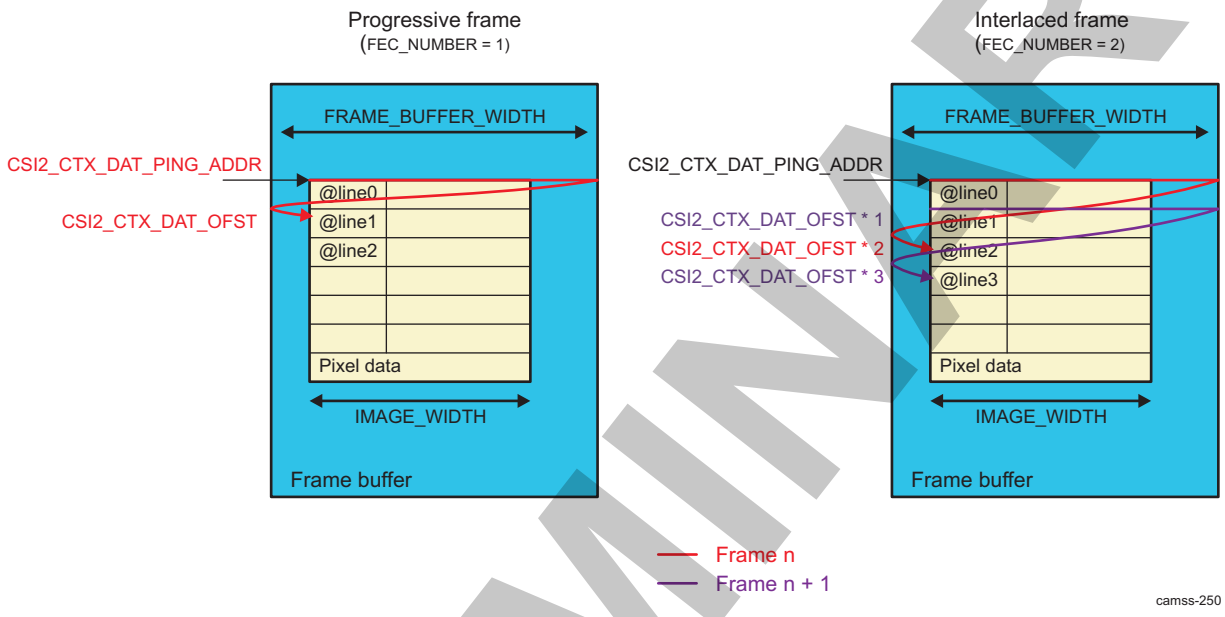
```
@LineX = CSI2_CTX_DAT_PING_ADDR_i + CSI2_CTX_DAT_OFST_i * Line_Number
```

For the pong frame:

```
@LineX = CSI2_CTX_DAT_PONG_ADDR_i + CSI2_CTX_DAT_OFST_i * Line_Number
```

Figure 8-72 shows how data are stored in memory regarding the DMA configuration.

Figure 8-72. ISS CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode



The burst size is defined in the CSI2_CTRL[6:5] BURST_SIZE bit field for bursts up to 16 × 64 bits or the CSI2_CTRL[16] BURST_SIZE_EXPAND bit for 16 × 128-bit bursts. It can be changed only while the CSI2_CTRL[0] IF_EN bit is reset to 0. The recommended value is the CSI2_CTRL[16] BURST_SIZE_EXPAND bit set to 1, which defines a burst of 16 × 64 bits (the maximum value); otherwise, by default it is set to 8 × 64 bits. When the BURST_SIZE_EXPAND bit is set, the BURST_SIZE setting has no effect. The DMA uses nonposted writes by default. The CSI2_CTRL[13] NON_POSTED_WRITE bit must be set to 1 to match DMA default configuration. It can be changed only while the CSI2_CTRL[0] IF_EN bit is reset to 0.

8.2.5.3.3.6 ISS CSI2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CSI2 real-time traffic, when required, based on the fullness of the CSI2 DMA read and write buffers. Programmable buffer thresholds are used to indicate when the local MFLAG signal is generated, which is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CSI2 MFLAG signal is asynchronous to any on-going OCP transaction. The threshold corresponds to the fullness of DMA buffer, and is defined by the following threshold parameters:

- High threshold: When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the CSI2_CTRL[22:20] MFLAG_LEVH register.
- Low threshold: When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the CSI2_CTRL[19:17] MFLAG_LEVL register.

8.2.5.3.3.7 ISS CSI2 Transcoding

Image transcoding is used mainly to reduce memory footprint and bandwidth when:

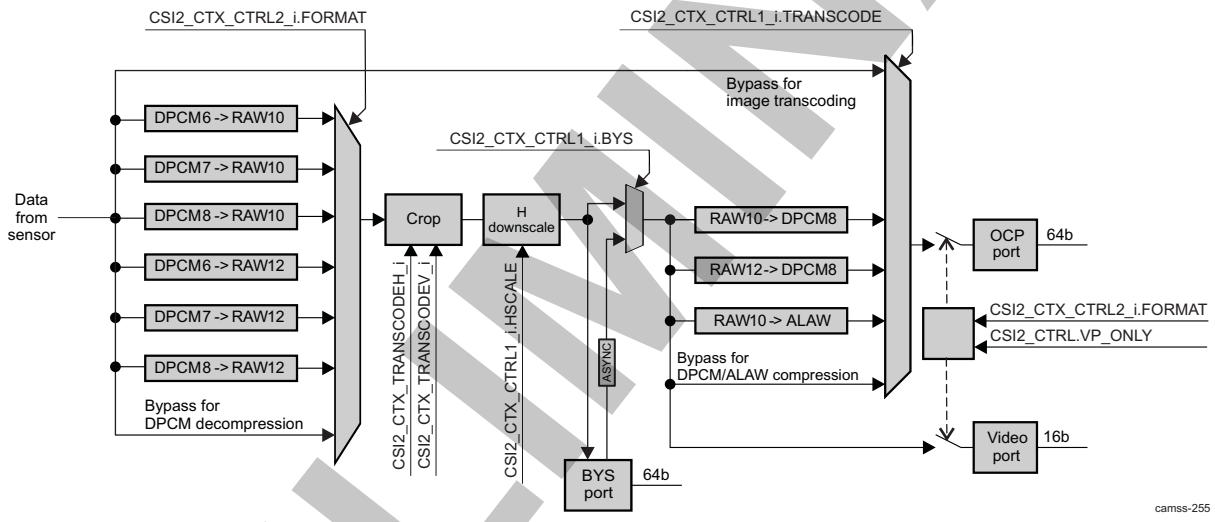
- The sensor does not support DPCM compression. In fact, A-Law and DPCM compressed pixels occupy only 6, 7, or 8 BPP of storage.

- Digital zoom is used
  - Data that is not going to be used by further processing does not need to the stored in system memory.
  - Pixels cannot be accessed from random locations in a DPCM-compressed frame. Transcoding avoids memory-to-memory processing of unused pixels.

Figure 8-73 shows the logical representation of the image transcoding operation.

- Data is extracted from the CSI2 stream by the protocol engine.
- It is DPCM decompressed if necessary. That is the case when the received stream is DPCM-compressed and transcoding has been enabled using the CSI2_CTX_CTRL1_i[27:24] TRANSCODE bit field.
- Data sent to the video port cannot be compressed: it is intended to be processed by the ISS ISP. Data sent to system memory can be optionally compressed.
- Internal data are aligned on MSB when they enter the cropping stage. For example:
  - 4 LSBs are 0s when RAW10 data are handled.
  - 2 LSBs are 0s when RAW12 data are handled.

Figure 8-73. ISS CSI2 Frame Processing



Only one context can use the BYS port at the time. Software must ensure that the CSI2_CTX_CTRL1_i[29] BYS is set only for one of the contexts. The BYS port can only be used for progressive formats. No field information is transmitted over the BYS port. See Section 8.2.5.3.3.10, *ISS CSI2 BYS Interface*, for more information on the BYS interface ports.
Data from the sensor can not go through the transcoding stage when data is received on BYS input port. Both sources are not necessarily synchronized and therefore resource (DPCM encoder, OCP port, video port, etc.) conflicts may occur, if data arrives simultaneously from BYS input port and the CSI-2 camera device. Software must ensure that this condition does not occur. The hardware does not perform any particular verification, if that condition is met.

Table 8-155 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the table are not supported for transcoding. The FORMAT and Corresponding Setting Value column corresponds to the value set in the CSI2_CTX_CTRL2_i[9:0] FORMAT register. The last column shows the formats for which the horizontal downscaling of RAW data is supported.

Table 8-155. ISS CSI2 Supported Transcoding Input Formats

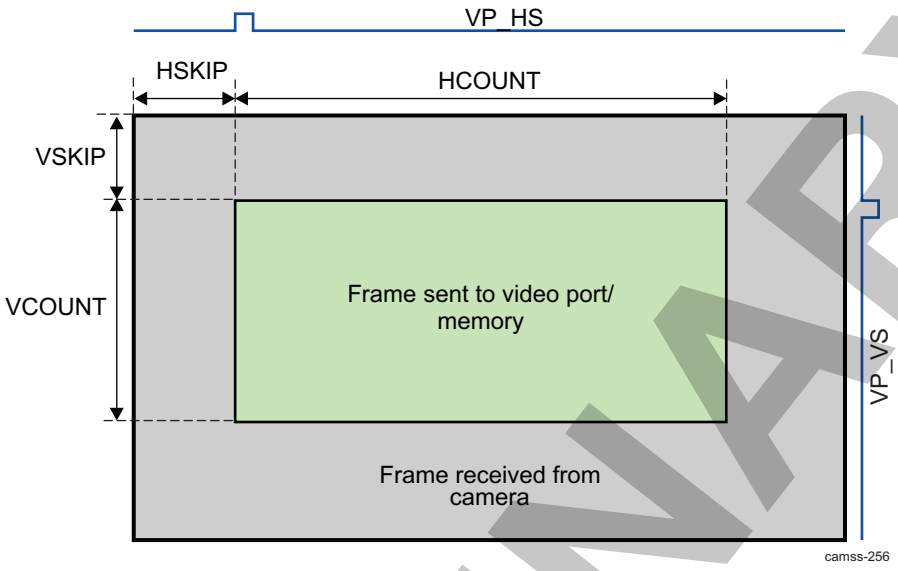
CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value		Cropping Engine Input Format	DPCM Decomposition Enabled	Video Port Enabled	Horizontal Downscale Supported
0x028	RAW6	RAW6			

Table 8-155. ISS CSI2 Supported Transcoding Input Formats (continued)

CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value		Cropping Engine Input Format	DPCM Decomposition Enabled	Video Port Enabled	Horizontal Downscale Supported
0x068	RAW6 + EXP8				
0x029	RAW7	RAW7			
0x069	RAW7 + EXP8				
0x02A	RAW8	RAW8			
0x12A	RAW8 + VP			Yes	
0x02B	RAW10	RAW10			Yes
0x0AB	RAW10 + EXP16				Yes
0x0E8	RAW6 + DPCM10 + VP		Yes	Yes	Yes
0x12F	RAW10 + VP			Yes	Yes
0x229	RAW7 + DPCM10 + EXP16		Yes		Yes
0x2A8	RAW6 + DPCM10 + EXP16		Yes		Yes
0x2AA	RAW8 + DPCM10 + EXP16		Yes		Yes
0x329	RAW7 + DPCM10 + VP		Yes	Yes	Yes
0x32A	RAW8 + DPCM10 + VP		Yes	Yes	Yes
0x2Cn	USER_DEFINED_BYTE_DATA + DPCM10 + EXP16		Yes		Yes
0x34n	USER_DEFINED_BYTE_DATA + DPCM10 + VP		Yes	Yes	Yes
0x02C	RAW12	RAW12			Yes
0x0AC	RAW12 + EXP16				Yes
0x12C	RAW12 + VP			Yes	Yes
0x36A	RAW8 DPCM12 + EXP16		Yes		Yes
0x3AA	RAW8 DPCM12 + VP		Yes	Yes	Yes
0x1Cn	USER_DEFINED_BYTE_DATA + DPCM12 + EXP16		Yes		Yes
0x14n	USER_DEFINED_BYTE_DATA + DPCM12 + VP		Yes	Yes	Yes
0x3A8	RAW6 + DPCM12 + EXP16		Yes		Yes
0x368	RAW6 + DPCM12 + VP		Yes	Yes	Yes
0x369	RAW7 + DPCM12 + EXP16		Yes		Yes
0x3A9	RAW7 + DPCM12 + VP		Yes	Yes	Yes
0x02D	RAW14	RAW14			Yes
0x0AD	RAW14 + EXP16				Yes
0x12D	RAW14 + VP			Yes	Yes

Image cropping parameters are controlled by software. Figure 8-74 shows the cropping operation.

Figure 8-74. ISS CSI2 Frame Cropping



CAUTION

Hardware does not check for validity of the settings. The following rules must be respected:

- CSI2_CTX_TRANSCODEH_i[12:0] HSKIP + CSI2_CTX_TRANSCODEH_i[28:16] HCOUNT <= image width
- CSI2_CTX_TRANSCODEV_i[12:0] VSKIP + CSI2_CTX_TRANSCODEV_i[28:16] VCOUNT <= image height

Furthermore, the CSI2_CTX_TRANSCODEH_i[28:16] HCOUNT bit field must comply with the following alignment constraints; otherwise, undefined behavior occurs. Table 8-156 shows the transcode alignment constraints

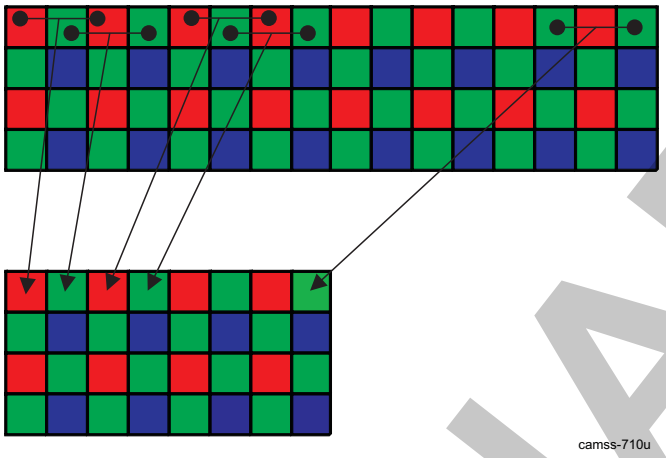
Table 8-156. ISS CSI2 Transcode Alignment Constraints

CSI2_CTX_CTRLi[27:24] TRANSCODE Value	Transcode	HCOUNT Must Be Multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

The CSI2_CTX_CTRL1_i[28] HSCALE configuration register enables horizontal downscaling of RAW data. It reduces the horizontal size and pixel clock by a factor of 2. The scaler uses a 2-tap horizontal filter operating on samples of the same color plane. The coefficients are: [1/2 ; 0 ; 1/2]. The formats that support horizontal downscaling are shown in Table 8-155, *ISS CSI2 Supported Transcoding Input Formats*.

Figure 8-75 shows the scaler operation.

Figure 8-75. ISS CSI2 Horizontal Scaler



The scaler can send data to the video port or the interface port. When data goes to the video port, no additional alignment constraints apply. But when data goes to the interface port, HCOUNT/2 must comply with the constraints from Table 8-156 (for example, for RAW10, HCOUNT must be a multiple of 8).

Table 8-157 lists possible combinations of input and output formats supported by the transcoding engine. The Transcode column corresponds to the CSI2_CTX_CTRL1_i[27:24] TRANSCODE bit field of a context.

Table 8-157. ISS CSI2_Supported Transcoding Output Formats

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
RAW6	0	Disabled	Yes	RAW10	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	Yes
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	Yes
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	Yes
	6	RAW10			6	RAW10	Yes
	7	RAW12 + EXP16			7	RAW12 + EXP16

Table 8-157. ISS CSI2_Supported Transcoding Output Formats (continued)

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14			9	RAW14	Yes

RAW pixels are packed into 64-bit words sent to the OCP master port, as defined in:

- Section 8.2.5.1.1.4.3.3, *ISS CSI2 RAW8*
- Section 8.2.5.1.1.4.3.4, *ISS CSI2 RAW10*
- Section 8.2.5.1.1.4.3.5, *ISS CSI2 RAW12*
- Section 8.2.5.1.1.4.3.6, *ISS CSI2 RAW14*

For RAW10 and RAW12, software can choose among packed and nonpacked storage. A-Law and DPCM-compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point.

Similarly, RAW data is sent over the video port, as described in:

- Section 8.2.5.1.1.4.3.3, *ISS CSI2 RAW8*
- Section 8.2.5.1.1.4.3.4, *ISS CSI2 RAW10*
- Section 8.2.5.1.1.4.3.5, *ISS CSI2 RAW12*
- Section 8.2.5.1.1.4.3.6, *ISS CSI2 RAW14*

Enabling of the OCP/video port is controlled by the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field and the CSI2_CTRL[11] VP_ONLY_EN and CSI2_CTX_CTRL1_i[2] VP_FORCE bits.

To enable transcoding, software configures the context normally and also configures the framing using the CSI2_CTX_TRANSCODEV_i and CSI2_CTX_TRANSCODEH_i registers. Software defines the after transcoding with the CSI2_CTX_CTRL1_i[27:24] TRANSCODE bit field.

8.2.5.3.3.8 ISS CSI2 EndOfFrame and EndOfLine (EOF and EOL) Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line to the TCTRL. It is active during or after the adequate interface bridge transaction and becomes inactive before the first transaction of the next line. Software can enable/disable generation of those signals for each context using the CSI2_CTX_CTRL1_i[7] EOF_EN and CSI2_CTX_CTRL1_i[6] EOL_EN bits. When data is sent to both OCP and video ports, the EOL/EOF timing defined for the OCP port is used.

8.2.5.3.3.9 ISS CSI2 Data Decompression

The data compression technique used is DPCM and PCM.

To select the DPCM decompression predictor for the CSI2 Interface, set the CSI2_CTX_CTRL2_i[10] DPCM_PRED bit to 1 for simple predictor or to 0 for advanced predictor.

8.2.5.3.3.10 ISS CSI2 BYS Interface

The module has one BYS port for data input and another one for data output. See Figure 8-69, *ISS CSI2_A Receiver Block Diagram*, and Figure 8-73, *ISS CSI2 Frame Processing*. The input video port is asynchronous from the functional clock. The output video port is synchronous to the functional clock and the data rate is controlled through software configuration.

The BYS ports are 4 pixels x 16 bits wide and carry 4 or 0 pixels per cycle. Pixels are LSB aligned inside 16-bit containers on the bus. Only RAW12 can be exchanged. Additional bits on the bus are provided for future compatibility. The CSI2_RECEIVER internally converts from the received format to RAW12 (decompression and left shift) before sending data to the BYS port. Data received on the BYS input port is converted according to the settings of the transcoding engine before it is send to the OCP port. See Section 8.2.5.3.3.7, *ISS CSI2 Transcoding*, for more details on image transcoding.

Table 8-158 shows an example of a typical bus transaction on the output port to BYS module, where the width is not a multiple of 4.

Table 8-158. BYS Port Transaction

Cycle Number	HS	VS	DATA[11:0]	DATA[15:12]	DATA[27:16]	DATA[31:28]	DATA[43:32]	DATA[47:44]	DATA[59:48]	DATA[63:60]
1	0	0	Any Data							
2	0	0	Any Data							
3	0	0	Any Data							
4	0	0	Any Data							
5	1	1	Pixel #0	0's	Pixel #1	0's	Pixel #2	0's	Pixel #3	0's
6	0	0	Pixel #4	0's	Pixel #5	0's	Pixel #6	0's	Pixel #7	0's
N	0	0	Last pixel	0's	0's	0's	0's	0's	0's	0's

Input and output BYS ports are independent. It is possible that:

- Data is sent to the BYS output port, but no data is received on the BYS input port;
- No data is sent to the BYS output port, but data is received on the BYS input port;
- Data is sent to the BYS output port and data is received on the BYS input port (not necessarily the same size and/or pixel rate).

The PCLK pulses are not necessarily regularly spaced.

On both video ports there must be at least 4 PCLK pulses before the 1st pixel of a frame (i.e. after reset) and there must be at least 4 PCLK cycles of vertical blanking between frames.

The software can control gating and speed of the pixel clock sent to the BYS output port using the CSI2_CTRL[24:23] BYS_CLK_CTRL bit. Software must ensure that the peak pixel clock provided to the BYS port is superior or equal to ¼ of the peak pixel clock from the sensor. The hardware automatically suppresses unneeded clock pulses to align the mean pixel clock of the BYS port with the mean pixel clock of the sensor. The BYS clock must be turned off when it is not needed, to save power, by setting the CSI2_CTRL[24:23] BYS_CLK_CTRL bit to 0x0 (default state).

The duration (in time units) of blanking periods on the output BYS port is imposed by the camera sensor. The number of PCLK pulses sent by the CSI2_RECEIVER module is defined by the chosen pixel clock and the blanking duration from the sensor.

The timings on the BYS input port are imposed by the BYS module. There is no signal indicating the line end. Software must set the number of pixels to acquire per line in the CSI2_CTX_CTRL3_i[31:16] ALPHA bit field. The configured value must be less of equal to the number of pixels provided by the BYS module. The CSI2_RECEIVER will discard additional pixels. There is no indication of the frame end on the BYS input port. The CSI2_RECEIVER flushes the data in the FIFO to the memory at every line end.

Software must ensure that all data of frame "n" has been received on BYS input port before the camera sends the frame start code of the next frame.

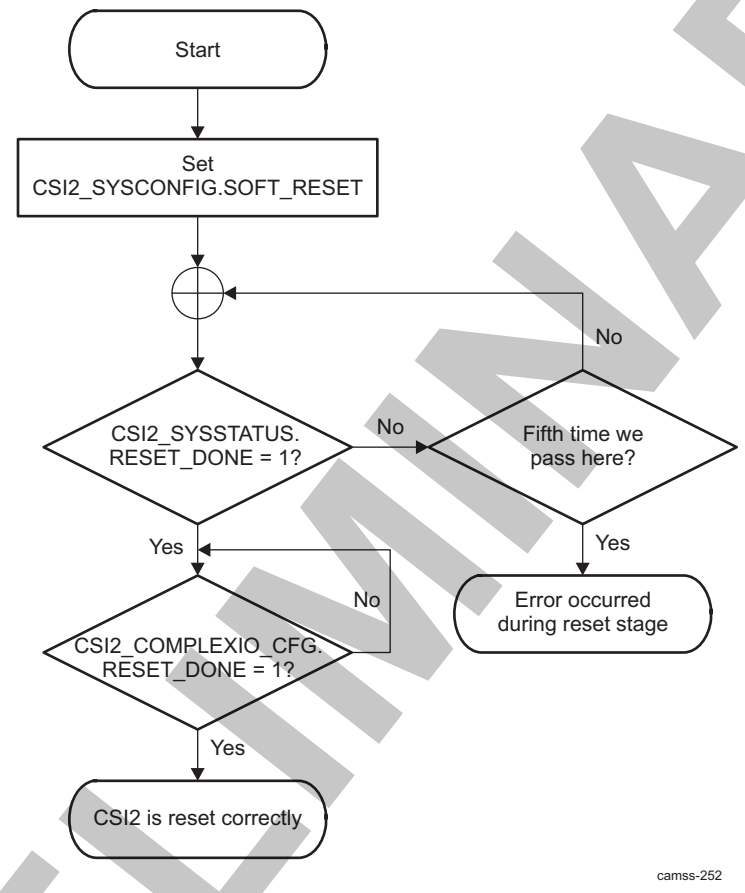
For more information on BYS modules functionality, see Section 8.2.9, *ISS BYS*.

8.2.5.4 ISS CSI2 Programming Model

8.2.5.4.1 ISS CSI2 Programming Reset Management

The CSI2_RECEIVER accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the complex I/O (CSI_PHY_A, B or C) and has the same effect as a hardware reset. Figure 8-76 shows how to reset CSI2 globally.

Figure 8-76. ISS CSI2 Receiver Global Reset Flow Chart



NOTE: Before setting the software reset bit to 1 in the CSI2_SYSCONFIG register, the user must have access to a CSI2 receiver register.

NOTE: The CSI2_COMPLEXIO_CFG[29] RESET_DONE bit is set to 1 only after the initialization of the CSI2 receiver, CSI2 complex I/O, and external camera completes.

8.2.5.4.2 ISS CSI2 Programming Enable Video/Picture Acquisition

Before using the receiver, a PHY initialization in D-PHY mode must be made for CSI_PHY_A, B or C which is associated with the CSI2 receiver. See Section 8.2.3.2.2, *ISS CSI PHY (D-PHY Mode) and Link Initialization Sequence.* To start a video/picture acquisition, perform the steps listed in Table 8-159.

Table 8-159. ISS CSI2 Global Initialization

Step	Register/Bit Field/Programming Model	Value
Reset the CSI2 receiver.	See Section 8.2.5.4.1, *Reset Management.*	
Configure the module power management. The module tries to enter smart-standby mode during the vertical blanking period. The CSI2_SYSCONFIG[0] AUTO_IDLE bit keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity.	CSI2_SYSCONFIG[13:12] MSTANDBY_MODE	0x2
Configure the interrupt generation as required. To enable context and/or complex I/O event reporting, enable the corresponding bit field in the CSI2_IRQENABLE register. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	CSI2_IRQSTATUS and CSI2_IRQENABLE	
Configure the complex I/O interrupt generation as required. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	CSI2_COMPLEXIO_IRQSTATUS and CSI2_COMPLEXIO_IRQENABLE)	
Start complex I/O: Set the CSI2_COMPLEXIO_CFG[28:27] PWR_CMD bit field to 0x1 to pass the complex I/O to the ON state, and then check that the state status reaches the ON state (CSI2_COMPLEXIO_CFG[26:25] PWR_STATUS = 0x1) (for complex I/O A).	CSI2_COMPLEXIO_CFG[28:27] PWR_CMD	0x1
Configure the complex I/O: • The complex I/O is fully functional with CSI2_COMPLEX_CFG set at its reset value. • CSI2_COMPLEX_CFG must be changed according to the data rate being used.	CSI2_COMPLEXIO_CFG	
Set RXMODE and STOPSTATE FSM to RXMODE state. Users can also configure the delay for the FSM to return from RXMODE to NORXMODE when all lines reach STOPSTATE.	CSI2_TIMING[15] FORCE_RX_MODE_IO1	0x1
Activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).	CSI2_CTRL[2] ECC_EN	0x1
Start the CSI2 receiver.	CSI2_CTRL[0] IF_EN	0x1
Configure the different contexts to be used.		
Link the context to a virtual channel and a data type.	See Section 8.2.5.4.6, *Linking a Context to a Virtual Channel and a Data Type.*	
Set the FEC_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see Section 8.2.5.3.3.5, *DMA Engine.*	CSI2_CTX_CTRL1_i[26:23] FEC_NUMBER	0x1 or 0x2
Capture an infinite number of frames (until the interface or the context is disabled).	CSI2_CTX_CTRL1_i[15:8] COUNT and CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x0
Enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the CSI2_CTX_IRQSTATUS_i[5] CS_IRQ bit).	CSI2_CTX_CTRL1_i[5] CS_EN	
Configure the DMA engine for the current channel: Configure the ping and pong addresses.	CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR and CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR	
Set the CSI2_CTx_DAT_OFST_i[15:5] OFST bit field to 0x0 so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).	CSI2_CTX_DAT_OFST_i[15:5] OFST	
Keep the ALPHA setting at its reset value (0x0) for RGB padding.	CSI2_CTX_CTRL3_i[29:16] ALPHA	

Table 8-159. ISS CSI2 Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the contexts.	CSI2_CTX_CTRL1_i[0] CTX_EN	0x1

8.2.5.4.3 ISS CSI2 Programming Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by setting the CSI2_CTX_CTRL1_i[0] CTX_EN bit to 0. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by setting the CSI2_CTRL[0] IF_EN bit to 0. This can have an immediate effect if the CSI2_CTRL[3] FRAME bit is set to 0, or it can be effective after all the enabled contexts receive the FEC if the CSI2_CTRL[3] FRAME bit is set to 1.

8.2.5.4.4 ISS CSI2 Programming Capture a Finite Number of Frames

The CSI2 receiver can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the steps listed in Table 8-160.

Table 8-160. ISS CSI2 Capture a Finite Number of Frames

Step	Bit Field	Value
Enable a write to the COUNT bit field.	CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x1
Set the bit field to the number of frames the CSI2 receiver must capture.	CSI2_CTX_CTRL1_i[15:8] COUNT	Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
Disable a write to the COUNT bit field.	CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK	0x0

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. Software reads the COUNT bit field to know how many frames must still be captured.

The COUNT bit can be updated during capture if the COUNT_UNLOCK bit is set to 1.

8.2.5.4.5 ISS CSI2 Programming a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the CSI2_CTX_CTRL3_i[15:0] LINE_NUMBER bit field. The event can be generated once or multiple times per frame, depending on the value of the CSI2_CTX_CTRL1_i[1] LINE_MODULO bit:

- If the LINE_MODULO bit = 0, the event is generated when the line number corresponding to the LINE_NUMBER bit field is received.
- If the LINE_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE_NUMBER value (LINE_NUMBER is used as a modulo).

8.2.5.4.6 ISS CSI2 Programming a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in the CSI2_CTX_CTRL2_i[9:0] FORMAT bit field.

For each context, a CSI2_CTX_CTRL2_i register defines with which channel and data type the context is associated:

- The VIRTUAL_ID bit field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT bit field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888)

can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT bit field also defines how DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the CSI2_CTX_CTRL2_i register.

8.2.5.4.7 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat progressive and interlaced frames. There is no progressive or interleaved mode, but the CSI2_CTX_CTRL1_i[23:16] FEC_NUMBER bit field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC_NUMBER 1: The current buffer is switched (ping to pong or pong to ping) after the FEC_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see Section 8.2.5.3.3.5, *DMA Engine*.

NOTE: If FEC_NUMBER 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

8.2.5.4.8 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

Table 8-161 lists the procedure to enable debug mode.

Table 8-161. ISS CSI2 Enable Debug Mode

Step	Bit	Value
Enable debug mode.	CSI2_CTRL[7] DBG_EN	0x1

- During debug mode the input does not come from the CSI2 receiver interface but from the CSI2_DBG_H and CSI2_DBG_P registers. The full CSI2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the CSI2_DBG_H register. The CSI2_CTRL[0] IF_EN bit has no affect during debug mode. To reset the FIFO in case of overflow, the CSI2_CTRL[7] DBG_EN bit must be reset to 0, and the interface must be enabled by setting the CSI2_CTRL[0] IF_EN bit to 0x1.
- The CSI2_DBG_H register is used to provide short packet and long packet headers.
- The CSI2_DBG_P register is used to provide long packet payload.

The following examples apply to the CSI2_DBG_H register:

- The sync codes for virtual channel 0 are written as CSI2_DBG_H = 0xFF00 0000 or 0xFF00 0001, or 0xFF00 0002 or 0xFF00 0003. To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, 0x547, write CSI2_DBG_H = 0x0123 4567, followed by CSI2_DBG_H = 0x89abcdef, and CSI2_DBG_H = 0x7654 3210.

8.2.5.5 ISS CSI2 Register Manual

8.2.5.5.1 ISS CSI2 Instance Summary

Table 8-162 summarizes the CSI2 instance.

Table 8-162. ISS CSI2 Instance Summary

Module Name	L3_MAIN Base Address	Size
ISS_CSI2_A_REGS1	0x5200 1000	368 bytes
ISS_CSI2_A_REGS2	0x5200 11C0	64 bytes

Address Offset	0x0000 0010		
Physical Address	0x5200 1010 0x5200 1410 0x5200 2410	**Instance**	ISS_CSI2_A_REGS1 ISS_CSI2_B_REGS1 ISS_CSI2_C_REGS1
Description	SYSTEM CONFIGURATION REGISTER This register is the OCP-socket system configuration register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		MSTANDBY_MODE		RESERVED										SOFT_RESET	AUTO_IDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x00000
13:12	MSTANDBY_MODE	Sets the behavior of the master port power management signals. 0x0: Force-standby. MStandby is only asserted when the module is disabled. 0x1: No-standby. MStandby is never asserted. 0x2: Smart-standby: MStandby is asserted based on the activity of the module. The module will try to go to standby during the vertical blanking period.	RW	0x0
11:2	RESERVED		R	0x000
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads return 0. 0x0: Normal mode. 0x1: The module is reset Note: Before setting the software reset bit to 1 in CSI2_SYSCONFIG register, the user must have access to a CSI2 receiver register.	RW	0
0	AUTO_IDLE	Internal OCP gating strategy 0x0: OCP clock is free-running. 0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity.	RW	1

Table 8-174. CSI2_CTRL

Address Offset	0x0000 0040		
Physical Address	0x5200 1040 0x5200 1440 0x5200 2440	**Instance**	ISS_CSI2_A_REGS1 ISS_CSI2_B_REGS1 ISS_CSI2_C_REGS1
Description	GLOBAL CONTROL REGISTER This register controls the CSI2 RECEIVER module. This register must not be modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED															BURST_SIZE_EXPAND	VP_CLK_EN	RESERVED	NON_POSTED_WRITE	RESERVED	VP_ONLY_EN	STREAMING_32_BIT	VP_OUT_CTRL		DBG_EN	BURST_SIZE		ENDIANNESS	FRAME	ECC_EN	RESERVED	IF_EN

Bits	Field Name	Description	Type	Reset
31:25	RESERVED	Reserved	R	0x000
24:23	BYS_CLK_CTRL	Controls the pixel clock sent to the BYS output port 0x0: Clock disabled (tied to 0) 0x1: PCLK=FCLK 0x3: reserved. 0x2: PCLK=FCLK/2	RW	0x0
22:17	RESERVED	Reserved	R	0x0000
16	BURST_SIZE_EXPAND	Sets the DMA burst size on the L3 interconnect. 0x0: Use the burst size defined in the BURST_SIZE register 0x1: Allow generation of 16x64-bit bursts	RW	0
15	VP_CLK_EN	VP clock enable. 0x0: The VP clock is disabled. 0x1: The VP clock is enabled.	RW	0
14	RESERVED	Read returns reset value	RW	0
13	NON_POSTED_WRITE	Not posted writes 0x0: Disable 0x1: Enable	RW	0
12	PWRSCPCLK	Controls autogating of the PWRSCP clock 0x0: PWRSCP clock is automatically cut when it isn't needed. 0x1: PWRSCP clock is free running	RW	0

Bits	Field Name	Description	Type	Reset
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the OCP master port is enabled. 0x1: The VP is enabled and the OCP master port is disabled.	RW	0
10	STREAMING_32_BIT	Indicates if 64-bit or 32-bit streaming burst is used. Valid only if CSI2_CTRL.STREAMING=1 0x0: 64-bit streaming burst is used; byte enable pattern is 0xFF 0x1: 32-bit streaming burst is used; byte enable pattern is 0x0F	RW	0
9:8	VP_OUT_CTRL	VP_PCLK control. Sets the VP_PCLK as a function of the ISS interconnect interface clock (OCPCLK). 0x0: No division: VP_PCLK = OCPCLK. 0x1: Division by 2: VP_PCLK = OCPCLK / 2. 0x3: Division by 4: VP_PCLK = OCPCLK / 4. 0x2: Division by 3: VP_PCLK = OCPCLK / 3. Example scenarios: - Low VP_PCLK, Memory -> VP: Same as typical memory -> VP, but VP_PCLK = OCPCLK/2 - Typical sensor -> VP: Autoidle enabled, FCLK at optimal rate, sensor provides DPCM compressed RAW12 data at 650 Mbps. Image timings VP_PCLK = (OCPCLK/2) and CCP2_CTRL[31:15] FRACDIV = 0xD000 2600 active pixels/line, 128 blanking pixels, no vertical blanking. (This scenario corresponds to the OTF operation at maximum CCP2 speed.)	RW	0x0
7	DBG_EN	Enables the debug mode. 0x0: Disable 0x1: Enable	RW	0
6:5	BURST_SIZE	Sets the DMA burst size on the L3 interconnect. 0x0: 1x64 OCP writes 0x1: 2x64 OCP writes 0x3: 8x64 OCP writes 0x2: 4x64 OCP writes	RW	0x0
4	ENDIANNESS	Select endianness for YUV4:2:2 8 bit and YUV4:2:0 legacy formats. 0x0: Use native MIPI CSI2 endianness: Little endian for all formats except for YUV4:2:2 8b and YUV4:2:0 Legacy which a big endian. 0x1: Store all pixel formats little endian.	RW	0
3	FRAME	Set the modality in which IF_EN works. 0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.	RW	0
2	ECC_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0
1	RESERVED	Read returns reset value	RW	0

Bits	Field Name	Description	Type	Reset
0	IF_EN	Enables the physical interface to the module. 0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code. 0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CSI2_CTX_CTRL1_i.PING_PONG bits are reset to 0 as well.	RW	0

Description	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	RESET_CTRL	RESET_DONE	PWR_CMD		PWR_STATUS		PWR_AUTO	RESERVED				DATA4_POL	DATA4_POSITION			DATA3_POL	DATA3_POSITION			DATA2_POL	DATA2_POSITION			DATA1_POL	DATA1_POSITION			CLOCK_POL	CLOCK_POSITION		

Bits	Field Name	Description	Type	Reset
31	PHY_REG_BANK	Selects among registers 0÷7 and 8÷15 when accessing PHY registers via the SCP bus. 0x0: 0÷7 0x1: 8÷15	RW	0
30	RESET_CTRL	Controls the reset of the complex I/O 0x0: Complex I/O reset active. 0x1: Complex I/O reset deasserted.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the byte clock provided by the associated CSIPHY (see Section 8.1.1.1.1, *ISS Clock Domains*. **Caution:** For the CSI2_COMPLEXIO_CFG[29] RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must to be active and sending the MIPI HS BYTECLK. Read 0x1: Reset completed. Read 0x0: Internal module reset is ongoing.	R	0
28:27	PWR_CMD	Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to Ultralow-Power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex I/O Read 0x2: Complex I/O in Ultralow-Power state Read 0x1: Complex I/O in ON state Read 0x0: Complex I/O in OFF state	R	0x0
24	PWR_AUTO	Automatic switch between ULP and ON states based on ULPM signals from complex I/O 0x0: Disable 0x1: Enable	RW	0
23:20	RESERVED		R	0x0
19	DATA4_POL	+/- differential pin order of data lane 4. 0x0: +/- pin order 0x1: -/+ pin order	RW	0

Bits	Field Name	Description	Type	Reset
18:16	DATA4_POSITION	Position and order of the data lane 4. The values 6 and 7 are reserved. This lane is not available for CSI2_B and CSI2_C receivers. 0x0: This data lane is not used. 0x1: Data lane 4 is at position 1. This position is not available to the CSI2_B and CSI2_C receivers. 0x2: Data lane 4 is at position 2. This position is not available to the CSI2_B and CSI2_C receivers. 0x3: Data lane 4 is at position 3. This position is not available to the CSI2_B and CSI2_C receivers. 0x4: Data lane 4 is at position 4. This position is not available to the CSI2_B and CSI2_C receivers. 0x5: Data lane 4 is at position 5. This position is not available to the CSI2_B and CSI2_C receivers. 0x6: Reserved 0x7: Reserved	RW	0x0
15	DATA3_POL	+/- differential pin order of data lane 3. 0x0: +/- pin order 0x1: -/+ pin order	RW	0
14:12	DATA3_POSITION	Position and order of the data lane 3. The values 6 and 7 are reserved. This lane is not available for CSI2_B and CSI2_C receivers. 0x0: This data lane is not used. 0x1: Data lane 3 is at position 1. This position is not available to the CSI2_B and CSI2_C receivers. 0x2: Data lane 3 is at position 2. This position is not available to the CSI2_B and CSI2_C receivers. 0x3: Data lane 3 is at position 3. This position is not available to the CSI2_B and CSI2_C receivers. 0x4: Data lane 3 is at position 4. This position is not available to the CSI2_B and CSI2_C receivers. 0x5: Data lane 3 is at position 5. This position is not available to the CSI2_B and CSI2_C receivers. 0x6: Reserved 0x7: Reserved	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0
10:8	DATA2_POSITION	Position and order of the data lane 2. The values 6 and 7 are reserved. This lane is not available for the CSI2_C receiver. 0x0: This data lane is not used. 0x1: Data lane 2 is at position 1. This position is not available to the CSI2_C receiver. 0x2: Data lane 2 is at position 2. This position is not available to the CSI2_C receiver. 0x3: Data lane 2 is at position 3. This position is not available to the CSI2_C receiver. 0x4: Data lane 2 is at position 4. This position is not available to the CSI2_B and CSI2_C receivers. 0x5: Data lane 2 is at position 5. This position is not available to the CSI2_B and CSI2_C receivers. 0x6: Reserved 0x7: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
7	DATA1_POL	+/- differential pin order of data lane 1. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. The values 6 and 7 are reserved. When CSI2 is used, the data lane 1 position must be different from 0, 6, or 7. 0x0: This data lane is not used. 0x1: Data lane 1 is at position 1. x2: Data lane 1 is at position 2. 0x3: Data lane 1 is at position 3. This position is not available to the CSI2_C receiver. 0x4: Data lane 1 is at position 4. This position is not available to the CSI2_B and CSI2_C receivers. 0x5: Data lane 1 is at position 5. This position is not available to the CSI2_B and CSI2_C receivers. 0x6: Reserved 0x7: Reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of clock lane. 0x0: +/- pin order (csi2_dx=+ and csi2_dy=-) 0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)	RW	0
2:0	CLOCK_POSITION	Position and order of the clock lane. The values 5, 6, and 7 are reserved. When CSI2 is used, the clock lane position must be different from 0, 5, 6, or 7. 0x0: This data lane is not used. 0x1: Clock lane is at position 1. 0x2: Clock lane is at position 2. 0x3: Clock lane is at position 3. This position is not available to the CSI2_C receiver. 0x4: Clock lane is at position 4. This position is not available to the CSI2_B and CSI2_C receivers. 0x5: Reserved 0x6: Reserved 0x7: Reserved	RW	0x0

BYTESWAP	GENERIC	BYS	HSCALE	TRANSCODE				FEC_NUMBER								COUNT								EOF_EN	EOL_EN	CS_EN	COUNT_UNLOCK	PING_PONG	VP_FORCE	LINE_MODULO	CTX_EN

Bits	Field Name	Description	Type	Reset
31	BYTESWAP	Allows swapping bytes two by two in the payload data. It does not affect: - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0x0: Disabled 0x1: Enabled	RW	0
30	GENERIC	Enables the generic mode. 0x0: Disabled. Data is received according to CSI2_CTX_CTRL2_i.FORMAT and the long packet code transmitted in the MIPI stream is used. 0x1: Enabled. Data is received according to CSI2_CTX_CTRL2_i.FORMAT and the long packet code transmitted in the MIPI stream is ignored.	RW	0
29	BYS	Controls BYS port. Must be 0 when TRANSCODE=0 0x0: Disabled. Data from the HSCALER is forwarded to the video port and/or OCP port 0x1: Enabled Data from the HSCALER is send to the BYS output port. Data received on the BYS input port is forwarded to the video port and/or OCP port	RW	0

Bits	Field Name	Description	Type	Reset
28	HSCALE	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. Must be disabled when transcoding is disabled. 0x0: Disable 0x1: Enable	RW	0x0
27:24	TRANSCODE	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x0: Feature disabled. 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x3: Outputs A-Law compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data.	RW	0x0
23:16	FEC_NUMBER	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR_i and CSI2_CTX_DAT_PONG_ADDR_i for the calculation of the address in memory (must be used only in interlace mode, otherwise set to 1).	RW	0x01
15:8	COUNT	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN bit is set to 0. Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit field COUNT_UNLOCK must be written in addition to COUNT bit field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value. 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire	RW	0x00
7	EOF_EN	Indicates if the end of frame signal must be asserted at the end of the line. Read 0x1: The end of frame signal is asserted at the end of each frame. Read 0x0: The end of frame signal is not asserted at the end of each frame.	RW	0

Bits	Field Name	Description	Type	Reset
6	EOL_EN	Indicates if the end of line signal must be asserted at the end of the line. Read 0x1: The end of line signal is asserted at the end of each frame. Read 0x0: The end of line signal is not asserted at the end of each frame.	RW	0
5	CS_EN	Enables the checksum check for the received payload (long packet only). 0x0: Disabled 0x1: Enabled	RW	0
4	COUNT_UNLOCK	Unlock writes to the COUNT bit field. Write 0x0: COUNT bit field is locked. Writes have no effect Write 0x1: COUNT bit field is unlocked. Writes are possible.	W	0
3	PING_PONG	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR_i or CSI2_CTX_DAT_PONG_ADDR_i) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0x1: PONG buffer Read 0x0: PING buffer	R	1
2	VP_FORCE	Forces sending of the data to both VPORT and OCP. Only applies to formats that existing in two versions: - One sending data to OCP port only - One sending data to VPORT only (tagged with the +VP extension) The format version sending data only to OCP should be chosen. When VP_FORCE is set, the data is sent to video port and to OCP port, no matter is format +VP or not (RAW8 + DPCM10 + VP or RAW8 + DPCM10 + EXP16). If this bit is cleared, data is only sent to one destination, so if the format is RAW8 + DPCM10 + VP, the data will be sent only to video port and if the format is RAW8 + DPCM10 + EXP16, the data will be sent only to OCP port. If CSI2_CTRL[11] VP_ONLY_EN bit is set, no data will be send to the OCP port although VP_FORCE is set. 0x0: Disabled 0x1: Enabled	RW	0
1	LINE_MODULO	Line modulo configuration 0x0: CSI2_CTX_CTRL3_i.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 0x1: CSI2_CTX_CTRL3_i.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)	RW	0
0	CTX_EN	Enables the context 0x0: Disabled 0x1: Enabled	RW	0

Table 8-194. CSI2_CTX_DAT_OFST_i

Address Offset	0x0000 0078 + (0x20 * i)	**Index**	i = 0 to 7
Physical Address	0x5200 1078 + (0x20 * i) 0x5200 1478 + (0x20 * i) 0x5200 2478 + (0x20 * i)	**Instance**	ISS_CSI2_A_REGS1 ISS_CSI2_B_REGS1 ISS_CSI2_C_REGS1
Description	DATA MEM ADDRESS OFFSET REGISTER - Context This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CSI2_CTX_DAT_PING_ADDR_i and CSI2_CTX_DAT_PONG_ADDR_i. For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data must have the same data format. The 5 LSBs are ignored: the offset must be a multiple of 32 bytes. This register is shadowed: modifications are taken into account after the next FSC sync code. Only full 32-bit values must be written.		
Type	RW

8.2.6 ISS TCTRL

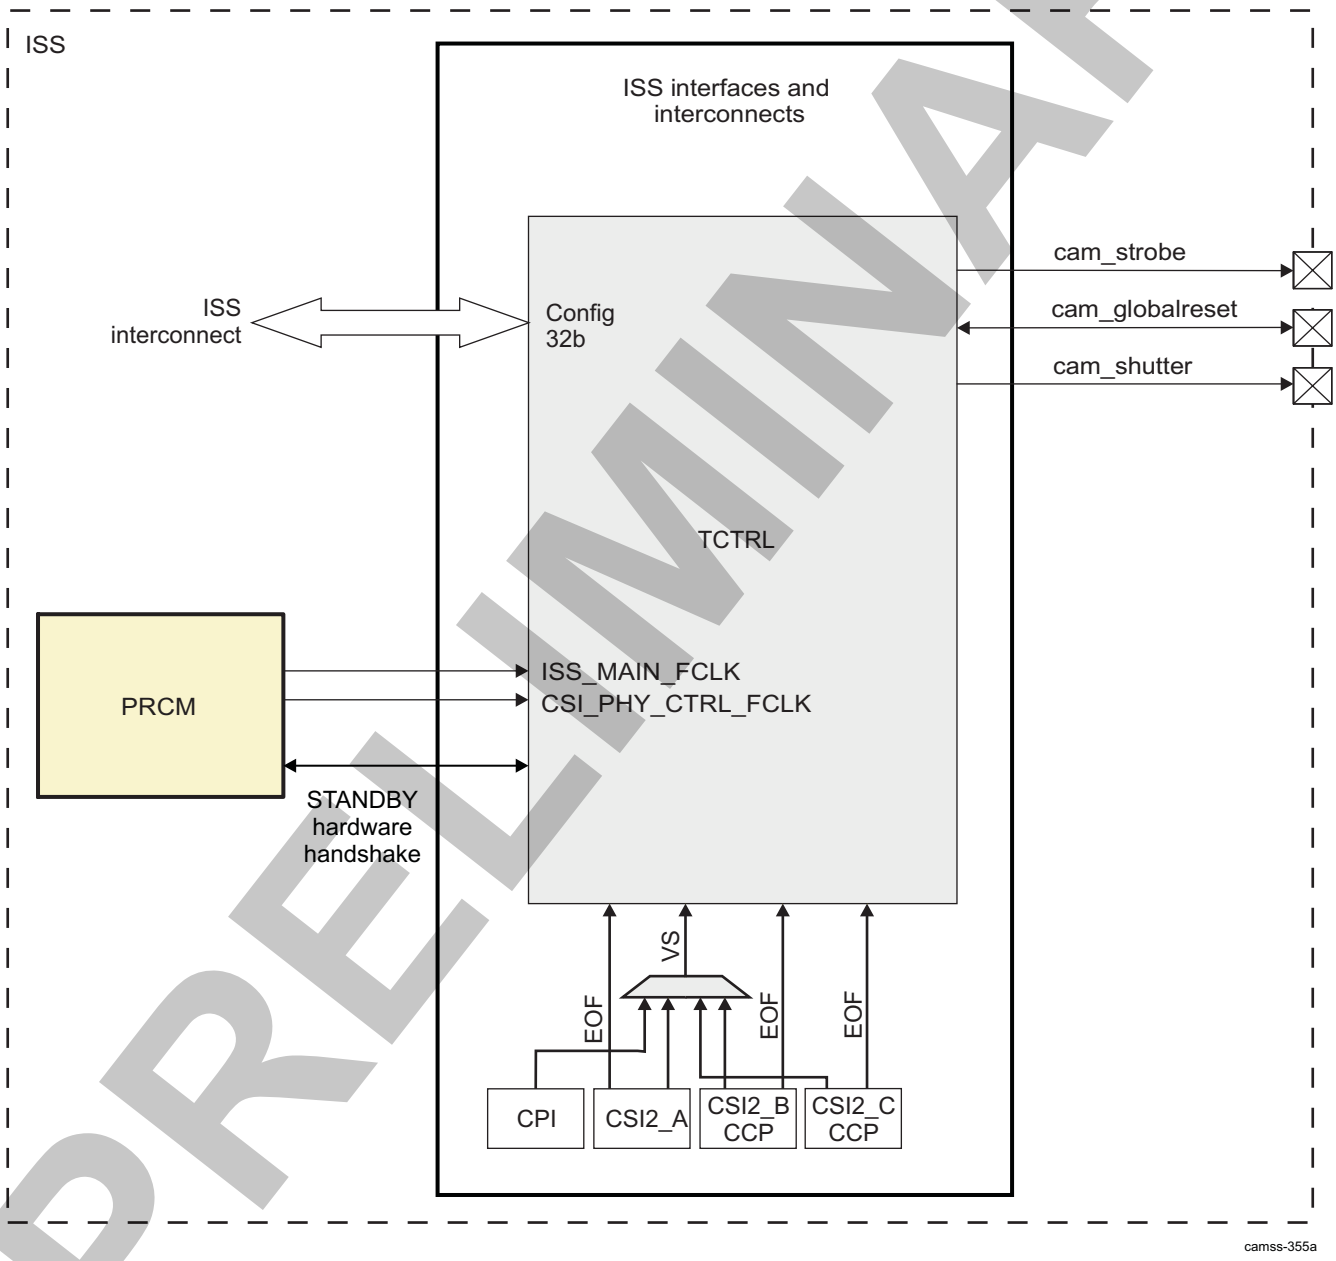
8.2.6.1 ISS TCTRL Environment

There are no particular environment attributes. See Section 8.2.2, *ISS Interfaces Environment*.

8.2.6.2 ISS TCTRL Integration

Figure 8-77 shows the integration of the TCTRL.

Figure 8-77. ISS TCTRL Integration



For information about the power domain, clocks, reset, and hardware requests, see Section 8.1.2.4, *ISS Power Management*.

8.2.6.3 ISS TCTRL Functional Description

8.2.6.3.1 ISS TCTRL Features

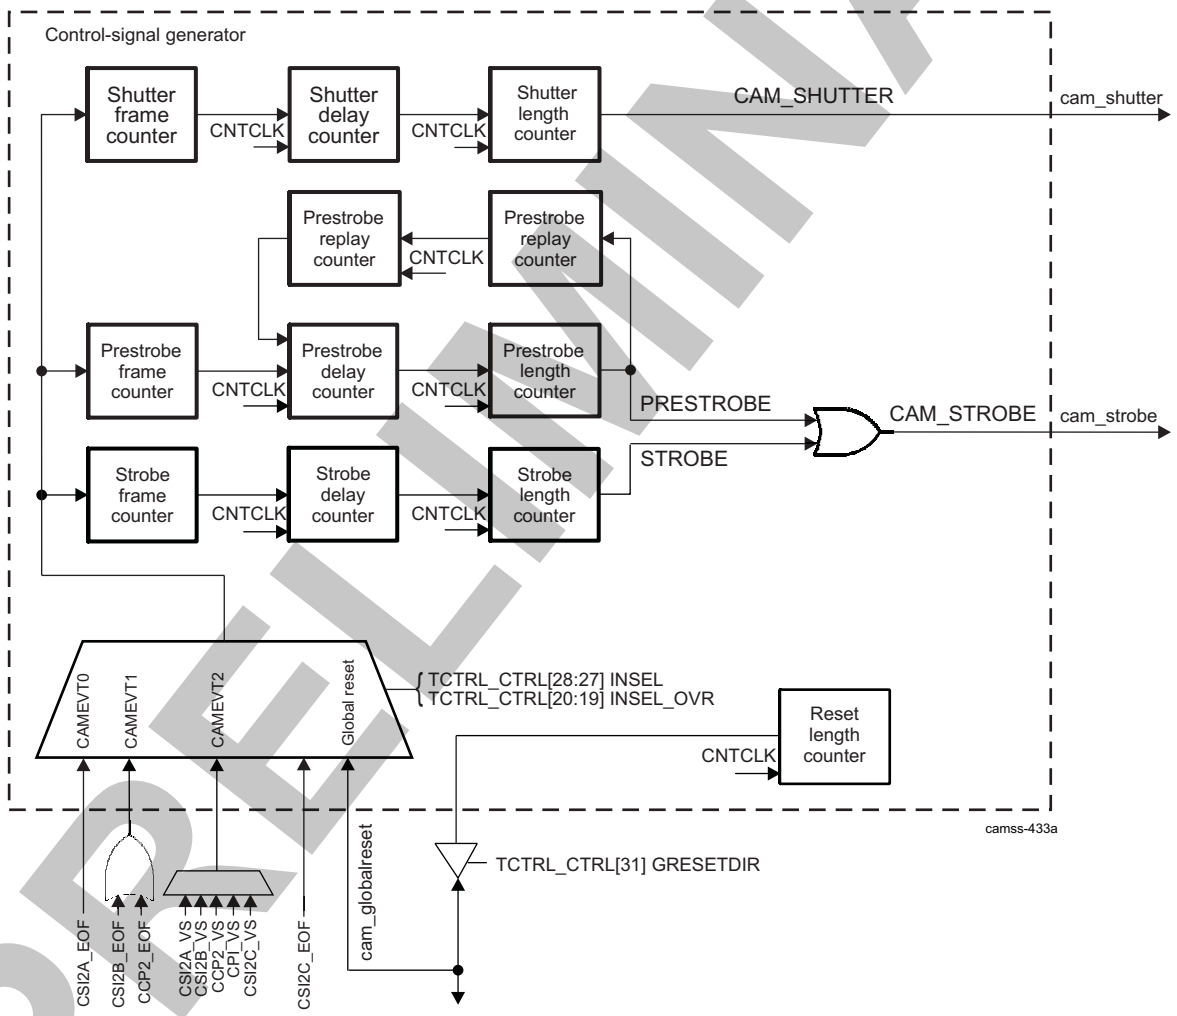
The TCTRL module receives synchronization events from one or multiple cameras and from an external global reset control mechanism. The synchronization event to be used is software configurable. The TCTRL generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters. It also provides a global reset output to erase sensor data before opening the mechanical shutter.

The TCTRL includes a timing generator and a control-signal generator.

8.2.6.3.2 ISS TCTRL Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter. Figure 8-78 shows the principle of control-signal generation.

Figure 8-78. TCTRL Control-Signal Generation



The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing control-signal generator can be synchronized on the vertical synchronization signal coming from the CSI2_A, CSI2_B, CSI2_C, CCP2, Parallel interface (CPI), or on an externally generated cam_globalreset signal.

A multiplexer controls which of the CSI2_A, CSI2_B, CSI2_C, CCP2, or Parallel interfaces drives control-signal generation. This multiplexer can also select the externally generated cam_globalreset signal as the trigger event. The TCTRL_CTRL[31] GRESETDIR bit defines the direction of cam_globalreset.

- The externally generated cam_globalreset is used as a trigger when TCTRL_CTRL[31] GRESETDIR = 0 and TCTRL_CTRL[28:27] INSEL = 3 and TCTRL_CTRL[20:19] INSEL_OVR = 0.
- The internally generated cam_globalreset is used as a trigger when TCTRL_CTRL[31] GRESETDIR = 1 and TCTRL_CTRL[28:27] INSEL = 3 and TCTRL_CTRL[20:19] INSEL_OVR = 0.

The cam_globalreset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on internally generated cam_globalreset . The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_globalreset.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the functional clock (ISS_MAIN_FCLK). The clock divider is programmable. Table 8-211 lists the possible frequencies as a function of the divisor values.

Table 8-211. ISS TCTRL Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL[18:10] DIVC	CNTCLK Clock	CNTCLK Precision (ns)
0 (default)	Clock gated. No clock.	N/A
1	304 MHz	3.29
2	152 MHz	6.58
3	101.333 MHz	9.87
4	76 MHz	13.16
...	...	...
510	0.596 MHz	1677.63
511	0.595 MHz	1680.92

There are three counters per control signal, plus three counters to control the pre-strobe generation, for a total of twelve counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received.
  - A new frame is detected by the TCTRL module when CAMEVTx is received.
  - The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass the frame counters.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the length of control-signal assertion. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

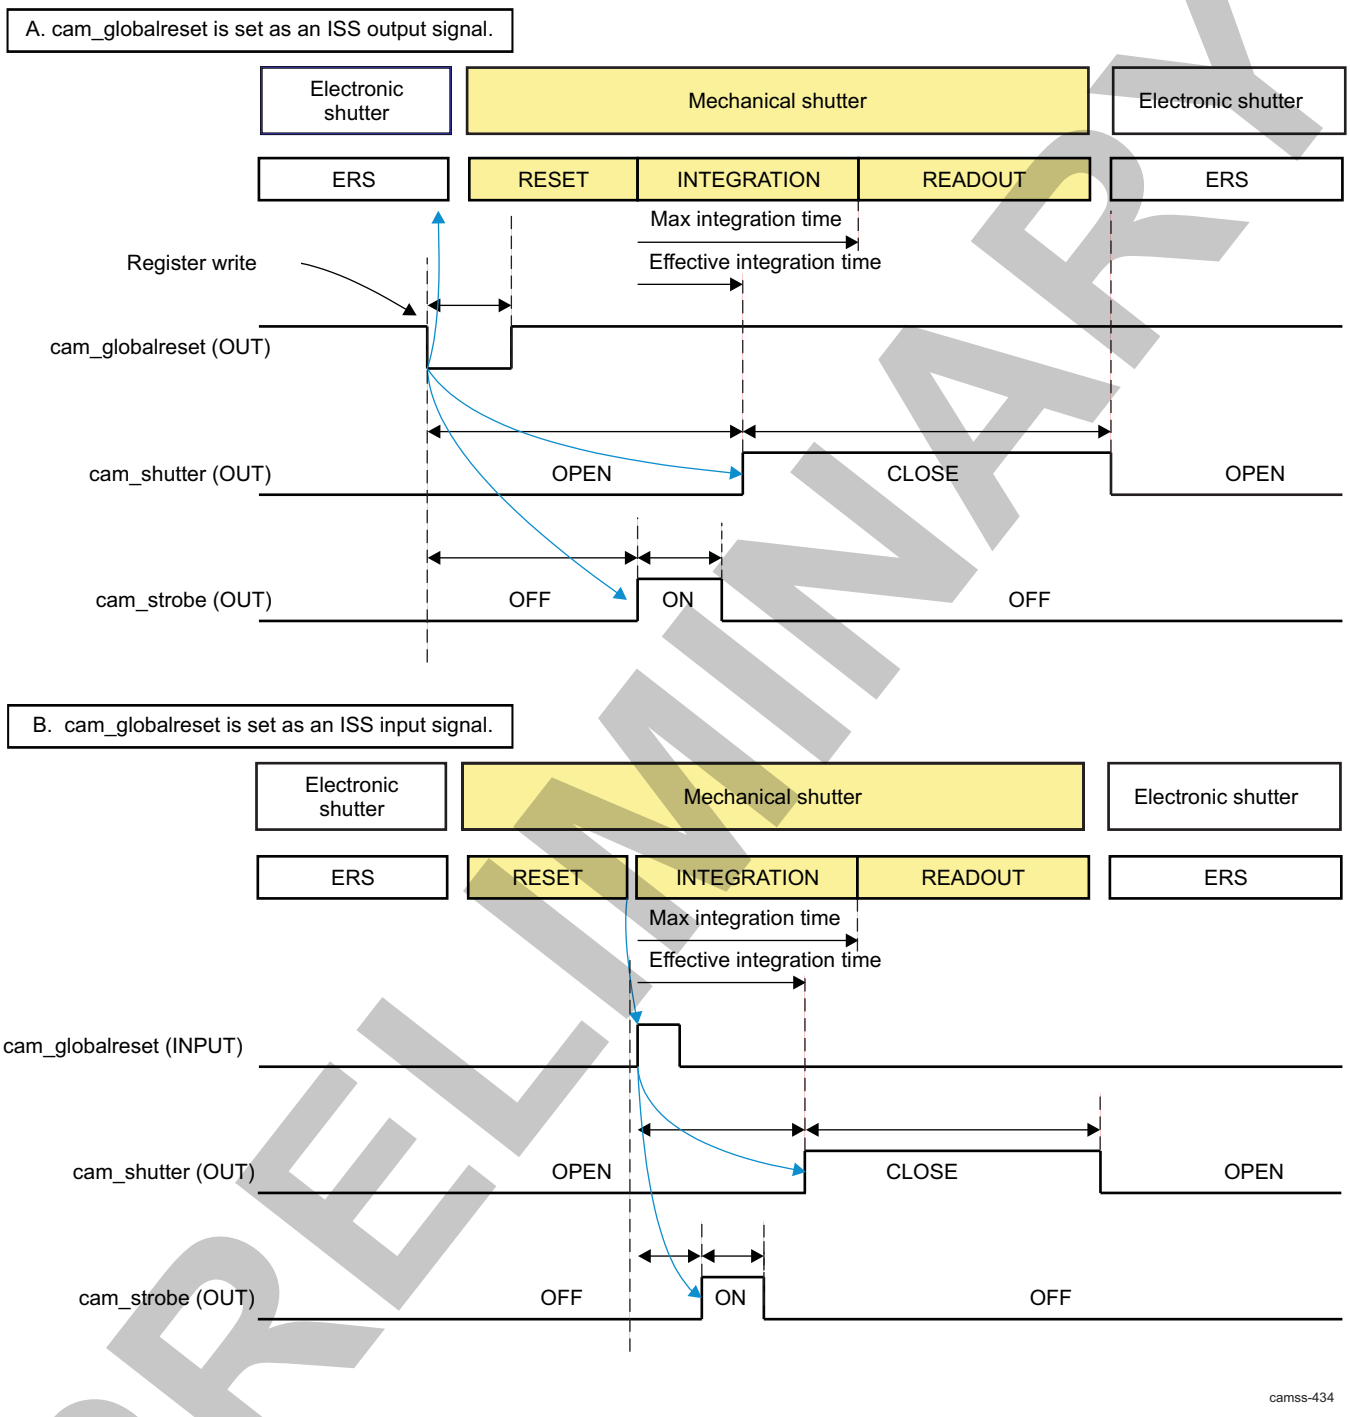
The polarity of the following signals can be individually selected:

- TCTRL_CTRL[26] STRBPSTRBPOL for the cam_strobe signals
- TCTRL_CTRL[24] SHUTPOL for the cam_shutter signal
- TCTRL_CTRL[30] GRESETPOL for cam_globalreset signal

Software can trigger the generation of cam_globalreset to the camera module. The length of signal-activation is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (the TCTRL_CTRL[29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of cam_globalreset can be selected (the TCTRL_CTRL[30] GRESETPOL bit).

Figure 8-79 shows the use of cam_globalreset set as an input or output signal. The cam_globalreset is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle.

Figure 8-79. ISS TCTRL Use of cam_globalreset With Global Reset Release Camera Modules



There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam_globalreset, cam_shutter, and cam_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

- Mechanical shutter mechanism:
  - Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
  - Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is

defined by the time between reset release and shutter close.
  - Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.
- Electronic rolling shutter (ERS) mechanism:
  - Each line of the sensor is reset separately and read after a fixed amount of time. Exposure time is defined by the time between reset and read.

8.2.6.4 ISS TCTRL Programming Model

The following settings must be done before enabling the TCTRL.

8.2.6.4.1 ISS TCTRL Camera-Control Signal Generator

Two configurations apply:

- First configuration: The control signals are based on the vertical synchronization information coming from the camera module or from externally generated cam_globalreset.
- Second configuration: The control signals are based on internally generated cam_globalreset.

8.2.6.4.1.1 ISS TCTRL Vertical Sync-Based Control-Signal Generation or Externally Generated cam_globalreset

To enable control-signal generation in the first configuration, follow the procedure listed in Table 8-212.

Table 8-212. ISS TCTRL Enabling the Control-Signal Generation in First Configuration

Step	Bit Field	Value
Select the input that triggers the control signals. The trigger signal can come from the CSI2_A, CSI2_B/CCP2, CSI2_C/CCP2, Parallel interface (CPI) or the externally generated cam_globalreset signal.	TCTRL_CTRL[28:27] INSEL	0x0: CSI2A 0x1: CSI2B or CCP2 0x2: VS signal 0x3: Global reset
	TCTRL_CTRL[20:19] INSEL_OVR	0x0: Use settings defined in INSEL 0x1: CSI2C or CCP2
Set the global reset as input signal. Writes to the TCTRL_CTRL[29] GRESETEN bit do not trigger the CAM_STROBE and CAM_SHUTTER signals and do not generate the CAM_GLOBALRESET signal.	TCTRL_CTRL[31] GRESETDIR	0x0
The following bits are cleared automatically to 0 after the signal assertion:	• TCTRL_CTRL[21] SHUTEN • TCTRL_CTRL[22] PSTRBEN • TCTRL_CTRL[23] STRBEN	
Set the polarity of the CAM_SHUTTER, CAM_STROBE, and CAM_GLOBALRESET signals.	• TCTRL_CTRL[24] SHUTPOL • TCTRL_CTRL[26] STRBPSTRBPOL • TCTRL_CTRL[30] GRESETPOL	
Set the clock divisor value, which generates the CNTCLK clock The clock is set by CNTCLK = ISS_MAIN_FCLK / TCTRL_CTRL[18:10] DIVC.	TCTRL_CTRL[18:10] DIVC	0x0: Disable CNTCLK 0 to 511: Divider
Set the frame counters.	• TCTRL_FRAME[5:0] SHUT • TCTRL_FRAME[11:6] PSTRB • TCTRL_FRAME[17:12] STRB	0: TCTRL does not delay any frame in input. 1 to 63

Table 8-212. ISS TCTRL Enabling the Control-Signal Generation in First Configuration (continued)

Step	Bit Field	Value
Set the delay counters.	• TCTRL_SHUT_DELAY • TCTRL_PSTRB_DELAY • TCTRL_STRB_DELAY	The possible values are 0 to 2^{25} - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is (2^{25} - 1) x 511/304 MHz = 56.40234948 s (TCTRL_CTRL[18:10] DIVC = 511).
Set the signal durations.	• TCTRL_SHUT_LENGTH • TCTRL_PSTRB_LENGTH • TCTRL_STRB_LENGTH	The possible values are 0 to 2^{24} - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 304 MHz input clock is (2^{24} - 1) x 511/304 MHz = 28.201173898 s (TCTRL_CTRL.DIVC = 511).
Enable the SHUTTER signal.	TCTRL_CTRL[21] SHUTEN	0x1
Enable the PRESTROBE signal.	TCTRL_CTRL[22] PSTRBEN	0x1
Enable the STROBE signal.	TCTRL_CTRL[23] STRBEN	0x1

8.2.6.4.1.2 ISS TCTRL Internally Generated cam_globalreset-Based Control-Signal Generation

To enable control-signal generation in the second configuration, follow the procedure listed in Table 8-213.

Table 8-213. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration

Step	Bit Field	Value
Select the input to global reset, to loop back the internally generated CAM_GLOBALRESET. Vertical synchronization events do not trigger the CAM_STROBE and CAM_SHUTTER signals.	TCTRL_CTRL[28:27] INSEL TCTRL_CTRL[20:19] INSEL_OVR	0x3: Global reset 0x0: Use settings defined in INSEL
Set the global reset as output signal.	TCTRL_CTRL[31] GRESETDIR	0x1
The following bits are cleared automatically to 0 after the signal assertion:	• TCTRL_CTRL[21] SHUTEN • TCTRL_CTRL[22] PSTRBEN • TCTRL_CTRL[23] STRBEN • TCTRL_CTRL[29] GRESETEN	0x0
Set the polarity of the CAM_SHUTTER, CAM_STROBE, and CAM_GLOBALRESET signals.	• TCTRL_CTRL[24] SHUTPOL • TCTRL_CTRL[26] STRBPSTRBPOL • TCTRL_CTRL[30] GRESETPOL	
Set the clock divisor value, which generates the CNTCLK clock The clock is set by CNTCLK = ISS_MAIN_FCLK / TCTRL_CTRL[18:10] DIVC.	TCTRL_CTRL[18:10] DIVC	0x0: Disable CNTCLK 0 to 511: Divider
Set the frame counters.	• TCTRL_FRAME[5:0] SHUT • TCTRL_FRAME[11:6] PSTRB • TCTRL_FRAME[17:12] STRB	0: TCTRL does not delay any frame in input. 1 to 63

Table 8-213. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration (continued)

Step	Bit Field	Value
Set the delay counters.	• TCTRL_SHUT_DELAY • TCTRL_PSTRB_DELAY • TCTRL_STRB_DELAY	The possible values are 0 to 2^{25} - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is (2^{25} - 1) x 511/304 MHz = 56.40234948 s (TCTRL_CTRL[18:10] DIVC = 511).
Set the signal durations.	• TCTRL_SHUT_LENGTH • TCTRL_PSTRB_LENGTH • TCTRL_STRB_LENGTH	The possible values are 0 to 2^{24} 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 304 MHz input clock is (2^{24} - 1) x 511/304 MHz = 28.201173898 s (TCTRL_CTRL[18:10] DIVC = 511).
Set the cam_global_reset assertion time.	TCTRL_GRESET_LENGTH	The possible values are 0 to 2^{24} - 1 cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 304 MHz input clock is (2^{24} 1) x 511/304 MHz = 28.201173898 s (TCTRL_CTRL[18:10] DIVC = 511).
Enable the CAM_SHUTTER signal.	TCTRL_CTRL[21] SHUTEN	0x1
Enable the PRESTROBE signal.	TCTRL_CTRL[22] PSTRBEN	0x1
Enable the CAM_STROBE signal.	TCTRL_CTRL[23] STRBEN	0x1
Enable the CAM_GLOBALRESET control-signal generation.	TCTRL_CTRL[29] GRESETEN	0x1

NOTE: Setting the following bits to 1 simultaneously leads to unpredictable behavior:

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN
- TCTRL_CTRL [29] GRESETEN

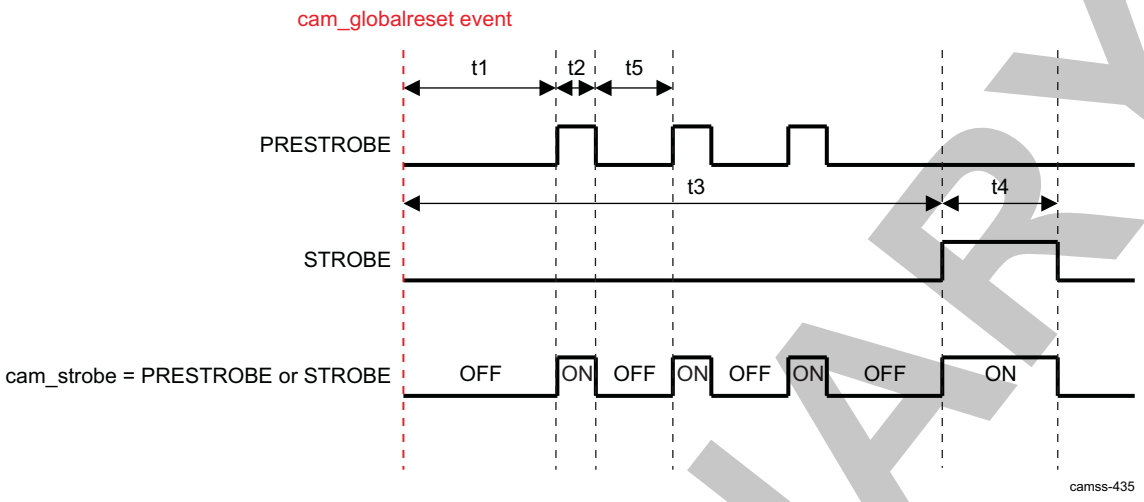
The following bits must be set before TCTRL_CTRL[29] GRESETEN is enabled:

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN

8.2.6.4.1.3 ISS TCTRL cam_strobe Signal Generation for Red-Eye Removal

The cam_strobe signal generation enables a strobe flash for red-eye removal. The process is shown in Figure 8-80. The dotted line corresponds to known timings from which the delay counters start decreasing: cam_globalreset event.

Figure 8-80. cam_strobe Signal-Generation for Red-Eye Removal



- t1: Set by the TCTRL_PSTRB_DELAY register
- t2: Set by the TCTRL_PSTRB_LENGTH register
- t5: Set by the TCTRL_PSTRB_REPLAY[24:0] DELAY bit field. The number of times the pulse is repeated is controlled by the TCTRL_PSTRB_REPLAY[31:25] COUNTER bit field.

  In the previous example, TCTRL_PSTRB_REPLAY[31:25] COUNTER = 2.

  – The possible delay values are 0 to 2^{25} - 1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is (2^{25} - 1) x 511/304 MHz = 56.402351158 s (TCTRL_CTRL[18:11] DIVC = 511).

  – The possible count values are 0 to 127 additional pulses.
- t3: Set by the TCTRL_STRB_DELAY register
- t4: Set by the TCTRL_STRB_LENGTH register

Description	TIMING CONTROL - CONTROL REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL		STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	INSEL_OVR	DIVC										RESERVED									

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the CAM_GLOBAL_RESET signal. 0x0: INPUT – CAM_GLOBALRESET is an input to the TIMING CONTROL module. The CAM_GLOBALRESET is externally generated. 0x1: OUTPUT – CAM_GLOBALRESET is an output of the TIMING CONTROL module. CAM_GLOBALRESET is internally generated. If GRESETEN is set to 1, the internally generated CAM_GLOBALRESET will trigger the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0
30	GRESETPOL	Sets the polarity of the global reset signal: CAM_GLOBALRESET. It applies whatever the direction of the CAM_GLOBALRESET signal: input or output. 0x0: active high 0x1: active low	RW	0
29	GRESETEN	Triggers the generation of the CAM_GLOBALRESET signal. The signal is asserted immediately. If enabled, the CAM_GLOBALRESET signal will be asserted for TCTRL_GRESET_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the CAM_GLOBALRESET signal is set with TCTRL_CTRL.GRESETPOL. Enabling this bit triggers the generation of the CAM_SHUTTER and CAM_STROBE signals (if previously enabled). The frame counters must be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0

Bits	Field Name	Description	Type	Reset
28:27	INSEL	Sets the mode that will trigger the SHUTTER, PRESTROBE and STROBE signals. 0x0: Synchronization event from camera 0 0x1: Synchronization event from camera 1 0x2: Synchronization event from camera 2 (serial interfaces muxed with the camera Parallel interface (CPI)) 0x3: GRESET – The CAM_GLOBALRESET input signal will trigger the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the CAM_GLOBALRESET signal is asserted. The polarity of the CAM_GLOBALRESET signal is set with TCTRL_CTRL.GRESETPOL.	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals. 0x0: Active high 0x1: Active low	RW	0
25	RESERVED		R	0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: CAM_SHUTTER 0x0: Active high 0x1: Active low	RW	0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal will be asserted after TCTRL_FRAME.STRB frames have been received and a delay of TCTRL_STRB_DELAY cycles have passed. The STROBE signal is asserted for TCTRL_STRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal will be asserted after TCTRL_FRAME.PSTRB frames have been received and a delay of TCTRL_PSTRB_DELAY cycles have passed. The PRESTROBE signal is asserted for TCTRL_PSTRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal will be asserted after TCTRL_FRAME.SHUT frames have been received and a delay of TCTRL_SHUT_DELAY cycles have passed. The SHUTTER signal is asserted for TCTRL_SHUT_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal must not be disabled by software.	RW	0
20:19	INSEL_OVR	Sets the mode that will trigger the SHUTTER, PRESTROBE and STROBE signals. 0x0: Use settings defined in INSEL 0x1: Synchronization event from camera 3 0x2: Reserved	RW	0x0
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = ISS_MAIN_FCLK / DIVC, except for some particular values shown hereafter. 0x0: No clock. CNTCLK is gated.	RW	0x000
9:0	RESERVED		R	0x000

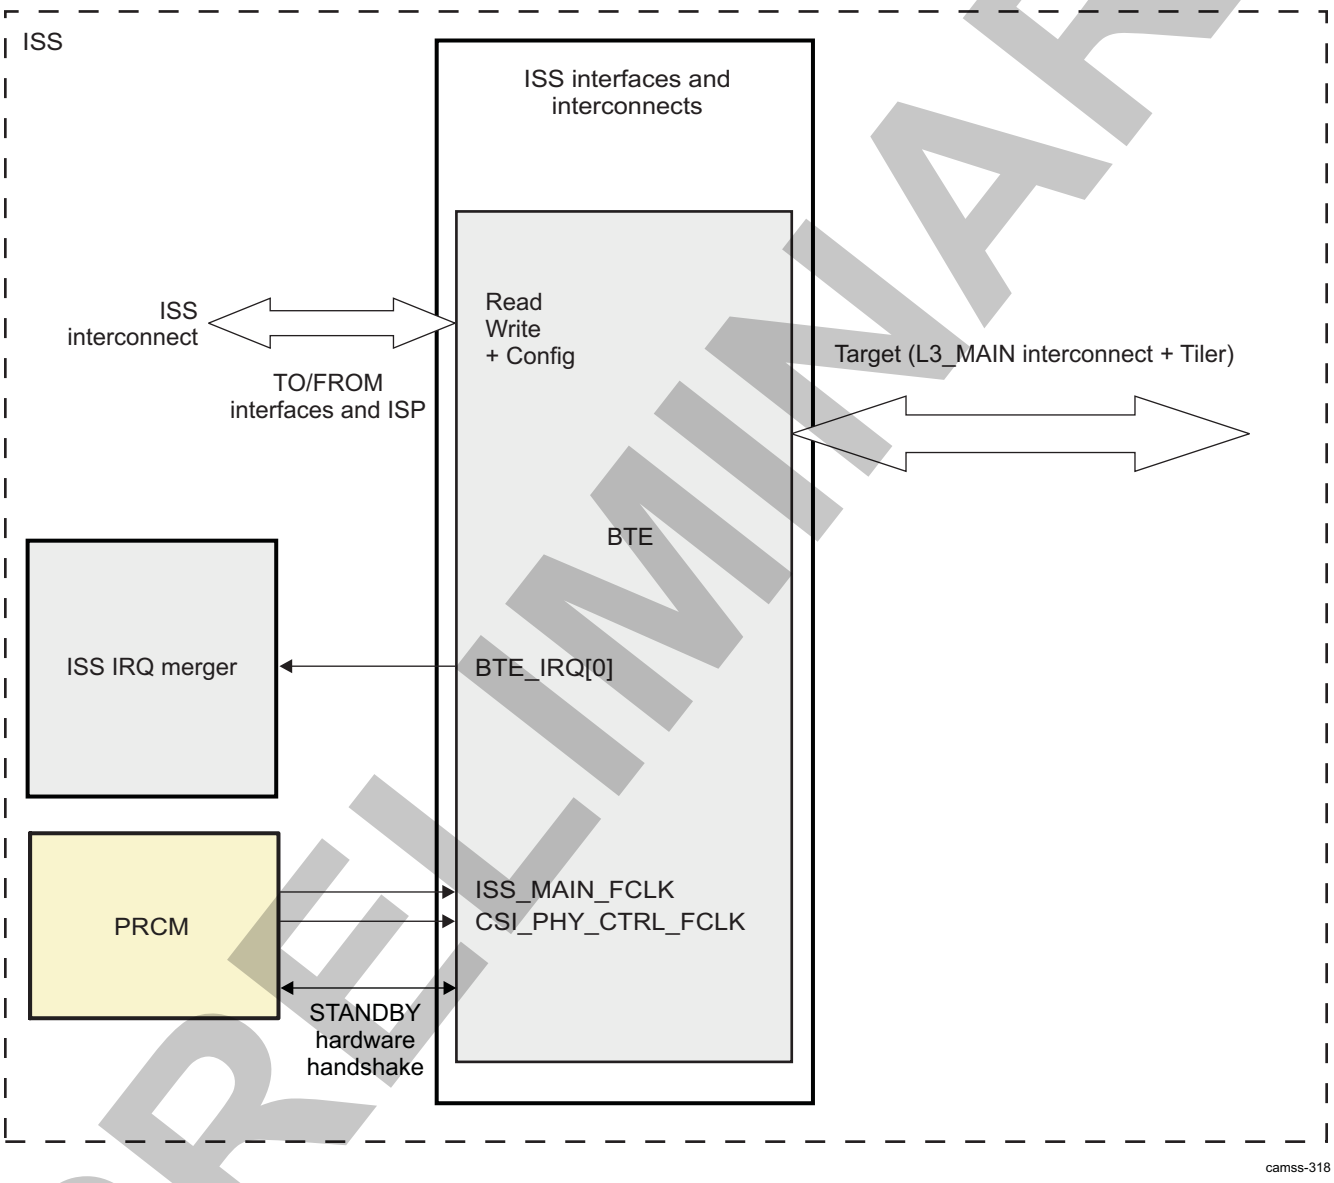
8.2.7 ISS BTE

8.2.7.1 ISS BTE Environment

There are no particular environment attributes (see Section 8.2.2, *ISS Interfaces Environment*).

8.2.7.2 ISS BTE Integration

Figure 8-81. ISS BTE Integration



For power domain, clocks, reset, and hardware requests, see Section 8.1.2.4, *ISS Power Management*.

8.2.7.2.1 ISS BTE PRCM Interface

8.2.7.2.1.1 ISS BTE Power Management

8.2.7.2.1.1.1 ISS BTE PRCM Handshake

The BTE supports the IDLE protocol to flush outstanding transactions. When an IDLE request is received, the BTE:

- Completes ongoing requests on OCPI (request, data and response phases) and stalls the port (SCmdAccept = 0)
- Flushes all contexts (same behavior than when the BTE_CONTEXT_CTRL_i[2] FLUSH bit is set by software) when the BTE_CONTEXT_CTRL_i[11] AUTOFLUSH bit is set. Otherwise, no context flushing is triggered by an IDLE request.
- Completes ongoing requests on OCPO (request, data and response phases)
- Acknowledges the IDLE request.

8.2.7.3 ISS BTE Functional Description

8.2.7.3.1 ISS BTE Features

The BTE increases access efficiency of raster initiators to tiled SDRAM. In fact, the TILER expects 2D-bursts corresponding to a row or column of subtiles for maximal efficiency. For more information about SDRAM and TILER, see Section 15.2, *Dynamic Memory Manager*.

The BTE is connected between one or multiple raster initiators. It can translate reads and writes. For reads, BTE prefetches sufficient data from tiled memory to translate raster requests. For writes, BTE buffers raster requests until is has sufficient data to generate requests to tiled memory. The features of the BTE are:

- Interfaces:
  - 32-bit-wide configuration interface (OCPC)
  - 128-bit-wide slave data port (OCPI)
  - 128-bit-wide master data port (OCPO)
- Incrementing to 2D burst translation for read and writes:
  - Four contexts. A context is a virtual frame buffer attached to a data flow requiring translation.
  - One-shot and continuous mode
- Local memories for temporal storage:
  - Cannot use external memories for temporal data storage
- Transparent for accesses that do not require translation. Requests are forwarded from OCPI to OCPO without modification.
- Local buffer

8.2.7.3.2 ISS BTE Functional Description Details

The main tasks and capabilities of the BTE are:

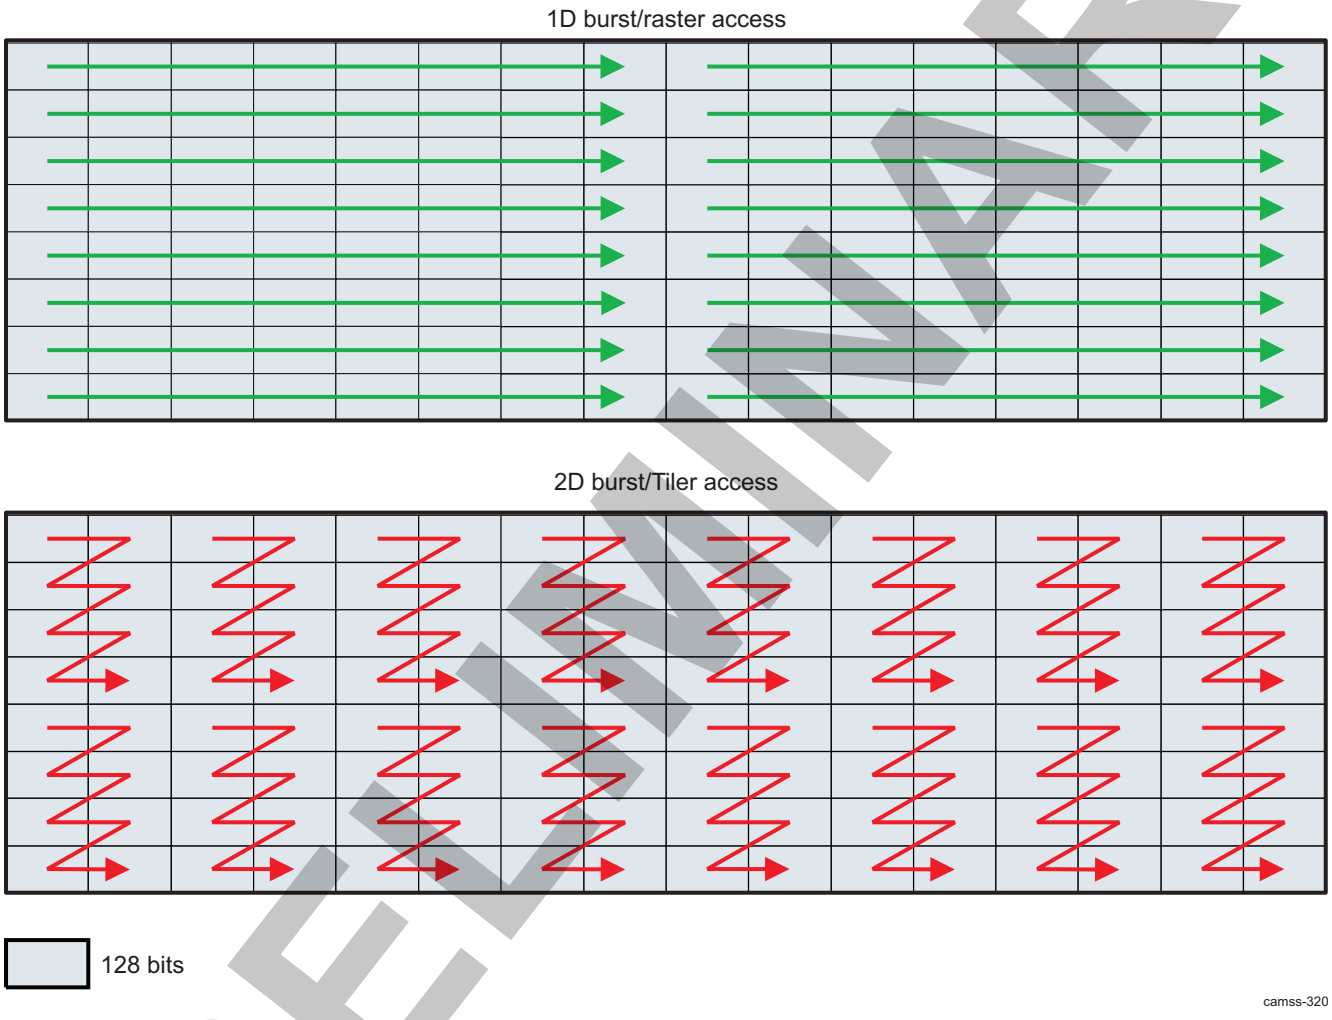
- Forward OCP transactions that do not need translation.
- For OCP writes requiring translation:
  - Store data received from OCPI to local buffers.
  - Read data from local buffers and send it to OCPO.
- For OCP read requiring translation:
  - Store data received from OCPO to local buffers.
  - Read data from local buffers and send it to OCPI.
- BTE DMA capability

8.2.7.3.2.1 ISS BTE Burst Translation Principle

The BTE receives raster accesses from the OCPI port and generates TILER accesses on OCPO.

The BTE keeps track of the amount of data written into the local memories. For translated writes, 2D bursts are sent to OCPO when there is sufficient data in the local memory to generate TILER accesses. For translated reads, 2D burst are generated to fill the local memory with data that is returned when raster accesses are received on OCPI. Figure 8-82 shows the BTE burst translation principle.

Figure 8-82. ISS BTE Burst Translation Principle



In the following sections, three address spaces are described:

- Virtual: Corresponds to the translated address region on OCPI. Accesses performed to this address space are translated by the BTE. It can be seen as a 64 KiB x 8 k lines frame buffer. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
- Physical: Corresponds to the addresses used to access the physical buffer of the BTE. The physical space is addressed in 128-bit-wide words. However, this document refers to byte addresses to preserve homogeneity.
- Tiler: Corresponds to addresses used by translated accesses. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see Section 8.2.7.3.2.5, *ISS BTE TILER Space Accesses: 2D Burst Generation*.

8.2.7.3.2.2 ISS BTE Virtual Address Space and Context Mapping

The location of the virtual space in the address map of OCPI is set by the BTE_CTRL[11:8] BASE bit field. It always occupies 64 KiB × 8k lines = 512 MiB. Software must map a virtual space into an unused region (a region, for example, that the ISS top level cannot access).

The virtual space is decomposed into contexts. A context corresponds to a 2D region in the virtual space that requires burst translation. It can also be seen as a virtual frame buffer.

Accesses to different contexts can be interleaved at OCP transaction level. OCP transactions spanning multiple contexts are not allowed.

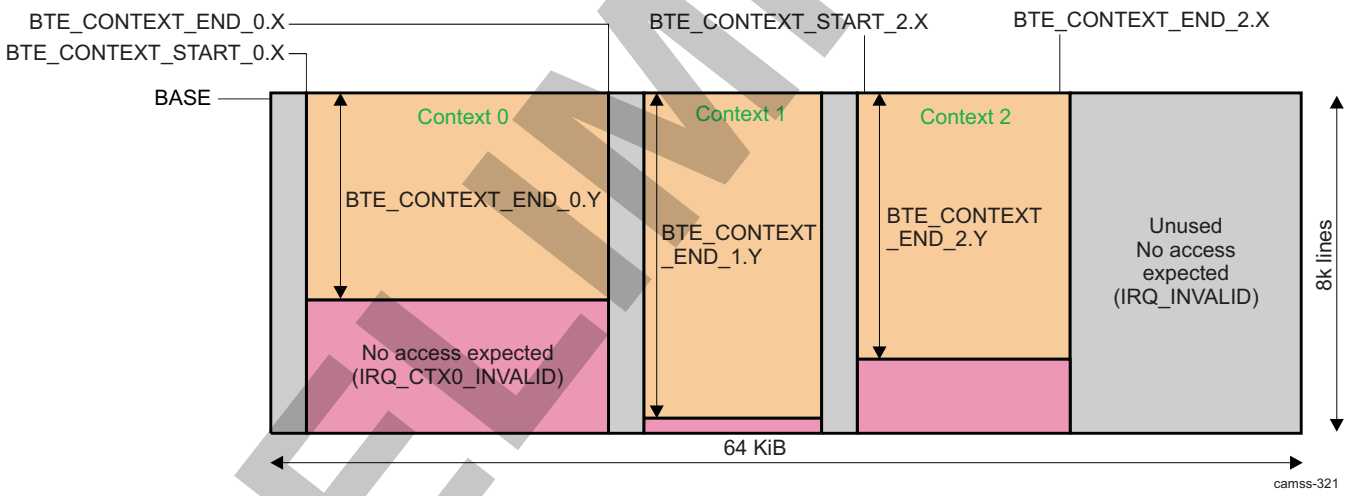
When the BTE receives an access from the OCPI port, it performs the following checks:

- If the access address is not between BASE 512 MiB and (BASE + 1) 512 MiB 1, it is handled as a transparent: request and data phases are simply forwarded to the OCPO without modification.
- If the access falls into the translated region:
  - If the access is a 2D burst, an IRQ_INVALID event is generated.
  - If the access does not map to an active context, an IRQ_INVALID event is generated. The BTE ignores bits [28:16] for this test.
  - Otherwise, context mapping is performed (see Figure 8-83).

Invalid requests are not forwarded to the OCPO.

Software must ensure that contexts do not overlap. The BTE hardware does not check for this condition. Wrong setup is likely to lead to corrupted data.

Figure 8-83. ISS BTE Context Mapping



The BTE internally keeps track of every context where the next access is expected. It internally maintains a 2D pointer, referred to as (SX_i, SY_i) in the remainder of this document. The expected byte address for an access into context x is:

ADDR = BTE_CTRL[11:8] BASE 512 MiB +
SX_i 16 bytes + SY_i 64 KiB

If an access to an unexpected location in a given context is received from OCPI, the BTE generates an IRQ_CTXx_INVALID event. The BTE provides a valid response on OCPI but does not store any data into the internal buffer. Subsequent accesses are handled normally: in other words, the BTE does not enter any specific error mode. When this happens, typically an initiator configuration is not aligned with the BTE context configuration.

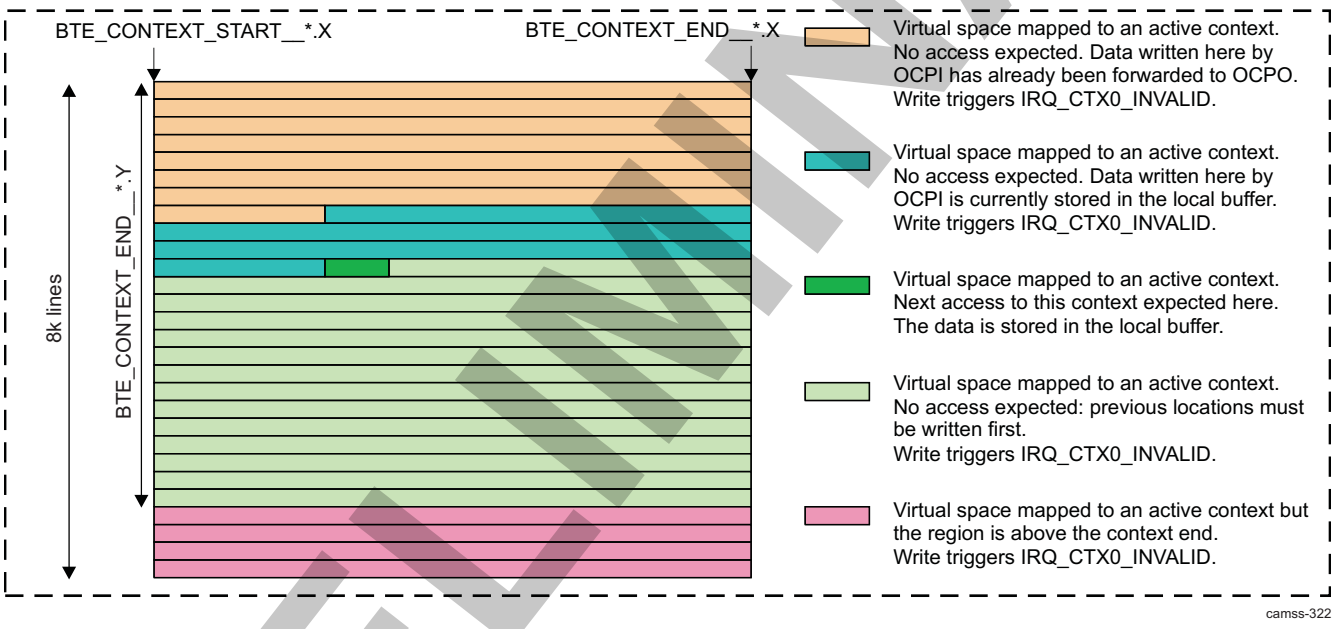
The (SX_i, SY_i) pointer of a context is updated on every access to this context. It is reset to SX_i = BTE_CONTEXT_START_i[15:7] X and SY_x = 0 when a context is enabled. SX_i is incremented by 1 for every received 16-byte word, except when it equals BTE_CONTEXT_END_i[15:4] X. In that case it is reset to BTE_CONTEXT_START_i[15:7] X and SY_i is incremented. SY_i is reset when it reaches the bottom-right corner of the context.

Therefore, the BTE can only translate raster accesses:

- Image data must be provided line by line, starting from the top-left corner of the context.
- A line stride of 64 KiB is expected.
- The maximum supported image height is 8k lines.

Figure 8-84 is an example of an active context. There is only one location in an active context where an access from OCPI is expected (green). Accesses to any other location trigger an IRQ_CTXx_INVALID event. Reads to contexts in write mode (BTE_CONTEXT_CTRL_i[7:6] MODE = 0) or writes to contexts in read mode (BTE_CONTEXT_CTRL_i[7:6] MODE = 1) trigger an IRQ_CTXx_INVALID event. When an access to an expected location is received but the burst length exceeds the context end, an IRQ_CTXx_INVALID event is triggered.

Figure 8-84. ISS BTE Expected Access Locations in the Virtual Space



Some alignment constraints are summarized as follows and are shown in Figure 8-85. They apply only to translated accesses.

- The context start addresses are aligned on 16-byte boundaries.
- The context width is aligned on 16-byte boundaries.
- The OCPI initiator must not use BYTEEN to qualify subwords in the middle of lines. The BTE interprets each BYTEEN as 0xFFFF. Access of partial words triggers an IRQ_CTXx_INVALID error.
- The line length sent by the initiator can be 1-byte aligned. The initiator can use BYTEEN to qualify valid data for the last access of the line. The BTE treats those accesses as full 16-byte writes and writes 0 data into its local buffers to complete the access. Those 0s are forwarded to OCPO when burst translation is performed. Software must ensure this data is discarded when the buffer is read back.
- The BTE does not impose any specific constraint on vertical alignment on the TILER tile and subtile grids. However, it is strongly recommended to configure the burst generation in such a way the requests performed to the TILER do not cross tile or subtile boundaries. For more information, see Section 8.2.7.3.2.5, *ISS BTE TILER Space Accesses: 2D Burst Generation*.
- The BTE accepts only one outstanding transaction per OCP tag on the OCPI port. When an initiator

tries to generate an OCP request on a tag ID that is already used (no response has been returned on OCPI), the OCPI port is stalled.

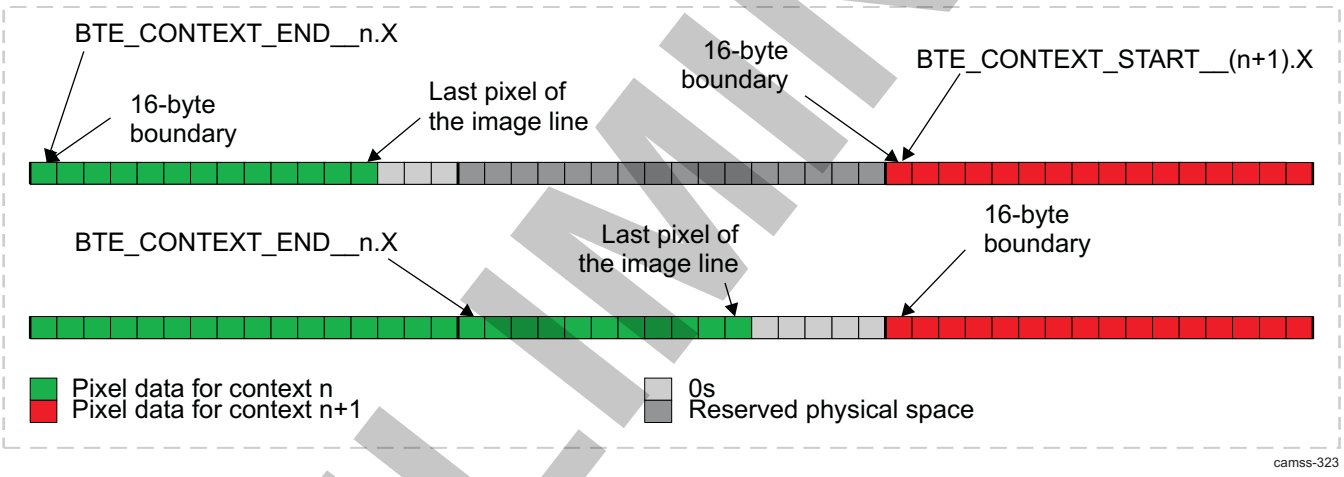
- The amount of memory allocated for each context must be a multiple of 512 bytes. Software must leave mod(BTE_CONTEXT_END_i BTE_CONTEXT_START_i + 1, 8) unused locations between the end of the context and the start of the next one. No accesses to this space from OCPI are allowed, but the BTE can use it to store data.
- While programming a BTE context, the BTE context End X value of all contexts must be less than MEMORY/64 in 128-bit address (equals MEMORY/4 in byte address)

NOTE: The generic BTE MEMORY size can be found by reading the BTE_HL_HWINFO[18:0] MEMORY bit field.

- While reading from a BTE-translated location, the CCP2 read burst size must be greater than or equal to (>=) 16 bytes (128 bits) for correct operation. Bus width translation is performed in the ISS. Therefore, 64-bit accesses lead to 128-bit accesses with BYTEEN = 0x00FF. On the BTE side, BYTEEN is always processed as 0xFFFF; thus, access to a BTE-translated 128-bit location is not correct if software uses 64-bit access.

Figure 8-85 shows the BTE context alignment constraints.

Figure 8-85. ISS BTE Context Alignment Constraints



8.2.7.3.2.3 ISS BTE TILER Context Configuration Example

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer (S = 1,/Y = 1,/X = 0). The YUV frame is made up of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the BTE_CONTEXT_BASE_i and BTE_CONTEXT_CTRL_i[12] ADDR32 bits. ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view format. Table 8-242 is an example of a BTE TILER context configuration.

Figure 8-86 shows BTE TILER mode addressing in 90- or 270-degree orientation.

Table 8-242. ISS BTE TILER Context Configuration Example

32	31	30	29	28	27	26 ... 4	3 ... 0
T	Orientation			Mode		Virtual Address	
1	S	/Y	/X	M1	M0	A26 ... A4	0

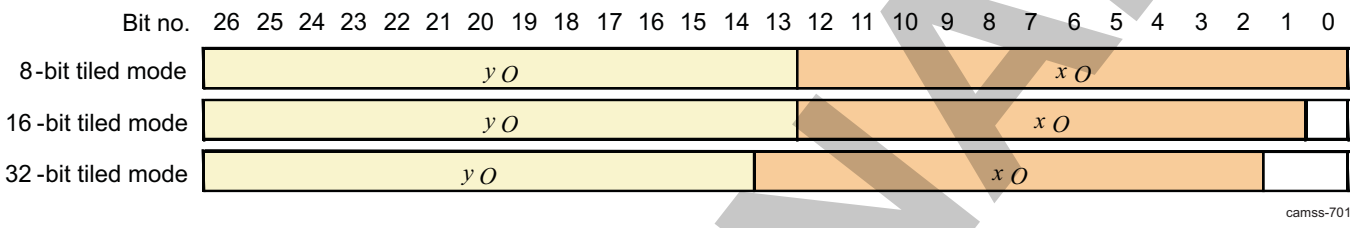
For the example described here, the following settings are used:

90-degree view, 8-bit data	ADDR[32:27] = 0b1 110 00
90-degree view, 16-bit data	ADDR[32:27] = 0b1 110 01

Software must also configure the BTE_CONTEXT_CTRL_i[9:8] GRID bit field to match the view and format set by the base address:

90-degree view, 8-bit data	GRID = 1	Stride = 8k
90-degree view, 16-bit data	GRID = 1	Stride = 8k

Figure 8-86. ISS BTE TILER Mode Addressing in 90- or 270-Degree Orientation



Bits [26:0] of the BTE_CONTEXT_BASE_i register are used to address a pixel in the virtual space of TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context register before it can start it by setting the BTE_CONTEXT_CTRL_i[0] START bit.

8.2.7.3.2.4 ISS BTE Local Memory Management

8.2.7.3.2.4.1 ISS BTE Introduction

The amount of data buffered is defined by the BTE_CONTEXT_CTRL_i[29:16] TRIGGER bit field. In write mode, translated 2D writes to OCPO are issued when the buffer fill level is greater than or equal to the value of the BTE_CONTEXT_CTRL_i[29:16] TRIGGER bit field. In read mode, translated 2D reads are sent to OCPO when the buffer level is less than the value of the BTE_CONTEXT_CTRL_i[29:16] TRIGGER bit field.

8.2.7.3.2.4.2 ISS BTE Buffer Flushing

8.2.7.3.2.4.2.1 ISS BTE One-Shot Mode

One-shot mode is enabled by setting the BTE_CONTEXT_CTRL_i[10] ONESHOT bit.

During normal operation, a data transfer from local memory to the TILER is automatically triggered when sufficient data is available in the buffer.

Three lines of data remain in the buffer once the OCPI initiator stops sending data into the context.

The BTE supports two ways to flush data remaining in the buffer:

- The last data (bottom-right corner) in a context is written. The last data is defined by the BTE_CONTEXT_END_i[15:4] X and BTE_CONTEXT_END_i[28:16] Y bit fields.
- Software writes the BTE_CONTEXT_CTRL_i[2] FLUSH bit. This is typically done when the context has been stopped before the full frame has been written.

An autoflush mode controls automatic context flushing when an IDLE request is received. It can be activated by setting the BTE_CONTEXT_CTRL_i[11] AUTOFLUSH bit to 1.

During a context flush, all remaining data in the buffer are written to the TILER.

Buffer flushing has lower priority than burst translation active contexts or forwarding transparent accesses. This prevents performance degradation.

If software wants to abort context operation at a random location, it must disable the context.

8.2.7.3.2.4.2.2 ISS BTE Continuous Mode

When continuous mode is selected (the BTE_CONTEXT_CTRL_i[10] ONESHOT bit set to 0), reception of frame n pushes the data remaining from frame 1 out of the memory to OCPO. This mode is particularly useful when vertical blanking periods are too short to perform a buffer flush at the end of the frame. Also, it avoids creating traffic peaks due to buffer flushing.

The frame height must be a multiple of eight lines and the BTE_CONTEXT_CTRL_i[14:13] INITSY bit field must be 0x0 in continuous mode.

8.2.7.3.2.4.3 ISS BTE Buffer Prefetch

The buffer must be prefilled before read requests requiring translation can be accepted. Buffer prefetch starts with the top-left corner of the frame when a context is enabled by setting the BTE_CONTEXT_CTRL_i[0] START bit. When enough lines have been prefetched, an IRQ_CTXx_DONE event is triggered to inform software that the context is ready to perform request translation. Typically, software enables the data flow requiring translation in response to this event. Context ready for transaction and last transaction can be controlled by BTE_CONTEXT_START and BTE_CONTEXT_END, respectively.

When a read request requiring translation is received while prefetch is ongoing, an IRQ_CTXx_ERR event is triggered. It informs software that the read traffic was enabled too early. The BTE returns 0s to OCPI for the failing request (it does not hold the response until real data is available).

After prefetch completion, when a request requiring translation is received but the required data is missing (the BTE is waiting for a response from OCPO), the BTE delays the response on OCPI until the missing data is received on OCPI.

This behavior avoids stalling the OCPI port for too long (that is, a prefetch of up to 3.25 lines of data). However, it avoids getting errors because of slow OCPI responses.

8.2.7.3.2.4.4 ISS BTE Bandwidth Limiter

Translated and transparent traffic has higher priority than prefetch and flushing traffic. However, overall system bandwidth is limited. Requesting too much bandwidth for prefetch and flushing traffic may increase latencies for higher priority traffic. That could affect higher priority traffic.

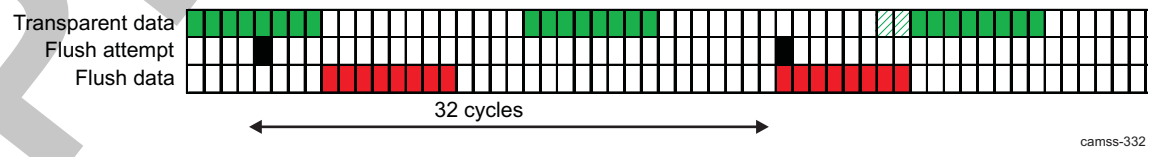
Software can limit the speed of prefetching and buffer flushing by using the BTE_CTRL[31:22] BW_LIMITER bit field. Typically, this register is used to avoid the buffer prefetch and flush traffic using all the available system bandwidth. This register does not slow down the translated or transparent traffic.

The example in Figure 8-87 assumes:

- 200-MHz functional clock
- 800 Mbps of transparent traffic = one 8 × 128-bit burst every 32 cycles

Without the bandwidth limiter, prefetch and flush traffic may use up to 3.2 0.8 = 2.4Gbps. Using BTE_CTRL[31:22] BW_LIMITER = 24 ensures that at a maximum one flush/prefetch request is issued every 32 cycles. A prefetch/flush request may be delayed by higher priority traffic of OCP port stalls. To avoid excessive traffic slowdown, the BTE tries to catch up by requesting the next flush/prefetch transaction earlier.

Figure 8-87. BTE Bandwidth Limiter Example

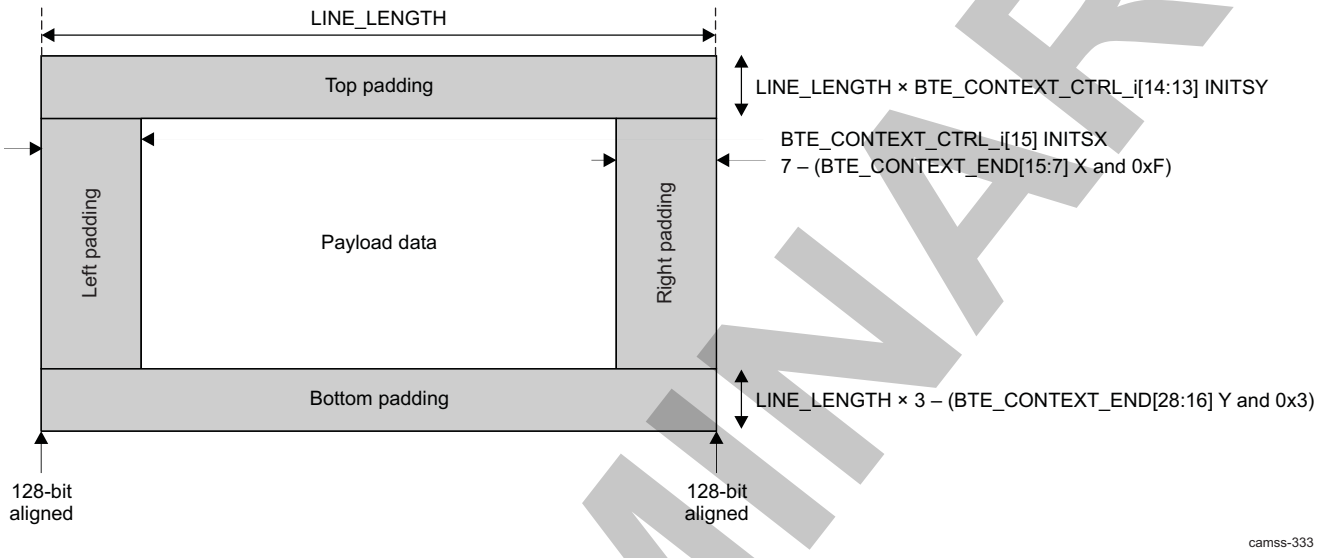


8.2.7.3.2.5 ISS BTE TILER Space Accesses: 2D Burst Generation

8.2.7.3.2.5.1 ISS BTE Buffer Fill Level

The BTE maintains an internal counter to keep track of the buffer fill level. This internal counter is used to detect when a translated OCP request is sent to the OCPO port. The counter also accounts for padding data. Figure 8-88 shows the BTE buffer fill-level padding.

Figure 8-88. ISS BTE Buffer Fill-Level Padding



In BTE context, the preferred parameter to be used is128-bit word as unit. The BTE_CONTEXT_START_i and BTE_CONTEXT_END_i registers are usually written as byte-aligned; however, the BTE_CONTEXT_START_i.X and BTE_CONTEXT_END_i.X bit fields are more readily understood (nominally) as (128 bytes = 8 x 128 bits = 8 words).

The (lower half) BTE_CONTEXT_END_i register must be written as byte-aligned, but the BTE_CONTEXT_END_i.X bit field is understood (nominally) as (128 bits = 1 word).

The BTE TRIGGER is based on word size (128 bits), but the related register (upper half) BTE_BTE_CONTEXT_CTRL_i register is not byte-aligned; it is word-aligned (128-bits).

LINE_LENGTH = ((BTE_CONTEXT_END_i[15:4] X) – BTE_CONTEXT_START_i[15:7] X) 4) & 0xFF8 + 8

NOTE: LINE_LENGTH is measured as a 128-bit word and can be used directly for TRIGGER calculation (3 * LINE_LENGTH + x)

Example 1: 64 x 15 pixels line = 64 x 15 Nb bytes in a line

(Nb bytes in a line – 16(128-bit word)) 4 = 0x3B

LINE_LENGTH = (0x3B & 0xFF8) + 8 = 0x40

TRIGGER = 0x40 * 3 + 2 = 0xC2

Example 2: 64 x 11 pixel line = 64 x 11 Nb bytes in a line

(Nb bytes in a line – 16(128-bit word)) 4 = 0x2B

LINE_LENGTH = (0x2B & 0xFF8) + 8 = 0x30

TRIGGER = 0x30 * 3 + 2 = 0x92

Figure 8-88 is a visual representation of the following explanation about how read or write events are triggered determined by the internal buffer size.

When context is started, the buffer fill level is initialized to LINE_LENGTH × BTE_CONTEXT_CTRL_i[14:13] INITSY + BTE_CONTEXT_CTRL_i[15] INITSX (see the previous equation for the LINE_LENGTH calculation). If the BTE reads or writes, the level of the internal buffer is incremented or decremented, respectively, by the burst size. Here, only full 16-byte accesses are performed. Other OCP BYTEEN patterns are forced to 0xFF.

The BTE_CONTEXT_CTRL_i [29:16] TRIGGER bit field triggers a buffer level read or write even. In write mode, if flushing, the data level is greater than 0; if not flushing, the BTE translates to OCPO when the level is greater than or equal to the value set by the register. If the level is smaller than the BTE_CONTEXT_CTRL_i[29:16] TRIGGER software setup, then the BTE reads data.

8.2.7.3.2.5.2 ISS BTE OCP Request Generation

Except on borders:

- TILER bursts are 32 bytes × 4 lines of data blocks.
- Bursts are aligned on subtile boundaries.

The BTE maintains an internal 2D pointer (DX_i, DY_i) that corresponds to the top-left corner of the next access to be issued to the TILER. It is initialized to (0, 0) when a context is enabled or wraps around. It is updated each time an access to the TILER is performed.

Table 8-243 lists all supported TILER formats and views.

Table 8-243. ISS BTE Supported TILER Formats and Views

Modes	View			Description	OFST	Subtile Grid		1 KiB Tile Grid		X		Y		GRID	Subtile Aligned		Tile Aligned	
	S	/Y	/X			X	Y	X	Y	LSB	MSB	LSB	MSB		X	Y	X	Y
8-bit	0	0	0	0-degree view	16384	4	4	32	32	0	13	14	26	0	[1:0]	[15:14]	[4:0]	[18:14]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	8192	4	4	32	32	0	12	13	26	1	[1:0]	[14:13]	[4:0]	[17:13]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														
16-bit	0	0	0	0-degree view	32768	8	2	64	16	0	14	15	26	2	[2:0]	[15]	[5:0]	[18:15]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	8192	4	4	32	32	0	12	13	26	1	[1:0]	[14:13]	[4:0]	[17:13]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														
32-bit	0	0	0	0-degree view	32768	8	2	64	16	0	14	15	26	2	[2:0]	[15]	[5:0]	[18:15]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	16384	8	2	64	16	0	13	14	26	3	[2:0]	[14]	[5:0]	[17:14]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														

The BTE_CONTEXT_BASE_i and BTE_CONTEXT_CTRL_i[9:8] GRID registers must the configured by software to choose the format and view. The format must match the data stored into the virtual space. The choice of the view depends on the desired behavior.

The GRID bit field controls the used OCP stride and OCP address generation. The OCP address is generated using the following formula:

OCP_ADDR = BTE_CONTEXT_BASE_n + DX_x + DY_x << Y_LSB

Y_LSB corresponds to the Y LSB column of Table 8-243.

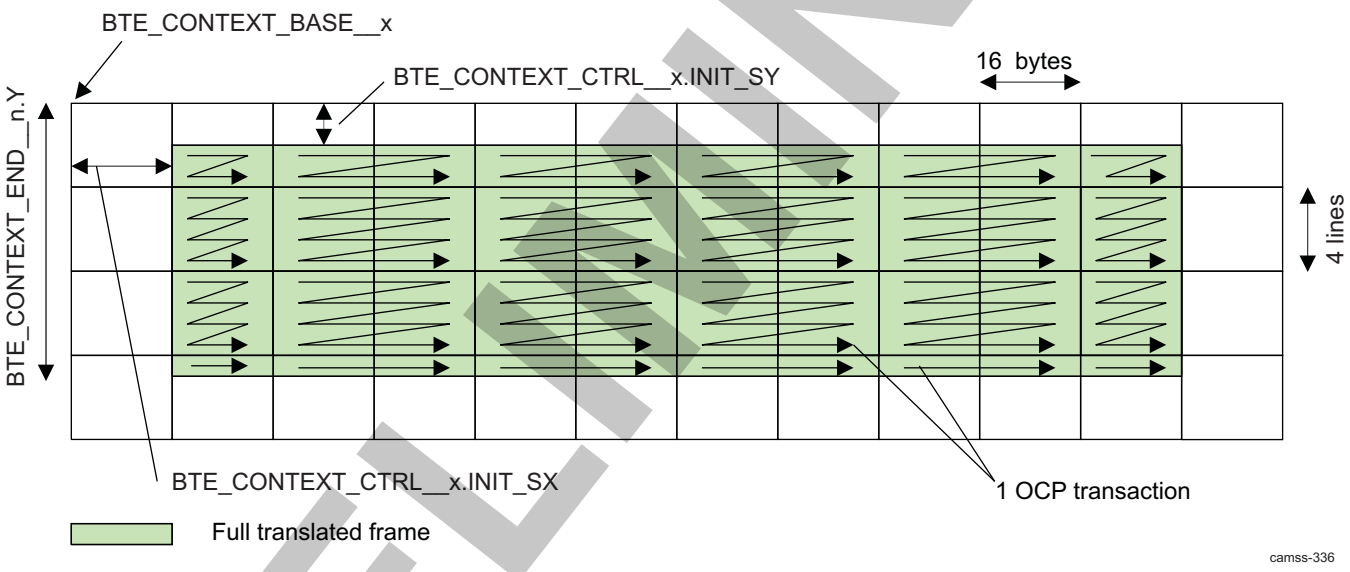
The OCP stride corresponds to the OFST column of Table 8-243. The tile and subtile grid information is currently not used by hardware.

The BTE does not automatically realign 2D bursts on tile or subtile boundaries. However, software can force the (SX_i, SY_i) (see Section 8.2.7.3.2.4, *ISS BTE Local Memory Management*, for the definition of SY_i) reset value to be used. It is set through the BTE_CONTEXT_CTRL_i[15] INITSX bit and the BTE_CONTEXT_CTRL_i[14:13] INITSY bit field.

The length and height of the 2D burst is adapted by the BTE to avoid sending dummy data to the TILER.

Figure 8-89 is an example of BTE 2D burst generation. The vertical start and end of the full 2D frame are not vertically aligned on the grid.

Figure 8-89. ISS BTE 2D Burst Generation



8.2.7.3.2.6 ISS BTE Posted and Nonposted Write Support

The BTE can handle posted and nonposted writes received on OCPI. Normally, only nonposted writes will be used.

For transparent accesses, posted and nonposted writes are forwarded to OCPO. The response provided by OCPO is returned to OCPI.

For translated accesses, the response to posted and nonposted writes is provided by the BTE. It does not wait for the response of the translated request that is sent to the TILER. In other words, the BTE has no true nonposted write support for translated accesses. The BTE does not ensure that the data has effectively been written to the destination memory when it returns the response to a nonposted translated write.

True nonposted write support is ensured for transparent accesses. Only nonposted writes must be used. Select nonposted write mode through the BTE_CTRL[5] POSTED bit.

8.2.7.3.2.7 ISS BTE Error Reporting

Unexpected accesses are flagged using interrupts. Also, when an SResp = ERR is received on OCPO, an interrupt is triggered. If the response corresponds to a transparent access, it is forwarded to OCPI.

The BTE is not an OCP checker: It expects only valid and supported transactions from the external world.

Also, it is not intended to detect all types of software errors; few cases are detected. Those cases are described in the functional description sections.

8.2.7.3.2.8 ISS BTE Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be enabled from ISS level by the ISS_HL_IRQENABLE_SET_i[11] BTE_IRQ bit. Table 8-244 lists the BTE interrupt events.

Table 8-244. ISS BTE Interrupt Events

Event	Description
IRQ_OCP_ERR	OCP error received from OCPO master port
IRQ_INVALID	An access to a location that is not mapped to any context has been performed. For more information, see Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
IRQ_CTXx_DONE	Context has been fully transferred to the TILER. This interrupt is triggered when flushing completes in one-shot mode. It is triggered once per frame in continuous mode.
IRQ_CTXx_INVALID	Unexpected address sequence or access direction (read of a context in write mode or write of a context in read mode). For more information, see Section 8.2.7.3.2.2, *ISS BTE Virtual Address Space and Context Mapping*.
IRQ_CTXx_ERR	Can occur only when a context is configured in read mode. This request triggers when a read request is received but insufficient data is buffered to perform the translation. For more information, see Section 8.2.7.3.2.4.3, *ISS BTE Buffer Prefetch*.

8.2.7.3.2.9 ISS BTE Debug Support

The BTE has no specific debug support.

8.2.7.4 ISS BTE Programming Model

8.2.7.4.1 ISS BTE Reset

The BTE can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the BTE_HL_SYSCONFIG[0] SOFTRESET bit to 1.
2. Read the BTE_HL_SYSCONFIG[0] SOFTRESET bit to check whether it is set to 1, which means the reset occurred.

If after five reads, the BTE_HL_SYSCONFIG[0] SOFTRESET bit still returns 0, assume that an error occurred during the reset stage.

Programmers must not set the BTE_HL_SYSCONFIG[0] SOFTRESET bit to 1 if the BTE is integrated in a subsystem; it is safer to use the software reset at subsystem level.

NOTE: A software reset does not reset the IDLE protocol signals.

8.2.7.4.2 ISS BTE Interrupts

All events are mapped to a single interrupt output, BTE_IRQ. Table 8-245 lists the procedure to configure or manage the BTE interrupts.

Table 8-245. ISS BTE Configure/Manage Interrupts

Step	Bit Field	Value
Each event that generates an interrupt can be individually enabled by setting the appropriate bit.	BTE_HL_IRQENABLE_SET	
Each event that generates an interrupt can be individually disabled by setting the adequate bit.	BTE_HL_IRQENABLE_CLR	
When an event occurs, the corresponding bit in the BTE_HL_IRQSTATUS_RAW register is set, regardless of whether or not the event is enabled. Bits in the BTE_HL_IRQSTATUS registers are set only when an enabled event occurs.	BTE_HL_IRQSTATUS_RAW and BTE_HL_IRQSTATUS	
Software can clear a pending event by setting the adequate bit in the BTE_HL_IRQSTATUS register.	BTE_HL_IRQSTATUS	

8.2.7.4.3 ISS BTE Context Configuration

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer (S = 1,/Y = 1,/X = 0). The YUV frame consists of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the BTE_CONTEXT_BASE_i and BTE_CONTEXT_CTRL_i[12] ADDR32 registers.

ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view and data format. Table 8-246 gives the format of the TILER address. Figure 8-90 shows BTE tiled mode addressing in 90- or 270-degree orientation.

Table 8-. TILER Address Format

32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T	Orientation			Mode		Virtual Address																										
1	S	⊳	⊱	M1	M0	A26 ... A4																			0							

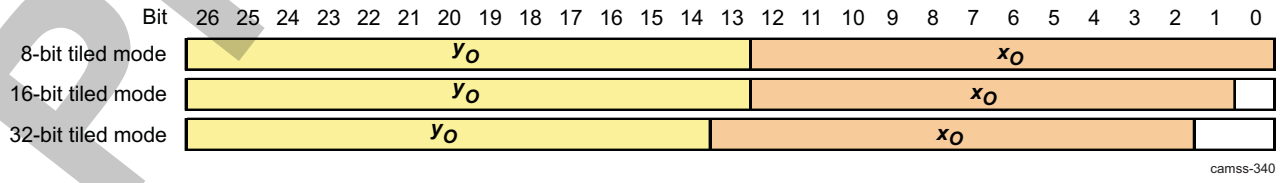
For the example described here, the following settings are used.

90-degree view, 8-bit data ADDR[32:27] = 0b1 110 00
90-degree view, 16-bit data ADDR[32:27] = 0b1 110 01

Software must also configure the BTE_CONTEXT_CTRL_i[9:8] GRID bit field to match the view and format set by the base address:

90-degree view, 8-bit data GRID = 1 Stride = 8k
90-degree view, 16-bit data GRID = 1 Stride = 8k

Figure 8-90. ISS BTE Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)



Bits [26:0] of the BTE_CONTEXT_BASE_i register are used to address a pixel in the virtual space of the TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context registers before it can start it by setting the BTE_CONTEXT_CTRL_i[0] START bit.

8.2.7.4.4 ISS BTE Change Context Configuration

All contexts operate independently. Software can change the configuration of an inactive context while other contexts are active and perform request translation.

When software must change the configuration of an active context, it must follow the sequence in Table 8-247.

Table 8-247. ISS BTE Change Context Configuration

Step	Bit Field	Value
Ensure that the initiator does not send any more data to this context until it is re-enabled.		
Disable the context. • The STOP condition is considered on a valid OCP boundary. • It preserves the internal states so that buffer flushing can be done. • The BTE no longer translates requests received for this context. Any transactions received for an inactive context trigger error interrupts. • The BTE completes all outstanding transactions on OCPO.	BTE_CONTEXT_CTRL_i[1] STOP	0x1
Flush all remaining data for the context, if needed. If software simply wants to abort the transfer to recover from some error condition, flushing is not needed. The context is automatically reset when it is enabled again.	BTE_CONTEXT_CTRL_i[2] FLUSH	0x1
Wait until the context completes pending OCP transaction and buffer flush (if enabled). It sets the IRQ_CTXx_DONE when it becomes idle.	BTE_HL_IRQSTATUS. IRQ_CTXx_DONE	Read 0x0
Change the context configuration.		
Enable the context by setting the BTE_CONTEXT_CTRL_i[0] START bit. Setting the START bit resets the internal state-machine of the context.	BTE_CONTEXT_CTRL_i[0] START	0x1

Alternatively, software can change the context mode to one-shot and wait until the CTXx_DONE_IRQ is triggered.

NOTE: Once a context is disabled it cannot be resumed simply by writing the START bit. In fact, doing so resets the internal FSM. If data is lost in the buffer, it will be lost.

Table 8-264. BTE_CTRL

Address Offset	0x0000 0030		
Physical Address	0x5200 2030	**Instance**	ISS_BTE
Description	BTE control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BW_LIMITER								RESERVED								BASE								RESERVED		POSTED	RESERVED	TAG_CNT			

Bits	Field Name	Description	Type	Reset
31:22	BW_LIMITER	Minimum number of OCP cycles between two consecutive buffer flushing or prefetch requests. Used to limit the bandwidth used to fill/empty buffers. 0: Maximum speed. Up to 1 request every 8 cycles (3.2GB @ 200 MHz) 1: Up to 1 request every 9 cycles. 1023: Minimum speed. Up to 1 request every 1031 cycles (24MB @ 200 MHz)	RW	0x000
21:12	RESERVED		R	0x000
11:8	BASE	Base address of the virtual space translated by the BTE. Start address = BASE*512MB End address = (BASE+1)*512MB – 1 For example: BASE=3 => 0x 0 6000 0000 - 0x 0 7FFF FFFF	RW	0x0
7:6	RESERVED		R	0x0
5	POSTED	Select among posted and nonposted writes for translated requests. 0x0: Use non posted writes 0x1: Use posted writes	RW	0
4	RESERVED		R	0
3:0	TAG_CNT	BTE could use up to TAG_CNT+1 tags on OCPO. There could only be one outstanding request per tag. TAG_CNT does not control the number of requests it could handle on OCPI. This register is internally shadowed. Modifications are taken into account when there are no outstanding transactions on OCPO. TAG ID 0 to TAG_CNT are used on OCPO.	RW	0xF

8.2.8 ISS CBUFF

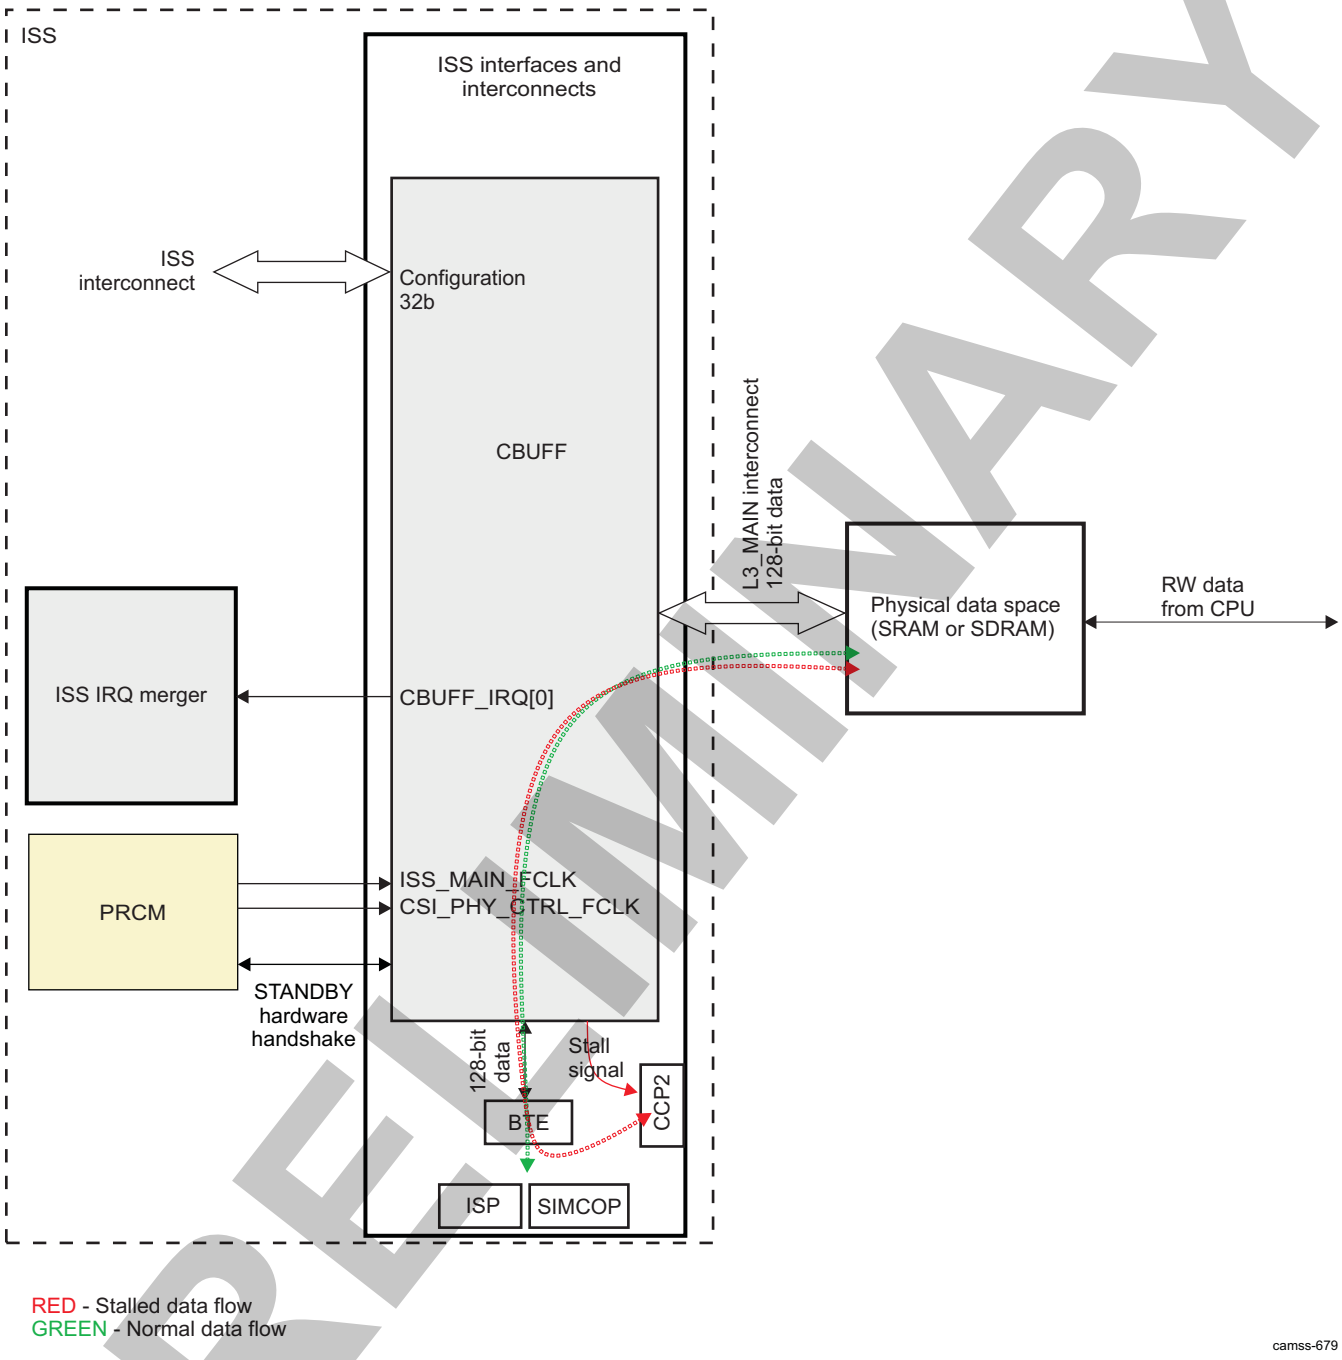
8.2.8.1 ISS CBUFF Environment

There are no particular environment attributes. See Section 8.2.2, *ISS Interfaces Environment*.

8.2.8.2 ISS CBUFF Integration

Figure 8-91 shows the integration of the CBUFF in the ISS. Because the CBUFF maps a virtual memory space from the physical memory, it therefore communicates with the ISS ISP and ISS interface modules for data to and from memory. This figure shows the normal data flow for further processing by the ISP and/or still-image coprocessor (SIMCOP) (in green) and the stall functionality of CBUFF (in red), which stall the data for a certain amount of time. An example of stalling is when the ISP processes the data faster than the input from CCP2 to memory. The CBUFF then must stall the data flow until a sufficient amount of data can be read from memory by the ISP.

Figure 8-91. ISS CBUFF Integration



For power domain, clocks, reset, and hardware requests, see Section 8.1.2.4, *ISS Power Management*.

8.2.8.2.1 ISS CBUFF PRCM Interface

8.2.8.2.1.1 ISS CBUFF Reset and Idle Mechanism

A reset signal is provided by the PRCM module to the top-level ISS power and clock-management module.

For standby, when none of the ISS modules require CBUFF execution actions, ISS PM executes the standby sequence, which reaches the CBUFF. When an IDLE request arrives, the CBUFF data is drained. After all transactions are drained, the CBUFF acknowledges the IDLE request to the ISS PM/CM. The IDLE request/acknowledge steps are:

When an IDLE request is received in smart-idle mode:

1. CBUFF stops accepting any new OCP requests on a clean OCP transaction boundary.
2. Waits until the interrupt output becomes inactive (no more enabled event pending)
3. Waits until all outstanding OCP transactions are complete on OCPO and OCPI. CBUFF keeps track of issued requests, data phases, and responses for that purpose.
4. CBUFF disconnects the OCPO port.
5. CBUFF acknowledges the IDLE request.

When a wake-up request is received in smart-idle mode:

1. CBUFF connects the OCPO port.
2. Starts accepting new requests from OCPI
3. Acknowledges the functional state

Idle mode is controlled through the CBUFF_HL_SYSCONFIG[3:2] IDLEMODE bit field. For software reset, it is recommended to use the global ISS reset; if a reset is required, it can be set from the CBUFF_HL_SYSCONFIG[0] SOFTRESET bit.

8.2.8.2.2 ISS CBUFF Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be mapped to the MPU subsystem by enabling the ISS_HL_IRQENABLE_SET_i[10] CBUFF_IRQ bit. Table 8-276 lists the procedure to manage CBUFF interrupts.

Table 8-276. ISS CBUFF Interrupt Management

Description	Bit Field	Value
Each event that generates an interrupt can be individually enabled by setting the appropriate bit.	CBUFF_HL_IRQENABLE_SET	
Each event that generates an interrupt can be individually disabled by setting the appropriate bit.	CBUFF_HL_IRQENABLE_CLR	
When an event occurs, the corresponding bit in the CBUFF_HL_IRQSTATUS_RAW register is set regardless of whether or not the event is enabled. Bits in the CBUFF_HL_IRQSTATUS registers are only set only when an enabled event occurs	CBUFF_HL_IRQSTATUS_RAW and CBUFF_HL_IRQSTATUS	
Software can clear a pending event by setting the appropriate bit in the CBUFF_HL_IRQSTATUS register.	CBUFF_HL_IRQSTATUS	

The CBUFF can generate three events per context and one global event. All events are merged into one physical interrupt line. Table 8-277 describes the CBUFF-generated events.

Table 8-277. ISS CBUFF-Generated Events

Event	Description
IRQ_CTXx_READY	Read mode: CPU can write data to the physical window pointed by CBUFF_CTX_STATUS_i[3:0] WB.
	Write mode: CPU can read data from the physical window pointed by CBUFF_CTX_STATUS_i[3:0] WB.
	Read/write mode: The OCPI initiator has completed writing a physical window.
IRQ_CTXx_INVALID	Invalid access
	OCPI writes the virtual space of context i in read mode.
	OCPI reads the virtual space of context i in write mode.
	OCPI writes the virtual space of context i outside the CBUFF_CTX_STATUS_i[11:8] WA window in write or read/write mode.

Table 8-277. ISS CBUFF-Generated Events (continued)

Event	Description
	OCPI reads the virtual space of context i outside the CBUFF_CTX_STATUS_i[11:8] WA window in read mode.
	OCPI reads the virtual space of context i outside the CBUFF_CTX_STATUS_i[3:0] WB window in read/write mode.
	CPU writes the DONE bit when physical windows are not ready for the CPU.
	This event indicates a wrong configuration of the CBUFF, the OCPI initiator or bogus software. When it happens, context i goes into an error state. In this state all accesses to the virtual space of context i are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory. Of course, the CBUFF still returns OCP responses to OCPI to ensure the integrity of the OCP.
	The error state can be left by disabling the context i and re-enabling it. Before doing so, software must ensure that there are no more outstanding requests to the virtual space of context i.
IRQ_CTXx_OVR	Physical space overflow or underflow event This event indicates a bandwidth mismatch between data producer and data consumer. When it happens, context i does not go into error state. However, the data in the physical space is likely to be corrupted.
IRQ_OCP_ERR	OCP error received in the OCPO master port. The OCP response is forwarded to OCPI normally.

8.2.8.3 ISS CBUFF Functional Description

The CBUFF maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

8.2.8.3.1 ISS CBUFF Features

The ISS CBUFF features are:

- Fully transparent for accesses out of the configured virtual space
- Three functional modes:
  - Read mode: Read requests received from OCPI and forwarded after translation to OCPO. Writes are handled by an external process and acknowledged by the CPU.
  - Write mode: Write request received from OCPI and forwarded after translation to OCPO. Reads are handled by an external process and acknowledged by the CPU.
  - Read/write mode: Read and write requests received from OCPI and forwarded after translation to OCPO
- Four independent contexts
- Virtual address space (linear) mapped into a physical space (circular)
- Maximum physical buffer size of 16 × 16 MiB:
  - Physical space consists of 2, 4, 8, or 16 windows.
  - Maximum allowed window size is 16 MiB.
- Support of 2D addressing modes
- Strong error detection mechanisms to prevent data corruption caused by bogus configuration
- Addresses are 128-bit aligned, but window fill level managing is byte accurate
- Bandwidth control feedback loop to stall in initiator connected to OCPI

8.2.8.3.2 ISS CBUFF Functional Description

The CBUFF maps a virtual address space to a physical space also called circular buffer.

The CBUFF can handle up to eight contexts. For most data formats, primarily four contexts are used. In cases where YUV4:2:0 data is exchanged, two contexts are consumed by the SIMCOP (JPEG encode) coming from the resizer module, which is the ISP output module. Moreover, a context is a virtual full-frame buffer that maps to a configurable number of physical windows.

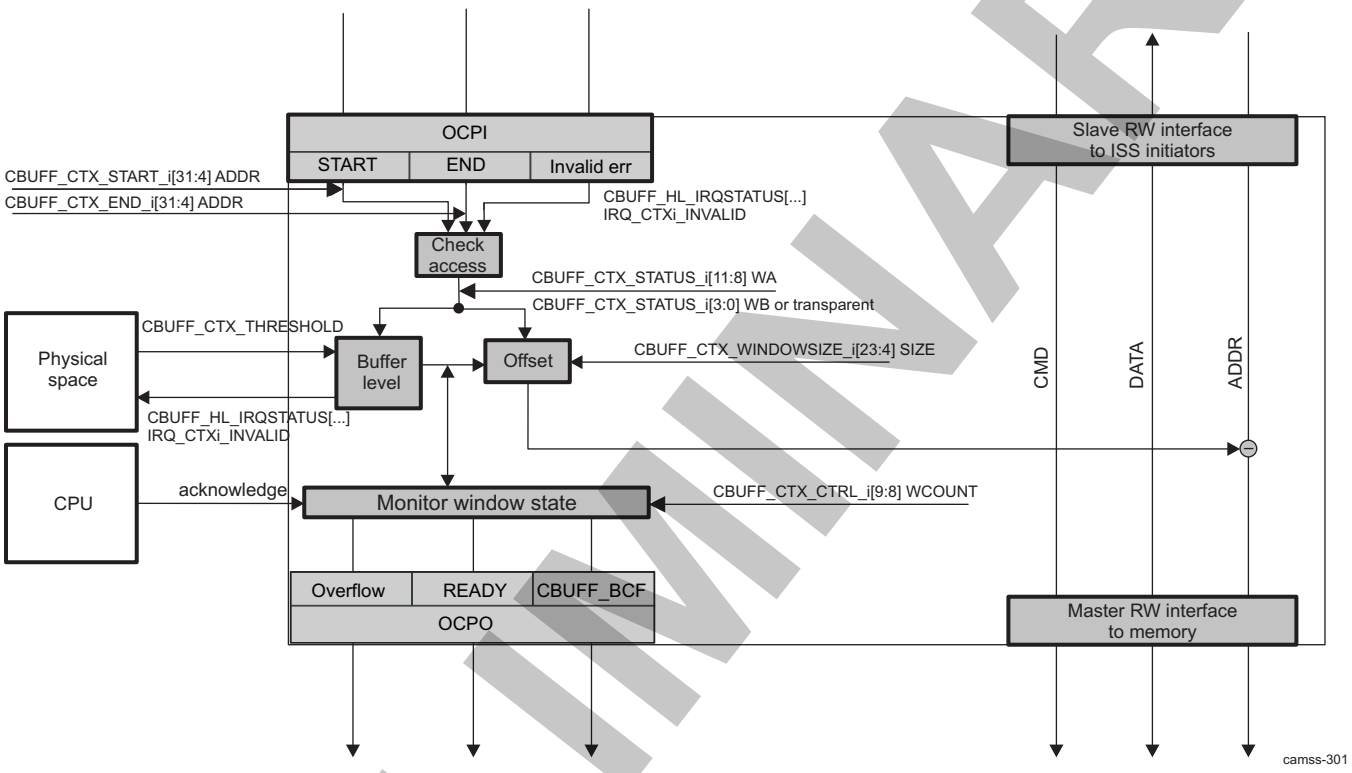
This section gives an overview of typical uses of the CBUFF.

8.2.8.3.2.1 ISS CBUFF Top-Level Diagram

Figure 8-92 shows the functional principle diagram. It does not include an exhaustive list of the interface signals or internal status registers.

A more detailed functional description is provided in the following sections.

Figure 8-92. ISS CBUFF Top-Level Diagram



8.2.8.3.2.2 ISS CBUFF Functional Modes

The CBUFF supports three functional modes (see Table 8-278).

Table 8-278. ISS CBUFF Functional Modes

Mode	Data Written by	Data Read by
Write mode	ISS initiator	CPU-controlled process
Read mode	CPU-controlled process	ISS initiator
Read/write mode	ISS initiator	ISS initiator

8.2.8.3.2.2.1 ISS CBUFF Write Mode

In write mode, the physical space is written by the CBUFF and it is read by the CPU. An IRQ_CTXx_READY event is set each time a physical window is available to be read by the CPU. This happens when the CBUFF_CTX_STATUS_i[11:8] WA pointer is moved by the CBUFF.

The CBUFF sets an IRQ_CTXx_READY event to inform the CPU that it can access the CBUFF_CTX_STATUS_i[3:0] WB physical window. The CBUFF cannot monitor CPU accesses to the physical window. The CPU must indicate when it has completed the processing of the CBUFF_CTX_STATUS_i[3:0] WB window by setting the CBUFF_CTX_CTRL_i[2:1] DONE bit field. This increments the window index CBUFF_CTX_STATUS_i[3:0] WB by one modulo the window count (defined by the CBUFF_CTX_CTRL_i[9:8] WCOUNT bit field).

The CBUFF ensures that one IRQ_CTXx_READY event is sent to the CPU per physical window to be read. In other words, when a new IRQ_CTXx_READY event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

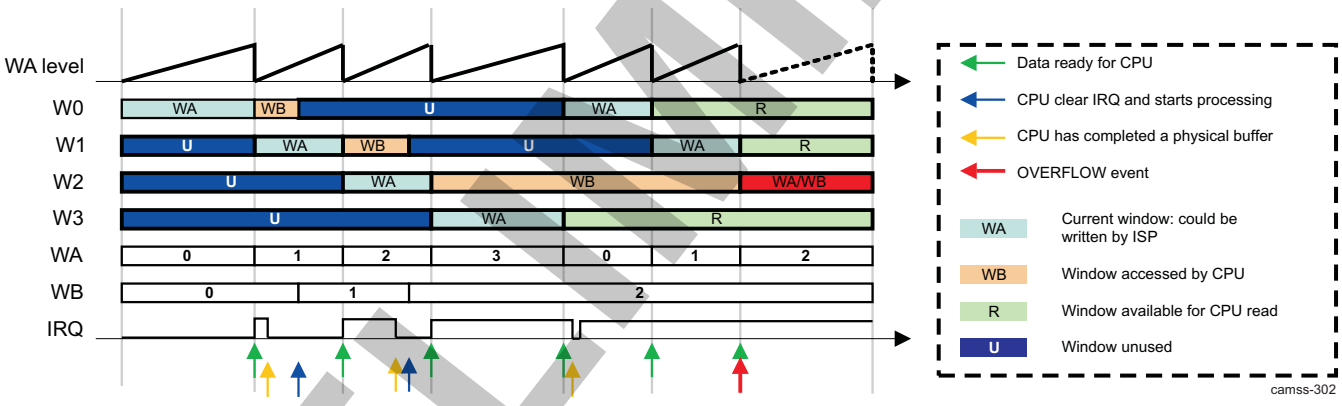
When the CPU reads the physical space too slowly, the CBUFF_CTX_STATUS_i[11:8] WA window pointer falls into the CBUFF_CTX_STATUS_i[3:0] WB window. This generates an IRQ_CTXx_OVR event when the OCPI initiator performs an access to that window. The CPU receives the IRQ_CTXx_READY event only if it is allowed to access a physical window. Therefore, it cannot generate an IRQ_CTXx_OVR event in a normal case. The OCPI initiator accesses are tracked based on activity on the OCP port.

When an IRQ_CTXx_OVR event occurs, the buffer content is likely to be corrupted. However, the CBUFF context continues processing data normally; it does not go into error state. Software must reset data generation and the CBUFF in a clean manner.

Figure 8-93 shows an example scenario with CBUFF_CTX_CTRL_i[9:8] WCOUNT = 1 (four windows). In normal operation, the CPU processes data at least at the same speed as it is written to the physical space. When this is not true, the number of windows to be read by the CPU increases. When no more physical windows are available for OCPI writes, an overflow occurs.

In the previous example, the CPU takes more time than expected to read the third buffer. Therefore, physical windows are not freed up. The OPCI initiator continues to write data into the physical window. That leads to an overflow when the OCPI initiator writes into the physical window that is read by the CPU (CBUFF_CTX_STATUS_i[11:8] WA = CBUFF_CTX_STATUS_i[3:0] WB and writes into CBUFF_CTX_STATUS_i[11:8] WA detected).

Figure 8-93. ISS CBUFF Write Mode CPU Interaction Example



(1) When there is no physical window available to be read by the CPU and the CPU writes the DONE bit, an IRQ_CTXx_INVALID event occurs.

(2) The bandwidth control feedback (BCF) feature can be used to prevent overflow. It must be supported by the module writing data into the virtual space (typically, an ISS).

8.2.8.3.2.2.2 ISS CBUFF Read Mode

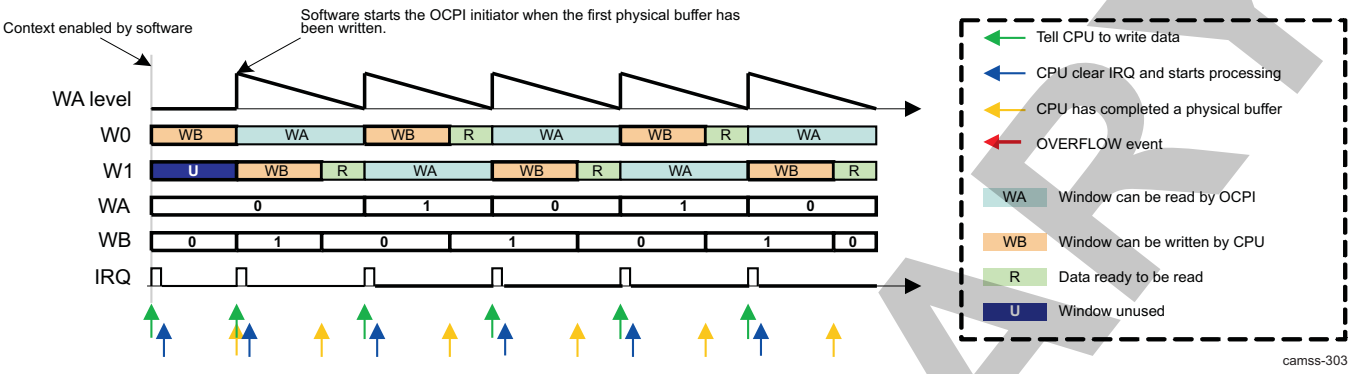
In read mode, the physical space is read by the CBUFF and it is written by the CPU. An IRQ_CTXx_READY event is set each time a physical window is available to be written by the CPU. This is true until all free buffers are used.

The CBUFF sets an IRQ_CTXx_READY event to inform the CPU that it can write the CBUFF_CTX_STATUS_i[3:0] WB window. The CBUFF cannot monitor CPU accesses to the physical space. It must indicate when it completes writing the CBUFF_CTX_STATUS_i[3:0] WB window by setting the CBUFF_CTX_CTRL_i[2:1] DONE bit field. This increments the CPU window index CBUFF_CTX_STATUS_i[3:0] WB by one modulo the window count (defined by the CBUFF_CTX_CTRL_i[9:8] WCOUNT bit field).

The CBUFF ensures that one IRQ_CTXx_READY event is sent to the CPU per physical window to be written. In other words, when a new IRQ_CTXx_READY event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

The following is an example of a normal operation in which the CPU writes data faster than it is read by the OCPI initiator. Figure 8-94 uses two physical windows (CBUFF_CTX_CTRL_i[9:8] WCOUNT = 0).

Figure 8-94. ISS CBUFF CPU Writes Data Faster Than it Is Read by the OCPI Initiator



Software must enable the ISS initiator only when at least one window is written by the CPU. Otherwise, an OVERFLOW event occurs when BCF is not used.

The CPU receives an interrupt each time a physical window is available to receive data. It clears the interrupt and then starts filling the physical window. When the buffer is completely written, it sets the CBUFF_CTX_CTRL_i[2:1] DONE bit field. This happens before the OCPI initiator has read all data from the previous physical window: the CPU must wait until the next IRQ_CTXx_READY event is received before it can write again to the physical space.

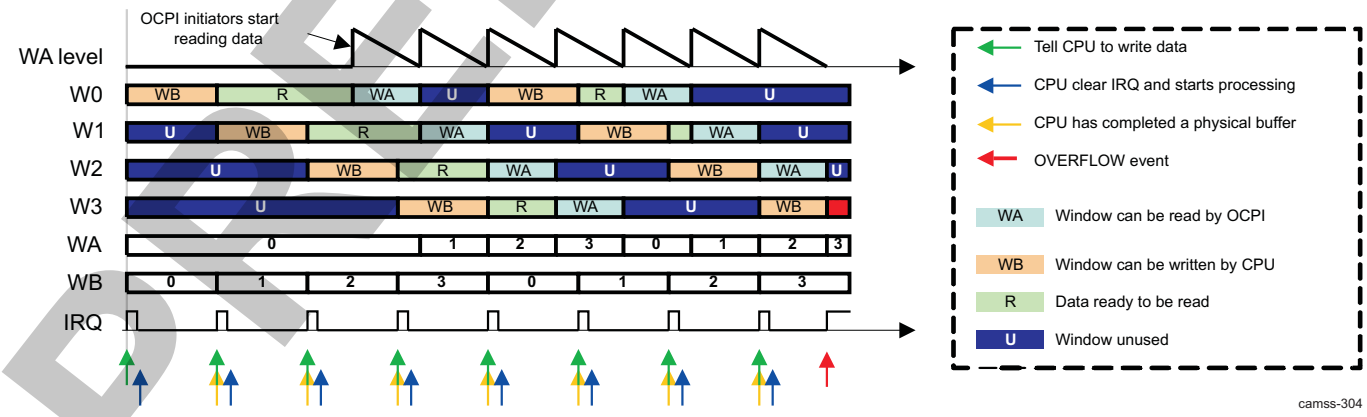
When the CPU writes buffers too slowly, the CBUFF_CTX_STATUS_i[11:8] WA window falls into the CBUFF_CTX_STATUS_i[3:0] WB window. This generates an IRQ_CTXx_OVR event only when the OCPI initiator performs reads to that window. The CPU receives the IRQ_CTXx_READY event only if it is allowed to access a physical window. Therefore, it does not generate an IRQ_CTXx_OVR event in a normal case. ISS accesses are tracked based on activity on the OCPI port.

When no buffer is available to be written by the CPU and the CPU writes the DONE bit, an IRQ_CTXx_INVALID event occurs.

When an IRQ_CTXx_OVR event occurs, the OPCI initiator reading the virtual space is likely to receive dummy data. However, the CBUFF context continues to process data normally; it does not go into error state. Software must reset the data consumer (OCPI initiator) and CBUFF context in a clean manner.

Figure 8-95 is an example of CBUFF read mode CPU interaction.

Figure 8-95. CBUFF Read Mode CPU Interaction Example



The BCF feature can be used to prevent overflow. It must be supported by the module reading data from the virtual space (typically, an ISS).

8.2.8.3.2.2.3 ISS CBUFF Read/Write Mode

Reads and writes are performed by OCPI initiators such as a camera interface, ISP, or SIMCOP. Address translation is performed for read and write data flows. The WA pointer is used for the write data flow, and the WB pointer is used for the read data flow. Therefore, address translation for the write data flow is the same as for write mode.

In this mode, the OCPI read data flow is stalled when there is not enough data to read in the physical space. A typical application is to store data from the camera in a CBUFF and to read it back by the ISP. When the camera is slower than the ISP, the ISP stalls.

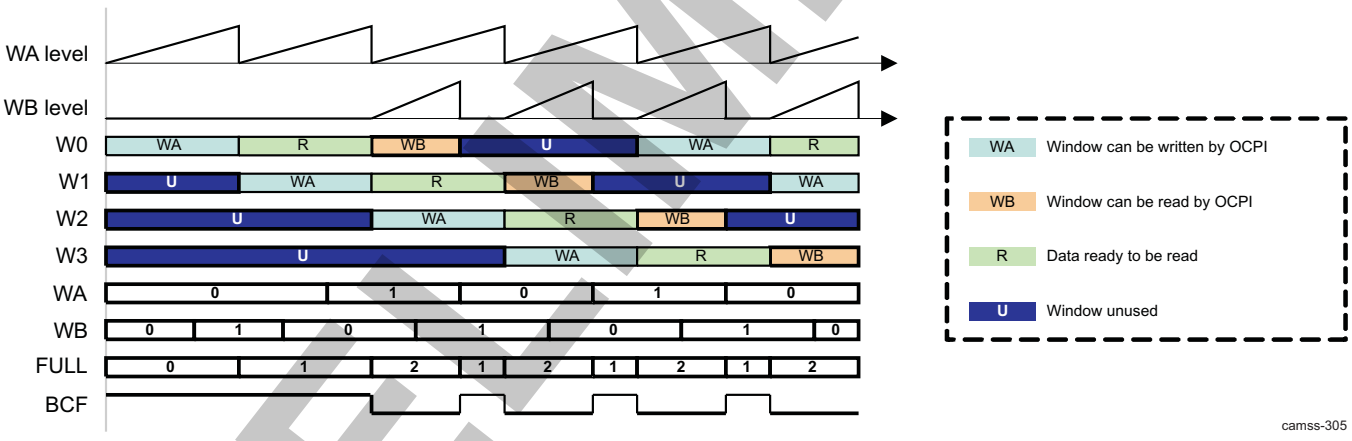
This mode does not rely on CPU synchronization. Synchronization is always performed using the BCF hardware mechanism. IRQ_CTXx_READY events are triggered in this mode when the OPCI write initiator has filled a physical window. Software can use this event for debug or performance bench marking purposes. Writes to the CBUFF_CTX_CTRL_i[2:1] DONE bit field are ignored in this mode.

The IRQ_CTXx_OVR event is triggered when an underflow occurs. In a normal case this will not occur, because the BCF signal is used to stall the read data flow when insufficient data is available in the physical space.

Figure 8-96 assumes:

- Read/write mode
- Four physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OCPI read initiator is faster than the OCPI write initiator. The BCF feature is used to stall the read initiator. CBUFF_CTX_CTRL_i[7:4] BCF = 2

Figure 8-96. ISS CBUFF Read/Write Mode Example



8.2.8.3.2.3 ISS CBUFF Events and Status Checking

8.2.8.3.2.3.1 ISS CBUFF Operations

A CBUFFx_READY_IRQ event is generated each time the CPU can read data from the CBUFF. The CPU can clear the event when it starts processing the data to avoid masking other events. The CPU can keep track of the location on the data internally or use the CBUFF registers to compute it.

The formula used is: ADDR = CBUFF_CTX_STATUS_i[3:0] WB CBUFF_CTX_WINDOWSIZE_i + CBUFF_CTX_PHY_i

When the CPU is done with processing, it must free the buffer by setting the CBUFF_CTX_CTRL_i[10] DONE bit. Otherwise, an overflow event may occur.

The CBUFF does not keep track of EOF events. They must be managed by the CPU using the EOF event of the module that writes into the CBUFF. At the EOF, data may remain in the current write windows. For example, when the window size is set to 8 lines and the image size is 20 lines, only two window-ready events are generated for a linear addressing scheme. The remaining four lines can be read after the EOF event.

No automatic reset of the CBUFF FSM occurs at the end of the image frame. Software must reset the context by clearing the CBUFF_CTX_CTRL_i[0] ENABLEABLE bit when the frame is completely processed. A new frame can start only when the CBUFF_CTX_CTRL_i[0] ENABLEABLE bit is set.

8.2.8.3.2.3.2 ISS CBUFF Status Checking

The CBUFF provides read-only access to the CBUFF_CTX_STATUS_i[11:8] WA and CBUFF_CTX_STATUS_i[3:0] WB pointers through the CBUFF_CTX_STATUS_i register. For example, the CBUFF_CTX_STATUS_i[3:0] WB index can be used by the CPU to compute the address of a physical window. Those indexes can also be used to evaluate latency margins.

8.2.8.3.2.3.3 ISS CBUFF Register Accessibility During Frame Processing

All registers are busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantly. However, module behavior is unpredictable when registers are changed during processing.

For correct operation, software must:

1. Disable all accesses to the virtual space managed by the context.
2. Disable the context by clearing the CBUFF_CTX_CTRL_i[0] ENABLEABLE bit.
3. Change the configuration.
4. Re-enable CBUFFx by setting the CBUFF_CTX_CTRL_i[0] ENABLEABLE bit.

8.2.8.3.2.4 ISS CBUFF Memory-to-Memory Operation BCF

The BCF mechanism matches the bandwidth between two processes.

The BCF feature can be used in all three CBUFF modes:

- Read mode: A CPU-controlled process writes data into physical space. The BCF signal is deasserted when the physical space contains enough data to start the read initiator connected to OCPI.
- Write mode: The BCF signal controls the write initiator connected to OCPI. When the CPU-controlled process does not read the data fast enough from the physical space, the BCF signal is asserted to stall filling of the buffer. It is deasserted when enough space is available in the physical space.
- Read/write mode: The BCF signal controls the read initiator connected to OCPI. Another initiator connected to OCPI fills the physical space. The BCF signal is deasserted when the physical space contains data that can be read by the read initiator. It is deasserted when insufficient data is available in the physical space.

The CBUFF_BCF output is controlled based on two factors:

- The window count available for the OCPI initiator to read/write
- The amount of data in the last available window (pretrigger)

The CBUFF_BCF signal is enabled by the CBUFF_CTX_CTRL_i[7:4] BCF bit field. It defines:

- Write mode: The amount of required free windows to allow writing from the ISS. In other words, when less than the required amount of BCF windows is available for ISS writes, the stall mechanism is triggered. The number of free windows is initialized to the total window count of the context. It is decreased by 1 each time the OCPI initiator finishes writing a window. It is increased by 1 each time the CPU finishes reading a window.
- Read and read/write modes: The minimum amount of required full windows to allow reading from the OCPI. When fewer than CBUFF_CTX_CTRL_i[7:4] BCF windows are available for ISS read, the stall mechanism is triggered. The number of full windows is initialized to 0. It is decreased by 1 each time the OCPI initiator completes reading a window. It is increased by 1 each time the CPU/OCPI initiator finishes writing a window.

Figure 8-97 is an example of BCF use. It assumes:

- Write mode: OCPI writes data into physical space and the CPU reads it.
- Two physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OCPI write initiator is faster than the CPU.
- CBUFF_CTX_CTRL_i[7:4] BCF = 1

Figure 8-97. ISS CBUFF Write Mode CPU Interaction Example BCF Used

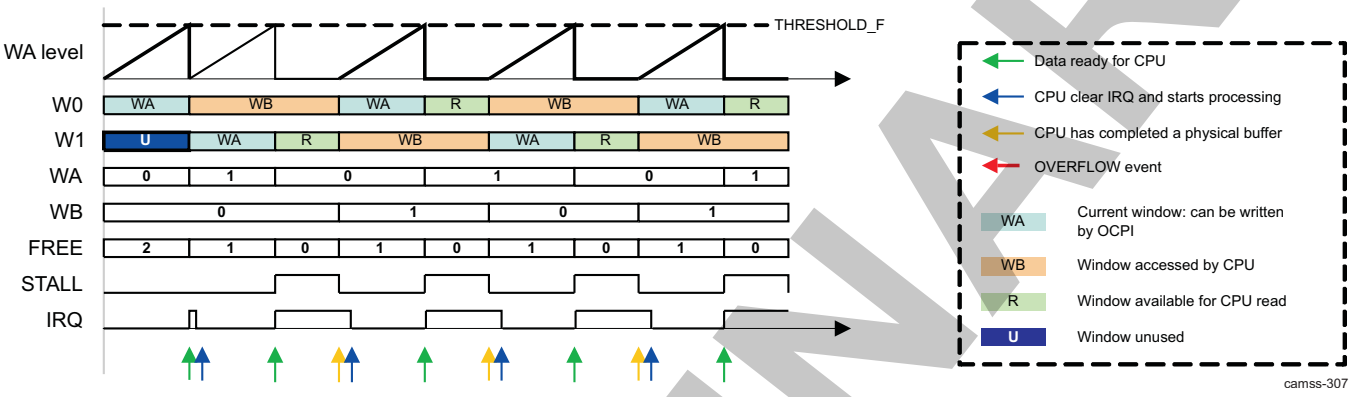


Figure 8-98 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- CBUFF_CTX_CTRL_i[7:4] BCF = 2

Figure 8-98. ISS CBUFF Read Mode CPU Interaction Example (1)

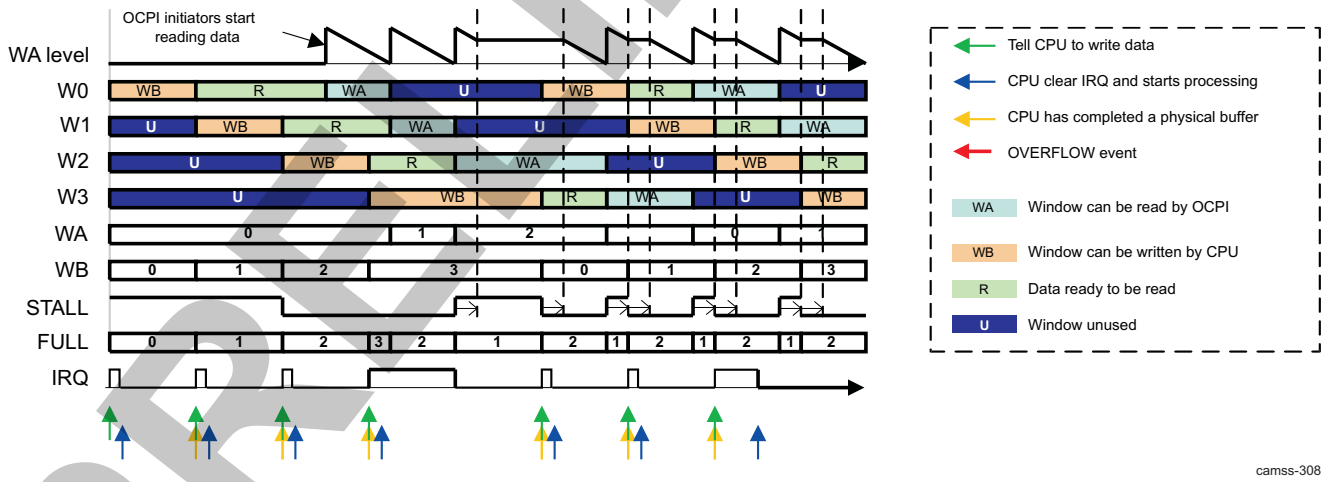

Figure 8-99 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Two physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- CBUFF_CTX_CTRL_i[7:4] BCF = 1

Figure 8-99. ISS CBUFF Read Mode CPU Interaction Example (2)

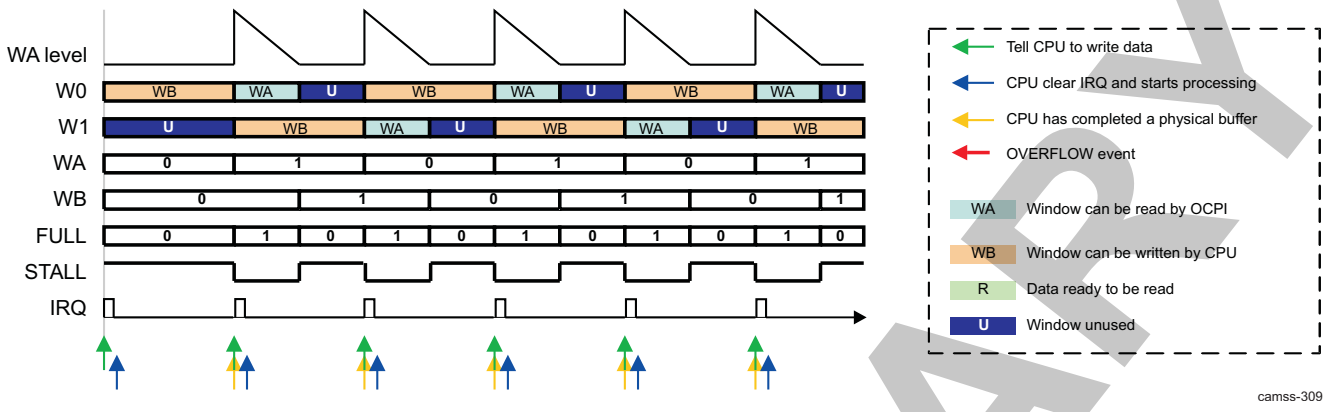

Figure 8-100 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- CBUFF_CTX_CTRL_i[7:4] BCF = 1

CBUFF supports pretriggering the BCF signal for finer latency compensation control. This mechanism is active only for the last window available for OCPI access. It typically improves the physical space use, which is particularly useful when on-chip SRAM is used as a ping-pong buffer.

Pretriggering is controlled through the CBUFF_CTX_THRESHOLD_S_i register. It defines:

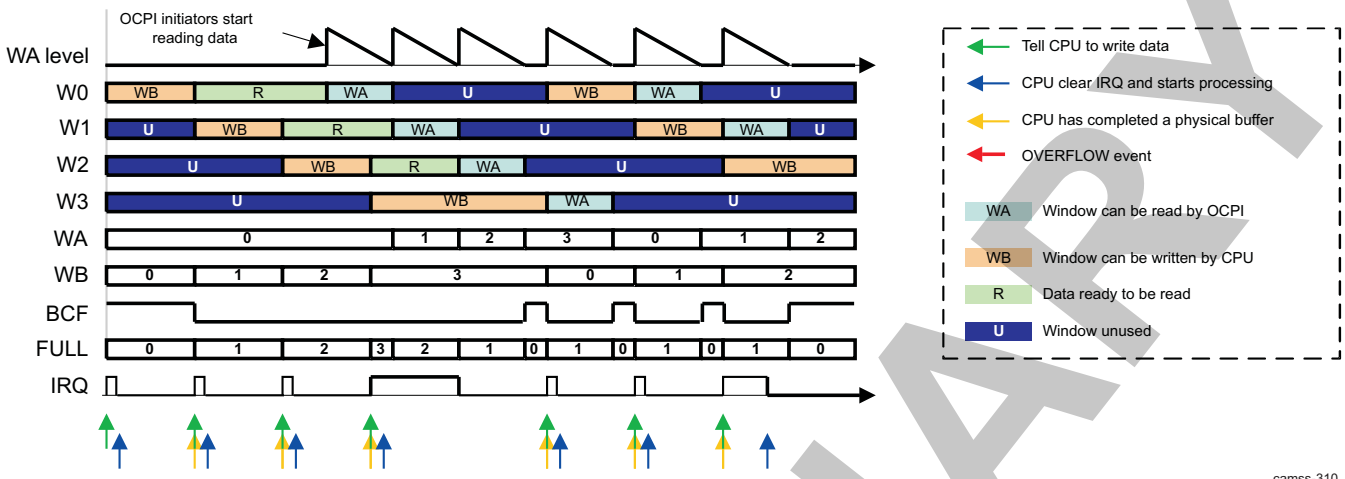
- Write mode: When the fill level of the last window available for ISS writes is greater than or equal to CBUFF_CTX_THRESHOLD_S_i, the CBUFF_BCF signal is asserted.
- Read mode: When the amount of data in the last window available for ISS reads is less than CBUFF_CTX_THRESHOLD_F_i/CBUFF_CTX_THRESHOLD_S_i, the CBUFF_BCF signal is asserted.

BCF pretriggering is disabled by setting CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i.

Figure 8-100 is an example of BCF pretriggering, assuming the following:

- Write mode: The CPU reads data from the physical space and the OCPI writes it.
- Two physical windows
- CBUFF_CTX_THRESHOLD_S_i = 1/3 CBUFF_CTX_THRESHOLD_F_i
- CBUFF_CTX_CTRL_i[7:4] BCF = 1

Figure 8-100. ISS CBUFF BCF Pretrigger Example: Write Mode

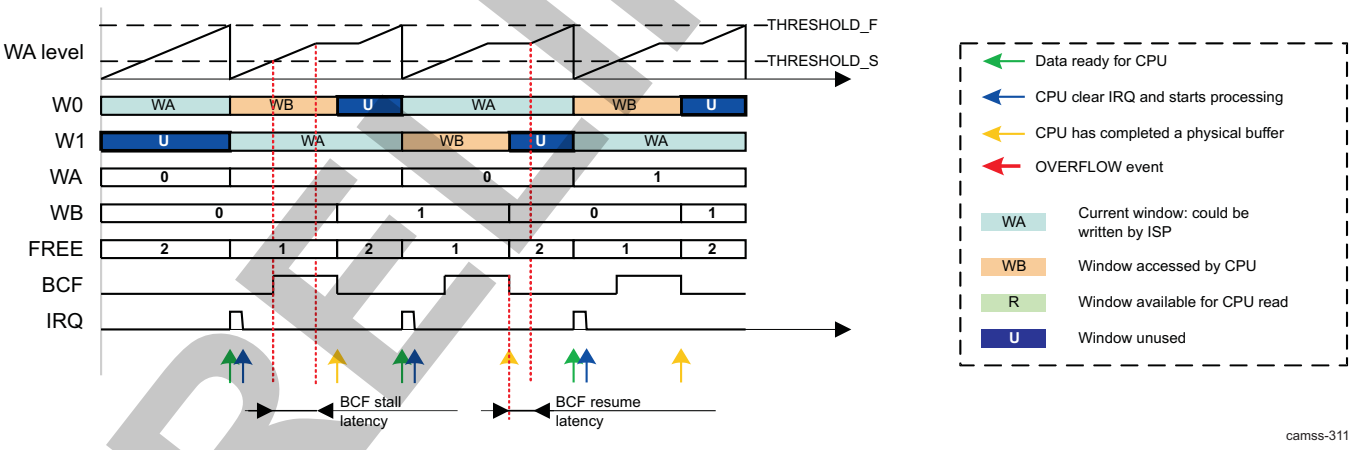


The CBUFF_BCF output signal is a logical OR of all internal BCF signals of CBUFF contexts. For example, when contexts 0 and 1 have enabled the BCF feature, both contexts can request a data flow stall.

Figure 8-101 is an example of pretriggering in read mode:

- Read mode: CPU writes data into the physical space and the OCPI reads it.
- Four physical windows
- CBUFF_CTX_THRESHOLD_S_i = 2/3 CBUFF_CTX_THRESHOLD_F_i
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- CBUFF_CTX_CTRL_i[7:4] BCF = 2

Figure 8-101. ISS CBUFF BCF Pretrigger Example: Read Mode



8.2.8.3.2.5 ISS CBUFF TILER Support

The CBUFF can translate 2D (BLOCK) bursts intended for the TILER. However, software must ensure that a given burst fits in a window.

The expected value for ADDR[32] is defined by the CBUFF_CTX_CTRL_i[11] TILERMODE bit.

- When ADDR[32] = CBUFF_CTX_CTRL_i[11] TILERMODE, the access is processed normally. ADDR[32] is not used for further processing.
- Otherwise, the access is treated as transparent.

8.2.8.3.2.6 ISS CBUFF Window Management and Address Remapping Details

This section explains the internal address remapping and windows management algorithm. Internally, the module maintains some variables in addition to the configuration registers. The module manages multiple contexts in parallel. Table 8-279 lists the CBUFF internal variables.

Table 8-279. ISS CBUFF Internal Variables

Variable	Description
WAx	Current window index for context x. Possible values are 0 to allowed window count. The current value can be read using the CBUFF_CTX_STATUS_i[11:8] WA bit field.
WBx	Window in the physical space that can be accessed by the CPU in read/write modes. Window that is read from OCPI in read/write mode. Possible values are 0 to allowed window count. The current value can be read using the CBUFF_CTX_STATUS_i[3:0] WB bit field.
VPAx	Start address, in the virtual space, of the CBUFF_CTX_STATUS_i[11:8] WA window
	Used as a base pointer for the read (read mode) or write data flow (write, read/write modes)
	This is an internal quantity that cannot be accessed by software.
VPBx	Start address, in the virtual space, of the CBUFF_CTX_STATUS_i[3:0] WB window
	Used as a base pointer for the read data flow.
	This is an internal quantity that cannot be accessed by software.
OFFSETAx	This is an internal quantity that cannot be accessed by software.
OFFSETBx	Address offset used when WAx or WBx is accessed
LEVELAx	This is an internal quantity that cannot be accessed by software.
LEVELBx	Address offset used when WAx or WBx is accessed

8.2.8.3.2.6.1 ISS CBUFF Startup

The status of a CBUFF context is reset when it is disabled. This does not affect the configuration registers or the CBUFF_IRQSTATUS register. Table 8-280 lists the internal state after reset.

Table 8-280. ISS CBUFF Internal State After Reset

Variable	Description
WAx	0
WBx	0
VPAx VPBx	CBUFF_CTX_START_i
OFFSETAx OFFSETBx	CBUFF_CTX_START_i – CBUFF_CTX_PHY_i
LEVELAx LEVELBx	0

8.2.8.3.2.6.2 ISS CBUFF Access Identification

For each access to the virtual space (OCPI slave port), the CBUFF first checks the address to classify the transaction into one of the categories listed in Table 8-281.

Table 8-281. ISS CBUFF Address identification

Address ID	Variable	Condition
0+2*x	WA_CBUFFx	CBUFF_CTX_CTRL_i[0] ENABLE = 1 and ADDR >= VPAx and ADDR < VPAx + CBUFF_CTX_WINDOWSIZE_i and ADDR <= CBUFF_CTX_END_i and Access type = write when read/write mode is selected
1+2*x	WB_CBUFFx	CBUFF_CTX_CTRL_i[0] ENABLE = 1 and CBUFF_CTX_CTRL_i[2:1] MODE = 2 and

Table 8-281. ISS CBUFF Address identification (continued)

Address ID	Variable	Condition
		Access type = read and ADDR>=VPBx and ADDR<VPBx + CBUFF_CTX_WINDOWSIZE_i and ADDR<= CBUFF_CTX_END_i
16+x	ERR_CBUFFx	CBUFF_CTX_CTRL_i[0] ENABLE = 1 and ADDR>= CBUFF_CTX_START_i and ADDR<= CBUFF_CTX_END_i
24	TRANSPARENT	Always true

Lower IDs correspond to higher priorities if multiple conditions are true. For example, when the current virtual window of CBUFF 0 is accessed, at least the tests for categories WA_CBUFFx and ERR_CBUFFx are true. The final category is WA_CBUFFx, because it has a higher priority.

NOTE: Tests must be performed in parallel to match the desired performance.

Further processing depends on the category:

- TRANSPARENT: Accesses flow though the module without changing its internal state or any translation.
- ERR_CBUFFx: The module goes into error state for the concerned context and sets the CBUFF_HL_IRQSTATUS.IRQ_CTXx_INVALID bit. When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between CBUFF_CTX_START_i and CBUFF_CTX_END_i is not transmitted to the OCPO master port. There are two ways to leave the error state:
  - Hardware reset
  - Disable and re-enable the context in error state.

    Accesses outside of the virtual space from the context in error state are not affected.
- WA_CBUFFx and WB_CBUFFx: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read, write, or read/write mode). Otherwise, a CBUFF_HL_IRQSTATUS.IRQ_CTXx_INVALID event is set and CBUFFx goes into the error state.

8.2.8.3.2.6.3 ISS CBUFF Address Translation

An offset is selected depending on the access category (see Section 8.2.8.3.2.6.1, *ISS CBUFF Startup*) and the internal state of the accessed buffer. Table 8-282 lists possible cases.

Table 8-282. ISS CBUFF Address Translation

Condition	Address Translation
CBUFF_CTX_CTRL_i[0] ENABLE = 1 and ADDR >= CBUFF_CTX_START_i and ADDR <= CBUFF_CTX_END_i and CBUFFx in error state	Access cancelled
Category = WA_CBUFFx	ADDROUT = ADDRIN-OFFSETAx
Category = WB_CBUFFx	Read/write mode only ADDROUT = ADDRIN-OFFSETBx
Category = ERR_CBUFFx	Access cancelled
Category = TRANSPARENT	ADDROUT = ADDRIN

8.2.8.3.2.6.4 ISS CBUFF Window Fill Level

Each time an access is performed into an active window (WA_CBUFFx when context x is enabled) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the OCPI slave port. All possible BYTEEN patterns, including nonaligned ones, are supported. Table 8-283 shows some examples. The basic idea is to count the number of 1s in the BYTEEN input for each 128-bit word and to sum the values.

Table 8-283. ISS CBUFF Window-Level Increment

BYTEEN	LEVELy Increment	Comment
0x0000	0	No access
0x0001	1	8-bit access
0x0002	1	8-bit access
0x0003	2	16-bit access
...	...	...
0x0007	3	24-bit access
...	...	...
0x000F	4	32-bit access
...	...	...
0x00F0	4	32-bit access
...	...	...
0xFFFF	16	128-bit access

The window level is compared to CBUFFx_THRESHOLD. Table 8-284 lists the situations that may occur:

Table 8-284. ISS CBUFF Window-Level Comparison(1)

Condition	Description
LEVELAx >= CBUFF_CTX_THRESHOLD_F_i	The CBUFF_CTX_STATUS_i[11:8] WA bit field of context x is full (write mode) or empty (read mode). Internal window indexes, levels, and offsets are updated.
LEVELBx >= CBUFF_CTX_THRESHOLD_F_i	Read/write mode only Window used to handle the read flow of context x is empty. Internal window indexes, levels, and offsets are updated.

(1) All situations described in Table 8-284 are mutually exclusive because only one level is updated each cycle.

8.2.8.3.2.6.5 ISS CBUFF Window Pointer and Offset Update

The following description refers to the update of WA in write mode:

When the current window of a context is full:

- A new window is opened. The update is done in a circular manner: the first physical window in is reused after the last one.
  - WA (WA + 1) modulo the number defined by CBUFF_CTX_CTRL_i[9:8] WCOUNT
  - LEVELA <- 0
  - VPA <- VPA + CBUFF_CTX_WINDOWSIZE_i
- When the window is moved from the last buffer to the first:
  - OFFSETA <- OFFSETA + CBUFF_CTX_WINDOWSIZE_i << (CBUFF_CTX_CTRL_i[9:8] WCOUNT + 1)
- Otherwise, OFFSETA does not change.

The algorithm used to update WA in read mode is the same, except that *full* refers to *all data of the window has been read* or *window empty*.

For read/write mode, the same algorithm is used to translate reads to the WBx window. Make the following changes:

- Replace WA with WB.
- Replace LEVELA with LEVELB.
- Replace VPA with VPB.
- Replace OFFSETA with OFFSETB.

8.2.8.3.2.7 ISS CBUFF Error State

Contexts may go into error state when they receive unexpected accesses. In that case, the CBUFF does not send dummy transactions to the OCPO port. It does not forward the failing transactions to OCPO and returns valid responses (SResp = DVA) on OCPI to preserve the integrity of the OCP.

Responses may be received on OCPO while the CBUFF responds to failing transactions on OCPI. The OCPO response phase is stalled (MRespAccept = 0) during that time to prevent corruption. OCPO cannot be stalled longer than one full OCP transaction. Responses received on OCPO are handled before another internally generated response can be sent back to the OCPI. In that case, command and data phases are eventually stalled. Not stalling OCPO for too long is required to avoid affecting system performance.

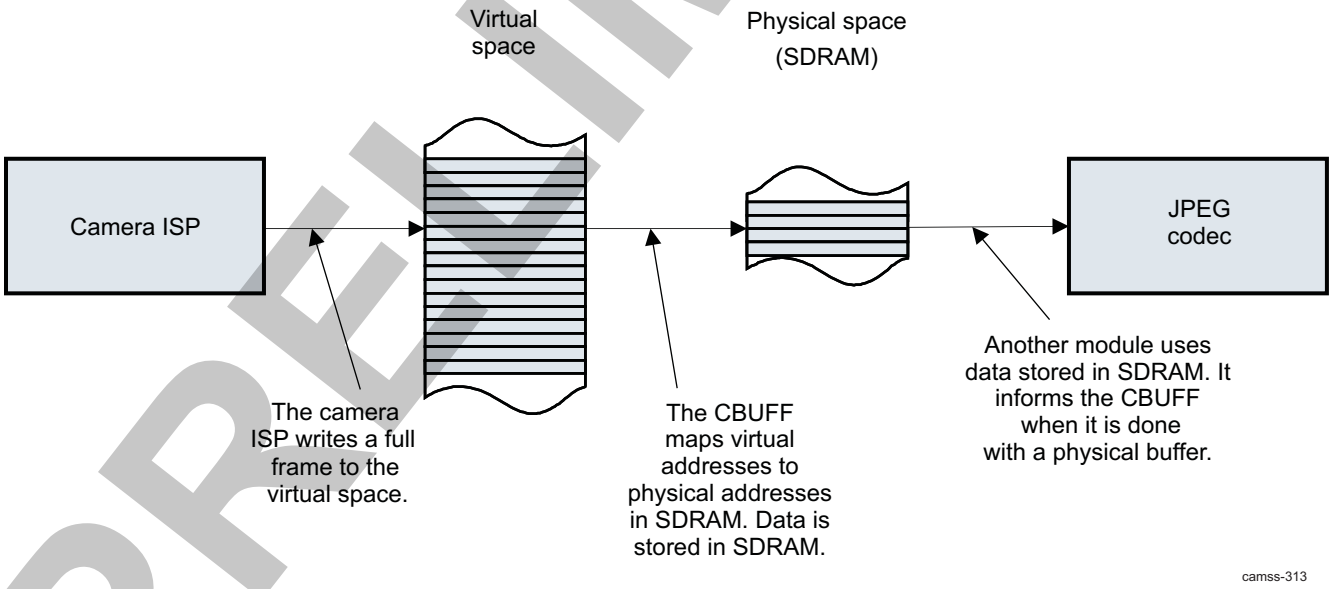
During normal operation (that is, no context is in error state), the OCPO response phase is never stalled.

8.2.8.3.2.8 ISS CBUFF Typical Configurations

8.2.8.3.2.8.1 ISS CBUFF Single-Slice Buffer

An OCP master (typically, the ISS) writes data with an incremental addressing scheme to the virtual space. The physical space is smaller than the virtual space. Therefore, physical space locations are read and written multiple times. Figure 8-102 shows the CBUFF single-slice buffer in write mode.

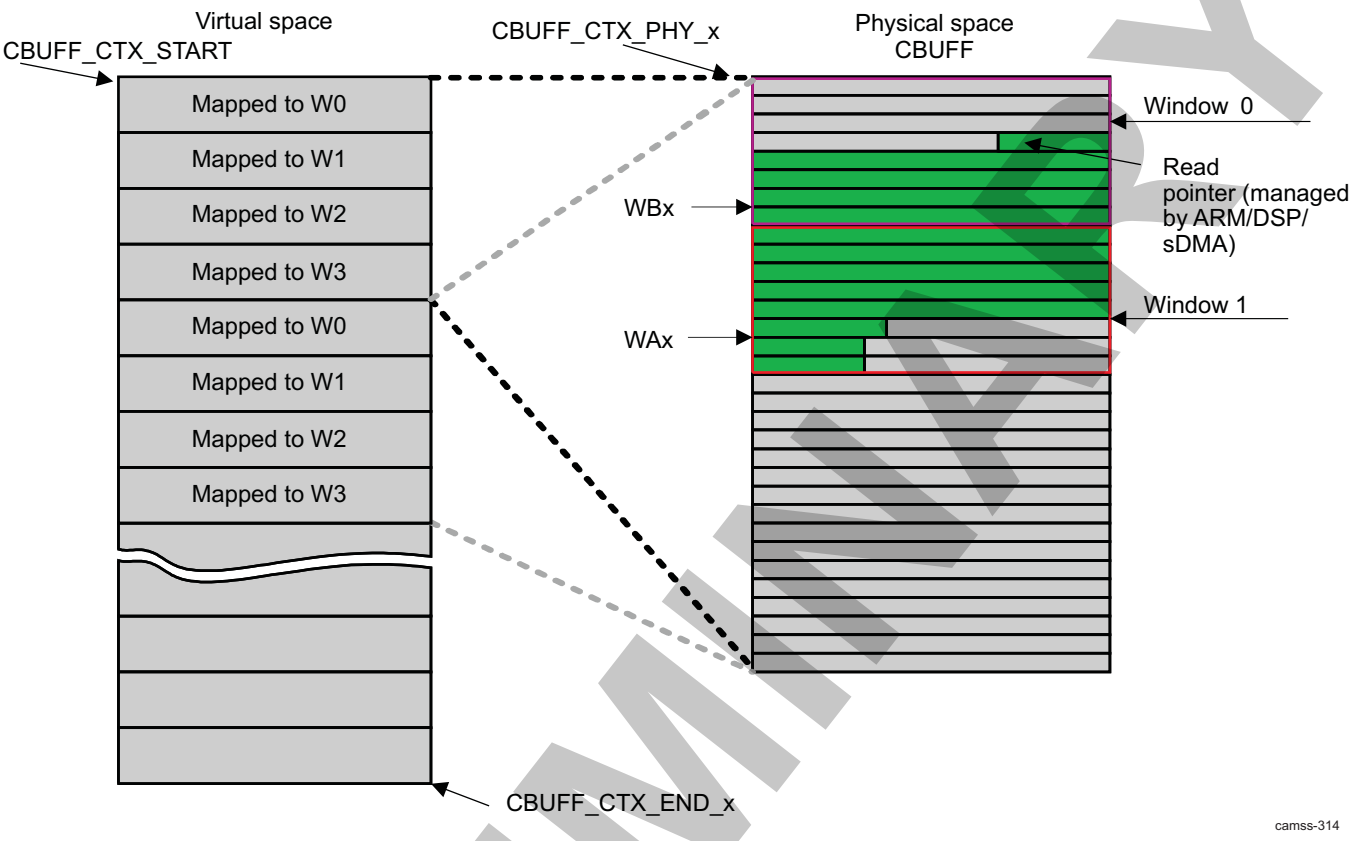
Figure 8-102. ISS CBUFF Single-Slice Buffer (Write Mode)



Physically, this CBUFF is in on-chip SRAM or SDRAM. The virtual space is defined by a start and end addresses. The physical space is defined by a start address, a window size, and a window count. It is contiguous in memory. When the CPU accesses physical memory for processing, it must know if the SDRAM is available for it to access and if the CBUFF is not using it. The CPU and CBUFF cannot track each other. For example, an interrupt must be triggered from the SIMCOP to the CBUFF to notify it when the processor is done working with SDRAM. For more information about the software configuration for these interrupts, see Section 8.2.8.3.2.2.1, *ISS CBUFF Write Mode*.

Figure 8-103 shows the buffer organization for a 4-window buffer.

Figure 8-103. ISS CBUFF Single-Slice Buffer Example (Write Mode)

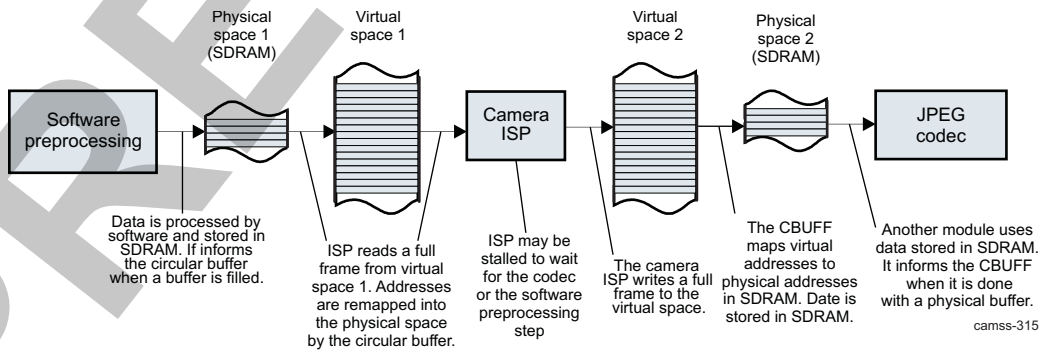


The CBUFF can manage multiple contexts in single-slice mode.

8.2.8.3.2.8.2 ISS CBUFF Extended-Slice Buffer

In extended-slice mode, at least two contexts managed by the CBUFF are used together. The two contexts provide address translation, one for the read data flow and the other for a write data flow. Figure 8-104 is an example of the CBUFF extended-slice buffer.

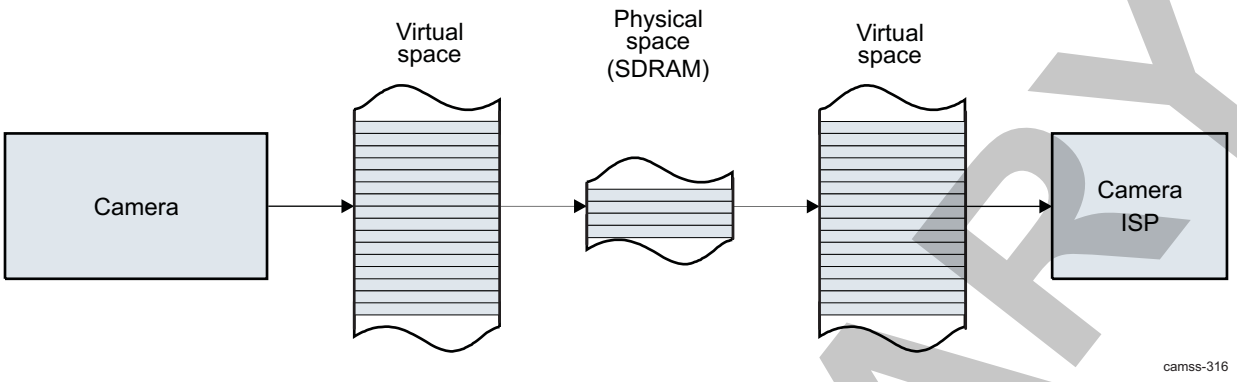
Figure 8-104. ISS CBUFF Extended-Slice Buffer Example



8.2.8.3.2.9 ISS CBUFF FIFO Mode

The CBUFF can behave like a FIFO to buffer data between two initiators connected to the OCPI. A typical use case is a camera interface writing data to the FIFO and an ISP reading data from the FIFO. Figure 8-105 shows the CBUFF FIFO mode.

Figure 8-105. ISS CBUFF FIFO Mode

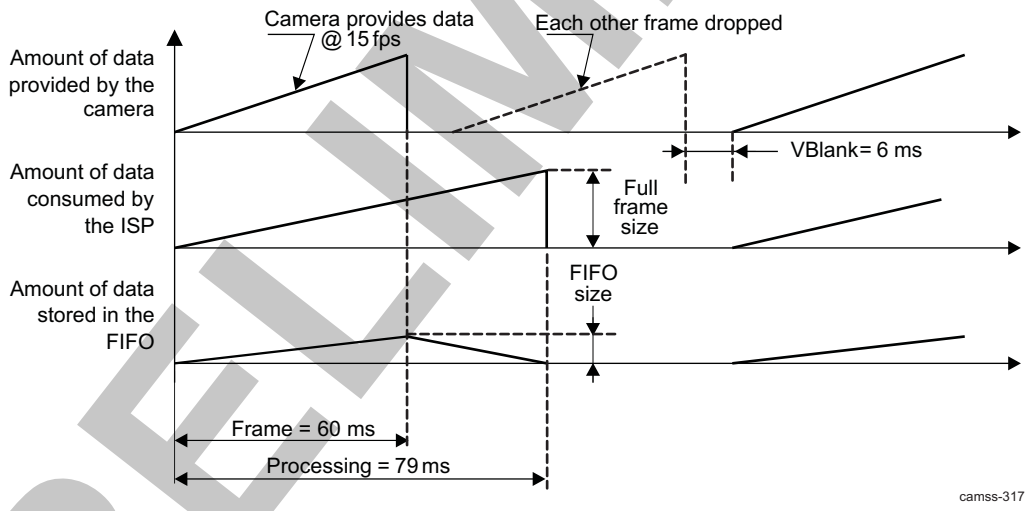


The CBUFF is used as a FIFO when the camera provides data at a higher rate than the ISP can process. To avoid storing one or multiple full-frame buffers, a FIFO buffer is used to store the data that cannot be processed immediately.

For this example, assume that the camera provides 24 MPix at 15 frames per second. A new frame is provided every 66 ms. The ISP needs 79 ms to process this frame. Therefore, the processing cannot be done on the fly, and each other frame must be dropped.

Figure 8-106 shows the accumulated amount of data provided by the camera since the start of the frame; the amount of data consumed by the ISP since it has started processing the frame; and the difference between the two, which must be stored in the FIFO.

Figure 8-106. ISS CBUFF FIFO Use Example



The FIFO is emulated as 16 windows (CBUFF_CTX_CTRL_i[9:8] WCOUNT = 0x3). The ISP is started by software when a few kilobytes of data are written to the physical space. Alternatively, the BCF mechanism can be used, but the minimum FIFO size is more complex to calculate.

The FIFO level reaches its maximum when the camera performs the last write of the frame. The camera provides the data at 1 byte/pixel 24 MPix/60 ms = 400 MBytes/s. The ISP reads data at 1 byte/pixel × 24 MPix/79 ms = 304 MBytes/s. Therefore, the minimum FIFO size is 60 ms × (400 MBytes/s – 304 MBytes/s) = 5.76 MBytes, which is four times less than a full-frame buffer.

Each window holds 256 KB of data. The camera starts writing to a new physical window every 256 KB/364 MBytes/s = 703 µs. The ISP starts reading from a new physical window every 842 µs.

The FIFO mode can also be used when the ISP is slower than the camera. In that case, the ISP is stalled when insufficient data is available in the physical space.

8.2.8.4 ISS CBUFF Programming Model

8.2.8.4.1 ISS CBUFF Reset Behavior

Upon hardware or software reset of the CBUFF, all registers in the CBUFF are reset to their reset values

This software reset has the same effect as a hardware reset. ISS high-level software reset ensures that traffic is stopped on clear boundary because the CBUFF is sending data to and from other modules. ISS top-level reset is preferred. For more information about ISS software reset, see Section 8.1.2.3, *ISS Reset*. Submodule reset is not preferred but is available through the following registers:

1. Set the CBUFF_HL_SYSCONFIG[0] SOFTRESET bit to 1.
2. Read the CBUFF_HL_SYSCONFIG[0] SOFTRESET bit to check whether it is set to 1, which means the reset occurred.

The reset is performed without waiting until all OCP traffic stops. To avoid OCP corruption, software must ensure there is no more ongoing traffic before performing a reset.

8.2.8.4.2 ISS CBUFF Register Setup

All registers of the context to be used must be initialized for correct operation. Table 8-285 lists the procedure for the CBUFF register setup.

Table 8-285. ISS CBUFF Setup Register

Step	Bit Field	Value
Set operation mode.	CBUFF_CTX_CTRL_i[2:1] MODE	0x0: Write mode 0x1: Read mode 0x2: Read/write mode 0x3: Reserved
Define the virtual address range managed by the CBUFF. It usually corresponds to the address region where one image frame is written by the OCPI initiator.	CBUFF_CTX_START_i and CBUFF_CTX_END_i	
Define the start address of the physical buffer.	CBUFF_CTX_PHY_i	
Set the window count and size. The window size usually depends on the use of the buffer. Eight or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency-related overflow protection.	CBUFF_CTX_CTRL_i[9:8] WCOUNT and CBUFF_CTX_WINDOWSIZE_i	
When the 2D addressing capability is not used, set to the window size in CBUFF_CTX_THRESHOLD_F_i. Otherwise, it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to lines by 4096 pixels, but the ISP sends lines of only 2560 pixels, CBUFF_CTX_WINDOWSIZE_i = 8 4096 and CBUFF_CTX_THRESHOLD_F_i = 8 2560.	CBUFF_CTX_THRESHOLD_F_i	
BCF signal-generation configuration is optional.	CBUFF_CTX_THRESHOLD_S_i and CBUFF_CTX_CTRL_i[7:4] BCF	
Enable the module. It can be disabled by clearing the ENABLE bit. This must be done only when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the CBUFF are reset when it is disabled. Pending interrupts are not affected.	CBUFF_CTX_CTRL_i[0] ENABLE

RESERVED																				TILERMODE	DONE	WCOUNT		BCF				RESERVED	MODE		ENABLE

Bits	Field Name	Description	Type	Reset
31:12	RESERVED		R	0x00000
11	TILERMODE	Sets the expected value for ADDR[32]. If ADDR[32]=TILERMODE, ADDR[31:4] is processed and eventually translated. Otherwise, the access is handled as transparent, regardless of the other address bits.	RW	0
10	DONE	Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0. This bit has no effect when MODE=2 (read/write) Write 0x0: No effect. Write 0x1: The CPU has completely processed the WB physical buffer.	W	0
9:8	WCOUNT	Window count 0x0: 2 windows 0x1: 4 windows 0x3: 16 windows 0x2: 8 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. 0: Control loop disabled. 1-15: The control feedback loop enabled. Behavior depends on functional mode, see Section 8.2.8.3.2.4, *ISS CBUFF Memory-to-Memory Operation BCF*.	RW	0x0
3	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
2:1	MODE	Selects the functional mode of this context 0x0: Write mode. ISS writes and CPU reads the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only writes are permitted between CBUFF_CTX_START_i and CBUFF_CTX_END_i. 0x1: Read mode. Hardware reads and CPU writes the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only reads are permitted between CBUFF_CTX_START_i and CBUFF_CTX_END_i. 0x2: Read/Write mode. Read and writes are monitored by the CBUFF. WB is used to track current read positions WA is used to track current write position.	RW	0x0
0	ENABLE	Enable/disable 0x0: Disables the context. This resets the internal state of the context. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the context takes effect immediately. Software must ensure that no more accesses to the context are outstanding before disabling it. Otherwise memory corruption may occur. 0x1: Enable the context. All accesses between CBUFF_CTX_START_i and CBUFF_CTX_END_i are processed by the CBUFF.	RW	0

8.2.9 ISS BYS

8.2.9.1 ISS BYS Overview

There are two Bayer scaler modules (BYS_A and BYS_B) in the device ISS. Each BYS module enables low-latency still image capture, as well as power and SDRAM bandwidth optimization for video record use cases by scaling the resolution provided by the sensor down to the required video resolution.

The BYS modules enable faster image capture latencies by avoiding sensor mode switches. Some image sensors can continuously output full resolution at viewfinder refresh rate. BYS receives full resolution at viewfinder rate and outputs either full resolution or viewfinder resolution. Either case can be selected with minimal latencies because only ISP internal parameters are changed. Therefore, the time-consuming sensor mode switch is avoided.

The BYS modules also collect statistics that can be used for translational video stabilization in the Bayer domain. Stabilization in the Bayer domain is more efficient from a system point of view (SDRAM bandwidth and power consumption) than stabilization in the YUV domain by performing the stabilization before the ISP processing.

Each BYS module provides the following list of features:

- Functional clock up to 304 MHz
- Interfaces:
  - Configuration interface
  - Input video port:
    - Four pixels wide (up to four pixels per functional clock cycle)
    - Asynchronous from the functional clock
    - HS/VS synchronization signaling
    - 12 bits per pixel
    - Up to 6532 × 8191 pixels for input image size
  - Output video port:
    - One pixel wide (up to one pixel per functional clock cycle)
    - Synchronous to the functional clock
    - HS/VS synchronization signaling
    - 12 bits per pixel
    - Up to 2982 × 1940 pixels for output image size
- Binning artifact correction (pixel shift with subpixel precision to compensate phase errors introduced by sensor binning)
- Down scaler:
  - Horizontal and vertical cropping
  - Defect pixel correction
  - Separable filter
  - Scaling range, down to 1/4x
  - Upscaling not supported
  - Traffic smoothing FIFOs:
    - FIFO between the horizontal and vertical scalers (1500 elements × 12 bits)
    - FIFO between the vertical scaler and the video port/LSC engine (2982 elements × 12 bits)
- Stabilization statistics collection after the down scaler:
  - Piece-wise interpolated gamma correction
  - Polynomial lens shading correction
  - Two independent accumulator engines (ACC0 and ACC1):
    - Configurable bin size, count and offset

- ACC0: 1968 bins of 23 bits
- ACC1: 3456 bins of 22 bits

8.2.9.2 ISS BYS Environment

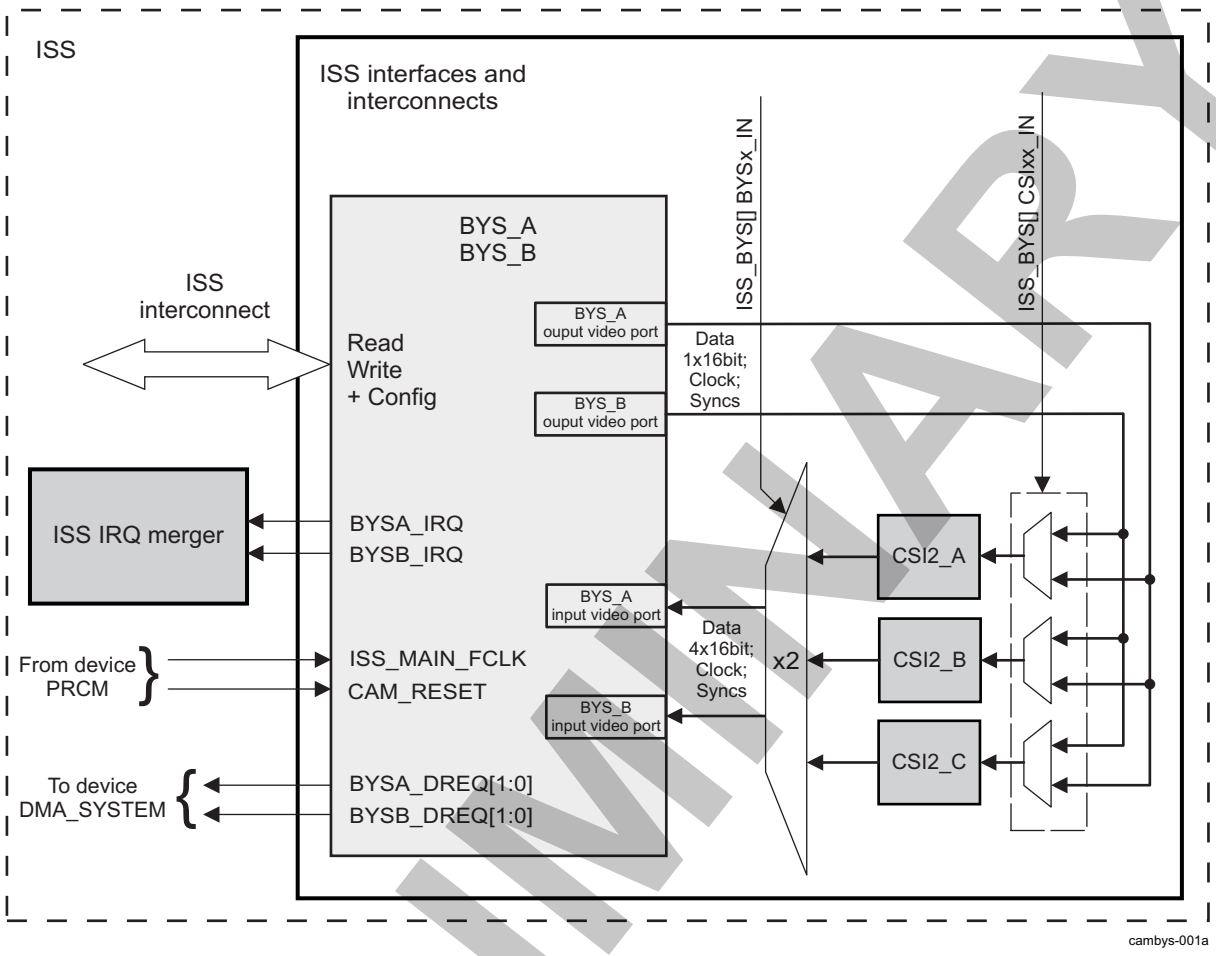
There are no particular environment attributes. See Section 8.2.2, *ISS Interfaces Environment*.

8.2.9.3 ISS BYS Integration

Figure 8-107 shows the BYS_A and BYS_B interconnection within the ISS and device. Each BYS module implements a slave port to ISS interconnect. There are no master ports, and the BYS modules cannot send data directly to memory (SDRAM). The BYS modules interface with the MIPI CSI-2 receivers using two separate parallel video ports for data input and data output, capable of supporting up to 4 pixels per functional clock cycle throughput. For exact details about BYS tap in/tap out points within the CSI2 receivers, see Section 8.2.5.3.3.7, *ISS CSI2 Transcoding*. Both BYS modules are integrated the same way and software chooses which camera interface is attached to a given BYS module. The configuration of BYS ports connectivity is made through the ISS_BYS register on ISS top level (see Section 8.1.3, *ISS Register Manual*) as follows:

- ISS_BYS[2:0] BYSA_IN bit field selects which CSI engine output is connected to the BYS_A input video port
- ISS_BYS[6:4] BYSB_IN bit field selects which CSI engine output is connected to the BYS_B input video port
- ISS_BYS[8] CSI2A_IN bit selects which BYS module output is connected to the CSI2_A input BYS video port
- ISS_BYS[10] CSI2B_IN bit selects which BYS module output is connected to the CSI2_B input BYS video port
- ISS_BYS[12] CSI2C_IN bit selects which BYS module output is connected to the CSI2_C input BYS video port

Figure 8-107. ISS BYS Integration



For additional details on power domain, clocks, reset, and hardware requests, see Section 8.1.2, *ISS Functional Description*.

8.2.9.3.1 ISS BYS Interrupt Requests

Each BYS module provides a single interupt request to the ISS top level (BYSA_IRQ and BYSB_IRQ). For more information on BYS interrupt signals mapping on the ISS top level, see Section 8.1.1, *ISS Integration*, and Section 8.1.2.1, *ISS Interrupts*.

8.2.9.3.2 ISS BYS DMA Requests

Each BYS module can generate two DMA request signals to the ISS top level (respectively to device DMA_SYSTEM module), using early deassertion. See also Section 8.1.1, *ISS Integration*, in Section 8.1, *ISS Overview*, for DMA request signals mapping on ISS top level:

- For BYS_A: BYSA_DREQ_0 is mapped to ISS_DREQ_5, and BYSA_DREQ_1 is mapped to ISS_DREQ_6
- For BYS_B: BYSB_DREQ_0 is mapped to ISS_DREQ_7, and BYSA_DREQ_1 is mapped to ISS_DREQ_8

The selection of one or multiple events (up to four events per DMA request signal) that trigger the DMA request is made by using the BYS_DMAENABLE_SET and BYS_DMAENABLE_CLR registers. The BSC_PAGE[] ACCn bit for the associated Boundary Signal Calculator (BSC) accumulator (n = 0 or 1, BSC accumulator index) is reset when the selected event is triggered. That also asserts the corresponding DMA request signal. Therefore, the first access from DMA_SYSTEM always accesses Page 0, as there is some delay from assertion of a DMA request to the first access. Refer to Section 8.2.9.4.7, *ISS BYS Boundary Signal Calculator*, for more information on BSC functionality.

The DMA request signal is deasserted when the first memory-mapped location of the accumulator is accessed (read or write):

- For BYS_A:
  - BYSA_DREQ_0 is cleared by an access to 0x5200 A000.
  - BYSA_DREQ_1 is cleared by an access to 0x5200 A800.
- For BYS_B:
  - BYSB_DREQ_0 is cleared by an access to 0x5200 E000.
  - BYSB_DREQ_1 is cleared by an access to 0x5200 E800.

The DMA request is reasserted when the last location of the accumulator is accessed:

- For BYS_A:
  - BYSA_DREQ_0 is cleared by an access to 0x5200 A7FC.
  - BYSA_DREQ_1 is cleared by an access to 0x5200 AFFC.
- For BYS_B:
  - BYSB_DREQ_0 is cleared by an access to 0x5200 E7FC.
  - BYSB_DREQ_1 is cleared by an access to 0x5200 EFFC.

, and BSC_PAGE[] ACCn < BSC_DMA_REQS[] ACCn. The value of BSC_PAGE[] ACCn is also incremented by 1 in that case.

This mechanism is used to trigger the DMA requests up to 16x each time one of the selected events occurs (the number of times a DMA request is triggered can be configured in the BSC_DMA_REQS[] ACCn bit field). It allows to completely readout the accumulator without software intervention and using a single DMA channel.

8.2.9.3.3 ISS BYS Reset

An active low asynchronous hardware reset (CAM_RESET) is provided by the PRCM module and propagated from ISS top level.

Software must ensure that there is no active traffic on the slave port and input/output video ports before requesting a hardware reset.

Alternatively, the BYS modules support a software reset, through the BYS_HL_SYSCONFIG[0] SOFTRESET bit.

When a BYS module comes out of reset, it starts accepting data only from a clean frame boundary. The same is expected for the camera interface engines connected to the output video port.

8.2.9.3.4 ISS BYS Clock Domains

Each BYS module has two clock domains:

- Functional clock (ISS_MAIN_FCLK) domain – up to 304 MHz.
- Input video port pixel clock (BYSIN_PCLK) – up to 304 MHz for interconnection with CSI2 engines.
- Output video port pixel clock (BYSOUT_PCLK) - up to 304 MHz.

Both clock domains are asynchronous. Most of the internal logic is in the functional clock domain. Data received on the input video port is resynchronized to the functional clock domain in early stages of the pipeline. The slave port interface to the ISS interconnect runs at half the functional clock (up to 152 MHz).

8.2.9.3.5 ISS BYS Power Management

No PRCM interface is implemented. Each BYS module implements an efficient autogating, so that the power consumption of unused logic is minimal. By default, the pixel clock on the output video port (BYSOUT_PCLK) is enabled four cycles before the first pixel is sent, active while the pixels are being sent, and disabled 4 pixels after the last pixel has been sent.

The functional clock for each BYS module can be cut by software to reduce power consumption, by switching off the modules from the ISS_CLKCTRL register on ISS top level, through bit [5] BYS_A and bit [7] BYS_B (see Section 8.1.3, *ISS Register Manual*). This should be done only when the BYS modules are not in use.

8.2.9.3.6 ISS BYS Video Ports

Each BYS module has one video port for data input (see Table 8-318) and another video port for data output (see Table 8-319).

Table 8-318. BYS Input Video Port Signals

Signal Name	I/O[1]	Description
BYSIN_PCLK	I	Pixel clock received from the CSI2 engines. Asynchronous from the functional clock
BYSIN_VS	I	Active during the first pixel of the frame
BYSIN_HS	I	Active during the first pixel of any line
BYSIN_DATA[15:0]	I	Input pixel 1 data. MSBs padded with 0s when less than 16 bits are used.
BYSIN_DATA[31:16]	I	Input pixel 2 data. MSBs padded with 0s when less than 16 bits are used.
BYSIN_DATA[47:32]	I	Input pixel 3 data. MSBs padded with 0s when less than 16 bits are used.
BYSIN_DATA[63:48]	I	Input pixel 4 data. MSBs padded with 0s when less than 16 bits are used.

(1) I = Input; O = Output

Table 8-319. BYS Output Video Port Signals

Signal Name	I/O[1]	Description
BYSOUT_PCLK	O	Pixel clock provided to the CSI2 engines. Synchronous to the functional clock. Mean clock rate defined by the BYS_FIFO_BW[31:16] OB bit field.
BYSOUT_VS	O	Active during the first pixel of the frame
BYSOUT_VE	O	Active during the last pixel of the frame
BYSOUT_HS	O	Active during the first pixel of any line
BYSOUT_HE	O	Active during the last pixel of any line
BYSOUT_DATA[15:0]	O	Output pixel 1 data. MSBs padded with 0s when less than 16 bits are used.

(1) I = Input; O = Output

The input video port is asynchronous from the functional clock (ISS_MAIN_FCLK). The output video port is synchronous to the functional clock and the data rate is controlled through software configuration (refer to Section 8.2.9.4.6, *ISS BYS Output Buffer*, for more information)

The input video port is 4 pixels × 16 bits wide and carry 4 or 0 pixels per pixel clock cycle. The output video port is 1 pixel × 16 bits wide and carry 1 or 0 pixels per pixel clock cycle. Pixels are LSB-aligned inside 16-bit containers on the bus. For example, when PIX_DEPTH = 12 bits, the following mapping is implemented for the BYS input video port:

Table 8-320. BYS Input Video Port Transaction

Cycle Number	HS	VS	DATA [11:0]	DATA [15:12]	DATA [27:16]	DATA [31:28]	DATA [43:32]	DATA [47:44]	DATA [59:48]	DATA [63:60]
1	1	1	Pixel 0	0s	Pixel 1	0s	Pixel 2	0s	Pixel 3	0s
2	0	0	Pixel 4	0s	Pixel 5	0s	Pixel 6	0s	Pixel 7	0s
…										

Table 8-320. BYS Input Video Port Transaction (continued)

Cycle Number	HS	VS	DATA [11:0]	DATA [15:12]	DATA [27:16]	DATA [31:28]	DATA [43:32]	DATA [47:44]	DATA [59:48]	DATA [63:60]
Last pixel of a line (but not last line)	0	0	Last pixel of the line	0s	0s	0s	0s	0s	0s	0s
…										
Last pixel of the frame (example where the width is not a multiple of 4)	0	0	Last pixel of the frame	0s	0s	0s	0s	0s	0s	0s

The output video port pixel clock may be free-running or gated during horizontal and vertical blanking times (control provided in the BYS_CTRL[5] VPORT_FORCEON bit). HS/VS are pulses and the BYS module counts pixels and lines to detect valid image areas.

On both video ports there must be at least four PCLK pulses before the first pixel of a frame (that is, after reset). There must be at least four PCLK cycles of vertical blanking between frames.

The minimum horizontal blanking on the input video port is eight functional clock cycles. It can be artificially created by cropping a few pixels, if the data source connected to this video port does not provide enough blanking.

Software does not need to provide the size of the image received from the camera. It can specify cropping settings. However, software must ensure that the image size received on the input video port is equal to or larger than what the bayer scaler expects:

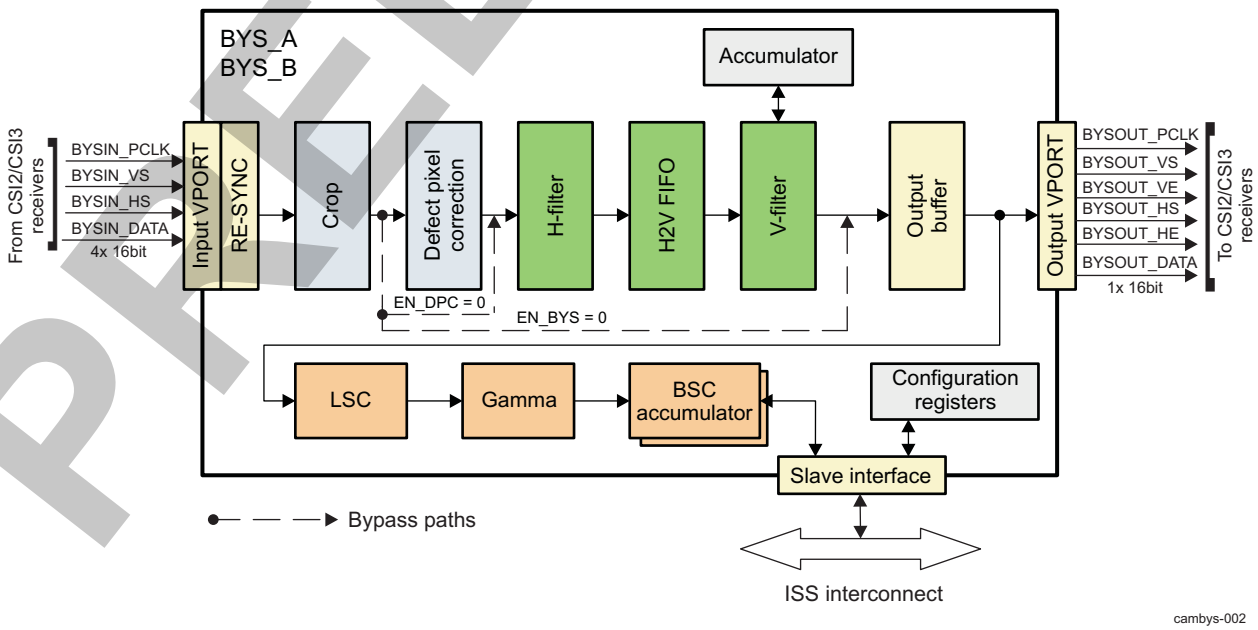
- Input image width >= BSC_SKIP_i[12:0] HSKIP + BSC_CNT_i[12:0] HCNT
- Input image height >= BSC_SKIP_i[28:16] VSKIP + BSC_CNT_i[28:16] VCNT

8.2.9.4 ISS BYS Functional Description

8.2.9.4.1 ISS BYS Block Diagram

Figure 8-108 shows a top-level overview of the BYS modules.

Figure 8-108. BYS Block Diagram



The following must be considered for the bypass paths from Figure 8-108:

- When BYS_CTRL[4] EN_BYS bit: 0x0
  - The bayer scaler is disabled and the processing logic is bypassed.
  - Cropping of the input image can still be performed.
  - Input and output bandwidth is limited to 1 pixel per functional clock cycle.
  - Data on the output video port is the same as data on the input video port (if no cropping is performed).
- When the BYS_CTRL[1] EN_DPC bit = 0x0:
  - Only the Defect Pixel Correction block is bypassed.
  - The EN_DPC bit is ignored, when the EN_BYS bit is set to 0x0.

8.2.9.4.2 ISS BYS Interrupt Events

All events generated by each BYS module are merged into single events at ISS top level (one event per BYS module, BYSA_IRQ and BYSB_IRQ). Each event at ISS top level can be enabled by the ISS_HL_IRQENABLE_SET_i[18] BYS_A_IRQ and/or [20] BYS_B_IRQ bits. For more information on ISS interrupts, see ISS Interrupts.

Table 8-321 lists the BYS modules interrupt events. Software control over each event is provided through the BYS_HL_IRQENABLE_SET, BYS_HL_IRQENABLE_CLR, and BYS_HL_IRQSTATUS registers.

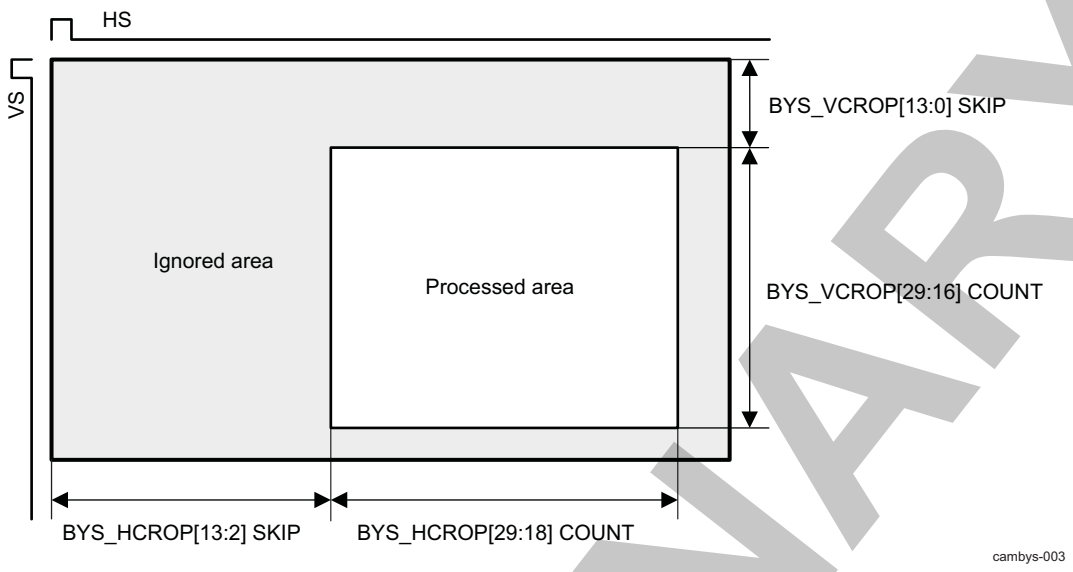
Table 8-321. BYS Interrupts

Event	Description
VPI_SOF	Start of frame event. Triggered when the first pixel is received on the input video port. Matches the moment where shadow registers are swapped. Refer to Section 8.2.9.4.8, *BYS Registers Shadowing*, for more details on shadowing mechanism.
VPO_EOF	Video port end of frame event. Triggered when the last pixel of a frame has been sent to the output video port.
EOFx (x = 0, 1)	End of frame event of Boundary Signal Calculator (BSC) pipeline "x". Triggered when the last active bin has been updated.
LINE	Line event. Triggered when the input line number before the cropping stage matches the BYS_LINE[12:0] LINE bit field value. The input line number is reset when a VS pulse is received on th input video port and incremented by one on every HS pulse. The event is triggered at the beginning of the line (that is, when the first pixel of the line is received). This feature is typically used to synchronize BYS with other downstream processing. NOTE: LINE and VPI_SOF events will by triggered in the same time when BYS_LINE[12:0] LINE = 0.
OB_OVR	Output buffer overflow event. This event occurs when the chosen buffer readout rate is too low for the incoming pixel rate. The pixels and BSC statistics for the frame are corrupted and must be discarded when this event has occurred. Software must reset the module and configure it properly (this overflow will be systematic failure and occur on every frame, if the configuration is not fixed).
H2V_OVR	Scaler H2V FIFO overflow event. This event occurs when data written by the horizontal filter stage arrives at a higher rate than what the vertical filter stage can process. This error is due to wrong configuration.

8.2.9.4.3 ISS BYS Cropping

The image received from the input video port can be cropped in the X and Y directions before any further processing is done. This technique is typically used when the full field of view is not required and digital zoom is enabled. Figure 8-109 shows an example of image cropping.

Figure 8-109. BYS Image Cropping



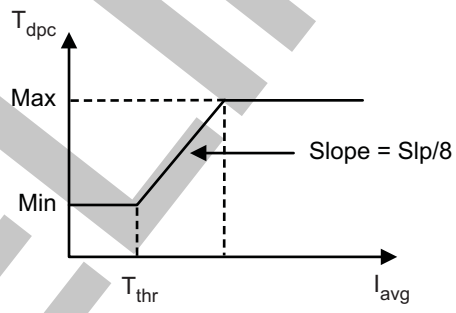
The settings for horizontal cropping are defined in the BYS_HCROP register. The vertical cropping settings are defined in the BYS_VCROP register.

8.2.9.4.4 ISS BYS Defect Pixel Correction

The main purpose of the defect pixel correction (DPC) block is to detect defects and avoid spreading them.

Figure 8-110 shows how the defect pixel threshold is computed.

Figure 8-110. BYS DPC Threshold Computation



I_{avg} = Average (pixels in the neighborhood)
T_{dpc} = Computed threshold to determine defects
Slp = Slope of threshold increase
T_{thr} = Minimum brightness level to begin increasing threshold
Min = Minimum DPC threshold value
Max = Maximum DPC threshold value

The sensitivity of the DPC algorithm is controlled by the BYS_DPCBRT and BYS_DPCTHR registers:

- The Slp parameter is controlled by the BYS_DPCBRT[23:16] SLP bit field.
- The T_{thr} parameter is controlled by the BYS_DPCBRT[11:0] THR bit field.
- The Min parameter is controlled by the BYS_DPCTHR[11:0] MIN bit field.
- The Max parameter is controlled by the BYS_DPCTHR[27:16] MAX bit field.

The DPC block is disabled by default. It can be enabled by setting the BYS_CTRL[1] EN_DPC bit to 0x1.

8.2.9.4.5 ISS BYS Scaler and H2V FIFO

The scaler consists of two independant horizontal and vertical stages with intermediate H2V FIFO, implemented to smooth the data traffic.

The **horizontal scaler** receives and processes 4 pixels per functional clock cycle. The output pixel rate depends on the input pixel rate and the selected horizontal scaling factor. Faulty pixels do not change the throughput.

The output of the horizontal scaler is stored in the H2V FIFO to smooth the data rate for the vertical scaler.

- Data is written into the FIFO at data production rate and the readout speed from the FIFO is controlled by the BYS_FIFO_BW[15:0] H2V register bit field. Typically, software must choose the lowest possible readout rate. No data is read when the buffer is empty (when the chosen rate is too high or during blanking periods).
- Software must choose such data rate, so that the internal buffer does not overflow. If misconfiguration causes an overflow, a H2V_OVR event occurs (see Section 8.2.9.4.2, *ISS BYS Interrupt Events*).
- The vertical scaler input pixel clock can be calculated as: BYS_FIFO_BW[15:0] H2V × ISS_MAIN_FCLK

The **vertical scaler** can process up to one input pixel per functional clock cycle. The output image of the vertical scaler is first cropped to the size defined by the BYS_OSIZE register, and the data is then sent to the output buffer FIFO.

8.2.9.4.5.1 Scaler Output Image Size Configuration

The output image size, set through the BYS_OSIZE register, must be aligned with other register settings. The BYS_OSIZE register can be used to crop the image after the scaling operation. That is mainly useful when the exact size cannot be chosen through the input size and scaling factor, or if odd and even lines do not have the same size because of different initial phases (refer to Section 8.2.9.4.5.2, *Scaler Phase Initialization Tables*, for more details).

BYS_OSIZE[] xSIZE <=
floor((BYS_xINIT[13:0] INI0 + (BYS_xCROP[] COUNT / 2 - 1) × BYS_SCALE[] xSCALE) / 8192, 1) +
floor((BYS_xINIT[29:16] INI1 + (BYS_xCROP[] COUNT / 2 - 1) × BYS_SCALE[] xSCALE) / 8192, 1)
where x = H or V.

8.2.9.4.5.2 Scaler Phase Initialization Tables

Software must choose properly the initial horizontal phase (through the BYS_HINIT register) and initial vertical phase (through the BYS_VINIT register), to get a correct image. The following constraint applies for correct operation:

BYS_HINIT[13:0] INI0 >= BYS_HINIT[29:16] INI1

The following formulas and tables explain how to set the BYS_HINIT and BYS_VINIT registers for a given scaling factor. Phase initialization parameters are different for normal mode (in Table 8-322 and Table 8-323) and 2x2 binning mode (in Table 8-324 and Table 8-325). The table indexes (ih, iv) start from 1.

ih = round((8192/BYS_SCALE[13:0] HSCALE)*256 - 256 + 1)

iv = round((8192/BYS_SCALE[29:16] VSCALE)*256 - 256 + 1)

The initial horizontal (HINIT) and vertical (VINIT) phases for normal mode (no binning) can be calculated as follows:

- For even line: BYS_HINIT[13:0] INI0 = Table 8-322 (ih)
- For even line: BYS_VINIT[13:0] INI0 = Table 8-322 (iv)
- For odd line: BYS_HINIT[29:16] INI1 = Table 8-323 (ih)
- For odd line: BYS_VINIT[29:16] INI1 = Table 8-323 (iv)

The initial horizontal (HINIT) and vertical (VINIT) phases for 2x2 binning mode can be calculated as follows:

- For even line: BYS_HINIT[13:0] INI0 = Table 8-324 (ih)

- For even line: BYS_VINIT[13:0] INI0 = Table 8-324 (iv)
- For odd line: BYS_HINIT[29:16] INI1 = Table 8-325 (ih)
- For odd line: BYS_VINIT[29:16] INI1 = Table 8-325 (iv)

Table 8-322. Even Line Initial Phases for Normal Mode (no Binning)

8.2.9.4.6 ISS BYS Output Buffer

The scaler filter typically generates heavy burst traffic and output FIFO is implemented to smooth this traffic.

Data is written into the output FIFO at data production rate and the readout speed from the FIFO is controlled by the BYS_FIFO_BW[31:16] OB bit field. Software must choose the lowest possible readout rate. No data is read when the buffer is empty (when the chosen rate is too high or during blanking periods).

Software must choose such data rate, so that the internal buffer does not overflow. If misconfiguration causes an overflow, an OB_OVR event occurs (see Section 8.2.9.4.2, *ISS BYS Interrupt Events*).

- The output video port pixel clock (BYSOUT_PCLK) can be calculated as: BYS_FIFO_BW[31:16] OB × ISS_MAIN_FCLK

8.2.9.4.7 ISS BYS Boundary Signal Calculator

8.2.9.4.7.1 BSC Polynomial Radial Lens Shading Compensation

In camera applications, optical elements often leave an artifact that reduces image intensity as pixels are farther from the center of the image. Stabilization quality is reduced when the corners of image are too dark. The lens shading compensation (LSC) feature solves this problem.

NOTE: LSC does not impact pixel data sent to the output video port.

The shading gain calculation is performed in the LSC_CORE submodule. Figure 8-111, *BYS LSC_CORE Algorithm*, shows approximate calculation details. Only one instance of the shading gain is computed per pixel received from the output buffer and sent to the gamma correction engine. The LSC algorithm is not applied to pixels sent to the output video port.

NOTE: Figure 8-111 and Figure 8-112 show the computation precision using the [SU]n.m notation for pixel depth of 12 bits, where:

- [SU]: Either S for a signed number or U for an unsigned number
- N: Number of integer bits
- M: Number of fractional bits

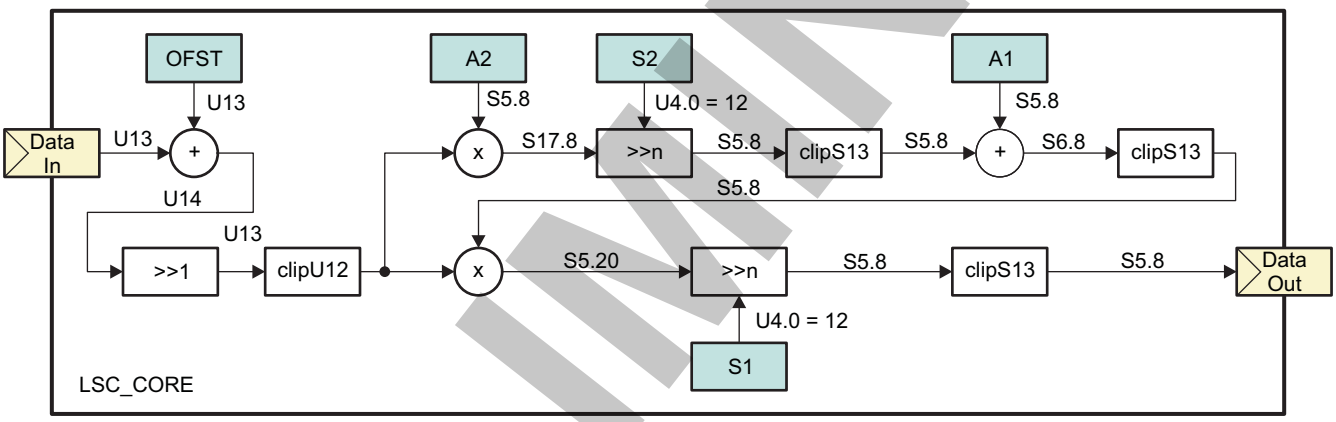
Some arithmetic notation examples are provided in the following table:

Notation	Signed?	Int/frac	Coding	Min	Max	Step
U16.0	Unsigned	Integer	16	0	65535	1
S16.0	Signed	Integer	16	–32768	32767	1
U10.5	Unsigned	Fractional	15	0	1023.96875	0.03125
U13.4	Unsigned	Fractional	17	0	8191.9375	0.0625
S13.4	Signed	Fractional	17	65536	4095.9375	0.0625

cambys-005

The position of the fractional point is configurable at some processing stages using the S0, S1, and S2 parameters. The position of the fractional point provided in Figure 8-111 is an example corresponding to the shown values of the Sx parameters.

Figure 8-111. BYS LSC_CORE Algorithm



cambys-006

The LSC_CORE is instantiated two times. One LSC_CORE instance is operating on the horizontal position and the other one is operating on the vertical position. The pixel position ranges from 0…8191 (i.e. U13). The algorithm details and precision requirements shown on Figure 8-112, *BYS LSC Algorithm*, below, are informative.

The LSC algorithm receives the pixel position and as well the pixel value from the output buffer. It executes the LSC_CORE algorithm on the horizontal and vertical coordinates. The results are combined together to compute a gain for each pixel received from the output buffer. The pixel is then multiplied by the gain and forwarded to the gamma correction stage.

Figure 8-112. BYS LSC Algorithm

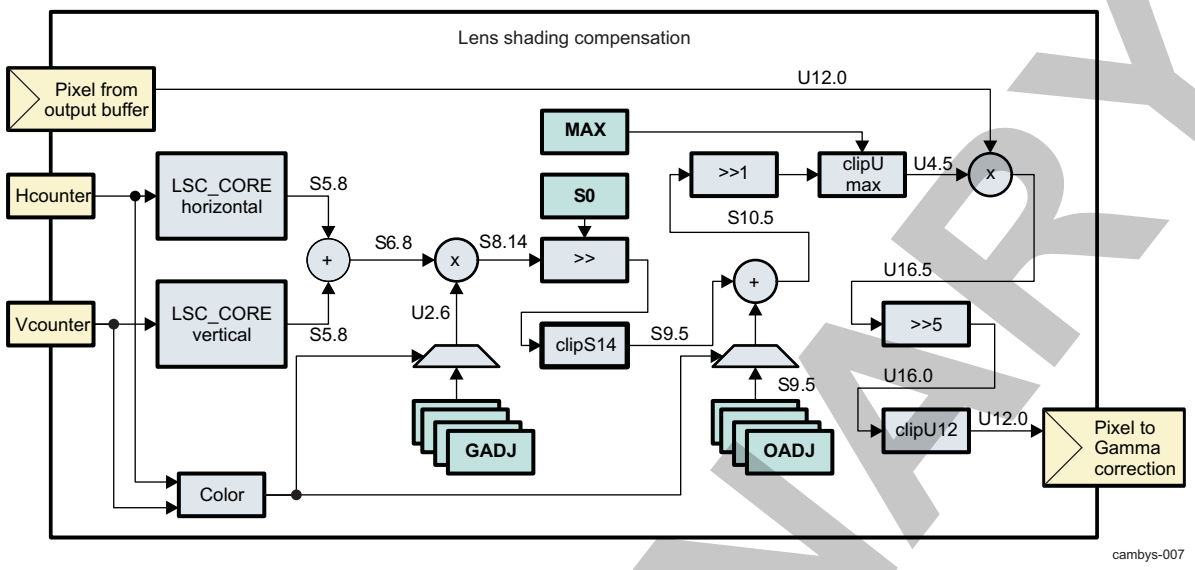


Table 8-326 lists the mapping of BYS module registers to the parameters used in Figure 8-111 and Figure 8-112.

Table 8-326. LSC Parameters Summary

Parameter	Description	Precision	Horizontal	Vertical
OFST	Initial X (horizontal) and Y (vertical) coordinates	U13	BSC_LSC_OFT[12:0] HOFST	BSC_LSC_OFT[28:16] VOFST
A2	X2 term coefficient, fixed point integer	S13	BSC_LSC_A2[12:0] HA2	BSC_LSC_A2[28:16] VA2
S2	X2 term coefficient, radix point position	U4	BSC_LSC_S[7:4] HS2	BSC_LSC_S[23:20] VS2
A1	X term coefficient, fixed point integer	S13	BSC_LSC_A1[12:0] HA1	BSC_LSC_A1[28:16] VA1
S1	X term coefficient, radix point position	U4	BSC_LSC_S[3:0] HS1	BSC_LSC_S[19:16] VS1
GADJ	Gain adjust	U8	BSC_LSC_GAN_0X[7:0] GAN_00 BSC_LSC_GAN_0X[23:16] GAN_01 BSC_LSC_GAN_1X[7:0] GAN_10 BSC_LSC_GAN_1X[23:16] GAN_11	
S0	Gain adjust, radix point position	U4	BSC_LSC_SHF[3:0] VAL	
OADJ	Offset adjust	S14 Valid range = (-4096 to +4095)	BSC_LSC_OFT_0X[13:0] OFT_00 BSC_LSC_OFT_0X[29:16] OFT_01 BSC_LSC_OFT_1X[13:0] OFT_10 BSC_LSC_OFT_1X[29:16] OFT_11	
MAX	Maximum gain	U9	BSC_LSC_MAX[8:0] VAL	

The software can configure different GADJ and OADJ parameters for each of the four color planes (Gb, B, Gr, and R). During LSC algorithm execution, the BSC selects the appropriate bit field for the GADJ and OADJ parameters to be used, based on the position of the pixel after the cropping and scaling operation. The following equations are used:

- GADJ(algorithm parameter) = GADJ(register setting)[Vcounter][Hcounter]
- OADJ(algorithm parameter) = OADJ(register setting)[Vcounter][Hcounter],

where Hcounter and Vcounter indicate the position of the pixel after the cropping and scaling operations (the top-left corner position is (0,0)).

By default, the LSC module is disabled (bypassed). Software must set the BSC_GLOBAL_CTRL[0] EN_LSC register bit to 0x1 to enable it.

8.2.9.4.7.2 BSC Gamma Correction

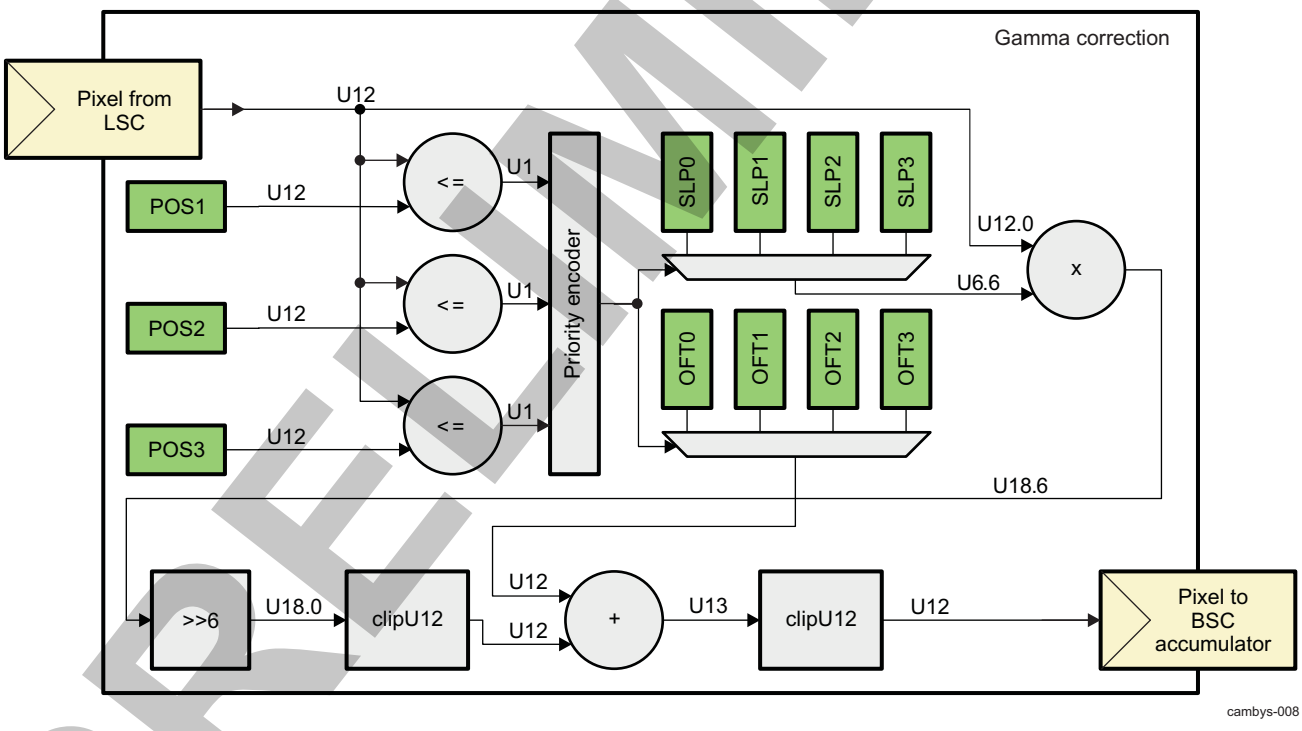
To prevent dark regions from contributing to statistics, gamma correction is applied before the BSC statistics are computed. Sensors typically have high gamma values (for example, 2.2) that produce dark images.

NOTE: Gamma correction does not impact pixel data sent to the output video port.

Gamma correction is implemented as a linear interpolation with four segments. Software can control the three inner control points. The two outer control points are fixed to (0,0) and (4095,4095). Figure 8-113, *BYS Gamma Internal Architecture*, shows the internal architecture of the gamma correction stage. The inner control points are defined by three parameters (assuming a 12-bit pixel depth):

- Position (U12.0 precision): controlled by the POSn bit field (n = 0 to 3, segment index) in the BSC_GAMMA_POS01 and BSC_GAMMA_POS23 registers
- Offset (U12.0 precision): controlled by the OFTn bit field (n = 0 to 3, segment index) in the BSC_GAMMA_OFT01 and BSC_GAMMA_OFT23 registers
- Slope (U12.6 precision): controlled by the SLPn bit field (n = 0 to 3, segment index) in the BSC_GAMMA_SLP01 and BSC_GAMMA_SLP23 registers

Figure 8-113. BYS Gamma Internal Architecture



The gamma correction algorithm first checks to which segment (n) of the gamma curve the input pixel (pixin) belongs:
If (pixin < POS1) then n = 0 (first segment);
else if (pixin < POS2) then n = 1 (second segment);
else if (pixin < POS3) then n = 2 (third segment);
else n = 3 (fourth segment);
Then it computes the output pixel value using the formula below:
$pix_{out} = SLP_n \times pix_{in} + OFT_n$

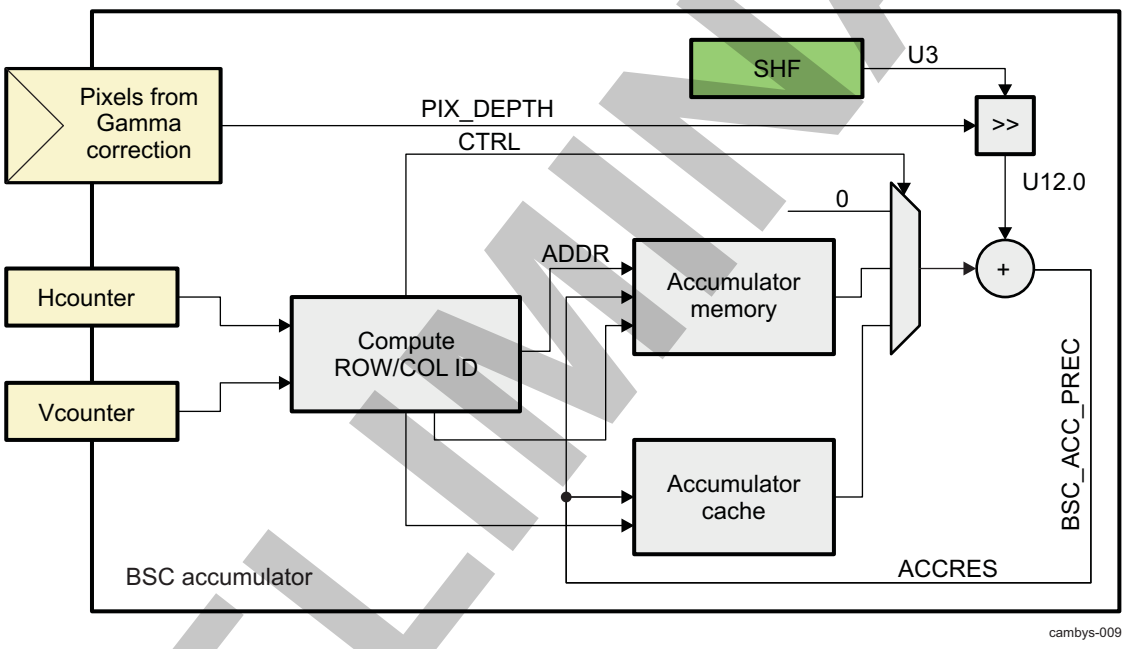
NOTE: The BSC_GAMMA_POS01[11:0] POS0 bit field is not required to implement a pure gamma function. However, it allows adding an offset to the curve. In some cases this may provide better noise robustness than multiplying low-intensity values by high gains.

By default, the Gamma Correction module is disabled (bypassed). Software must set the BSC_GLOBAL_CTRL[1] EN_GAMMA register bit to 0x1 to enable it.

8.2.9.4.7.3 BSC Accumulator

BSC decomposes the image into paxels (rectangular regions of the image) and accumulates pixel values for each paxel. The BSC accumulator module has two independent pipelines, Pipe 0 and Pipe 1, each with one with associated accumulators, ACC0 and ACC1 respectively, which can operate on the same pixel. Figure 8-114 shows a logical representation of one processing pipeline. It receives RAW12 data from the gamma correction engine and stores accumulation results in an on-chip memory. Software can read this memory using the MMR interface.

Figure 8-114. BYS BSC Accumulator Overview



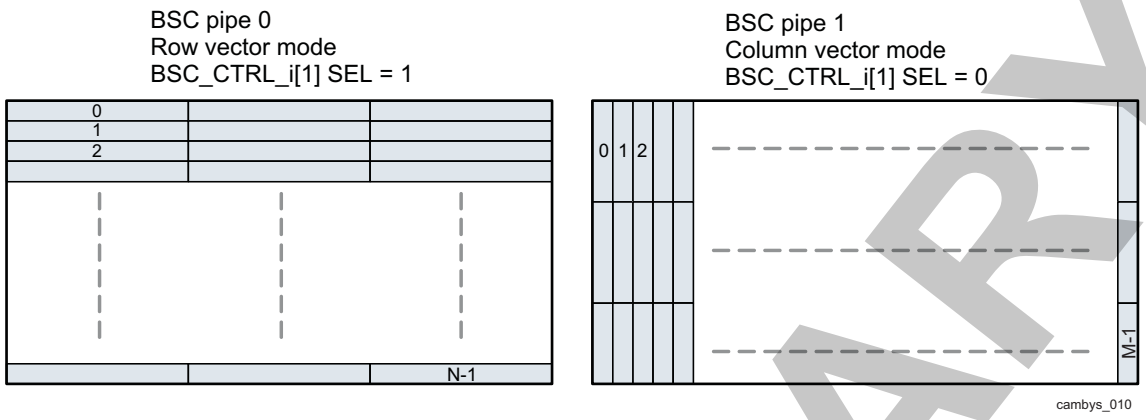
Hcounter and Vcounter correspond to the pixel coordinates (after cropping and scaling operations).

The BSC accumulator computes the bin ID (= ADDR in the accumulator memory) for each incoming pixel. It also determines, if the new data is used as it is, if it is accumulated to data already in the accumulator cache, or if it is accumulated with data stored in the memory. Then the accumulation operation is performed and the result is stored in either the accumulator memory or the accumulator cache.

When BSC is used for translational stabilization, one of the processing pipelines is typically used for row summations and the other one for column summations. However, hardware does not impose any particular restrictions and software may chose to use both pipelines for row summations or to have square bins.

Figure 8-115 shows a possible configuration. BSC pipe 0 (ACC0) computes row sums using wide rectangle bins (when BSC_CTRL_i[1] SEL regietsr bit is set to 0x1) and pipe 1 (ACC1) computes column sums using tall rectangle bins (when BSC_CTRL_i[1] SEL bit is set to 0x0). Both pipes operate independently and therefore, bins from both pipes can spatially overlap. The numbers in the bins represent the accumulator ID (that is, the address offset in the BSC accumulator memory).

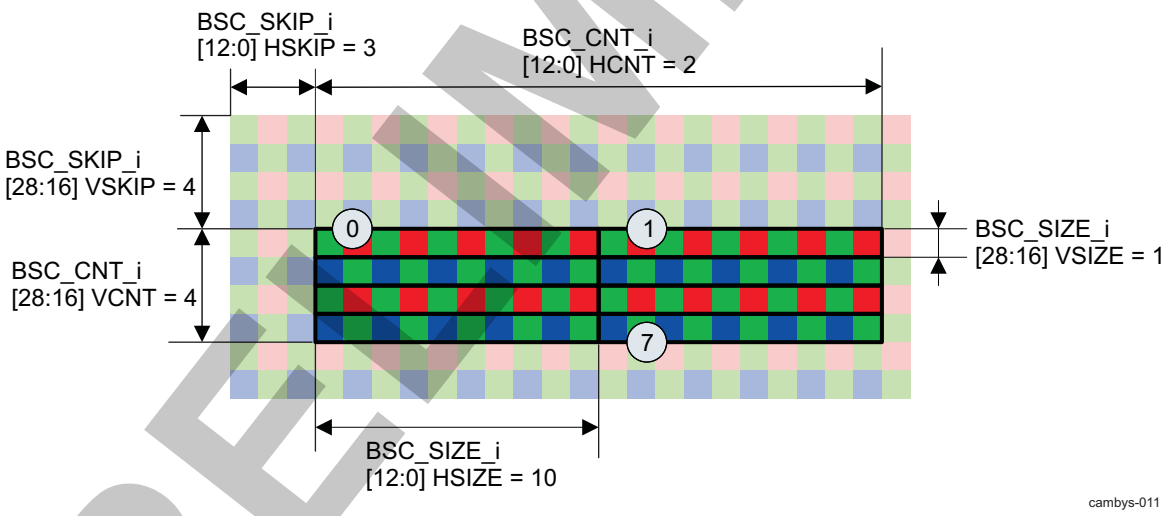
Figure 8-115. BYS BSC Bin Mapping for Row and Column Sums



Software chooses the bin size using BSC_SIZE_i[12:0] HSIZE and BSC_SIZE_i[28:16] VSIZE bit fields. The offset from the top left image corner to the first bin is defined by the BSC_SKIP_i[12:0] HSKIP and BSC_SKIP_i[28:16] VSKIP bit fields. Software also defines the numbers of bins in each direction using the BSC_CNT_i[12:0] HCNT and BSC_CNT_i[28:16] VCNT bit fields.

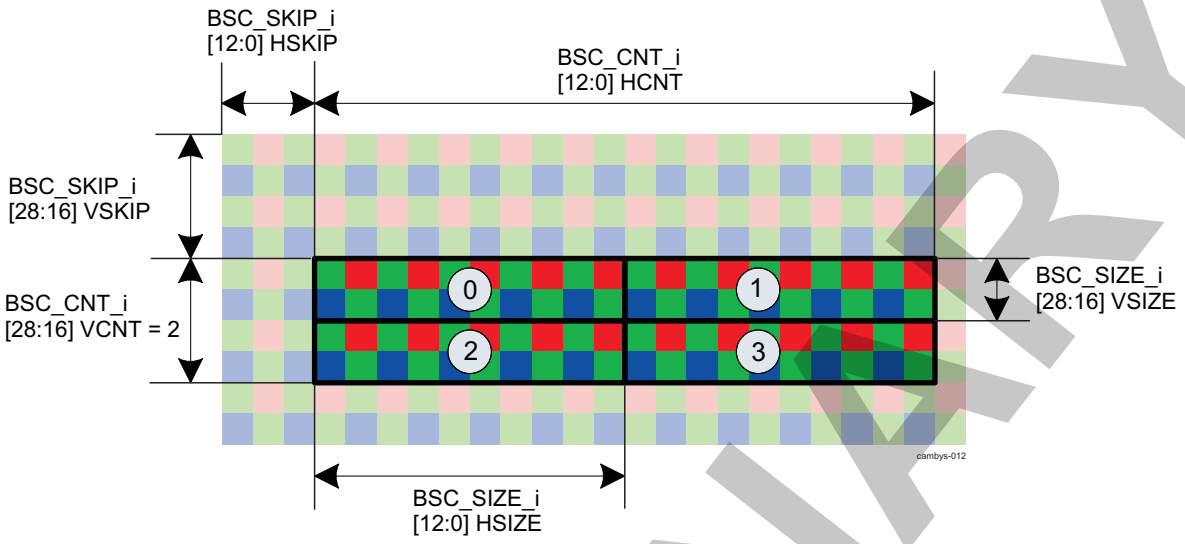
Figure 8-116 and Figure 8-117 show how the framing and bin size parameters, controlled by software, map to the pixels in the images when row accumulation is selected (BSC_CTRL_i[1] SEL bit = 0x1). In these two figures, only pixels shown with saturated colors are considered for the accumulation operation. All pixels in a given bin are summed together and stored in the accumulator.

Figure 8-116. BYS BSC Bin Dimensions and Framing - Example 1



NOTE: In Figure 8-116, the number of rows per bin is odd. This typically leads to irregular vectors (that is, one sums Gb+B, the next one sums R+Gr). Software can compute luminance vectors with pixel resolution by summing vectors two by two.

Figure 8-117. BYS BSC Bin Dimensions and Framing - Example 2



The following formulas are used to compute the bin ID for a given input pixel, located at coordinates (H,V) in the image provided by the gamma correction module.

- Hardware first checks, if the incoming pixel is in the valid image region. That is the case when all of the following four conditions below are valid:
  - H >= BSC_SKIP_i[12:0] HSKIP
  - H < BSC_SKIP_i[12:0] HSKIP + (BSC_CNT_i[12:0] HCNT * BSC_SIZE_i[12:0] HSIZE)
  - V > BSC_SKIP_i[28:16] VSKIP
  - V < BSC_SKIP_i[28:16] VSKIP + (BSC_CNT_i[28:16] VCNT * BSC_SIZE_i[28:16] VSIZE)
- If the incoming pixel is in the valid image region, the accumulator ID is computed as follows by the hardware:
  - When BSC_CTRL_i[1] SEL = 0x0, then ID = floor((H – HSKIP) / HSIZE) + HCNT × floor((V - VSKIP) / VSIZE)
  - When BSC_CTRL_i[1] SEL = 0x1, then ID = VCNT × floor((H – HSKIP) / HSIZE) + floor((V - VSKIP) / VSIZE)

Hardware does not perform the accumulation operation, when the computed accumulator ID is higher than the implemented BSC buffer size (1968 bins for ACC0, and 3456 bins for ACC1). Accumulated values are clipped to the accumulator size: 23 bits for ACC0, and 22 bits for ACC1. Therefore, no accumulator overflow can occur.

By default, BSC accumulators are initialized to 0 when the first pixel of a bin is processed. This feature can be disabled by setting the BSC_CTRL_i[2] NOINIT register bit to 0x1. Not resetting the accumulators between frames allows cumulating data over multiple frames. Software may also choose to shift pixel values before accumulation to avoid saturation, by using the BSC_CTRL_i[10:8] SHF register bit field.

Software can access the BSC accumulator during memory cycles left unused by hardware. Internal accesses performed by the hardware have higher priority than external accesses done by software. Therefore, software accesses are stalled until the memory becomes available. Software must properly synchronize its accesses with hardware operations. See Section 8.2.9.4.7.4, *BSC Memory Bandwidth Availability*, and Section 8.2.9.4.7.5, *BSC Memory Synchronization*, for more details.

The following constraints apply to BSC configuration:

- When BSC_CTRL_i[1] SEL = 0x0
  - Up to two accesses per functional clock cycle can be performed to the memory.
  - The value set in BSC_CNT_i[12:0] HCNT register bit field must be an even number.
  - The value set in BSC_SIZE_i[12:0] HSIZE register bit filed must be >= 1.
- When BSC_CTRL_i[1] SEL = 0x1

- Only one memory access per functional clock cycle can be performed (that is, half of the BSC memory bus bandwidth).
- The value set in BSC_SIZE_i[12:0] HSIZE register bit field must be >= 2.

8.2.9.4.7.4 BSC Memory Bandwidth Availability

The hardware accesses the BSC accumulators on the left and the right border of every bin. Hardware can accommodate two accesses per functional clock cycle. Therefore, the BSC memory load (BYS_MEM_LOAD) can be computed using the formula

BYS_MEM_LOAD = PCLK / (ISS_MAIN_FCLK × BSC_SIZE_i[12:0] HSIZE),

where PCLK is the pixel readout rate from the output buffer (refer to Section 8.2.9.4.6, *ISS BYS Output Buffer*, for more details). Software can use the available BSC memory bandwidth to access the memory. Only one software access every two functional clock cycles is possible because the slave interface to the ISS interconnect runs at half the functional clock speed. Software and hardware accesses cannot be shared in the same slave interface clock cycle (that is, one software access accounts for two hardware accesses).

For example, when BSC_SIZE_i[12:0] HSIZE = 2 and PCLK = ISS_MAIN_FCLK, it is possible to perform one software access every two slave interface clock cycles, which corresponds to the maximum bandwidth supported by the slave interface to the ISS interconnect.

8.2.9.4.7.5 BSC Memory Synchronization

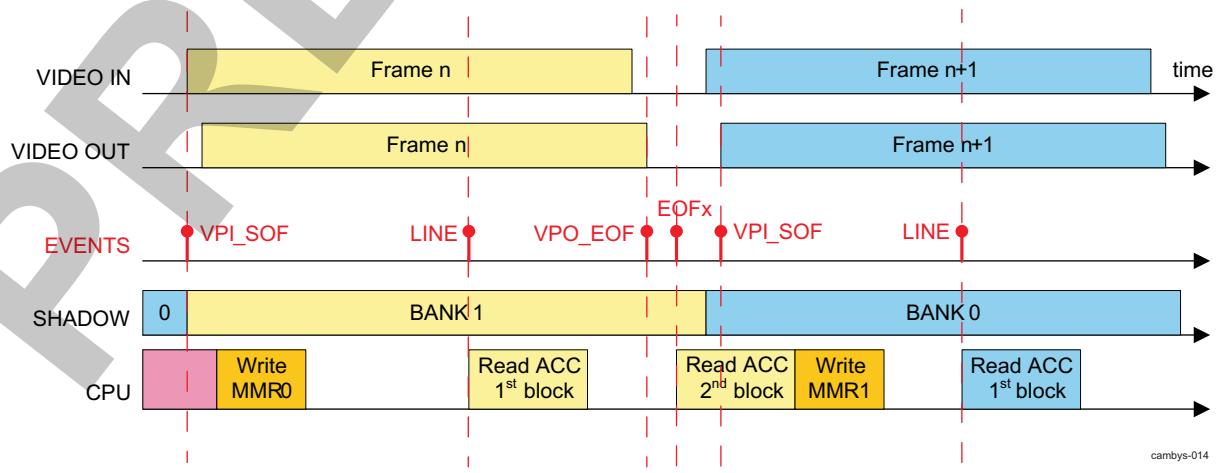
Accumulator bins are updated as pixels are received. When all pixels have been received for a given bin, the accumulator memory is ready to be read by software. Software can determine when to read out the BSC data by configuring and receiving the appropriate interrupt events.

Software can simply readout statistics for BSC accumulator pipe “x” when they have been collected for the full frame (indicated by EOFx event, see Section 8.2.9.4.2 *ISS BYS Interrupt Events*), and there is enough vertical blanking between frames.

This is not possible with small vertical blanking, because hardware may already be updating BSC accumulators before software has read all the data. In this case, it is preferred to configure the hardware to trigger two interrupt events (EOFx + LINE): one event when half of the accumulators are updated and another event when the second half of the accumulators are updated. This gives time equal to a half frame for reading half the accumulators.

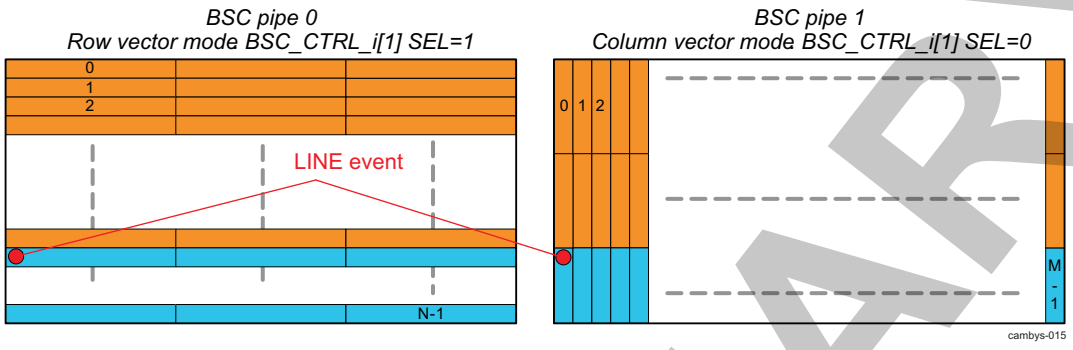
Figure 8-118 below shows an example:
The software reads accumulator results and updates registers settings on a frame by frame basis. Synchronization relies on the VPI_SOF interrupt event (for MMR updates), LINE event (to readout the first block of accumulators) and EOFx event (to readout the second block of accumulator data). The VPO_EOF event is shown for reference, but not used in this example. For more details on registers shadowing mechanism, refer to Section 8.2.9.4.8, *BYS Registers Shadowing*.

Figure 8-118. BYS Hardware – Software Memory Synchronization Example



The LINE event is triggered when a significant amount of accumulated data is ready. Ideally, it will be triggered in the middle of the active image, but that is not always possible. Figure 8-119 shows an example where the LINE event is triggered after approximately two-thirds of the image.

Figure 8-119. BYS BSC Partial Readout



NOTE: Accumulators colored with orange in Figure 8-119 can be read after the LINE event. Accumulators colored with cyan can be read after EOFx events. The accumulator IDs are not contiguous in row vector mode (three separate regions).

8.2.9.4.7.6 BSC Memory DMA Requests

Each BYS module handles up to two physical DMA request signals (one per BSC accumulator pipeline). These request signals can be propagated to the device DMA_SYSTEM module to transfer accumulator content without software intervention during timing-critical periods. Refer to , *ISS BYS DMA Requests*, for more information on DMA signals mapping and configuration.

The device DMA_SYSTEM must be configured as presented in Table 8-327.

Table 8-327. BYS Configuration for DMA_SYSTEM

Setting	Read Operation	Write Operation
Address mode	Double indexed	Post incremented
Start address	Memory location of the accumulator pipes for BYS_A: • 0x5200 A000 for ACC0 • 0x5200 A800 for ACC1 Memory location of the accumulator pipes for BYS_B: • 0x5200 E000 for ACC0 • 0x5200 E800 for ACC1	Destination address in the device SDRAM memory
Element size	4 bytes	32 bit
Element index	0 bytes	N/A
Element numbers per frame	512 (2 KiB per DMA request)	512 (2 KiB per DMA request)
Frame number	BSC_DMA_REQS[] ACCn + 1 (n = 0 or 1, BSC accumulator index)	BSC_DMA_REQS[] ACCn + 1 (n = 0 or 1, BSC accumulator index)
Frame index	– 2 KiB	N/A

The BYS module is typically configured to read the complete accumulator content when it has been updated.

- BSC_DMA_REQS[] ACCn = ceil(ENTRIES_TO_READ / 512) – 1, where n = 0 or 1 is the BSC accumulator index, and ENTRIES_TO_READ is up to 1968 for ACC0, and up to 3456 for ACC1.
- Trigger event = EOFx (all data has been updated, see Section 8.2.9.4.2, *ISS BYS Interrupt Events*).

It is also possible to read out the buffer in two halves, when column mode is selected (when BSC_CTRL_i[1] SEL = 0x0) and vertical blanking is low. That is done by enabling the follwong two trigger events (see Section 8.2.9.4.2, *ISS BYS Interrupt Events*):

- LINE: when the first half of the buffer has been updated
- EOFx: when the second half of the buffer has been updated

In that case, the value of BSC_DMA_REQS[] ACCn register bit field must correspond to the first half of the buffer (with adequate rounding to the 2 KiB boundaries).

NOTE: Readout in two halves for row mode (when BSC_CTRL_i[1] SEL = 0x1) must be done using software. The implemented hardware DMA request generation mechanism is not designed for that.

Software may use interrupts generated by the device DMA_SYSTEM to detect when all data has been transferred. Refer to *System DMA* chapter for more information.

8.2.9.4.8 ISS BYS Registers Shadowing

Table 8-328 shows which BYS registers are shadowed. All registers that are expected to be changed on a frame-by-frame basis are shadowed to remove register updates from the critical software timing path.

Table 8-328. BYS Shadow Registers

Register	Shadowed ?	Register	Shadowed ?

BYS_DPCTHR	YES	BSC_CNT_i	YES
BYS_LINE	YES		

Two instances exist for each shadow register. Software can choose which instance is accessed by hardware and which one is accessed by software. In automatic mode, register banks are swapped just before the first pixel of a new frame is received at the input video port. Software has a complete frame to update registers without interfering with hardware operation.

The following four shadowing modes are supported and can be selected by the BYS_CTRL[3:2] EN_SHADOW bit field:

1. EN_SHADOW = 0x0: No shadowing; hardware and software access bank 0

2. EN_SHADOW = 0x1: No shadowing; hardware and software access bank 1
3. EN_SHADOW = 0x2: Shadowing; hardware access bank 0 and software bank 1
4. EN_SHADOW = 0x3: Shadowing; hardware access bank 1 and software bank 0

Software can monitor the BYS_CTRL[8:7] SHADOW_STATE bit-field to check which mode is currently being used by HW.

Hardware automatically swaps between mode 2 and mode 3, when the first pixel of a valid frame is received on the input video port. The VPI_SOF interrupt event also notifies software of reception of the first pixel . Software may use this event to preload shadowed registers for the next frame.

NOTE: Hardware first swaps banks and then processes the first pixel, so that the same settings apply to all pixels of the frame. The BYS module implements a global shadowing mechanism: all settings are modified in the same time. Therefore, software must ensure that no more processing is ongoing when banks are swapped. Practically, this implies that there is enough vertical blanking between frames so that the VPO_EOF and EOFx interrupt events are triggered before the VPI_SOF event of the next frame.

After reset, registers shadowing and data processing are disabled, and both software and hardware access bank 0. Software must program all registers belonging to used functions except the BYS_CTRL register. The BYS module ignores incoming pixels during the configuration phase because after reset the BYS_CTRL[4] EN_BYS register bit is 0x0. Therefore, no side effects can occur, even if the input video stream is active.

After the new settings have been written by software into bank 0, the next step is to set the BYS_CTRL[4] EN_BYS bit to 0x1 and BYS_CTRL[3:2] EN_SHADOW bit field to 0x3. Hardware continues to see EN_BYS = 0, as it now accesses bank 1 which still contains reset values. Hardware swaps banks when the first pixel of the next valid frame is received on the input video port. Hardware now accesses bank 0 (EN_BYS = 1) and therefore processes the frame with proper settings.

CAUTION

The above mechanism ensures that new settings can only be applied on clean frame boundaries. Changing settings in the middle of a frame (that is, without using the shadowing mechanism) can lead to unpredictable behavior of hardware.

RESERVED																								SHADOW_STATE		NO_AUTOGATING	VPORT_FORCEON	EN_BYS	EN_SHADOW		EN_DPC	EN

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x00 0000
8:7	SHADOW_STATE	Indicates the shadow register currently in use by the hardware. Register written by hardware. Software must check this before writing the BYS_CTRL register when BYS is active, so that a write into EN_SHADOW bit-field does not unintentionally swap banks. Read 0x0: No shadowing. Hardware and software access bank 0. Read 0x1: No shadowing. Hardware and software access bank 1. Read 0x2: Shadowing. Hardware access bank 0 and software access bank 1. Read 0x3: Shadowing. Hardware access bank 1 and software access bank 0.	R	0x0

Bits	Field Name	Description	Type	Reset
6	NO_AUTOGATING	Control internal autogating. ** DEBUG FEATURE ** 0x0: Autogating enabled. This is the recommended behavior 0x1: Autogating disabled Power consumption is increased. Only for debug purposes.	RW	0
5	VPORT_FORCEON	Controls gating of the output video port clock 0x0: Auto-gating. The video port clock is - enabled when pixels are sent - enabled 4 cycles before the 1st pixel is sent - disabled 4 pixels after the last pixel has been sent - disabled otherwise 0x1: The pixel clock is free-running during blanking	RW	0
4	EN_BYS	Enable bayer scaler 0x0: Disabled. Bayer scaler processing is bypassed (i.e. the output of the bayer scaler is the same than the bayer scaler input) 0x1: Bayer scaler enabled	RW	0
3:2	EN_SHADOW	Controls register shadowing. Register written by software. 0x0: No shadowing. Hardware and software access bank 0 0x1: No shadowing. Hardware and software access bank 1 0x3: Shadowing. Hardware access bank 1 and software access bank 0. 0x2: Shadowing. Hardware access bank 0 and software access bank 1.	RW	0x0
1	EN_DPC	Enable defect pixel correction 0x0: Defect pixel correction bypassed 0x1: Defect pixel correction enabled	RW	0
0	EN	Enable the BYS module 0x0: Module disabled. Incoming pixels are ignored. 0x1: Enabled Incoming pixels will be processed.	RW	0

8.3 ISS ISP

This section describes the image signal processor.

8.3.1 ISS ISP Overview

The image signal processor (ISP) is part of the image subsystem (ISS) of the device and is a key component for imaging and video applications. It describes all ISP modules in the multimedia device; that is, the video port (VP), image pipe interface (IPIPEIF), image pipe module (IPIPE), resizer (RSZ), hardware 3A (H3A), image sensor interface (ISIF), and buffer logic (BL). For better understanding, see the first top-level ISS diagram and feature list in Section 8.1, *ISS Overview*.

8.3.1.1 ISS ISP Features

The video-processing hardware removes the need for expensive camera modules to perform processing functions. The ISS can support the following features:

- On-the-fly or memory-to-memory processing
- Up to 304-MHz pixel throughput
- Statistic data collection:
  - On-the-fly or memory-to-memory operation
  - Data collection for auto exposure
  - Data collection for auto white balance
  - Data collection for auto focus
  - Boundary signal calculation for video stabilization
- IPIPE front end: RAW data processing:
  - On-the-fly or memory-to-memory processing
  - 16-bit-wide RAW Bayer data path between image and sensor linearization module
  - 12-bit-wide RAW Bayer data path between sensor linearization module and gamma correction module. Gamma correction module outputs 10-bit data.
  - Programmable Bayer RGB positions
  - Sensor data linearization for dynamic range extension
  - Programmable 2D lens shading compensation (LSC) correction
  - Per-pixel gain and offset control
  - Black level compensation
  - Boxcar filter
  - Data collection for histogram generation
  - Defect pixel correction (LUT_DPC) with look-up table (LUT)
  - Defect pixel correction (OTF_DPC) with on-the-fly detection and correction
  - 2D noise filtering
  - Green imbalance correction (GIC)
  - Digital gains and offset
  - 8- to 10-bit A-law decompression and 10- to 8-bit A-law compression
- IPIPE back end: RGB and YUV data processing:
  - RGB-to-RGB color correction
  - Gamma correction (GC)
  - RGB -> YUV4:2:2: Color conversion, cosited Chroma filtering and downsampling
  - 2D edge enhancement (EE)
  - 3D LUT for color correction
  - False Chroma suppression (FCS)
- Two resizers:

- Performance: input and output rates up to 304 MPix/s
- YUV4:2:2 to RGB56, ARGB888, YUV4:2:2, and YUV4:2:0 data output
- YUV4:2:0 to YUV4:2:0 data output
- RAW to RAW data output
- Range from x1/4096 to x20. Supports memory-to-memory rescaling.

The ISP comprises the following modules:

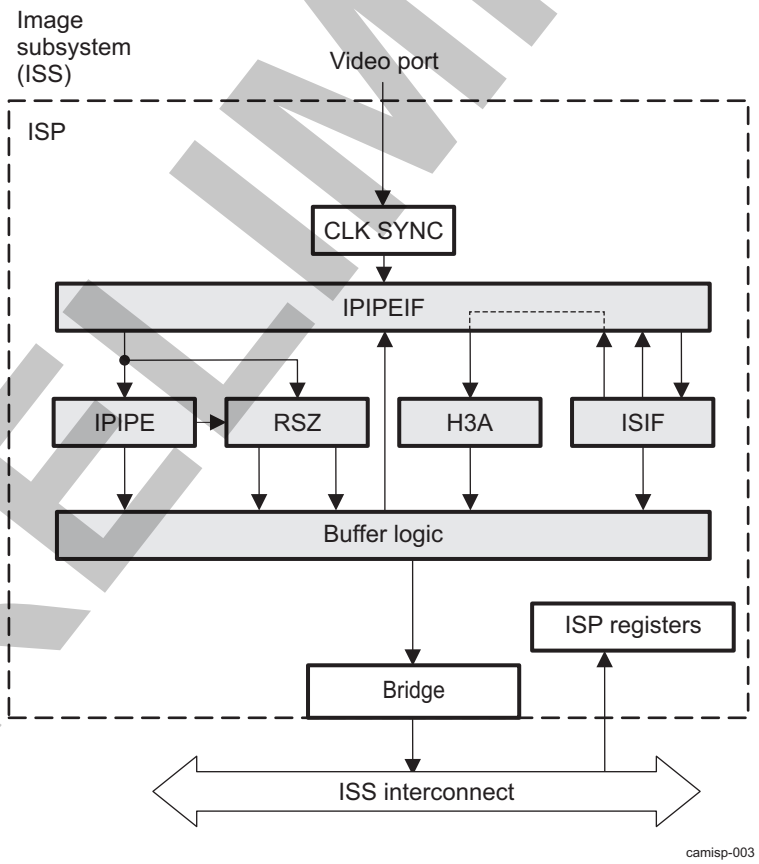
- IPIPE interface (IPIPEIF)
- Image sensor interface (ISIF) accelerator
- Auto exposure, auto white balance, and auto focus engine (H3A)
- Image pipe accelerator (IPIPE)
- Two resizer (RSZ) accelerators
- Buffer logic (BL): Receives module requests, performs arbitration, and creates read/write bursts to the memory subsystem

8.3.1.2 ISS ISP Block Diagram

Figure 8-120 is the ISP top-level block diagram. The ISS supports five simultaneous pixel flows (CCP2, CSI2_A, CSI2_B, CSI2_C and parallel interface [CPI]), but only one of them at a time can use the video-processing hardware; the others can go directly to memory (CPI must always use ISP).

The ISP 128-bit master port and 32-bit slave port are connected to the level 3 interconnect (L3_MAIN).

Figure 8-120. ISS ISP Block Diagram



8.3.2 ISS ISP Integration

This section describes the integration of the ISP modules in the ISP and includes information about clocks, resets, and hardware requests.

The ISP is part of the ISS of the device and is a key component for imaging and video applications such as camera viewfinder, video record, and still image capture.

The ISS is coupled with a low-interrupt-latency imaging processor unit subsystem (Cortex-M4 IPU) running a real-time operating system to reach optimal performance. Primarily, the IPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks. The ISS can also be configured using the main micro-processor unit subsystem (Cortex-A15 MPU) or the system DMA controller (DMA_SYSTEM). Typically, the MPU can run some less latency-sensitive tasks, and the DMA_SYSTEM can be used to transfer large configuration tables used by the ISS (for example, Gamma tables).

8.3.2.1 ISS ISP PRCM Interface

The ISP and its internal modules, as integrated in the ISS, use the same power and clock management details. See Section 8.1.2, *ISS Functional Description*, for the ISP top-level power, reset, and clock management (PRCM) interface.

8.3.2.1.1 ISS ISP Clocks

The PRCM module, through the local power and clock management inside the ISS, provides a unique PCLK that can be enabled from the ISP5_CTRL register.

The modules inside the ISP require three clocks:

- PCLK: This clock is asynchronous to the other clocks. It is provided by the module sending the data to the IPIPEIF module on the VP. The frequency is up to 304 MHz.
- ISP_FCLK: This clock is sourced from ISS_MAIN_FCLK and is synchronous with the configuration clock domain. This is the clock used for the MTC interface. The frequency is up to 304 MHz.
- GCK_MMR: This is the clock for the configuration bus. It is created from the ISP_FCLK and runs at half the speed of the ISP_FCLK. The frequency is up to 152 MHz.

8.3.2.1.2 ISS ISP Reset

The ISP supports global software reset along with internal hardware reset, if needed.

Software reset is done through the ISP5_SYSCONFIG[1] SOFTRESET bit. Before issuing a software reset, the ISP must be in standby mode. The following must be done:

1. Ensure that the interfaces are stopped from sending data and/or the ISP modules are disabled. Before reset, the last interrupt triggered by the ISP when the frame processing completes is RSZ_INT_DMA. RSZ_INT_DMA must be used to enable clean termination of the processing. Software must wait a few hundred cycles to trigger a soft reset after RSZ_INT_DMA is asserted; this is to ensure that the BL is completely drained.
2. Ensure that ISP5_SYSCONFIG[5:4] STANDBYMODE = 2 (smart standby). Set the ISP5_CTRL[24] MSTANDBY bit to 1 and poll for ISP5_CTRL[20] MSTANDBY_WAIT = 1. Then, the soft reset can be applied (ISP5_SYSCONFIG[1] SOFTRESET = 1).

In case an ISP overflow or underflow event happens (for example, RSZ_FIFO_OVF, ISIF_OVF, etc.), it is not sufficient to reset the ISP. In that case a reset must occur at the ISS level.

8.3.2.2 ISS ISP Interrupt Tree

There are four ISP output interrupt lines that are mapped to the ISS top interrupt request (IRQ) merger (for more information, see Section 8.1.2.1.1, *ISS Interrupt Merger*). Table 8-419 summarizes the ISP submodule interrupt events that can be mapped to the four ISP interrupt lines. An interrupt event can be enabled on any of the four interrupt lines through the ISP5_IRQENABLE_SET_i and ISP5_IRQENABLE_SET2_i registers (i = 0 to 3, one register per interrupt line). Each event must be enabled on only one interrupt line.

Table 8-419. ISS ISP Interrupt Tree Table

Register	Module	Destination	Comments
ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ	IPIPEIF	ISP to ISS merger four IRQ lines	See Section 8.3.2.3.1.

ISP5_IRQENABLE_SET_i[0] ISIF_INT_0			
ISP5_IRQENABLE_SET2_i[3] ISIF_OVF			

8.3.2.3 ISS ISP IPIPEIF Integration

8.3.2.3.1 ISS ISP IPIPEIF Interrupts

The IPIPEIF module generates two interrupts:

- IPIPEIF_IRQ: This event is triggered to the BL module when a new frame starts (VS signal). The interrupt is active high and is asserted for one GCK_MMR clock cycle.
- IPIPEIF_UDF: Interrupt generated when an underflow occurs in the IPIPEIF module.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ and ISP5_IRQENABLE_SET2_i[1] IPIPEIF_UDF bits (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See Section 8.1.2,*ISS Functional Description*.

For additional information on IPIPEIF events see Section 8.3.3.2.15, *ISS ISP IPIPEIF Module Events and Status Checking*.

8.3.2.4 ISS ISP IPIPE Integration

8.3.2.4.1 ISS ISP IPIPE Interrupts

IPIPE can generate several interrupts:

- IPIPE_INT_DPC_RNEW: This event is triggered when there is permission to initialize LUT-DPC table lines 0 and 1.
- IPIPE_INT_DPC_INI: This event is triggered when the defect pixel correction (DPC) table is initialized.
- IPIPE_INT_HST: This event is triggered when the histogram is done.
- IPIPE_INT_BSC: This event is triggered when boundary signal calculation is done.
- IPIPE_INT_DMA: This event is triggered when the boxcar SDRAM transfer is done. On this timing, IPIPE_INT_EOF is sent to the BL. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_LAST_PIX: This event is triggered when the last pixel of a frame comes into IPIPE. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_EOF: This event is triggered for end of frame.
- IPIPE_BOXCAR_OVF: This event is generated when an overflow occurs in the IPIPE-BOXCAR output buffer. The interrupt avoids polling the IPIPE_SRC_STA[0] VAL0 bit for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level.
- IPIPE_HST_ERR: This event is triggered when the MPU/IPU or system direct memory access controller (DMA_SYSTEM) is still reading the memory that is being used by the module. This is an indication that the read operation was not fast enough.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i and ISP5_IRQENABLE_SET2_i registers (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See Section 8.1.2, *ISS Functional Description*.

8.3.2.4.2 ISS ISP DMA Requests

The ISP generally outputs four direct memory access (DMA) requests, which can be used to read or write memories inside the IPIPE module. These memories are:

- BSC memory: This memory must be read during a vertical blanking period. It is used by the video stabilization application.
- HIST memory: This memory must be read during a vertical blanking period. It is used by the 3A application. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the IPIPE_HST_TBL[0] SEL bit.
- GAMMA memory: This memory must be set during a vertical blanking period. The imaging application typically uses multiple gamma tables.
- DPC memory: This memory must be set during a frame acquisition. The memory is not big enough to store all faulty pixels for a given frame.

To generate the DMA requests, the following events must be used:

- The IPIPE_INT_BSC event is used to generate the DMA request for the BSC memory. It maps on DMA line 1, ISS_DREQ_1.
- The IPIPE_INT_HST event is used to generate the DMA request for the HIST memory. It maps on DMA line 2, ISS_DREQ_2. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the IPIPE_HST_TBL[0] SEL bit. When the DMA request is set, it is required to read 4 KiB from the ping buffer address (0x2000) or the pong buffer address (0x3000). Software must ensure that when one buffer is selected no other accesses (for example, IPU) occur in the other buffer.
- The IPIPE_INT_LAST_PIX event is used to generate the DMA request for the GAMMA memory. This same event can also be used to initialize the DPC LUT (not the preferred method; it is better to use IPIPE_INT_DPC_INI). Basically, when the last pixel is output from the IPIPE module, it is safe to modify the IPIPE memories. It maps on DMA line 4, ISS_DREQ_4.
- The IPIPE_INT_DPC_INI event signals that DPC table memory initialization can occur. IPIPE_INT_DPC_INI is used to generate two back-to-back DMA requests, the first one mapping on

IPIPE_INT_DPC_RNEW0 and the second one mapping on IPIPE_INT_DPC_RNEW1. After initialization (steady state), the IPIPE_INT_DPC_RNEW0 and IPIPE_INT_DPC_RNEW1 events are used to generate the DMA request for the DPC LUT renewal. It maps on DMA line 3, ISS_DREQ_3. To select which event is used to initialize the DPC (IPIPE_INT_LAST_PIX or IPIPE_INT_DPC_INI), set the ISP5_CTRL[25] DPC_EVT_INI bit.

NOTE: The size of the DPC table in SDRAM must be a multiple of the number of DMA requests. It ensures that during burst capture mode the DMA always loads the correct data from frame-to-frame. The DMA automatically warps back to the start of the table after all expected DMA requests are received. There is a total of ceil(nb_faulty_pixel/128) + 2 DMA requests per frame when the IPIPE_INT_DPC_INI EVENT is used. Hence, the size of the DPC table in the SDRAM is (ceil(nb_faulty_pixel/128) + 2) × 128 × 32 bits.

NOTE: If DMA channels are not used but the MPU/IPU is used, an error check must be performed for IPIPE HST. See ISP5_CTRL[26] HST_RD_CHK for details.

The DMA request assertion and deassertion to the DMA_SYSTEM is automatic and no software intervention is needed. The ISP contains two registers (ISP5_DMAENABLE_SET and ISP5_DMAENABLE_CLR) that must be used to enable or disable generation of the DMA requests.

The DMA request deassertion is based on late deassertion; that is, the DMA request is disabled only when all the data corresponding to the transfer size have been read or written. To deassert the DMA request and generate the hw_eoi signal, hardware counts the number of 32-bit accesses that are done in the memory range of the corresponding DMA request through the ISP slave port. When the number of accesses corresponding to the DMA request is done, the DMA request is cleared. Multiple DMA requests can be active simultaneously.

Software must not attempt to read or write in the memory range of the DMA requests that are enabled because CPU accesses, instead of DMA_SYSTEM accesses, will be counted. Software can freely access ISP memories for which the DMA request is disabled, and can access registers while the DMA_SYSTEM performs the transfers.

8.3.2.5 ISS ISP RSZ Integration

8.3.2.5.1 ISS ISP RSZ PRCM Interface

8.3.2.5.1.1 ISS ISP RSZ Reset

The RSZ module has no stand-alone software reset. RSZ must be reset at the ISP level. See Section 8.3.2.1.2, *ISS ISP Reset*.

8.3.2.5.2 ISS ISP RSZ Interrupts

RSZ can generate several interrupts:

- RSZ_INT_EOF0: This event is triggered for end of frame.
- RSZ_INT_EOF1: This event is triggered for end of frame.
- RSZ_FIFO_IN_BLK_ERR: This event is triggered when the minimum vertical blanking period has not been respected, thus causing errors in the input data buffering submodule. This event is triggered when the RSZ_INT_REG event of frame N is triggered before RSZ_INT_DMA of frame N + 1. This event typically occurs at the transition between two frames because there is not enough vertical blanking between frames. Hardware cannot recover from this error. It requires a reset. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.
- RSZ_FIFO_OVF: This event typically occurs while processing a frame, because the VP pixel clock is too high. Because hardware cannot recover from this error, a reset is required. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.

This event signifies overflow in two different scenarios:

- In Bypass or Operating (normal/downscale) modes, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the input circular data buffer. The rsz_stall_input signal can be asserted by programming appropriate thresholds to prevent input FIFO overflow.
- In Pass-through mode, the RSZ_FIFO_OVF event is triggered when an overflow occurs in the output MTC buffer. There is no hardware mechanism to prevent overflow in Pass-through mode.

- RSZ_INT_CYC_RZA/RSZ_INT_CYC_RZB: This event is triggered as circular interrupt every time that RSZ_IRQ_RZA/RSZ_IRQ_RZB output lines are written to the RZA_SDR_Y/RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value must be such that the circular buffer vertical size (set by the RZBA_SDR_Y_PTR_E/RZBB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZA/RSZ_IRQ_RZA.
- RSZ_INT_DMA: This event is triggered when the last EOF (of the two MTC interfaces) is sent to the BL and the RSZ core returns to idle. This event is active high for one GCK_MMR clock cycle.
- RSZ_INT_LAST_PIX: This event is triggered when the last pixel of the valid area is received. This event is active high for one GCK_MMR clock cycle.
- RSZ_INT_REG: This event is triggered when the new value of the shadowed registers, if updated, takes effect on the next RSZ_INT_REG event. Then again, shadowed registers can be updated for the next frame after the RSZ_INT_REG event is triggered. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i register (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See Section 8.1.2, *ISS Functional Description*.

8.3.2.6 ISS ISP H3A Integration

8.3.2.6.1 ISS ISP H3A Interrupts

H3A can generate the following interrupts:

- H3A_INT: This event is triggered at the end of the last window or last paxel, whichever completes last. This always triggers at the same time as H3A_INT_EOF.
- H3A_INT_EOF: This event is triggered and generated at the end of the last window. This event is active high for one GCK_MMR clock cycle.
- H3A_OVF: This interrupt is generated when an overflow happens in the H3A output buffer. The interrupt avoids polling the H3A_PCR[21] OVF bit for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level. The event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from ISP5_IRQENABLE_SET_i and ISP5_IRQENABLE_SET2_i (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See Section 8.1.2, *ISS Functional Description*.

8.3.2.7 ISS ISP ISIF Integration

8.3.2.7.1 ISS ISP ISIF Interrupts

The ISIF can generate several interrupts:

- ISIF_INT_0: This event is triggered when the VD0 interrupt on line 0 is configured. The VD0 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT0. For more information, see Section 8.3.3.6.19.1.
- ISIF_INT_1: This event is triggered when the VD1 interrupt on line 1 is configured. The VD1 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT1. For more information, see Section 8.3.3.6.19.1.
- ISIF_INT_2: This event is triggered when the VD2 interrupt on line 2 is configured. The VD2 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal

lines (horizontal pulse signals) set in VDINT2. SFor more information, see Section 8.3.3.6.19.1.

- ISIF_INT_3: This event is triggered LSC interrupt is an interrupt issued by the 2D-LSC block. For more information, see Section 8.3.3.6.10.1.5.
- ISIF_OVF: This Interrupt is generated when an overflow happens in the ISIF module. The interrupt avoids polling the ISIF_MODESET[11] OVF bit for errors.

The interrupts are enabled from the ISP5_IRQENABLE_SET_i and ISP5_IRQENABLE_SET2_i registers (where i = 0 to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from ISP is sent to the ISS top level where it is muxed with other ISS modules for a total output of six interrupt lines. See Section 8.1.2, *ISS Functional Description*.

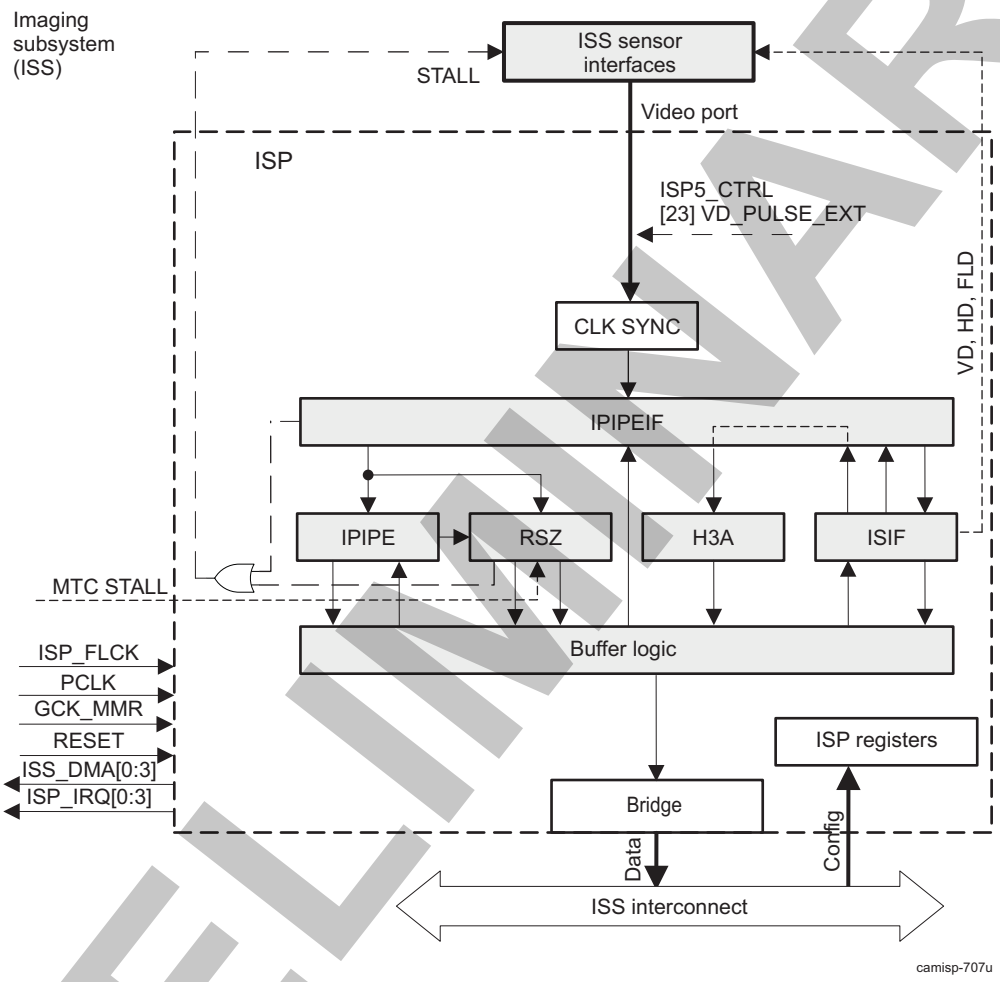
8.3.2.8 ISS ISP BL Integration

See Section 8.3.2, *ISS ISP Integration*.

8.3.3 ISS ISP Functional Description

The functionality of the ISP is part of the overall performance of the ISS. For the top-level ISS diagram with ISP inside and for a features list, see Section 8.1, *ISS Overview*. Figure 8-121 is an overview of the ISP module. It outputs DMA and interrupt requests, has clocks coming in, and a stall signal to the CCP2 interface receiver from the resizer. It also shows the top-level configuration for input to IPIPEIF. For the scaled-in functional details of each submodule inside the ISP, see its functional description section.

Figure 8-121. ISS ISP High-Level Diagram



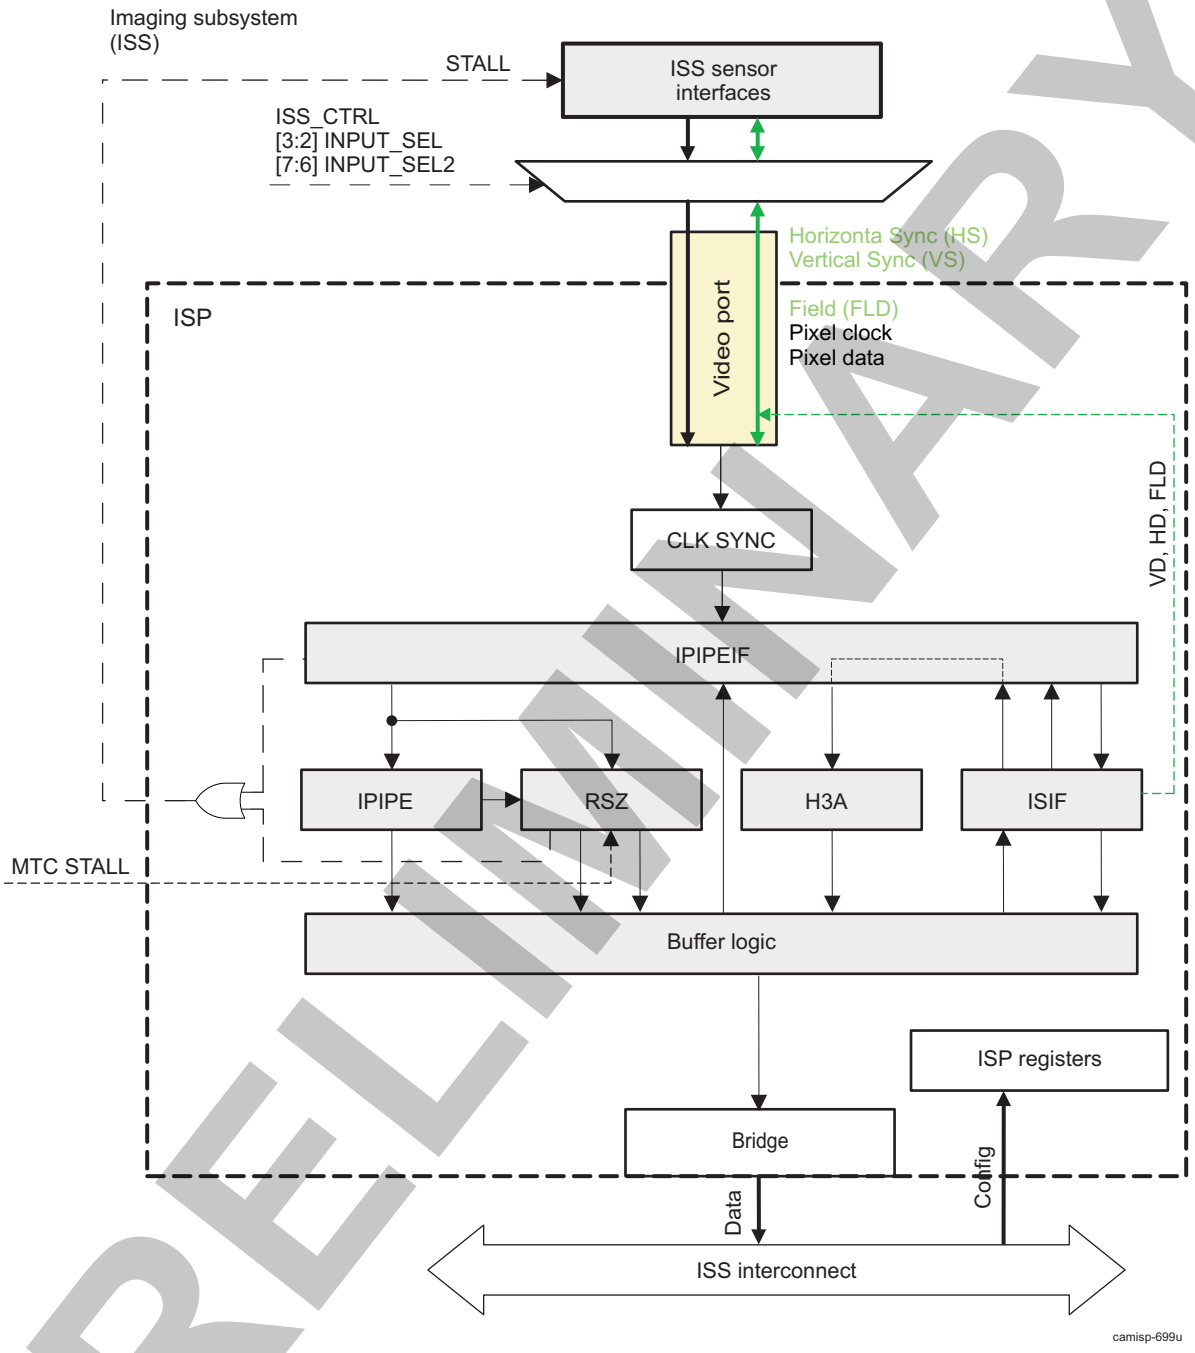
8.3.3.1 ISS ISP VP Functional Description

8.3.3.1.1 ISS ISP VP Overview

The VP supports a parallel interface that is used for interfacing with image sensors. The ISP VP can transport 8- to 16-bit RAW data and 8-/16-bit YCbCr data.

Figure 8-122 shows the VP module connections to other submodules of the ISP.

Figure 8-122. ISS ISP VP High-Level Diagram



8.3.3.1.2 ISS ISP VP Data Formats

The VP can be used to connect external camera receivers to the ISS. Data paths inside the ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG, etc.). Table 8-420 shows how the CCP2/CSI2 modules are connected to the VP in function of the image format.

Table 8-420. ISS ISP VP Format Mapping

Source		Format	Connected to																ISIF	Data Provided to ISIF Linearization Engine

8.3.3.1.3 ISS ISP VP Top-Level Communication With CCP2 RX and CSI2 RX

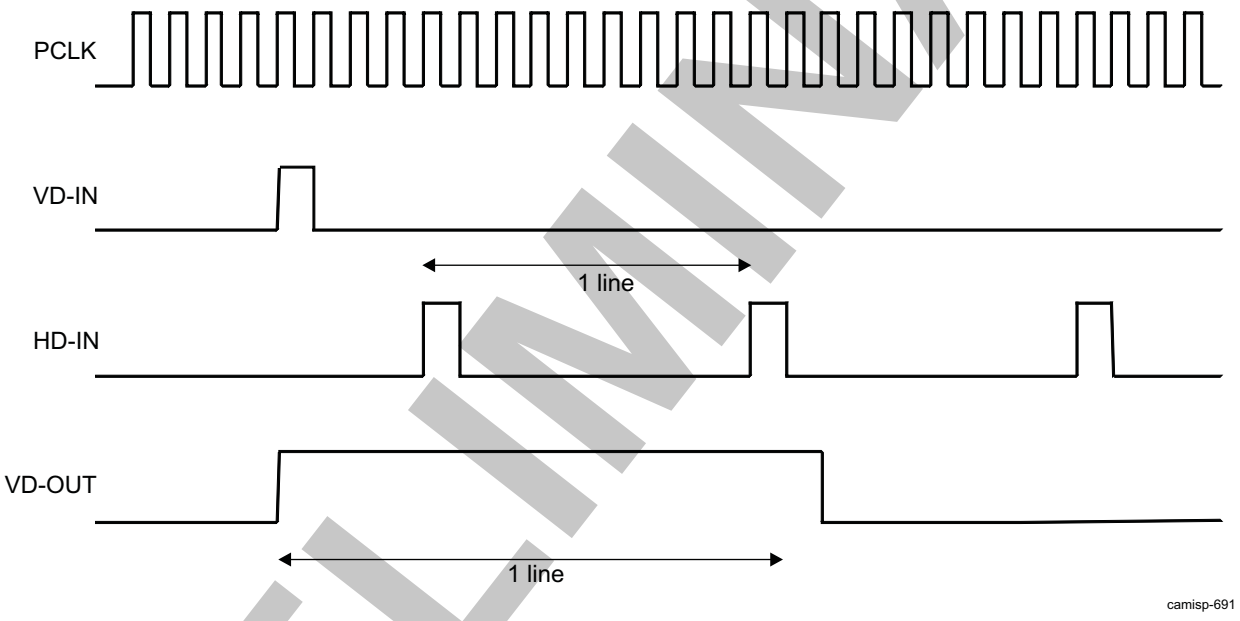
At the ISS level, the VP is connected to the VP of the CCP2 RX and CSI2 RX interface modules. The selection, which interface VP is connected to the ISP is done on ISS top level through ISS_CTRL[3:2] INPUT_SEL and [7:6] INPUT_SEL2 register bit fields.

VP implementation differences force the introduction of a bridge between the CCP2 RX/CIS2 RX modules and the VP. The role of the bridge is to perform VD pulse extension. The CCP2 RX module assumes that the VD signal is active for at least one pixel clock cycle, and the CSI2 RX module assumes that the VD signal is asserted for four pixel clock cycles. However, the ISP assumes that the VD pulse is active on at least one line.

Figure 8-123 shows how the VD pulse extension works. Assume that VD-IN is the VD signal at the input of the pulse extension bridge, and VD-OUT is the VD signal at the output of the pulse extension bridge.

VD-OUT is asserted at the same time as VD-IN. VD-OUT is kept high until one full line is received. A line is delimited by two rising edges of the HD signal. VD-OUT is deasserted on the next cycle after the falling edge of the HD signal.

Figure 8-123. ISS ISP VP VD Pulse



The ISP5_CTRL[23] VD_PULSE_EXT bit controls whether the VD extension bridge is enabled or disabled. By default, the bridge is enabled. When the bridge is disabled, the VD pulse must be unmodified: VD-OUT = VD-IN. At the ISS level, it is expected that ISP5_CTRL[23] VD_PULSE_EXT = 1 when the VP gets data from the CSI2 RX modules and ISP5_CTRL[23] VD_PULSE_EXT = 0 when the VP gets data from the parallel interface or the CCP2 RX module.

CAUTION

A minimum of four lines per frame is required on the VP when the VD pulse extension bridge is enabled; therefore, the VD extension bridge is not functional if a 1-/2-/3-line frame is sent to the VP.

8.3.3.1.4 ISS ISP VP Pixel Clock Inversion

The ISP always uses the rising edge of the pixel clock to sample the pixel data. The ISP provides the capability to invert the pixel clock so it can shift the resampling of a pixel clock period by half. This is controlled by the ISP5_CTRL[22] PCLK_INV bit. By default, the inversion is disabled. The pixel clock must be disabled at ISS level before setting the PCLK_INV bit to 0x1. This can be done through the proper ISS_CLKCTRL[] VPORTx_CLK register bit on ISS top level, depending on the interface (CCP2 or CSI2) that is sending data on the ISP video port.

The 4 bits in Table 8-421 are resynchronized from the GCK_MMR clock domain to the PCLK clock domain. There must be at least three clock cycles between the time these bits are modified and the HD/VD pulse for start of frame comes.

Table 8-421. ISS ISP VP GCK_MMR to PCLK Clock Resynchronization

Module	Register	Bit Field
ISP	ISP5_CTRL	VD_PULSE_EXT
ISIF	ISIF_MODESET	HDVDD
ISIF	ISIF_MODESET	FIDD
ISP	ISP5_CTRL	ISIF_CLK_ENABLE

8.3.3.2 ISS ISP IPIPEIF Functional Description

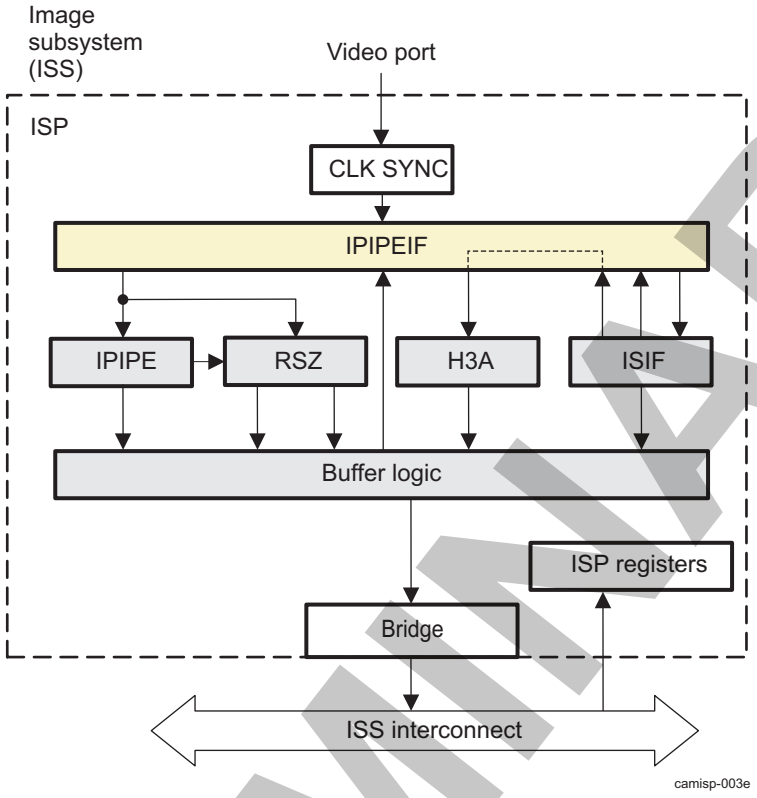
8.3.3.2.1 ISS ISP IPIPEIF Overview

The IPIPEIF module provides data and synchronization signals (HD, VD) for the ISIF, IPIPE, RSZ, and H3A modules. The data source of this module is the VP, ISIF, or SDRAM using BL, and the selected data is output to ISIF, IPIPE, H3A, and RSZ. This module supports:

- Up to 16-bpp data on the VP
- Up to 304-MHz pixel clock on the VP, up to 8K × 8K imaging resolution
- RAW and YUV data formats on the VP and BL ports
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from VP
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF
- Dark-frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL
- Simple defect correction to prevent the subtraction of defect pixels
- 8-10, 8-12 DPCM of 10-8, 12-8 DPCM compressed data in SDRAM
- Simple and advanced DPCM predictor
- Inverse A-Law decompression of RAW data 10-8 A-Law compressed from SDRAM
- 8-bit, 12-bit unpacking of 8-bit,12-bit packed SDRAM data
- Gain multiply for output data to the IPIPE module
- Horizontal Bayer rescaler in the data paths to the IPIPE and H3A modules: Supports (1, 2, 1) averager filter and supports horizontal pixel decimation
- Data rate control when reading data from SDRAM: Fraction clock divider
- (1, 2, 1) averager filter and supports horizontal pixel decimation in the data path to the IPIPE for YUV data.

Figure 8-124 show the IPIPEIF module connections to other submodules of the ISP.

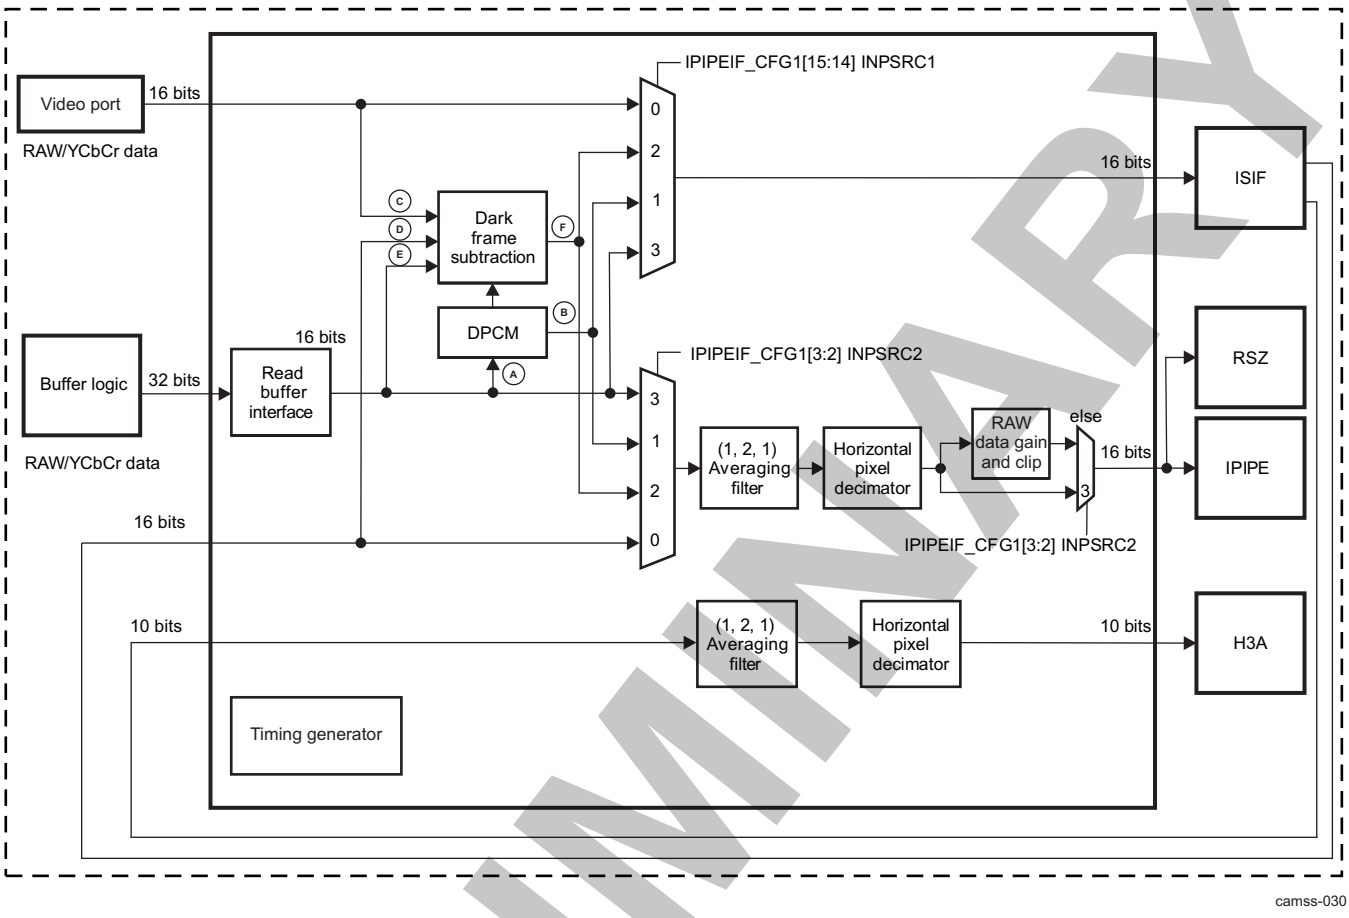
Figure 8-124. ISS ISP IPIPEIF High-Level Diagram



8.3.3.2.2 ISS ISP IPIPEIF Top-Level Block Diagram

The following sections describe the function of each subblock in the IPIPEIF, as shown in Figure 8-125.

Figure 8-125. ISS ISP IPIPEIF Top-Level Block Diagram



camss-030

NOTE: When the IPIPEIF receives data from the VP, the timing generator must be configured for HD, VD, and WEN. For more information, see Section 8.3.3.2.5, *ISS ISP IPIPEIF Timing Generation.*

8.3.3.2.3 ISS ISP IPIPEIF Input Interface

The IPIPEIF module comprises two major interface blocks: VP and BL. The data types can be RAW or YUV.

8.3.3.2.3.1 ISS ISP IPIPEIF Input From VP

The VP typically receives data from the image sensor. At the ISS level, it is connected to the serial interface receivers.

8.3.3.2.3.2 ISS ISP IPIPEIF Input From BL

The BL is the interface with the memory (SDRAM). In that case, the SDRAM address and line offset registers must be programmed in units of 32 bytes.

- SDRAM start address (byte) = (IPIPEIF_ADDRU[10:0] ADDRU) << 16 + (IPIPEIF_ADDRL[15:0] ADDRL)
- SDRAM address offset (byte) = IPIPEIF_ADOFS[11:0] ADOFS

Two types of data can be stored in memory: pixel data and dark frame data.

For pixel data, the HD and VD signals are reconstructed with:

- IPIPEIF_HNUM
- IPIPEIF_VNUM
- IPIPEIF_LPFR
- IPIPEIF_PPLN

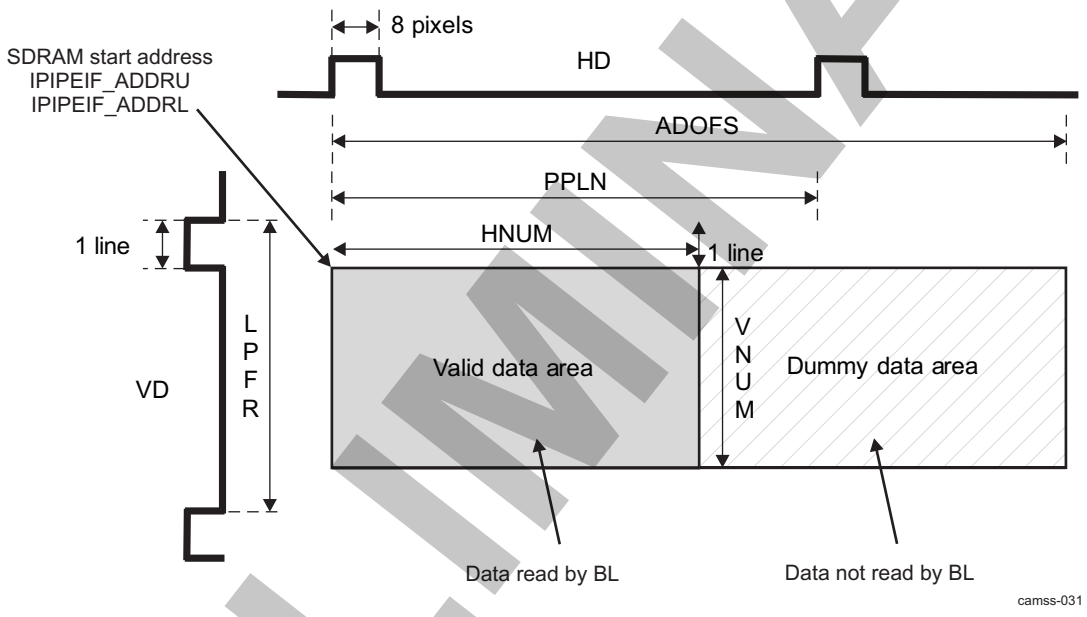
The IPIPEIF_HNUM and IPIPEIF_VNUM registers define the number of pixels per line and lines per frame to read from the SDRAM, and the IPIPEIF_LPFR and IPIPEIF_PPLN registers define the interval of VD and HD, respectively.

Vertical blanking for the frame is defined with the following equation: IPIPEIF_LPFR – IPIPEIF_VNUM – 1.

Horizontal blanking for the frame must be at least eight ISP_FCLK cycles, and is defined with the following equation: IPIPEIF_PPLN – IPIPEIF_HNUM > 7.

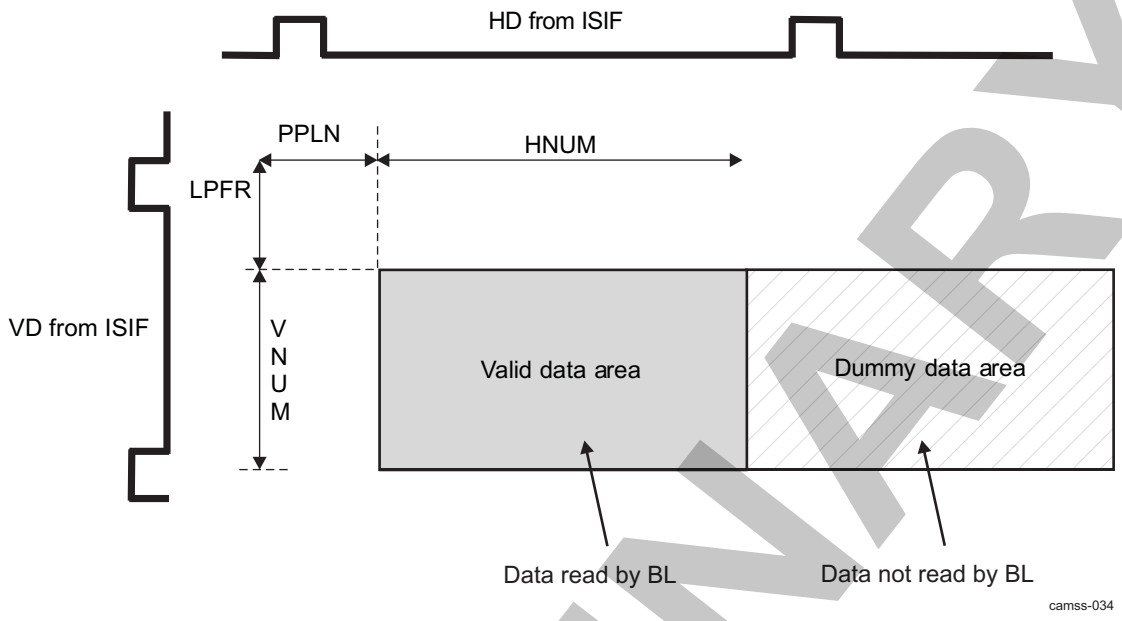
Figure 8-126 shows the global frame definition for all SDRAM input modes, except for dark frame subtract.

Figure 8-126. ISS ISP IPIPEIF Global Frame Definition in SDRAM Input Modes (Except Dark Frame)



For dark frame data, the HD and VD signals come from the VP through the ISIF. The IPIPEIF_PPLN and IPIPEIF_LPFR registers must be used to indicate the horizontal and vertical start position of the subtraction from the ISIF data, as shown in Figure 8-127. The value of the IPIPEIF_LPFR[12:0] LPFR bit field must be greater than 0 because the first line from the VP or ISIF cannot be subtracted from. The IPIPEIF_HNUM and IPIPEIF_VNUM registers must be used to set the number of valid pixels horizontally and the number of valid lines vertically.

Figure 8-127. ISS ISP IPIPEIF Global Frame Definition in Dark Frame Subtract Mode



8.3.3.2.3.2.1 ISS ISP IPIPEIF Double-Buffer Input Function When Reading From BL

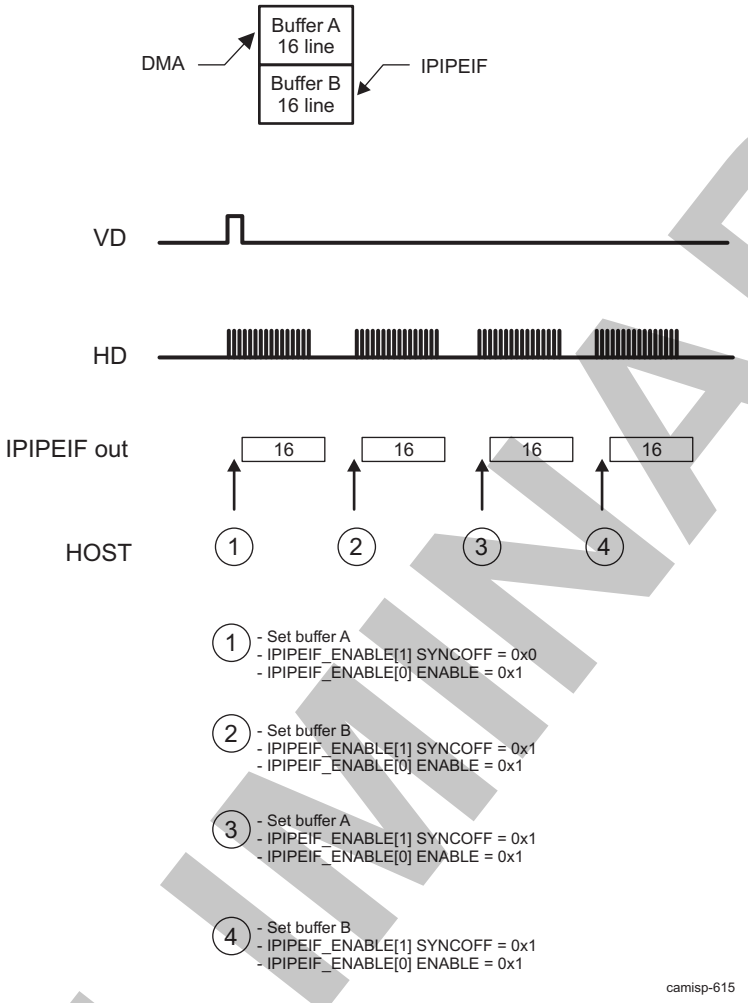
The IPIPEIF module supports a double-buffer input function. This feature is most useful when SDRAM space is limited, because it enables to read continuously from two buffers and to push data to the rest of the ISP (ISIF, H3A, etc.) for further processing.

Consider the following configuration where data are read from two buffers, A and B. The intent is not only to read continuously from these buffers but also to ensure that the ISP modules consider the data as being from the same frame; that is, VD is generated the first time buffer A is read, but it must not toggle until all the frames are read.

The IPIPEIF module can mask the VD sync signal by setting the IPIPEIF_ENABLE[1] SYNCOFF bit such that the IPIPEIF module drives the data to the ISP modules as if it is a continuous frame data.

In the following example, there are 16 lines per trigger and input circular addressing. VNUM = 16 (see Figure 8-126), and the VD signal is generated only for the first frame (see Figure 8-128).

Figure 8-128. ISS ISP IPIPEIF Double-Buffer Functionality



8.3.3.2.4 ISS ISP IPIPEIF Data Path Selection

The data path configuration through the IPIPEIF module is set with the IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 bit fields. Table 8-422 lists the possible combinations for these two bit fields.

Table 8-422. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	0	This data path is described in Section 8.3.3.2.4.1, *ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0*.	Video record, view finder, on-the-fly still image capture applications
0	1	This data path is described in Section 8.3.3.2.4.2, *ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1*.	Memory-to-IPIPE-to-memory operation
0	2	This data path is described in Section 8.3.3.2.4.3, *ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2*.	Image capture with on-the-fly dark frame subtraction

Table 8-422. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations (continued)

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	3	This data path is described in Section 8.3.3.2.4.4, *ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3*.	On-the-fly data acquisition done in VP, forwarded to the ISIF, and then to the H3A through IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory YUV4:2:2 or RAW data processing with the IPIPE and RSZ modules from memory to memory fetched by IPIPEIF
1	0	This data path is described in Section 8.3.3.2.4.5, *ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0*.	Memory-to-ISIF-to-memory operation
1	1	This data path is possible but there is no use case associated.	N/A
1	2	This data path is not supported.	N/A
1	3	This data path is not supported.	N/A
2	0	This data path is described in Section 8.3.3.2.4.6, *ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0*.	Dark frame subtraction is performed and data sent to the ISIF module for further processing, back to IPIPEIF, and then to IPIPE and RSZ.
2	1	This data path is not supported.	N/A
2	2	This data path is not supported.	N/A
2	3	This data path is not supported.	N/A
3	0	This data path is described in Section 8.3.3.2.4.7, *ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0*.	Memory-to-ISIF-to-memory operation
3	1	This data path is not supported.	N/A
3	2	This data path is not supported.	N/A
3	3	This data path is possible but there is no use case associated.	N/A

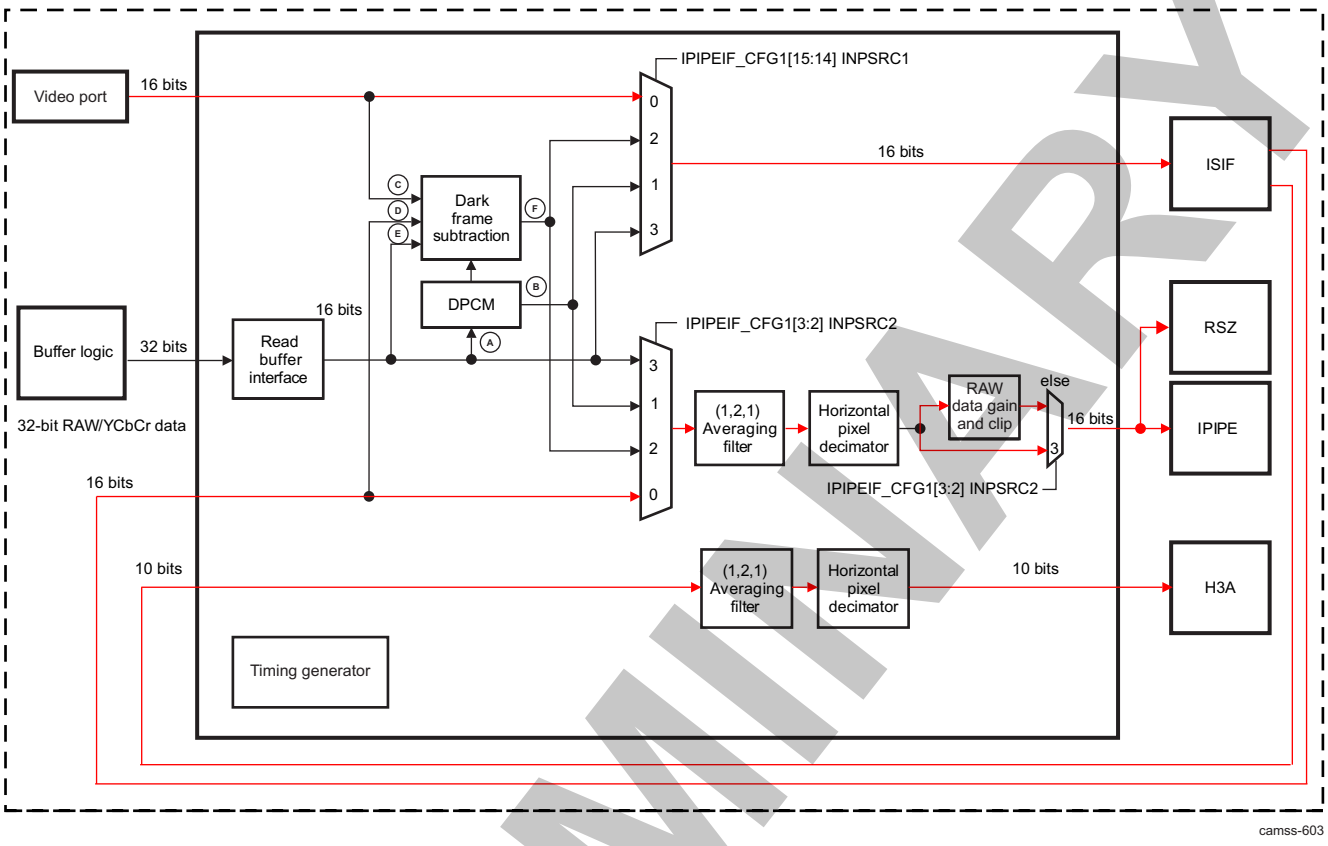
8.3.3.2.4.1 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration can be used for the video record, viewfinder, and on-the-fly still image capture applications. The full ISP processing capability is used in a single pass.

Figure 8-129 shows the data path.

Figure 8-129. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0 Data Path



8.3.3.2.4.2 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1

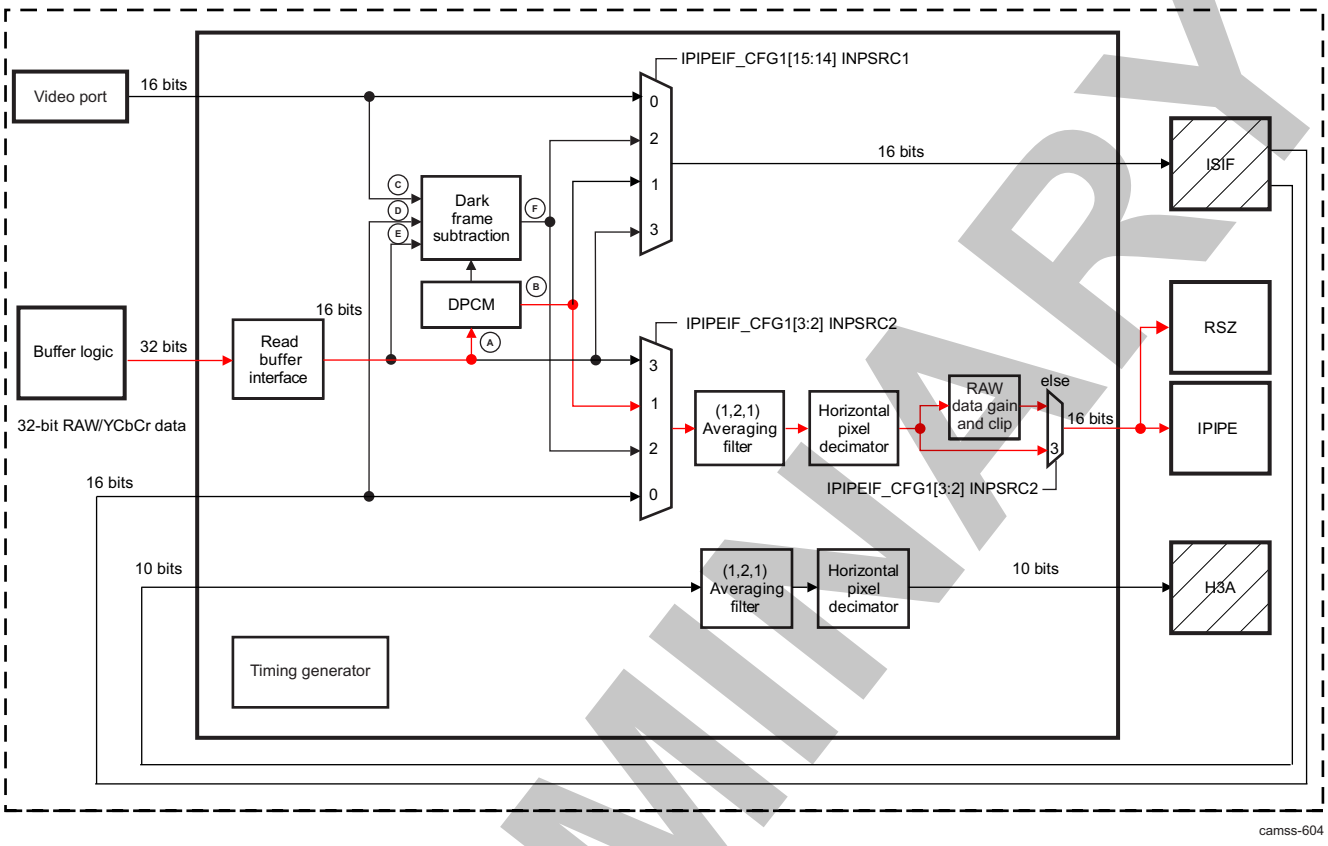
Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 1.

This configuration can be used to process data with the IPIPE module from memory to memory. The data stored in SDRAM can be decompressed (A-law or DPCM) before being forwarded to the IPIPE module.

NOTE: In this configuration, the ISIF and H3A modules are assumed to be disabled.

Figure 8-130 shows the data path.

Figure 8-130. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1 Data Path



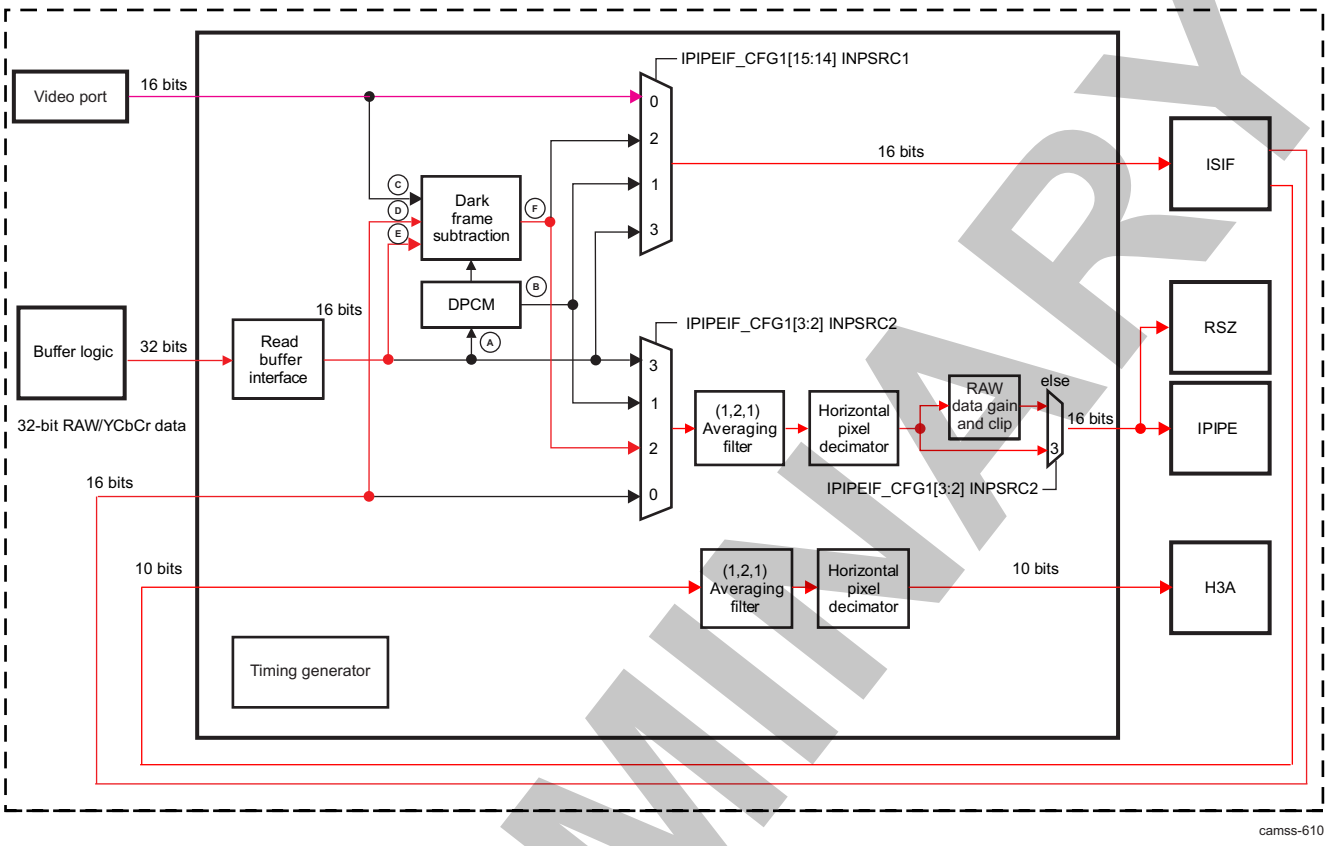
8.3.3.2.4.3 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 2.

This configuration can be used for image capture with on-the-fly dark-frame subtraction. In the first case, the dark frame can come from BL and data from the ISIF. In the second case, the dark frame can come from the VP and data from BL.

Figure 8-131 shows the data path.

Figure 8-131. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2 Data Paths



8.3.3.2.4.4 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 3.

In the first case, on-the-fly data acquisition is done with the VP, forwarded to the ISIF, and then sent to the H3A through the IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory.

In the second case, the configuration can be used to process YUV4:2:2 or RAW data with the IPIPE and RSZ modules from memory-to-memory. The YUV4:2:2 or RAW data stored in the SDRAM is fetched and forwarded to the IPIPE and RSZ modules. ISIF and H3A are assumed to be disabled in this configuration.

Figure 8-132 and Figure 8-133 show the two possible data paths.

Figure 8-132. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: First Case

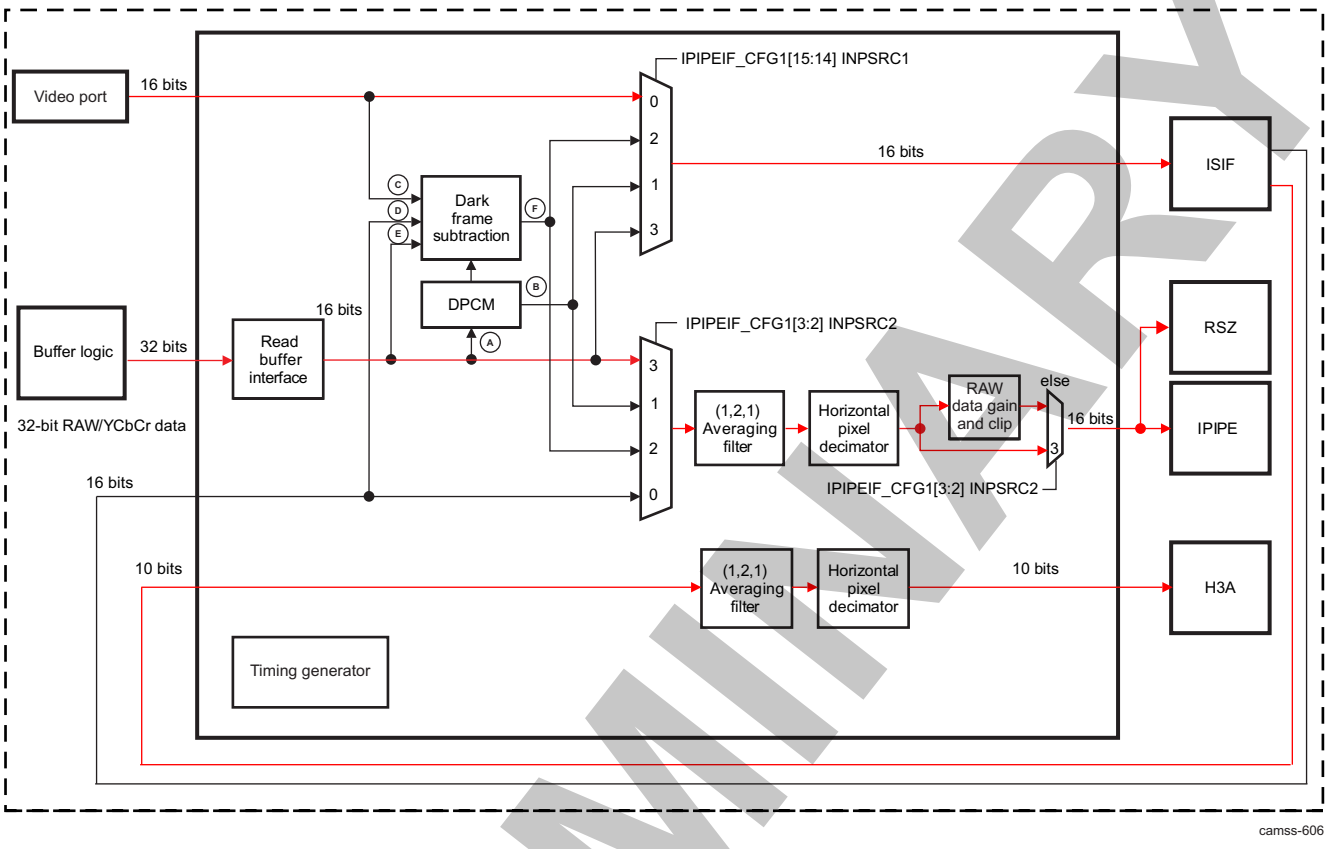


Figure 8-133. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: Second Case

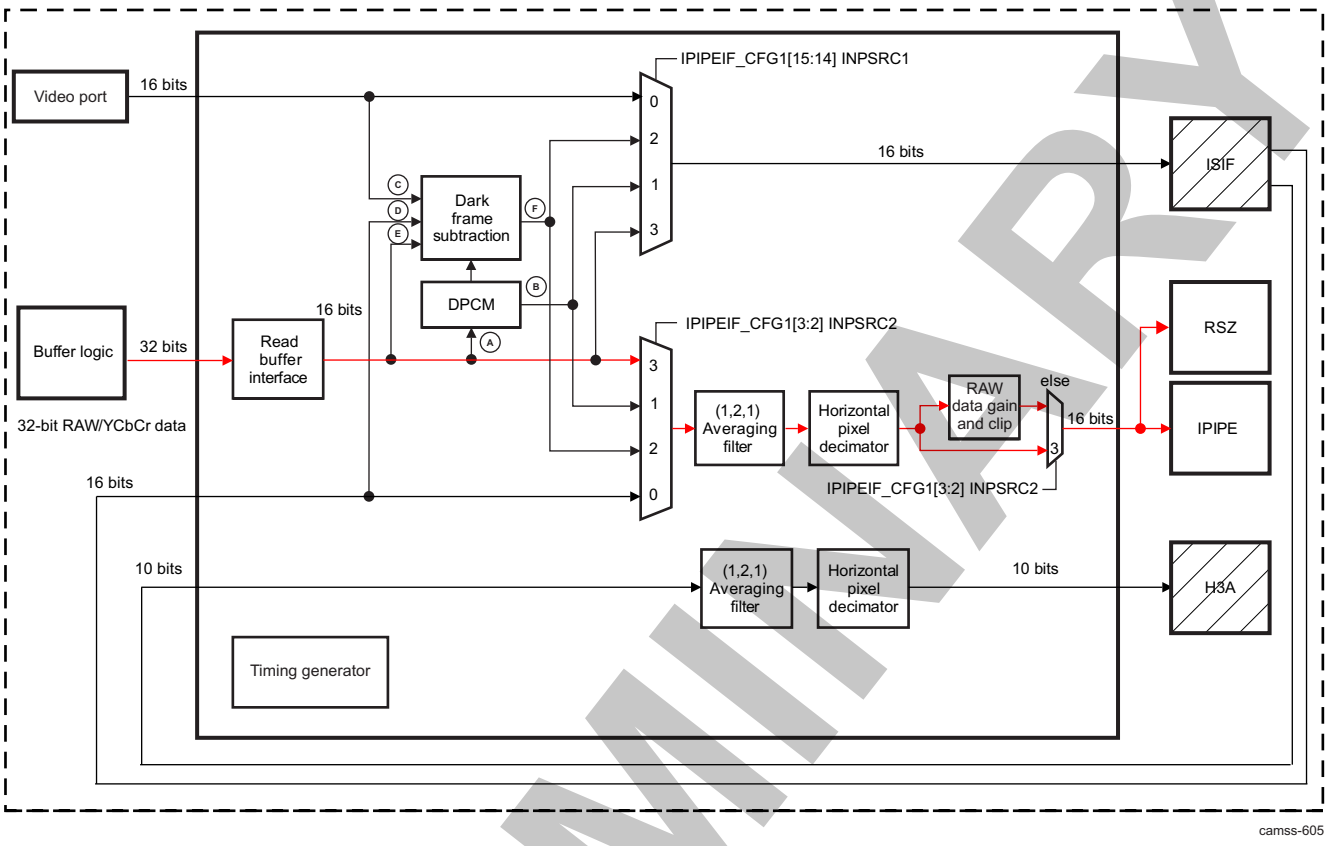


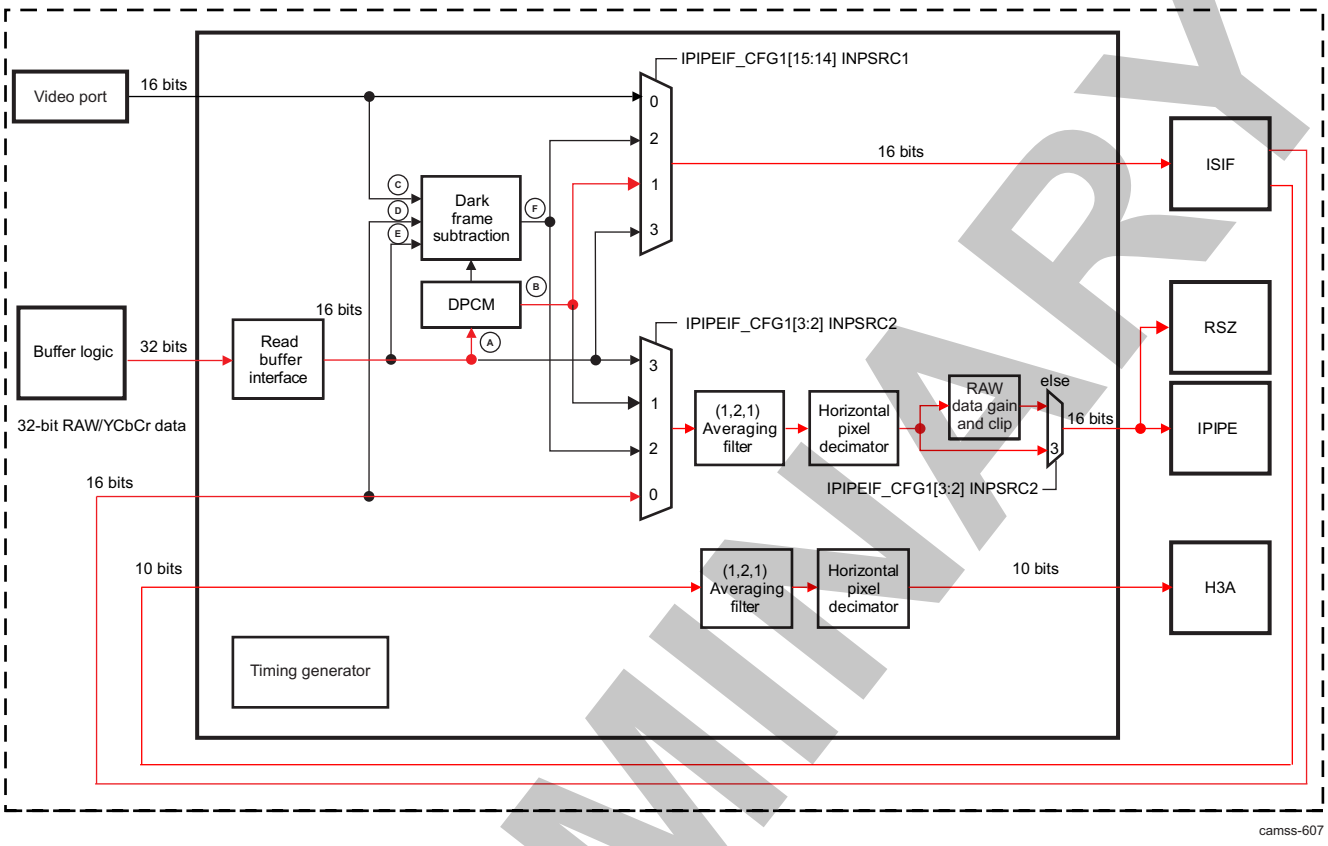
8.3.3.2.4.5 ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 1 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration is a memory-to-memory operation. RAW data is read by the BL interface, decompressed, and pushed to the ISIF. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE and H3A modules.

Figure 8-134 shows the data path.

Figure 8-134. ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0 Data Path



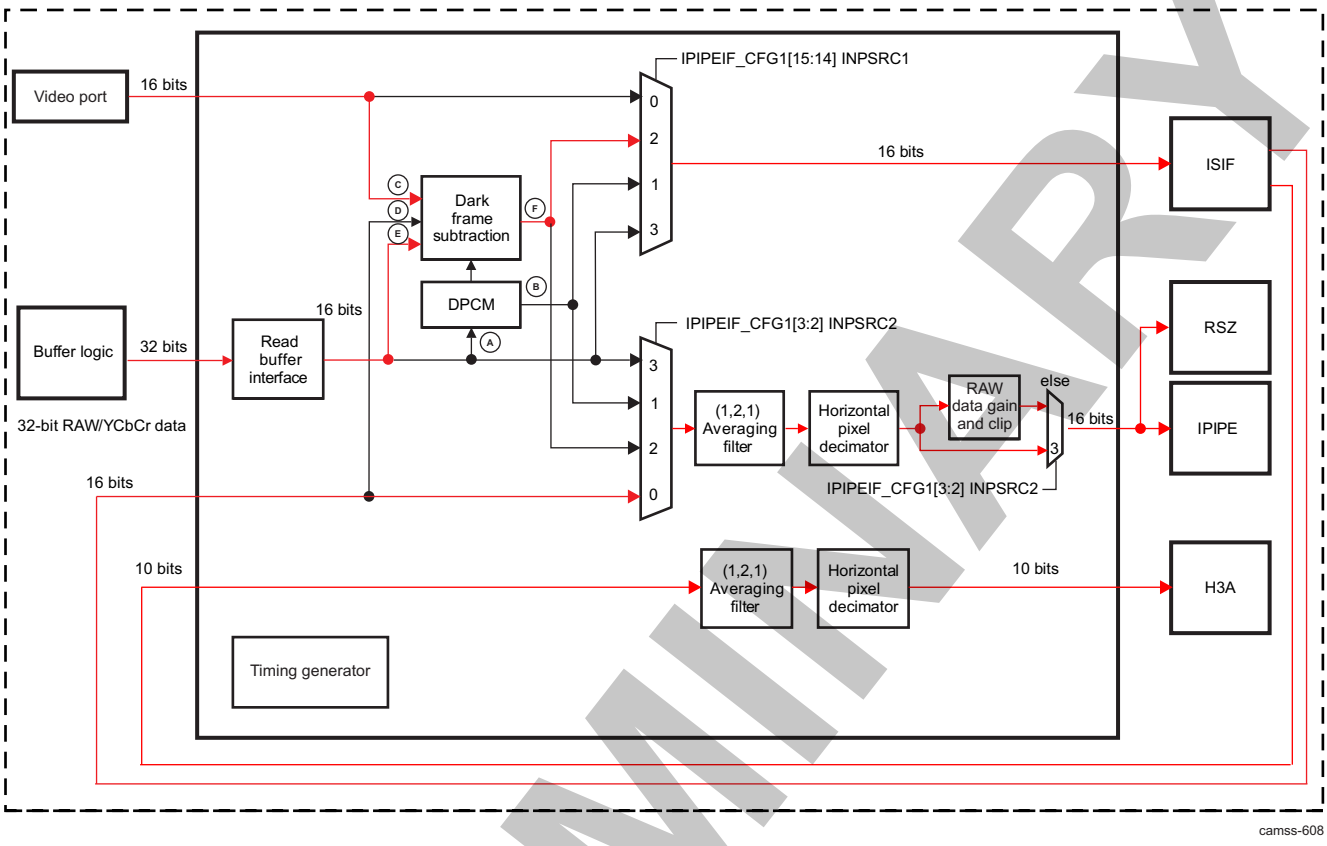
8.3.3.2.4.6 ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 2 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

In this configuration, dark frame subtraction is performed and data is sent to the ISIF module. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ modules. There are two possible dark frame subtractions: the first is with data coming from the VP and the dark frame coming from BL; the second is with data coming from BL and the dark frame coming from the VP.

Figure 8-135 shows the data path.

Figure 8-135. ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0 Data Path



8.3.3.2.4.7 ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0

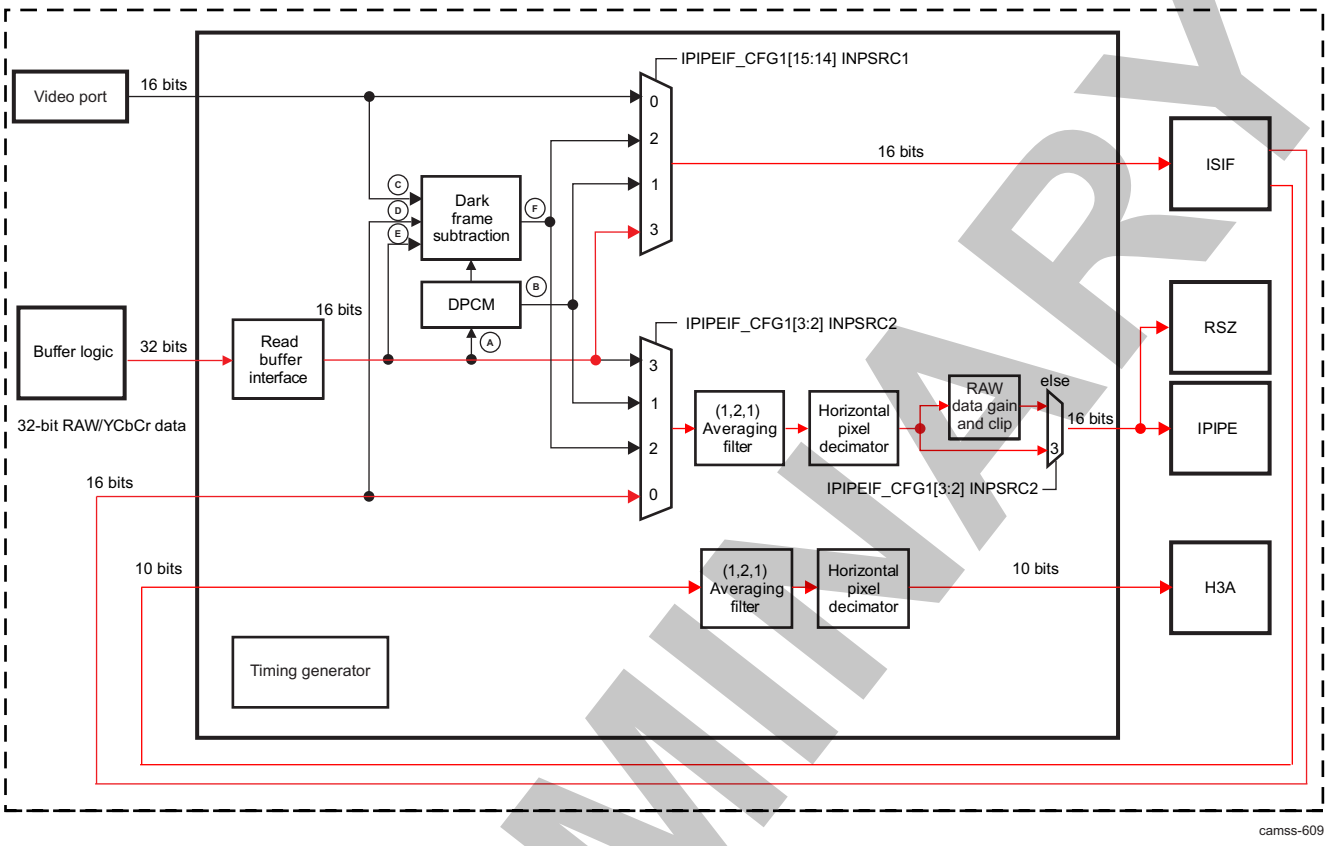
Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 3 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration is a memory-to-memory operation. Data is loaded from the SDRAM. Input data is expected as 16 bpp. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ module.

In this configuration data is assumed to be YUV only, and H3A and RAW data gain are assumed to be disabled.

Figure 8-136 shows the data path.

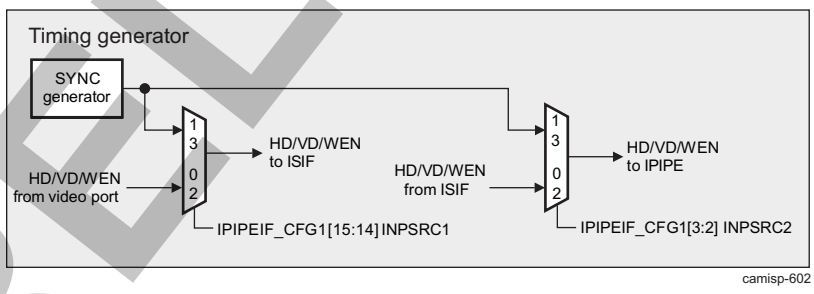
Figure 8-136. ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0 Data Path



8.3.3.2.5 ISS ISP IPIPEIF Timing Generation

Figure 8-137 shows the ISS ISP IPIPEIF timing generator submodule.

Figure 8-137. ISS ISP IPIPEIF Timing Generator Submodule



When the IPIPEIF module input source is from the VP (IPIPEIF_CFG1[15:14] INPSRC1 = 0 or 2) or the ISIF (IPIPEIF_CFG1[3:2] INPSRC2 = 0 or 2), the IPIPEIF_CFG1[10] CLKSEL bit must be set to 0 so that data is latched using the PCLK, HD, and VD signals from the VP.

When the IPIPEIF module input source is not from the VP (IPIPEIF_CFG1[15:14] INPSRC1 = 1 or 3), the IPIPEIF_CFG1[10] CLKSEL bit must be set to 1 so that the IPIPEIF module generates its proper PCLK, HD, and VD signals (through the use of the SYNC generator). The IPIPEIF_CLKDIV register is then used to select a divide ratio of the SDRAM (DMA) clock for the pixel clock frequency, which is used to clock the data into the PCLK. See Section 8.3.3.2.5.1, *ISS ISP IPIPEIF Fractional Clock Divider*.

When the IPIPEIF_CFG1[15:14] INPSRC1 or IPIPEIF_CFG1[3:2] INPSRC2 bit field is not set to 0, the IPIPEIF SDRAM data reading and timing generation can be enabled (IPIPEIF_ENABLE[0] ENABLE) in one-shot mode or continuous mode (IPIPEIF_CFG1[0] ONESHOT).

8.3.3.2.5.1 ISS ISP IPIPEIF Fractional Clock Divider

When the input data of the IPIPEIF module does not come from the VP but from memory, it is useful to have control of the rate at which the data is fetched from memory to avoid overflow conditions or to avoid peak bandwidth requirements. The IPIPEIF_CFG1[10] CLKSEL bit is equal to 1 for fractional divider use.

The ISP clock ISP_FCLK is divided to generate the pixel clock, which goes to the ISIF and IPIPE modules when data is read from memory (IPIPEIF_CFG1[15:14] INPSRC1 = IPIPEIF_CFG1[3:2] INPSRC2 = 1 or 3). The IPIPEIF_CLKDIV register selects the divider ratio: M and N values in the IPIPEIF_CLKDIV[15:0] CLKDIV bit field.

Given an input clock of clock rate ISP_FCLK, the fractional clock divider generates an output clock with average clock rate f_{OUT}.

Where f_{OUT} = ISP_FCLK x M/N, and M = 1 through 256, and N = 1 through 256.

The fractional clock divider logic is synchronous and uses only the positive clock edge of the input clock.

8.3.3.2.6 ISS ISP IPIPEIF Decompression (DPCM) Subblock: Unpack and Decompression Function

The IPIPEIF module can read RAW data from memory. The RAW data can be previously packed/compressed into memory. Unpack, A-Law decompression, and DPCM decompression are available in the IPIPEIF module.

Figure 8-138 shows the DPCM subblock.

Figure 8-138. ISS ISP IPIPEIF DPCM Subblock

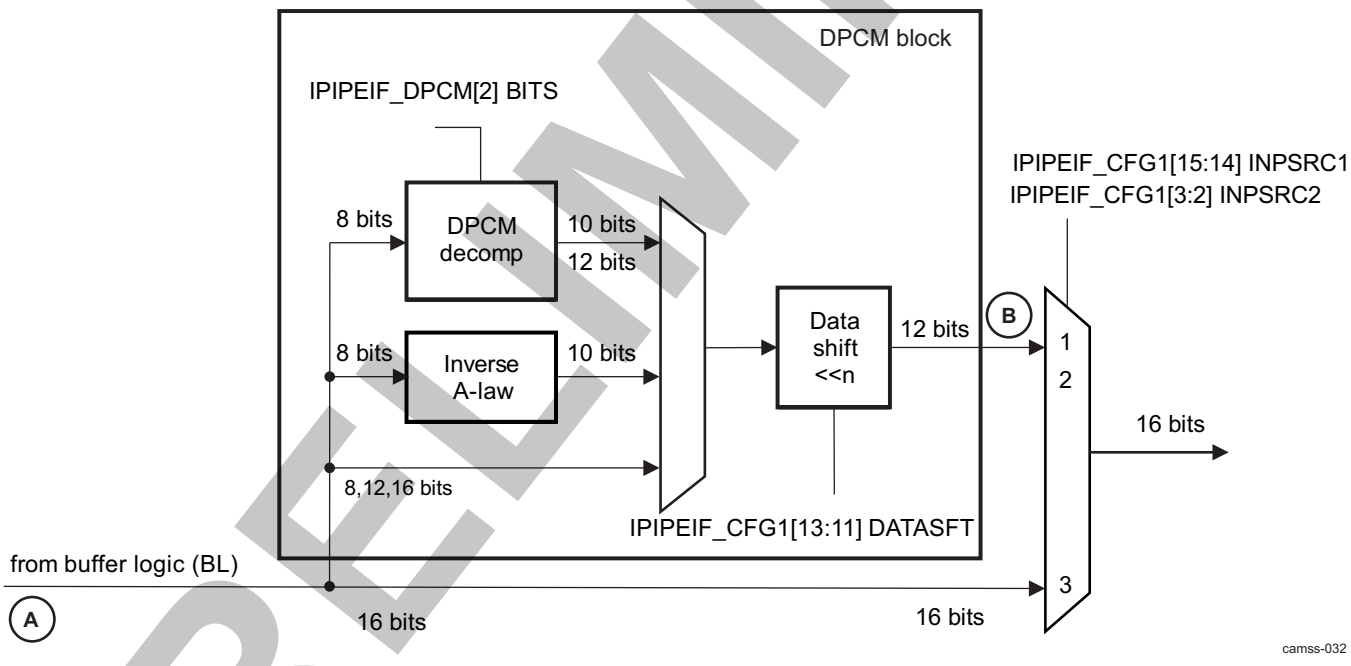


Table 8-423 provides the possible configuration of the DPCM block.

Table 8-423. ISS ISP IPIPEIF DPCM Block Possible Configuration

Number of Bits per Pixel at DPCM Block Input	Number of Bits per Pixel at DPCM Block Output	Description	Registers
16	16	It can correspond to YUV4:2:2 or RAW16 data.	IPIPEIF_CFG1[9:8] UNPACK = 0x0 In this configuration, IPIPEIF_CFG1[3:2] INPSRC2 = 0x3. In this configuration data bypasses the DPCM block.

Table 8-423. ISS ISP IPIPEIF DPCM Block Possible Configuration (continued)

Number of Bits per Pixel at DPCM Block Input	Number of Bits per Pixel at DPCM Block Output	Description	Registers
8	8	PACK8: YUV	IPIPEIF_CFG1[9:8] UNPACK = 0x1 IPIPEIF_DPCM[0] ENA = 0x0 IPIPEIF_CFG1[13:11] DATASFT = 0x01 In this configuration an 8-bit packed RAW data is used in DFS mode or YUV4:2:0 pass through. (See Section 8.3.3.2.13, *ISS ISP IPIPEIF YUV4:2:2 8-bits Packed Data Input Coming From ISIF Module*.)
8	10	DPCM10: The 8-bit input data are DPCM-decompressed in 10 bits.	IPIPEIF_CFG1[9:8] UNPACK = 0x1 IPIPEIF_DPCM[0] ENA = 0x1 IPIPEIF_DPCM[2] BITS = 0x0 Set the IPIPEIF_DPCM[1] PRED(1) (2) IPIPEIF_CFG1[13:11] DATASFT = 0x2
8	12	DPCM12: The 8-bit input data are DPCM-decompressed in 12 bits.	IPIPEIF_CFG1[9:8] UNPACK = 0x1 IPIPEIF_DPCM[0] ENA = 0x1 IPIPEIF_DPCM[2] = 0x1 Set the IPIPEIF_DPCM[1] PRED(1) (2) IPIPEIF_CFG1[13:11] DATASFT = 0x0
8	10	ALAW10: The 8-bit input data were previously A-law compressed. The 8 bits are A-law decompressed and padded with 0.	IPIPEIF_CFG1[9:8] UNPACK = 0x2 IPIPEIF_CFG1[13:11] DATASFT = 0x2
12	12	PACK12: The input is coded on 12 bits and is packed in the SDRAM. This mode is compatible with the ISIF module packing capability. If inverse A-law and DPCM decompression are not enabled, the data read from the SDRAM can be shifted by the IPIPEIF_CFG1[13:11] DATASFT bit field to select which 12 bits to use. MSB input data bit must be shifted such that it corresponds to bit 11 after the shift.	IPIPEIF_CFG1[9:8] UNPACK = 0x3 Set the IPIPEIF_CFG1[13:11] DATASFT

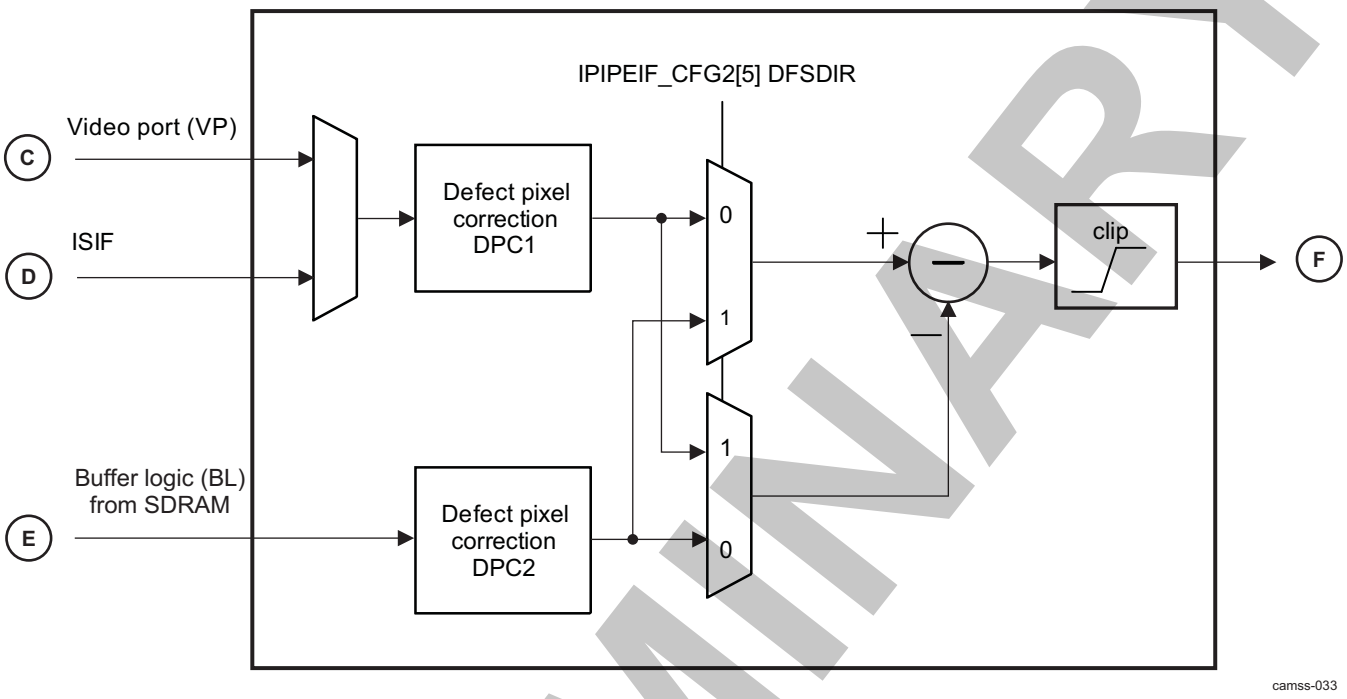
(1) The simple predictor uses only the value of the previous same color component as a prediction value. Therefore, only 2-pixel memory is required. It is typically used for 10–8–10 or 12–8–12 bit conversions.

(2) The advanced predictor uses four previous pixel values, when the prediction value is evaluated. This means that the values of the other color components are also used, when the prediction value is defined. Therefore, the advanced predictor is slightly better than the simple predictor but consumes more power and memory. It can, however, improve image quality. It is typically used for 10–7–10 and 10–6–10 bit conversions.

8.3.3.2.7 ISS ISP IPIPEIF Dark-Frame Subtraction Functionality

Figure 8-139 shows the ISS ISP IPIPEIF dark-frame subtraction subblock.

Figure 8-139. ISS ISP IPIPEIF Dark-Frame Subtraction Subblock



The dark-frame subtract (DFS) function is used to remove fixed pattern baseline noise from the sensor for a high-quality still image capture use case, where there is a mechanical shutter. Typically, the ISIF module previously writes a dark frame (frame captured when the shutter is closed) to SDRAM using 8 bits of linear data packed into 2 pixels per 16 bits.

In this mode, RAW data from the ISIF and SDRAM is used. Data can also be read from SDRAM with the IPIPEIF_CFG1[9:8] UNPACK bit field set to 1. Each pixel read from SDRAM is subtracted from each pixel sent from the VP or ISIF.

The mux at the input of the dark-frame subtraction subblock is implicitly controlled by the selection of the IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 bit fields:

- When IPIPEIF_CFG1[15:14] INPSRC1 = 0x2, the selected input ports are VP and BL. Therefore, the dark frame operation can be:
  - Dark frame = VP – BL
  - Dark frame = BL – VP
- When IPIPEIF_CFG1[3:2] INPSRC2 = 0x2, the selected input ports are ISIF and BL. Therefore, the dark frame operation can be:
  - Dark frame = ISIF – BL
  - Dark frame = BL – ISIF

The output of the DFS operation is 12 bits wide (U12Q0). There must be adequate SDRAM bandwidth if this feature is enabled. If the data fetched from memory arrives late, an underflow bit (IPIPEIF_DTUF) must be triggered to know it.

When SDRAM data underflow occurs, the data from SDRAM is coming in at a lower rate than the rate at which it is being read/requested by the IPIPEIF. In DFS operation mode, IPIPEIF reads data from both SDRAM and the VP/ISIF. To ensure not corrupting subsequent data processing downstream in the case of SDRAM data underflow, the IPIPEIF stalls the input data, storing remaining sensor data into an internal FIFO (16-deep), and then stops sending new data downstream. The IPIPEIF recommences DFS processing when data from SDRAM becomes available, by using the pixel data from the FIFO and that from SDRAM for processing. To avoid an overflow of the internal FIFO, the IPIPEIF deasserts the stall

only when the number of FIFO slots indicated by the IPIPEIF_DTUDF[5:2] FIFOWMRKLVL register bit field are free. A safe number of free locations can be configured taking into consideration the pixel clock frequency with respect to that of the functional clock, as the pixel clock speed is allowed to vary up to the functional clock speed. When the pixel clock and functional clock are equal, the stall deassertion can be programmed to occur when the 16-deep FIFO is empty.

When receiving data from CCP2 and there is underflow from obtaining dark frame data through an IPIPEIF SDRAM read, the CCP2 read interface should be stalled to maintain pixel-to-pixel match between sensor image and dark frame data; otherwise, out-of-sync behavior can cause corrupted dark frame subtraction output.

- When the IPIPEIF_DTUDF[1] ENM2MSTALL register bit is set to 1, and an SDRAM read underflow has been detected, IPIPEIF immediately stops sending data to downstream modules. Simultaneously, the IPIPIEIF requests the CCP2 to stop sending sensor image data through an IPIPEIF_STALL signal (similar the ISP resizer CCP2 stall signal) as well to avoid data corruption (see Figure 8-122 for more information, both RSZ and IPIPEIF stall signals are OR-ed within ISP boundary to provide a single STALL signal to CCP2). There is a latency period from underflow detection until final data stalling at IPIPEIF boundary, during which period the sensor data is stored internally through a FIFO in IPIPEIF video port interface path.
- When the IPIPEIF_DTUDF[1] ENM2MSTALL bit is set to 0, and at reset, this stall mechanism is disabled

8.3.3.2.7.1 ISS ISP IPIPEIF Defect Pixel Correction

NOTE: For DPC memory access locations, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

A simple DPC can be applied to the ISIF or VP input data path and SDRAM input data path, respectively. This DPC algorithm is intended to correct hot pixels during RAW dark frame acquisition or dark frame readout from SDRAM before dark frame subtraction.

The following code describes DPC algorithm:

```
If (image(n) < TH) || ((image(–2)  TH)&&(image(n+2)>TH)
 image(n) = image(n)
Else if image(–2) > TH
 image(n) = image(n+2)
Else if image(n+2) > TH
 image(n) = image(–2)
Else
 image(n) = (image(–2)+ image(n+2))/2

// Where TH is equal to IPIPEIF_DPC1[11:0] TH for DPC1
// Where TH is equal to IPIPEIF_DPC2[11:0] TH for DPC2
```

The IPIPEIF_DPC1[12] ENA bit enables DPC for the VP/ISIF input path, and the IPIPEIF_DPC2[12] ENA bit enables DPC for the SDRAM input path. The algorithm requires a threshold value that is set by the IPIPEIF_DPC1[11:0] TH or IPIPEIF_DPC2[11:0] TH bit field that is a 12-bit unsigned value.

8.3.3.2.7.2 ISS ISP IPIPEIF DFS Subtraction Direction

The IPIPEIF_CFG2[5] DFSDIR bit selects how the DFS subtraction is performed.

- Set the IPIPEIF_CFG2[5] DFSDIR bit to 0 when the RAW data is coming from the VP/ISIF and the dark frame is stored in SDRAM.
- Set the IPIPEIF_CFG2[5] DFSDIR bit to 1 when the RAW data is coming from SDRAM and the dark frame is coming from the VP/ISIF.

After subtraction, a clip ensures that the value is not negative.

Table 8-424 lists the different modes supported in DFS.

Table 8-424. ISS ISP IPIPEIF DFS Modes Supported

Description	DFDIR Value
DFS of 8-bit RAW image stored in SDRAM from image from VP	IPIPEIF_CFG2[5] DFSDIR = 0x0
DFS of 8-bit RAW image stored in SDRAM from image from ISIF	IPIPEIF_CFG2[5] DFSDIR = 0x0
DFS of 8-bit RAW image from VP from image read from SDRAM through the BL	IPIPEIF_CFG2[5] DFSDIR = 0x1

NOTE: DFS input depends on the settings of INPSRC1 and INPSRC2.

8.3.3.2.8 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for IPIPE Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (IPIPEIF_CFG1[1] DECIM), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can be enabled by setting the IPIPEIF_CFG1[7] AVGFILT bit. It operates on every other pixel (same color) in RAW Bayer input or every Y component in YCbCr data in the following equation:

output = (input[i – 1] + 2 × input[i] + input[i + 1]) >> 2

The averaging filter operates on every other pixel (same color) in RAW Bayer input or YUV data.

If the data is YUV4:2:2, the option to average and decimate is given under the conditions listed in Table 8-425.

Table 8-425. ISS ISP IPIPEIF Averaging Filter Conditions for YUV4:2:2 Data

IPIPEIF_CFG1[3:2] INPSRC2	IPIPEIF_CFG2[3] YUV16	Comments
0	1	YUV4:2:2 data is coming from the ISIF module. Averager and decimation is possible on the data path to the IPIPE module.
1	1	YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
3		YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
Other value	Other value	For YUV4:2:2 data, averager and decimation is not possible on the data path to the IPIPE module.

The averager implements a (1, 2, 1) FIR filter on Luma and Chroma. The following registers have a part in the behavior of the YUV data averaging and decimation:

- IPIPEIF_INIRSZ[12:0] INIRSZ
- IPIPEIF_CFG1[7] AVGFILT
- IPIPEIF_CFG1[1] DECIM

8.3.3.2.9 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for IPIPE Data Path

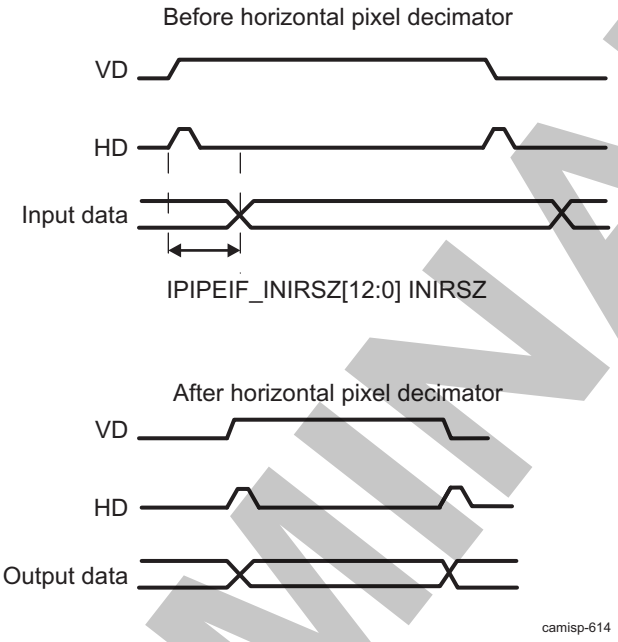
The IPIPE input is limited to 5376 pixels per horizontal line due to restrictions in the line memory width in the IPIPE.

To process image sensor resolutions with more than 5376 pixels per line with no resolution loss, vertical frame division mode (FDM) must be used; that is, the image must be divided into vertical chunks of less than 5376 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

Alternatively, if a loss in resolution is acceptable, the line width decimator (the IPIPEIF_CFG1[1] DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 5376 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the IPIPEIF_RSZ[6:0] RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled (IPIPEIF_INIRSZ[13] ALNSYNC = 0x1), the IPIPEIF_INIRSZ[12:0] INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator, as shown in Figure 8-140.

Figure 8-140. ISS ISP IPIPEIF Resizer Offset Definition



8.3.3.2.10 ISS ISP IPIPEIF RAW Data Gain for IPIPE Data Path

A gain factor ranging from 0.00195(1/512) to 1.99805(1023/512) is multiplied to the RAW output of the IPIPEIF. The gain is not applied if the input data is YCbCr. The gain constant is set in the IPIPEIF_GAIN[9:0] GAIN bit field using U10Q9 format.

The output value is clipped after gain control through the value of the IPIPEIF_OCLIP[11:0] OCLIP bit field.

8.3.3.2.11 ISS ISP IPIPEIF (1, 2 ,1) Averaging Filter for H3A Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (the IPIPEIF_RSZ3A[9] DECIM bit), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can also be used to reduce noise before H3A statistics generation. It operates on every other pixel (the same color) in a RAW Bayer input or every Y component in YCbCr data. The averaging filter can be enabled by setting the IPIPEIF_RSZ3A[8] AVGFILT bit, and it operates with the following equation:

output = (input[i – 1] + 2 × input[i] + input[i + 1]) >> 2

8.3.3.2.12 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for H3A Data Path

The H3A input is limited to 3008 pixels per horizontal line due to restrictions in the line memory width in the H3A.

To process image-sensor resolutions with more than 3008 pixels per line with no resolution loss, vertical FDM must be used; that is, the image must be divided into vertical chunks of less than 3008 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

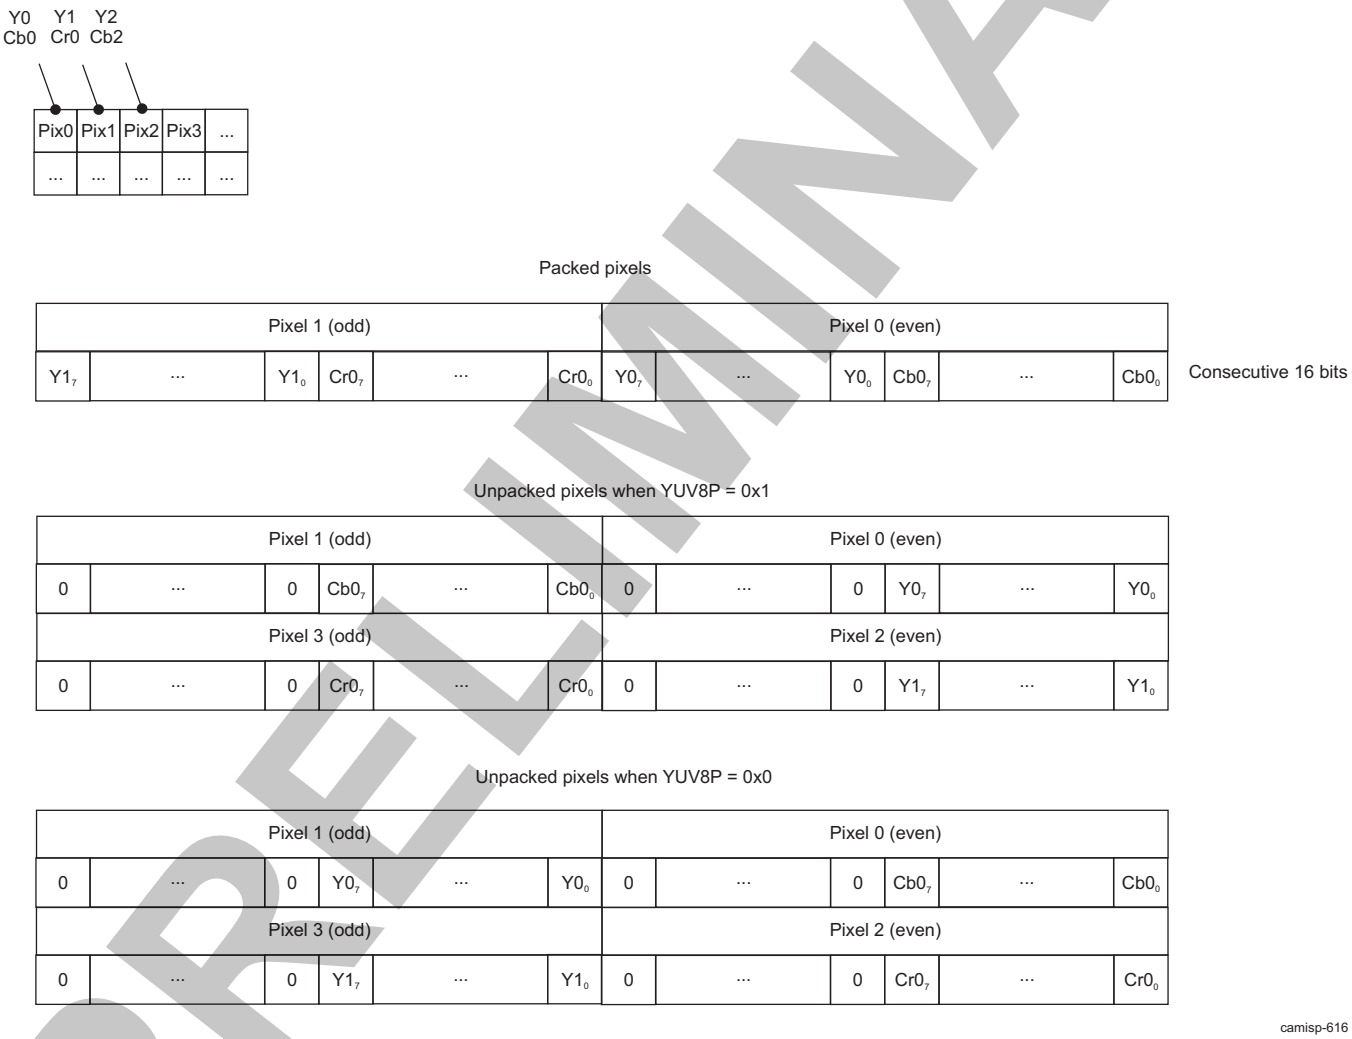
Alternatively, if loss of resolution is acceptable, the line width decimator (the IPIPEIF_RSZ3A[9] DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 3008 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the IPIPEIF_RSZ3A[6:0] RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled (IPIPEIF_INIRSZ3A[13] ALNSYNC = 0x1), the IPIPEIF_INIRSZ3A[12:0] INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator (see Figure 8-140).

8.3.3.2.13 ISS ISP IPIPEIF YUV4:2:2 8-bit Packed Data Input Coming From ISIF Module

This section applies when data coming from the ISIF is 8 bits (IPIPEIF_CFG2[6] YUV8 = 0x1). When IPIPEIF_CFG1[3:2] INPSRC2 = 0 and IPIPEIF_CFG2[3] YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the IPIPEIF_CFG2[7] YUV8P bit. See Figure 8-141.

Figure 8-141. ISS ISP IPIPEIF YUV8P Settings



8.3.3.2.14 ISS ISP IPIPEIF YUV4:2:0 Data Input for Memory-to-Memory Resize Operations

The ISP RSZ module can resize YUV4:2:0 data. The YUV4:2:0 data can come from the memory (through BL) or from the VP through the CCP2 RX module, which reads data from SDRAM and pushes it to the IPIPEIF module VP. The possible data paths are:

- SDRAM → IPIPEIF (BL) → RESIZER → SDRAM
- SDRAM → CCP2 RX → IPIPEIF (VP) → RESIZER → SDRAM

- SDRAM → IPIPEIF (BL) → IPIPE → RESIZER → SDRAM
- SDRAM → CCP2 RX → IPIPEIF (BL) → IPIPE → RESIZER → SDRAM

When the data comes from BL, the IPIPEIF module must be set up to process the Luma data first, and then the Chroma data.

- For 420Y (first pass):
  - IPIPEIF_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
  - IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
  - IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
  - IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
  - IPIPEIF_CFG2[3] YUV16 = 0x1 (data_input[7:0] = 0 and data_input[15:8] = valid)
- For 420C (second pass):
  - IPIPEIF_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
  - IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
  - IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
  - IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
  - IPIPEIF_CFG2[3] YUV16 = 0x0 (data_input[7:0] = valid and data_input[15:8] = 0)

8.3.3.2.15 ISS ISP IPIPEIF Module Events and Status Checking

The IPIPEIF module generates an IPIPEIF event through the IPIPEIF_IRQ interrupt at the end of each frame. This interrupt is set through the ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ bit. The input interrupt source generation is selected through the IPIPEIF_CFG2[0] INTSW bit in a certain configuration. The following pseudo code describes INTSW.

```
if (IPIPEIF_CFG2[0] INTSW==0) // Interrupt source from VP
 if (IPIPEIF_CFG1[15:14] INPSRC1==1,2 or 3)
 if (CFG1.ONESHOT==1) // In one shot mode
 Interrupt happens at the end of frame
 else // In continuous mode
 Interrupt is the start position of VD which is generated by IPIPEIF timing generator
 else // IPIPEIF_CFG1[15:14] INPSRC1==0, data is from VP
 Interrupt is the start position of VD from VP

else // Interrupt source from ISIF: IPIPEIF_CFG2[0] INTSW==1
 if (IPIPEIF_CFG1[3:2] INPSRC2==1,2 or 3)
 if (CFG1.ONESHOT==1) // In one shot mode
 Interrupt happens at the end of frame
 else
 Interrupt is the start position of VD which is generated by IPIPEIF timing generator
 else // IPIPEIF_CFG1[3:2] INPSRC2==0, data is from ISIF
 Interrupt is the start position of VD from ISIF
```

In addition to this interrupt, the host must check the IPIPEIF_DTUF status flag of the ISP5_IRQSTATUS_RAW2_i[1] IPIPEIF_UDF bit (if this is enabled and mapped to the ISP IRQ lines) to see if an underflow occurred. For more information, see Section 8.3.4.2.4, *ISS ISP IPIPEIF Interframe Operations*.

If IPIPEIF reads image data from memory, IPIPEIF stalls data output by masking the clock at underflow. When the next data is available at the input side, IPIPEIF restarts sending data. Underflow does not occur in this operation.

In DFS operation (see Section 8.3.3.2.7, *ISS ISP IPIPEIF Dark-Frame Subtraction Functionality* for more information), if the data read from memory are not available before they are required, the behavior of IPIPEIF is as follows:

- If image data is being received from the parallel port (CPI), then underflow occurs. The event is flagged by IPIPEIF_UDF IRQ. The ISP5_IRQSTATUS_RAW2_i[1] IPIPEIF_UDF bit is also set.
- If image data is being received through CCP2, then IPIPEIF raises IPIPEIF_STALL signal to stall CCP2_RD. The IPIPEIF_DTUDF[1] ENM2MSTALL bit controls whether the IPIPEIF raises

IPIPEIF_STALL signal at underflow event or not.

8.3.3.3 ISS ISP IPIPE Functional Description

8.3.3.3.1 ISS ISP IPIPE Overview

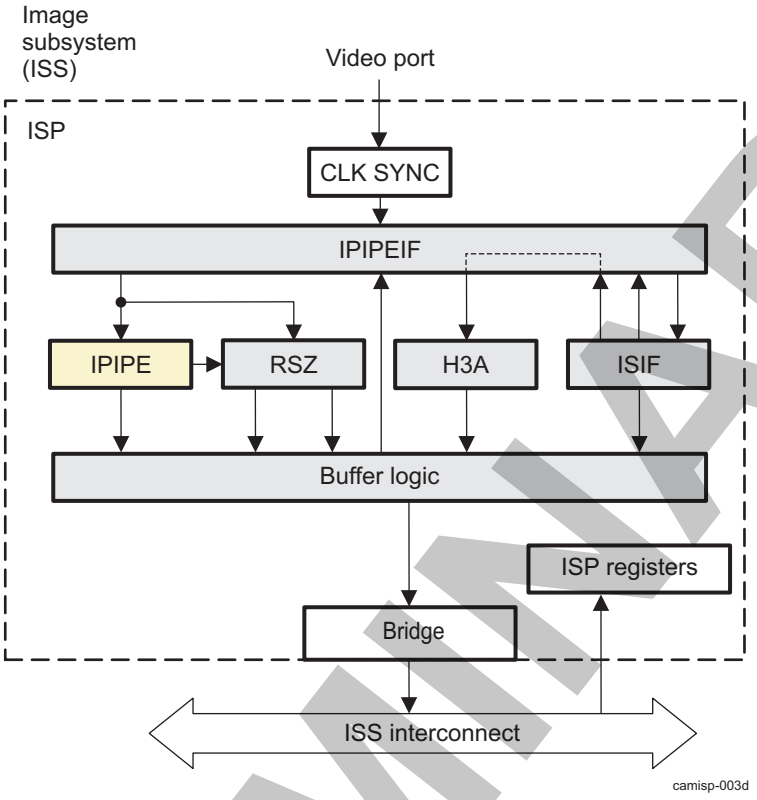
- The input interface extracts the valid region from the Bayer RAW data:
  - Up to 12-bit input pixel resolution
  - Requires at least 8 pixels for horizontal blanking and four lines for vertical blanking. In one-shot mode; 16 blanking lines after processing area are required.
  - The maximum horizontal and vertical offset of IPIPE processing area from synchronous signal is 65534.
  - Supports RGB Bayer pattern for input
- The DPC module fixes defect pixels using two methods: LUT-based and on-the-fly adaptive.
- The 2D noise-filter module reduces noise in RAW data.
- The green-imbalance-correction (GIC) module reduces Gb/Gr difference to remove line crawl noise.
- The white balance module applies offset and gain adjustments to each color.
- The color filter array (CFA) interpolation module implements CFA interpolation. The output from the CFA interpolation module is RGB-4:4:4 formatted data. CFA also reduces aliasing caused by undersampling by digital anti-aliasing (DAA).
- The RGB2RGB blending module applies a 3 × 3 matrix transform to the RGB data generated by the CFA interpolation module.
- The gamma correction module independently applies gamma correction to each RGB component. Gamma is implemented using a piece-wise linear interpolation approach with a 512-entry LUT for each color.
- The second RGB2RGB blending module applies a 3 × 3 matrix transform to the RGB data after gamma correction.
- 3D-LUT converts RGB data to RGB data using 9 × 9 × 9 table and tetrahedral interpolation.
- The RGB2YCbCr conversion module applies 3 × 3 matrix transformation to the RGB data to convert it to YCbCr data. This module also implements offset. The global brightness and contrast enhancement module fixes brightness and contrast tone.
- The 4:2:2 conversion module applies the Chroma low-pass filter and downsampling to Cb and Cr to convert 4:4:4 data to 4:2:2 data.
- The 2D edge-enhancer module improves image clarity with a Luma nonlinear filter.
- The Chroma artifact reduction module reduces color artifacts using gain control and a 2D median filter.
- The output interface module transfers data from IPIPE to SDRAM in the form of one YCbCr (4:2:2 or 4:2:0), RGB (32/16 bits), or Bayer data.
- The histogram function can record histograms of up to four distinct areas into up to 256 bins.
- The boxcar function makes 1/8 or 1/16 size (1/64 or 1/256 in area) images.
- The boundary signal calculator (BSC) makes vectors of row and column summations.

IPIPE has four processing paths:

- Case 1: IPIPE reads CCD RAW data and applies all IPIPE functions and stores the YCbCr (or RGB) data to SDRAM.
- Case 2: IPIPE reads CCD RAW data and stores the Bayer data after white balance to SDRAM.
- Case 3: IPIPE reads YCbCr-4:2:2 data and applies edge enhance, Chroma suppression, and resize to output YCbCr data to SDRAM.
- Case 4: IPIPE reads YCbCr-4:2:0 data and applies resize to output YCbCr data to SDRAM.

Figure 8-142 shows the connections from the IPIPE module to other submodules of the ISP.

Figure 8-142. ISS ISP IPIPE High-Level Diagram

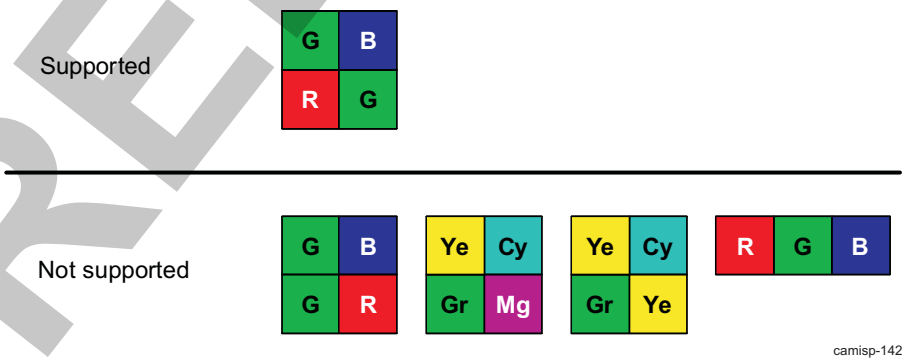


8.3.3.3.2 ISS ISP IPIPE Top-Level Block Diagram

The IPIPE is a programmable hardware image-processing module that generates image data in YCbCr-4:2:2 or YCbCr-4:2:0 format from RAW CCD/CMOS data. The IPIPE module supports output of Bayer data.

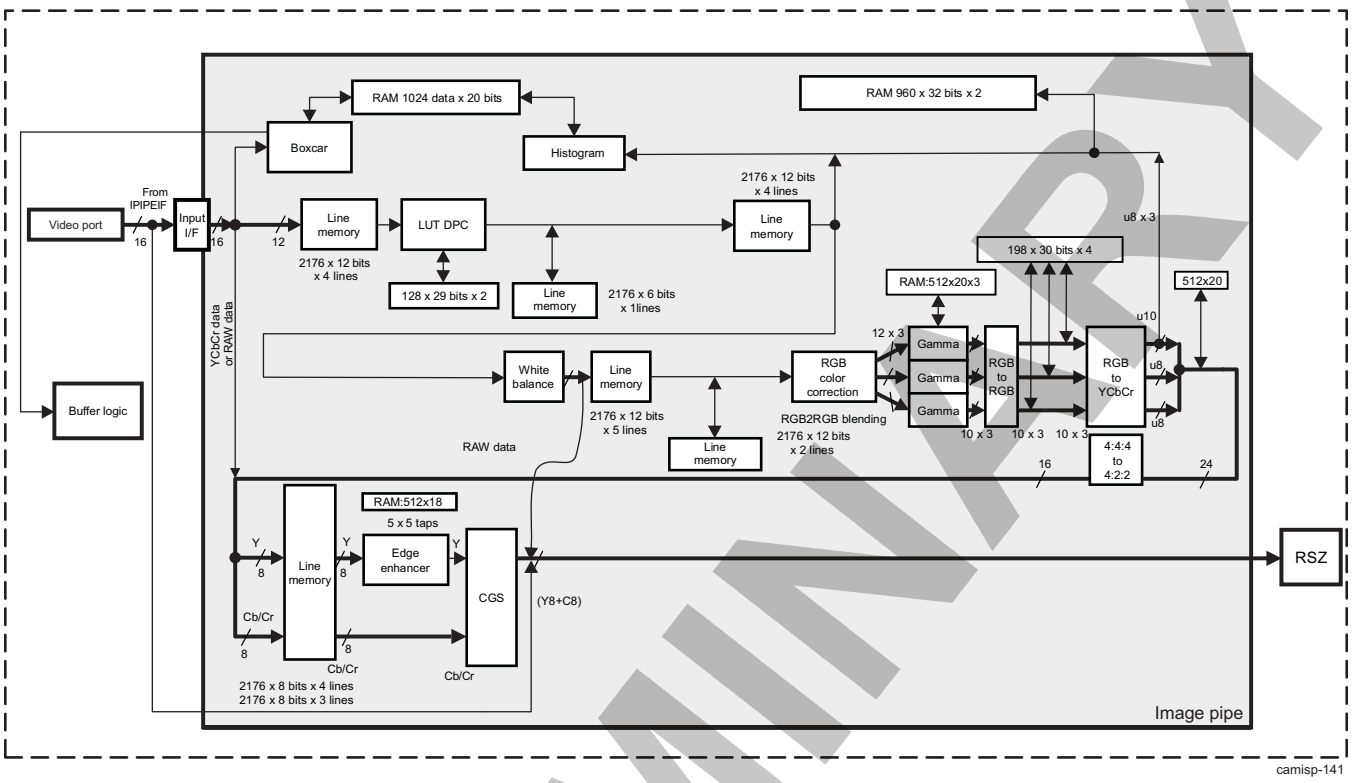
The IPIPE module supports RAW data in Bayer format, as shown in Figure 8-143. Other RGB formats or complementary color formats are not supported.

Figure 8-143. ISS ISP IPIPE Supported CFA Format



As shown in Figure 8-144, many internal modules are used to process Bayer data into YCbCr data.

Figure 8-144. ISS ISP IPIPE Module Block Diagram



8.3.3.3.3 ISS ISP IPIPE Input Interface

The IPIPE module receives 16-bit input data through the IPIPEIF module, which can be 12-bit RAW image data or 16-bit YCbCr data.. The IPIPE module can work with up to 5376 pixels in each horizontal line, except in RAW pass-through mode. If the image width is larger than 5376, the image must be scaled down at the IPIPEIF module level. Otherwise, the input image must be split into several blocks.

If the input data is YCbCr, all RGB processing modules are skipped, and only edge enhancer and Chroma suppression are applied to the input data.

If the input data is YCbCr-4:2:0, only Y or C can be processed at a time, and only the resizer process can be applied. Because the RSZ module is outside the ISIF module, the data is passed to it directly by skipping the RGB and YCbCr processing modules.

In RAW pass-through mode, images up to 8190 pixels per line can be processed. In RAW pass-through mode, the input data is written out directly to SDRAM.

The IPIPE module is enabled through the IPIPE_SRC_EN[0] EN bit.

The IPIPEIF module must be selected as the IPIPE module source with the IPIPE_SRC_MODE[1] WRT bit set to 1 from the input port of the IPIPEIF. This is required to enable and transfer data properly from the interface to the IPIPE.

The IPIPE module has two processing modes, which can be selected through the IPIPE_SRC_MODE[0] OST bit:

- One-shot mode: IPIPE_SRC_MODE[0] OST = 0x1
- Free-run mode: IPIPE_SRC_MODE[0] OST = 0x0

The input and output formats are selected in the IPIPE_SRC_FMT[1:0] FMT bit field (see Table 8-426).

Table 8-426. ISS ISP IPIPE Input and Output Selections

IPIPE_SRC_FMT[1:0] FMT	IPIPE Module Input	IPIPE Module Output
0x0	RAW Bayer	YCbCr or RGB
0x1	RAW Bayer	RAW Bayer
0x2	RAW Bayer	Disabled
0x3	YCbCr 16 bits	YCbCr

The 16-bit data input to the IPIPE module is in the formats (YCbCr-8bit is not allowed) shown in Figure 8-145.

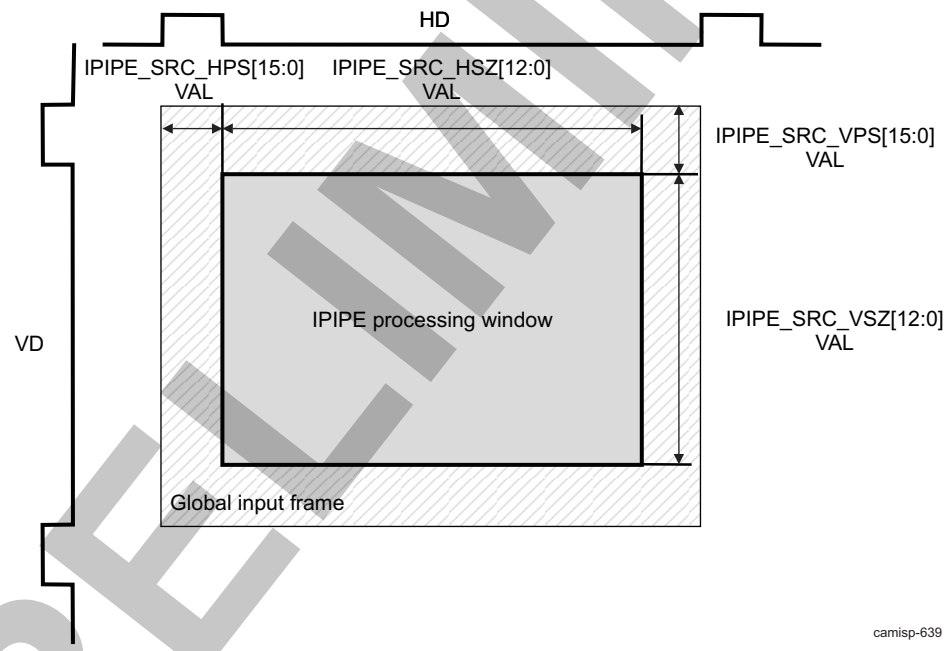
Figure 8-145. ISS ISP IPIPE Module Input Format

IPIPE input	RAW	LOW	LOW	LOW	LOW	RAW11	RAW10	RAW9	RAW8	RAW7	RAW6	RAW5	RAW4	RAW3	RAW2	RAW1	RAW0
	YCbCr 16b	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0
	Y 8bit	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW
	CbCr 8bit	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0

camisp-143

The window to process can be defined by its vertical and horizontal start position (IPIPE_SRC_VPS and IPIPE_SRC_HPS, respectively) and vertical and horizontal size (IPIPE_SRC_VSZ and IPIPE_SRC_HSZ, respectively). Figure 8-146 shows the window settings for processing.

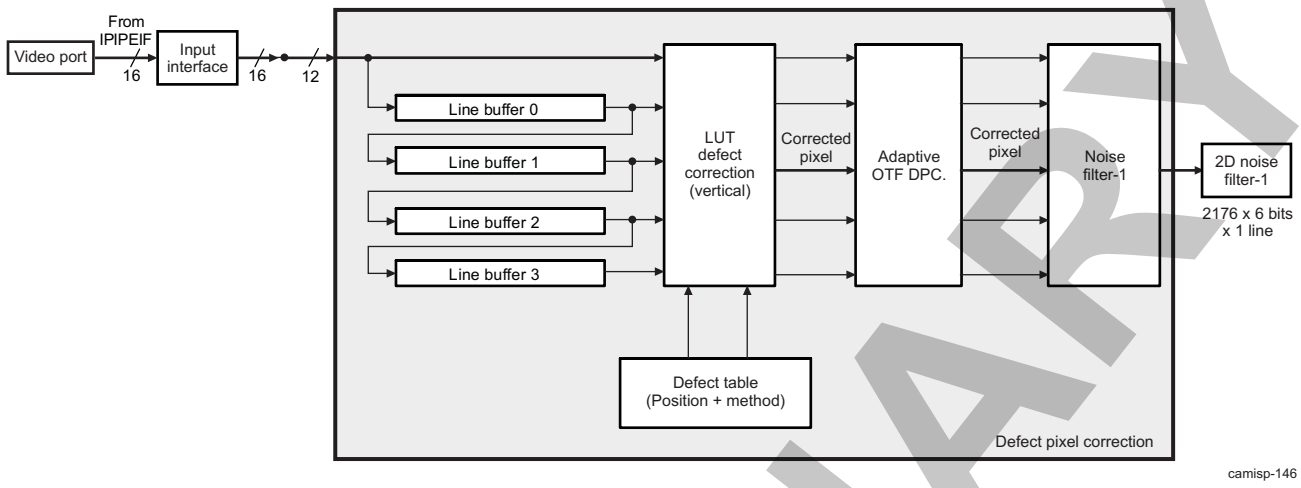
Figure 8-146. ISS ISP IPIPE Module Processing Window Settings



8.3.3.3.4 ISS ISP IPIPE Defect Pixel Correction

The DPC module corrects defect pixels using two methods:LUT-based method (LUT DPC) and on-the-fly adaptive method (OTF DPC). Figure 8-147 shows defect pixel correction.

Figure 8-147. ISS ISP IPIPE Defect Pixel Correction



8.3.3.3.4.1 ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

LUT DPC is the first stage of the IPIPE image-processing pipeline. The LUT DPC module corrects defects in input data. It supports up to a 256-defect point table. However, the table can be renewed as required during image processing. Therefore, the maximum amount of defect information is limited only by system-level performance.

The module uses two sets of 128 × 29 memories to hold defect information. The table contains the information of horizontal position (13 bits), vertical position (13 bits), and correction method (3 bits), as shown in Table 8-427. The LUT DPC is enabled through the IPIPE_DPC_LUT_EN[0] EN bit.

Table 8-427. ISS ISP IPIPE Defect Information Packing

Correction Method	Vertical Position	Horizontal Position
28…26	25…13	12…0

The information must be listed from left to right and from the top to bottom. The first position in the defect information table and the number of defects that are used can be specified. The address of the table must be programmed in the IPIPE_DPC_LUT_ADR[9:0] ADR bit field. Thus, the address of the first valid data is stated.

The LUT type can be:

- With a finite number of entries:
  - IPIPE_DPC_LUT_SEL[1] TBL = 0x0
  - The size of the LUT is set in the IPIPE_DPC_LUT_SIZ[9:0] SIZ bit field.
- With an infinite number of entries:
  - IPIPE_DPC_LUT_SEL[1] TBL = 0x1

The correction methods, set in Table 8-427, are described in Table 8-428.

Table 8-428. ISS ISP IPIPE Correction Method Description

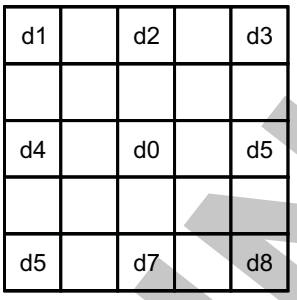
Correction Method	d0 =	Comment
0	Black or white dot	Replace with a black (or white) dot to force OTF-DPC to work on the pixel. White or black dot replacement can be selected through the IPIPE_DPC_LUT_SEL[0] DOT field.
1	d4	Copy from left
2	d5	Copy from right

Table 8-428. ISS ISP IPIPE Correction Method Description (continued)

Correction Method	d0 =	Comment
3	(d4 + d5)/2	Horizontal interpolation
4	(d2 + d7)/2	Vertical interpolation
5	d2	Copy from top
6	d7	Copy from bottom
7	(d2 + d4 + d5 + d7)/2	2D interpolation

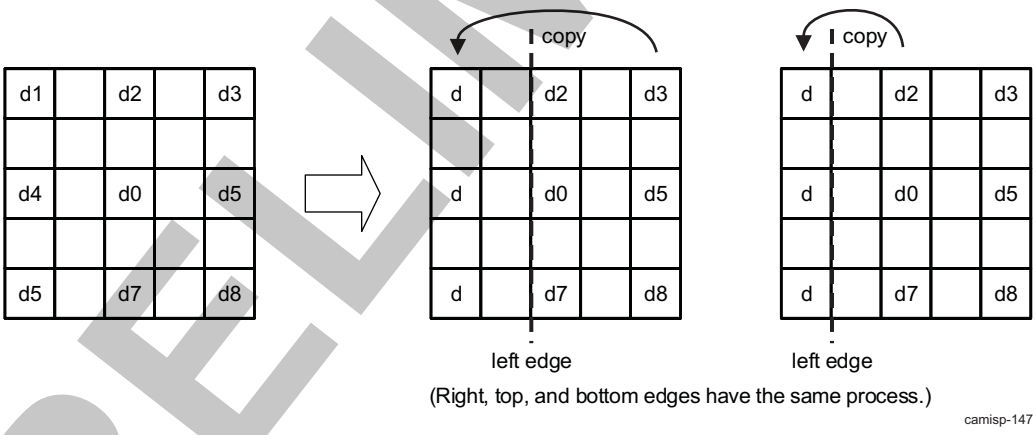
The pixels in the defect correction algorithm are numbered as shown in Figure 8-148.

Figure 8-148. ISS ISP IPIPE Pixel Numbering in Defect Correction Algorithm



The pixels at the edges are mirrored as way described in Figure 8-149. The figure shows the typical correction by overwriting far-edge pixels and mirroring them with other edge pixels. The example shows how by using a noise filter the correct-by-definition pixels are copied over bad pixels.

Figure 8-149. ISS ISP IPIPE Mirroring in Defect Correction and Noise Filter

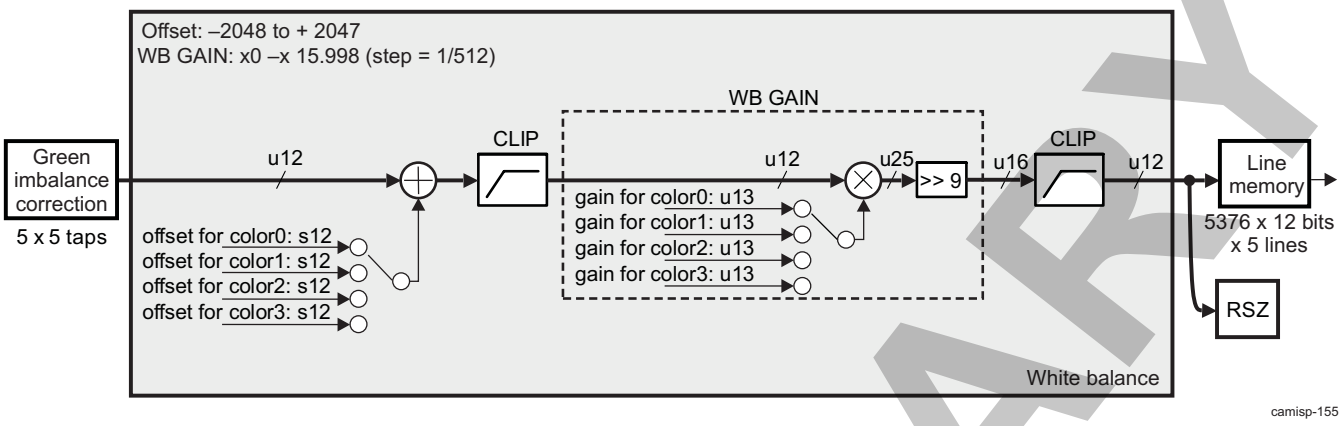


8.3.3.3.5 ISS ISP IPIPE White Balance

The white balance module executes white balance to each color component. White balance gain adjusts the ratio of each color existing in a CFA pattern. An offset can be applied before white balance correction (IPIPE_WB2_OFT_R, GR, Gb, or B registers).

Figure 8-150 is a block diagram of the white balance module. In the white balance gain adjuster, the RAW data is multiplied by a selected gain (IPIPE_WB2_WGN_R, Gr, Gb, or B registers) corresponding to the color. The white balance gain can be selected from four 13-bit values. Firmware can assign any combination of 4 pixels in horizontal and vertical directions. The precision of each gain is shown in the figure.

Figure 8-150. ISS ISP IPIPE White Balance



8.3.3.3.6 ISS ISP IPIPE RGB2RGB Blending Module

The RGB2RGB blending module transforms the RGB data generated by the CFA interpolation module using a 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 8-151. Each gain range is from –8 to +7.996 with step 1/256 = 0.004, and is set in the IPIPE_RGB1_MUL_RR to IPIPE_RGB1_MUL_BB registers. The offset range for each component is from –4096 to 4095, and is set in the IPIPE_RGB1_OFT_OR to IPIPE_RGB1_OFT_OB registers.

Figure 8-151. ISS ISP IPIPE RGB2RGB Conversion Formula

$$\begin{pmatrix} R\_out \\ G\_out \\ B\_out \end{pmatrix} = \begin{pmatrix} gain\_RR & gain\_GR & gain\_BR \\ gain\_RG & gain\_GG & gain\_BG \\ gain\_RB & gain\_GB & gain\_BB \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_R \\ offset\_G \\ offset\_B \end{pmatrix}$$

camisp-650

8.3.3.3.7 ISS ISP IPIPE Gamma Correction Module

NOTE: For the memory access locations of the gamma correction module, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

The gamma correction module performs gamma correction independently for each color in the RGB color space by using a piece-wise linear interpolation. ROM tables and RAM tables are selectable through the IPIPE_GMM_CFG[4] TBL bit. Each ROM table and RAM table has 512 entries, and each entry accommodates a 10-bit offset and 10-bit slope. The range of slope value is from –512 to +511. The ROM table has 1024 entries and an output 8-bit value.

Figure 8-152 is a block diagram of the gamma correction module. It is composed of two tables and one selector. When the BYPASS bit is asserted, the input data is divided by 16 (the IPIPE_GMM_CFG[0] BYPR, IPIPE_GMM_CFG[1] BYPG, and IPIPE_GMM_CFG[2] BYPB bits).

Figure 8-153 shows an example of the gamma curve. Figure 8-154 shows offset and slope packing.

Figure 8-152. ISS ISP IPIPE Gamma Correction Module Block Diagram

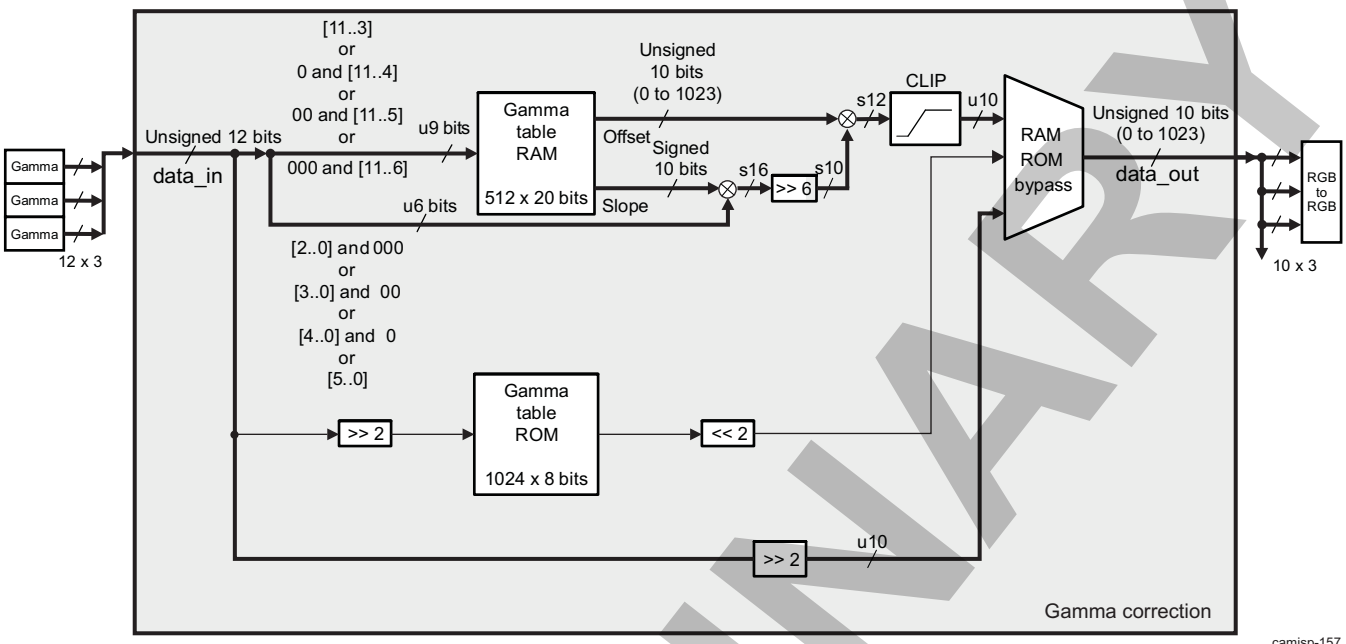


Figure 8-153. ISS ISP IPIPE Gamma Curve Example

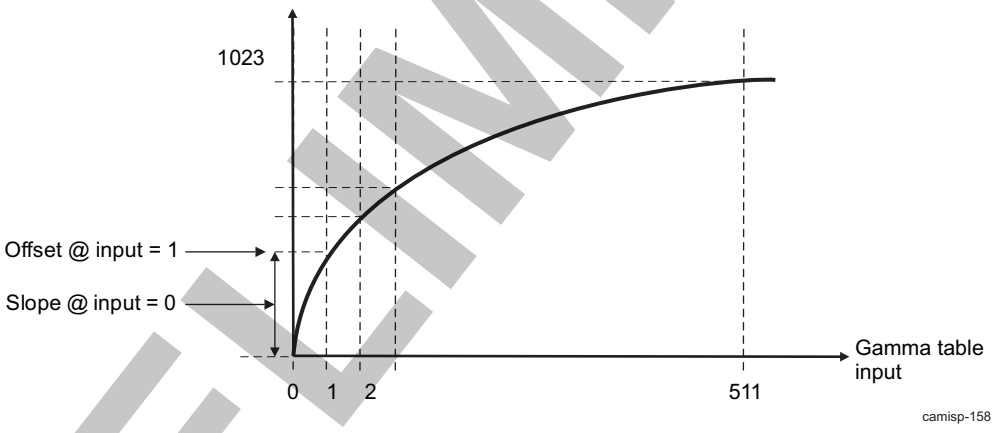

Figure 8-154. ISS ISP IPIPE Gamma Table Offset and Slope Packing

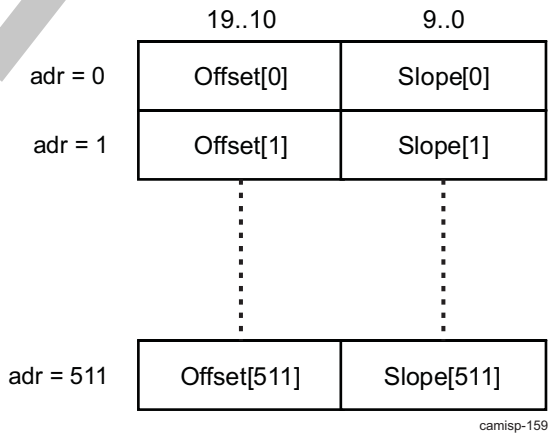


8.3.3.3.8 ISS ISP IPIPE Second RGB2RGB Conversion Matrix

The second RGB2RGB blending module transforms the RGB data after gamma correction using the 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 8-155. Each gain range is from –4 to +3.996 with step 1/256 = 0.004 (s3.8), and is set in the IPIPE_RGB2_MUL_RR to IPIPE_RGB2_MUL_BB registers. The offset is –1024 to 1023 (s11), and is set in the IPIPE_RGB2_OFT_OR to IPIPE_RGB2_OFT_OB registers.

Figure 8-155. ISS ISP IPIPE RGB2RGB Second Conversion Formula

$$\begin{pmatrix} R\_out \\ G\_out \\ B\_out \end{pmatrix} = \begin{pmatrix} gain\_RR & gain\_GR & gain\_BR \\ gain\_RG & gain\_GG & gain\_BG \\ gain\_RB & gain\_GB & gain\_BB \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_R \\ offset\_G \\ offset\_B \end{pmatrix}$$

camisp-650

8.3.3.3.9 ISS ISP IPIPE RGB2YCbCr Conversion Matrix

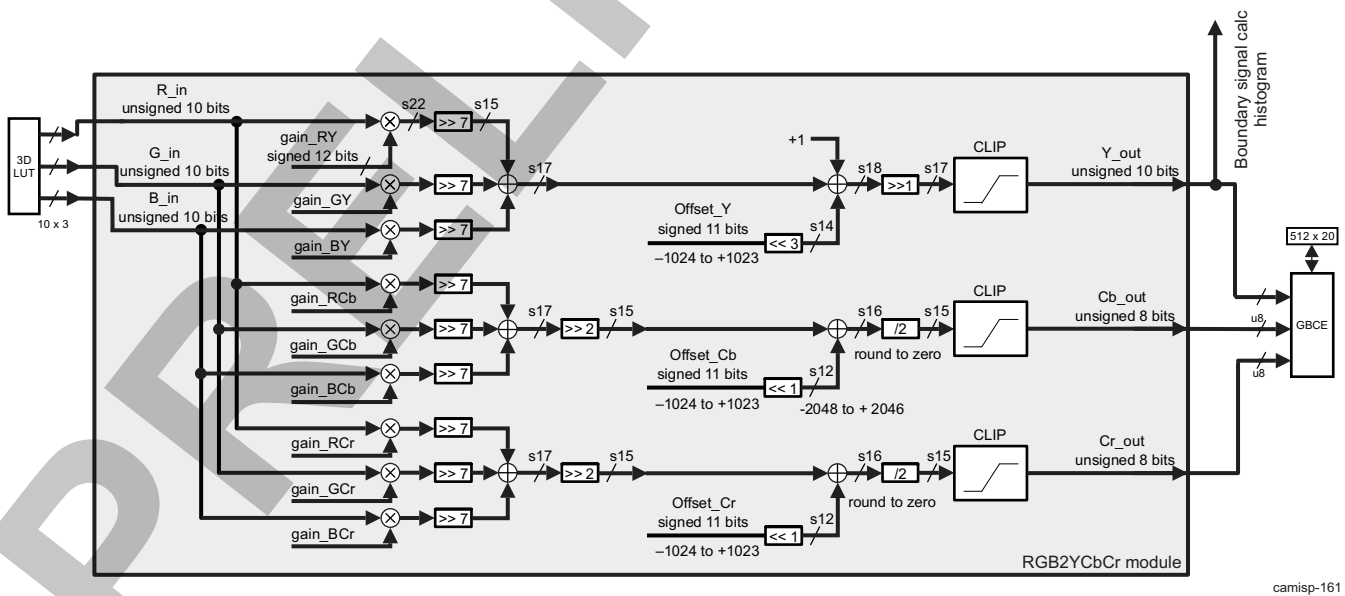
This module transforms the RGB data to YCbCr data format using a 3 × 3 matrix transformation in combination with an added offset. While transferring, the brightness control and contrast control can be adjusted using the IPIPE_YUV_ADJ[15:8] BRT and IPIPE_YUV_ADJ[15:8] CRT bit fields, respectively. Then, the transform is calculated using the formula shown in Figure 8-156. Each gain range is from –8 to +7.996 with step 1/256 = 0.004, configured in the IPIPE_YUV_MUL_RY to IPIPE_YUV_MUL_BCR registers. The offset is –1024 to +1023 for Y, Cb, and Cr, configured in the IPIPE_YUV_OFT_Y to IPIPE_YUV_OFT_CR registers. Figure 8-157 is the block diagram of the RGB to YCbCr blending module. The output is calculated by the equation.

Figure 8-156. ISS ISP IPIPE RGB2YCbCr Conversion Formula

$$\begin{pmatrix} Y\_out \\ Cb\_out \\ Cr\_out \end{pmatrix} = \begin{pmatrix} gain\_RY & gain\_GY & gain\_BY \\ gain\_RCb & gain\_GCb & gain\_BCb \\ gain\_RCr & gain\_GCr & gain\_BCr \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_Y \\ offset\_Cb \\ offset\_Cr \end{pmatrix}$$

camisp-655

Figure 8-157. ISS ISP IPIPE RGB2YCbCr Module Block Diagram



camisp-161

8.3.3.3.10 ISS ISP IPIPE 4:2:2 Conversion Module

The 4:2:2 conversion module converts the image data to YCbCr-4:2:2 format by taking the average of every two Cb and Cr components. Y and Cb/Cr sampling point of spatial cosited or spatial centering are selectable using the IPIPE_YUV_PHS[0] POS bit. Horizontal 3 taps and 4- or 2-tap filters are used for spatial cosited and spatial centering, respectively. The module is enabled from the IPIPE_YUV_PHS[1] PLF bit.

Figure 8-158. ISS ISP IPIPE Chroma Subsampling Position

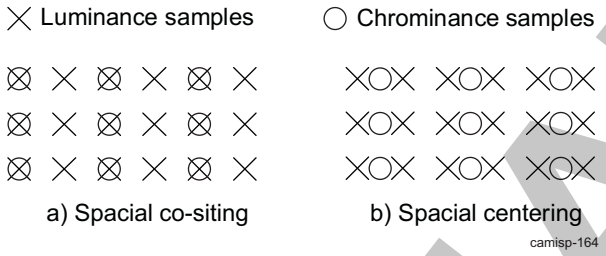


Figure 8-159 is a block diagram of the 4:2:2 conversion module.

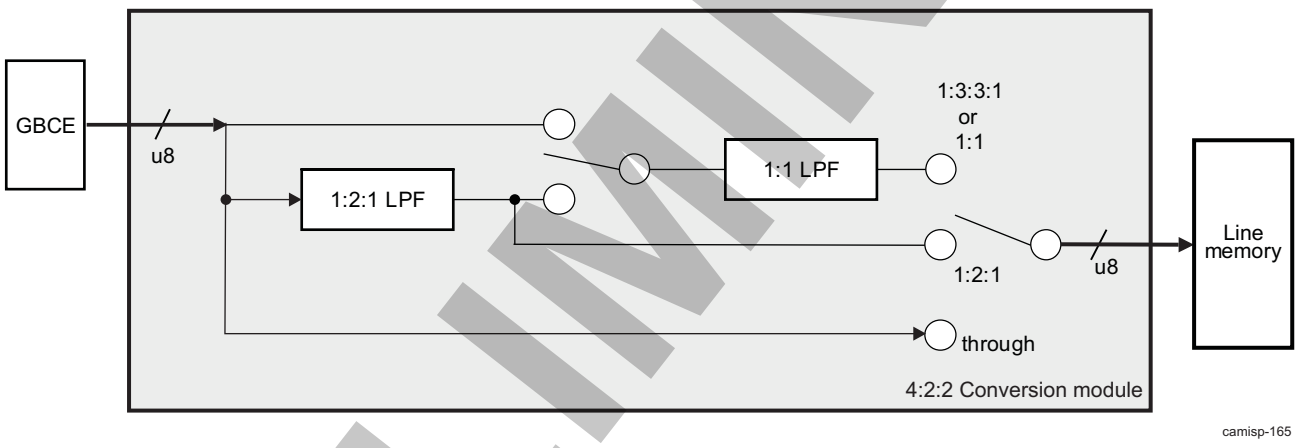
Figure 8-159. ISS ISP IPIPE 4:2:2 Conversion Module Block Diagram



8.3.3.3.11 ISS ISP IPIPE 2D Edge-Enhancer

NOTE: For the location of 2D edge-enhancer memory accesses, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

The edge-enhancer module operates on the Luma (Y data) component of images to improve the image quality and can be enabled from the IPIPE_YEE_EN[0] EN bit. Edges in input images are detected by a 2D high-pass filter, and its sharpness is increased by the value from a nonlinear table. Figure 8-161 shows a block diagram of the Luma nonlinear edge-enhancer. Entry for the nonlinear table is 10-bit and the output is in signed 9-bit.

In edge-enhancer mode when IPIPE_YEE_TYP[0] SEL is set to 0, linear filter with programmable coefficient is applied to the Y input. Here, M is a 5 × 5 matrix with programmable coefficients (IPIPE_YEE_MUL_xx, where xx = 00, 01, 02, 10, 11, 12, 20, 21, 22). A down shift of high-pass filter is applied to the edge-enhancer from the IPIPE_YEE_SHF[3:0] SHF bit field (shf_{HFP} in the formula in Figure 8-160).

Figure 8-160. ISS ISP IPIPE 2D Edge-Enhancer Linear Filter

$$HPF(h,v)=\left(\sum_{j=-2}^{2}\sum_{i=-2}^{2}M_{i,j}Y(h+i,v+j)\right)>>shf_{HPF}$$

$$M=\begin{pmatrix} M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,0} & M_{1,0} & M_{0,0} & M_{1,0} & M_{2,0} \\ M_{2,1} & M_{1,1} & M_{0,1} & M_{1,1} & M_{2,1} \\ M_{2,2} & M_{1,2} & M_{0,2} & M_{1,2} & M_{2,2} \end{pmatrix}$$

camisp-801

Then, the HPF value is shrunk by a threshold value (u6) specified by the IPIPE_YEE_THR register ($threshold_{HPF}$ in the formula), and clipped to signed 10 bits to get the index for the LUT.

Figure 8-161. ISS ISP IPIPE 2D Edge-Enhancer Indexing

$$index = clip(shrink(HPF, threshold_{HPF}), -512, 511)$$

$$clip(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \le x \le limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

$$shrink(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \le x \le threshold \\ x - threshold & threshold < x \end{cases}$$

camisp-661

Moreover, the edge-enhancement intensity is looked up from the LUT through the formula shown in Figure 8-162 and in Table 8-429.

Figure 8-162. ISS ISP IPIPE 2D Edge Intensity LUT Formula

$$E_{int} = LUT[index]$$

camisp-662

Table 8-429. ISS ISP IPIPE Edge-Enhancer LUT Mapping

Address (32-bit Word Address)	Bit Position	LUT Index
0x00000h	[8:0]	1

	[17:9]	–1

Figure 8-163 shows the LUT packing, and Figure 8-164 shows the 2D edge-enhancer block diagram.

Figure 8-163. ISS ISP IPIPE 2D Edge-Enhancer LUT Packing

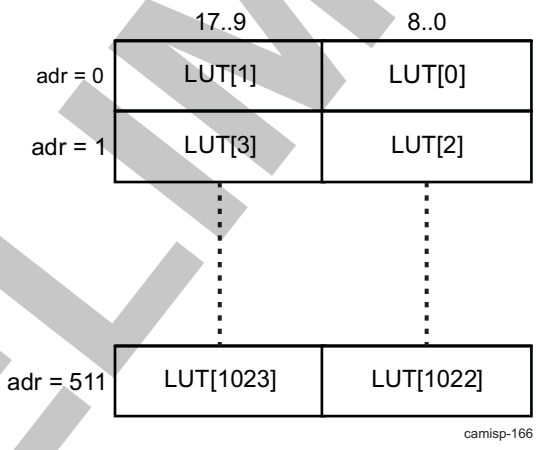

Figure 8-164. ISS ISP IPIPE 2D Edge-Enhancer Block Diagram

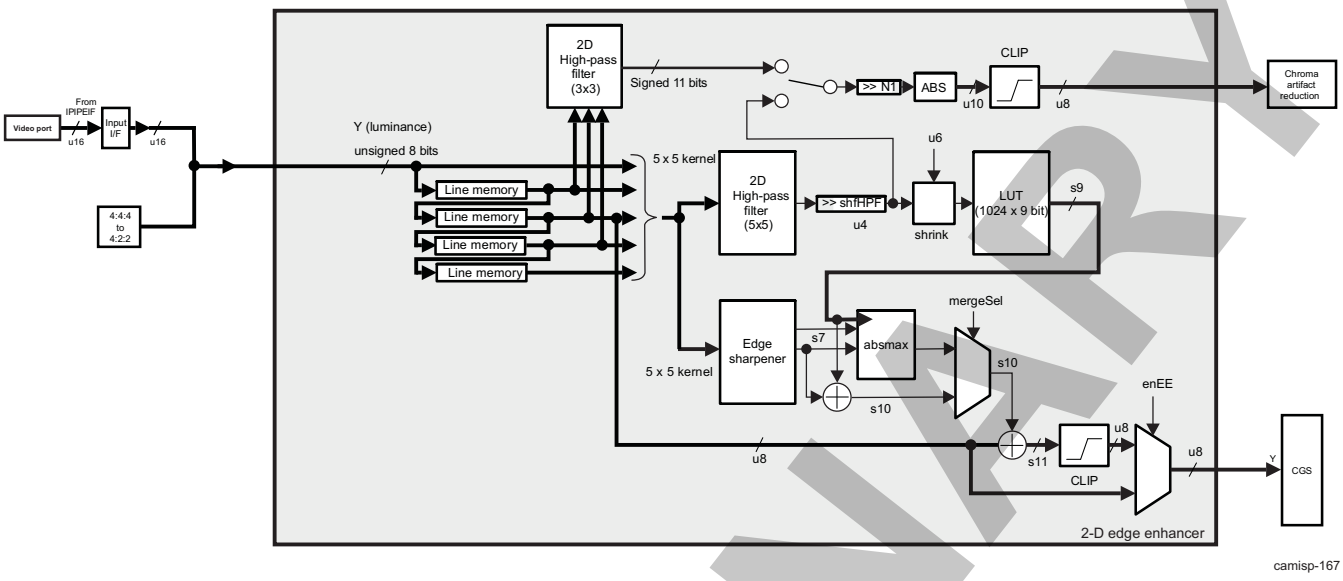

In edge sharpener mode, enabled when IPIPE_YEE_TYP[0] SEL = 1, edge clarity is enhanced without producing a halo artifact. In this module, edge intensity is derived by the 2D linear filter with fixed coefficients shown in Figure 8-165.

Figure 8-165. ISS ISP IPIPE Edge Sharpener Details

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = \text{clip}\left(\text{shrink}\left(g \times \left(\left(\sum_{j=-2}^{2} \sum_{i=-2}^{2} S_{i,j} Y(h+i, v+j) \right) >> 3 \right), threshold_{LOW} \right) >> 6, -threshold_{HIGH}, threshold_{HIGH} \right)$$

camisp-663

The gain (g) and threshold values for the shrink/clip function ($threshold_{LOW}$, $threshold_{HIGH}$) are determined by the IPIPE_YEE_E_GAN, IPIPE_YEE_E_THR_1, and IPIPE_YEE_E_THR_2 registers. The bit width of g and $threshold_{HIGH}$ is in U6, and $threshold_{LOW}$ is in U12Q6.

This edge intensity is then clipped by a threshold value in the formula shown in Figure 8-166.

Figure 8-166. ISS ISP IPIPE 2D Edge-Intensity Clipping Formula

$$S_{\text{int}} = \begin{cases} clip(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

camisp-664

The threshold value (grad) is a function of the activity around the target pixel, which is derived from gradient values. Gain and offset are specified by IPIPE_YEE_G_GAN and IPIPE_YEE_G_OFT

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

The output from edge-enhancer and edge sharpener are merged with the function shown in Figure 8-167.

Figure 8-167. ISS ISP IPIPE 2D Edge Enhancer and Sharpener Merger Formula

$$E_{merge} = \begin{cases} E_{\text{int}} + S_{\text{int}} & IPIPE\_YEE\_TYP[0]SEL = 0 \\ \text{absmax}(E_{\text{int}}, S_{\text{int}}) & IPIPE\_YEE\_TYP[0]SEL = 1 \end{cases}$$

$$\text{absmax}(x, y) = \begin{cases} x & abs(y) \le abs(x) \\ y & otherwise \end{cases}$$

camisp-666

The E_{merge} value is added to the Y input value to make the final output.

For Chroma suppression, another 2D high-pass filter (HPF) is implemented. One of the four coefficient sets shown in Figure 8-168 is selectable.

Figure 8-168. ISS ISP IPIPE 2D Edge Chroma-Suppression Coefficient Sets

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 \\ 1 & -2 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & -2 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \text{ or } \begin{pmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

camisp-667

At the end of the edge-enhancer process, brightness and contrast adjustment are applied to the Y signal. The formula shown in Figure 8-169 describes the process.

Figure 8-169. ISS ISP IPIPE 2D Edge-Brightness and Contrast Adjustments Formula

$$Y_{ctr\_brt} = \text{clip8}(\text{clip8}((Y_{EE} \times CTR) >> 4) + BRT)$$

$$\text{clip8}(x) = \begin{cases} x & x \le 255 \\ 255 & 255 < x \end{cases}$$

camisp-668

In the formula from Figure 8-169, Y_{EE} is the output (Y) of the Edge-Enhancer, as shown in Figure 8-164. CTR is a U8Q4 contrast enhancement factor (configured through the IPIPE_YUV_ADJ[7:0] CTR bit field), BRT is a U8 brightness enhancement factor (configured through the IPIPE_YUV_ADJ[15:8] BRT bit field), and Y_{CTR_BRT} is the output with brightness and contrast adjustment applied.

8.3.3.3.12 ISS ISP IPIPE Histogram

NOTE: The boxcar function can be used simultaneously with the histogram function if needed.

NOTE: For the locations of histogram memory access, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

The histogram module counts the number of pixels that have a value in a region and can be enabled from the IPIPE_HST_EN[0] EN bit. Moreover, if enabled, the IPIPE_HST_MODE register can be set to work constantly or one time. If the IPIPE_HST_MODE[0] OST bit is set to 1, the histogram is disabled by clearing the IPIPE_HST_EN[0] EN bit to 0 after one run (one-shot mode).

After enabling the module, the following features are available:

- The data to be summed is taken from the DPC memory or RGB2YCbCr module. The choice is made in the IPIPE_HST_SEL[2] SEL bit.
- When data are collected from the DPC memory, the sampled colors are R/G/B/Y. Y is derived in the following method:

  Y = (HST_MUL_R*R + HST_MUL_GR*Gr + HST_MUL_GB*Gb + HST_MUL_B*B) (4)

  For the G histogram, Gb, Gr, or the average is used, through the IPIPE_HST_SEL[1:0] TYP bit field.
- Two sets of 512 × 20-bit memory are used.

- The number of bins can be set from 32 to 256 in the IPIPE_HST_PARA[13:12] BIN bit field.
- The number of regions (areas) from 1 to 4; each region can be enabled through IPIPE_HST_PARA[x] RGNx (where x = 0 to 3). The positions of the regions are defined in IPIPE_HST_x_VPS and IPIPE_HST_x_HPS, and the vertical and horizontal size are defined by IPIPE_HST_x_VSZ and IPIPE_HST_x_HSZ, respectively (where x = 0 to 3).
- The number of regions × the number of bins <= 256.
- Each region can be turned on/off counting.
- The regions have priority orders.
- Each region has its own start coordinate X/Y (12 bits) and horizontal/vertical sizes (12 bits)
- When regions are overlapped, the value in the overlapped region is accumulated only in the region with the highest priority.
- The number of colors to be counted is from 1 to 4. Each color in all regions can be turned off counting (the IPIPE_HST_PARA[7:4] bit field).
- The value of each pixel is down-shifted (0–11) before counting using the IPIPE_HST_PARA[11:8] SHF bit field.
- When the value of a bin reaches (2^{20} – 1), the value is saturated until the memory is cleared.
- Number of bins: 32, 64, 128, or 256

The histogram memory can be cleared at the VD signal. When the memory is cleared, the first line of each frame cannot be sampled by the histogram if the width of the frame is larger than 512. If the width of the frame is smaller than 512, the first ceil (512/width) lines cannot be collected, where ceil(x) is the smallest integer value above x. If the clearing function is not enabled, the histogram bins are accumulated over the previous values.

The histogram has two banks of memories, which can be switched alternatively. The two memory banks are slipped into four histogram memory tables. Only two tables can be used at a time: output memory tables 0 and 1, or tables 2 and 3. To initialize tables, set the IPIPE_HST_TBL[1] CLR bit to 1, and to select which set of tables to uses, switch the IPIPE_HST_TBL[0] SEL bit between 0 and 1.

A gain for each color can be applied using the IPIPE_HST_MUL_x registers, where x = R, GR, GB, or B.

8.3.3.3.13 ISS ISP IPIPE Boxcar

The boxcar module generates a boxcar by taking mosaic image data and averaging the red, green, and blue pixels in an 8 × 8 or 16 × 16 block to produce one red, green, and blue output, as shown in Figure 8-170 and in Figure 8-171. Here, similar to the histogram module, the boxcar is enabled from the IPIPE_BOX_EN[0] EN bit, and if the mode is set to run once (one shot) (IPIPE_BOX_MODE[0] OST = 1), the enable bit is cleared after the run. The size of the blocks is determined from the IPIPE_BOX_SHF[0] SEL bit, where if set to 0 = 8 × 8, and 1 = 16 × 16.

The result of this operation is a full-color image with (1/64) or (1/256) area of the original image. The maximum input horizontal width is 8190 pixels when a 16 × 16 block is used; the width is 4096 when an 8 × 8 block is used. Also, the image size (width and height) must be a multiple of 16 for a 16 × 16 block, and a multiple of 8 for an 8 × 8 block. Boxcar operation works on 12-bit Bayer data and outputs 16-bit data. The output data is 48-bit RGB data for each 8 × 8 or 16 × 16 block. The 48-bit data is aligned in 64-bit format in SDRAM as shown in Figure 8-172. The first address of SDRAM access is specified by the IPIPE_BOX_SDR_SAD_H and IPIPE_BOX_SDR_SAD_L registers. The output data are written to SDRAM continuously line by line; there is no address offset between lines. After the image transfer of each frame completes, the ipipe_eof signal is sent to buffer logic. This signal is issued at the same timing as ipipe_int_dma.

Figure 8-170. ISS ISP IPIPE Boxcar Operation (8 × 8 Block)

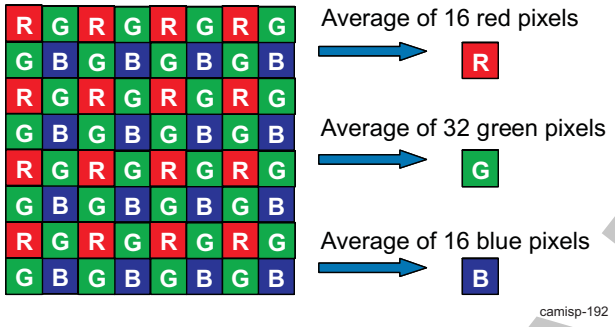

Figure 8-171. ISS ISP IPIPE Boxcar Operation (16 × 16 Block)

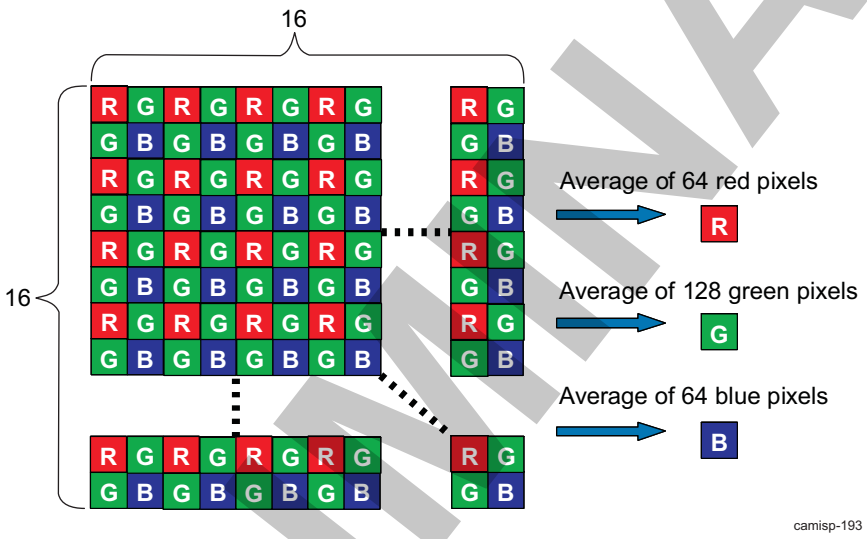

Figure 8-172. ISS ISP IPIPE Boxcar Data Packing in SDRAM

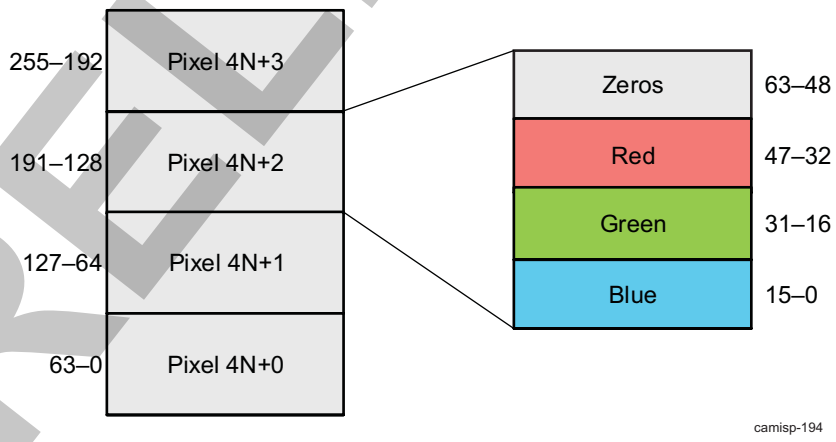


The right-shift value is specified by the IPIPE_BOX_SHF register, which has a range of 0 to 4. (The shift down is performed to fit the 20-bit accumulated value into 16-bit output.) For green signal processing, a divide-by-two operation rounds off the LSB.

8.3.3.4 ISS ISP RSZ Functional Description

8.3.3.4.1 ISS ISP RSZ Overview

The RSZ module rescales images into various sizes ranging from x1/4096 scale-down to x16 scale-up. It also works in conjunction with the rotational engine (ROT) in SIMCOP for rotating images. The RSZ data slave interfaces support a parallel VP. The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same.

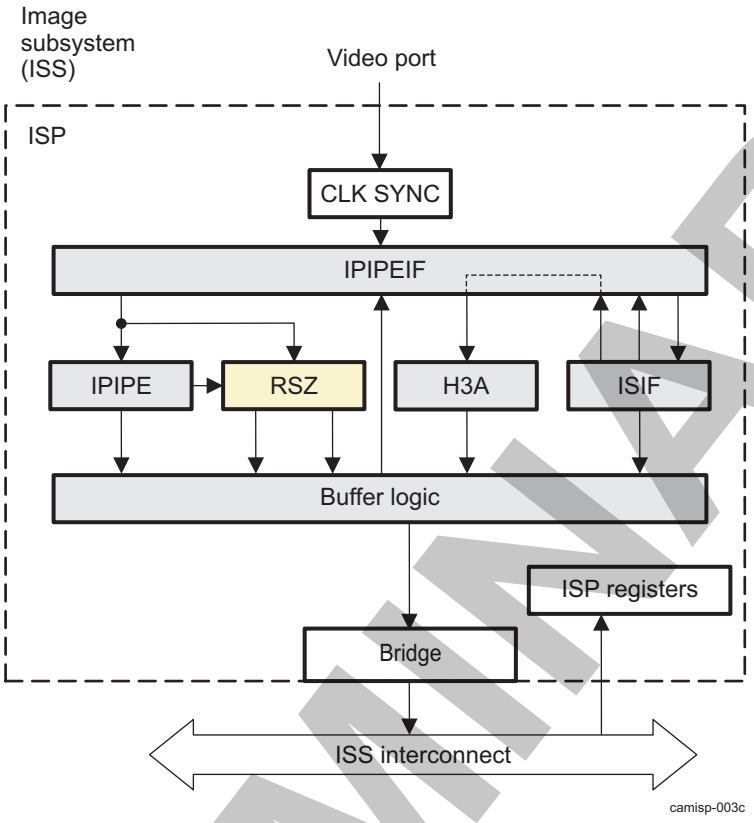
The RSZ module has the following capabilities:

- Input/output data formats:
  - Common input data for the two resizer engines
  - Independent output data formats for the two resizer engines
  - Supports YUV4:2:2 input and then supports YUV4:2:2/YUV4:2:0 or RGB5:6:5/ARGB32 output:
    - Output rates up to 304 MPix/s for YUV4:2:2/YUV4:2:0 or RGB5:6:5 output:
    - Output rates up to 243 MPix/s for ARGB32 output
  - Supports YUV4:2:0 input data and then supports only YUV4:2:0
    - YUV4:2:0 input format not supported natively:
      - Two passes required: Luma followed by Chroma or vice versa
        - Input and output rates up to 152 MPix/s in this configuration (YUV4:2:0)
      - Only supported from memory to memory
  - Supports RAW Bayer input and RAW Bayer output:
    - RAW format invariant. Takes whichever RAW format at the input and writes it out unmodified: 16 bits are read, 16 bits are written out.
    - No resizing can take place on RAW data.
- Resizer capabilities:
  - Input image cropping:
    - Common for the two resizer engines: Same input data before and after cropping
    - Supported on YUV4:2:2 and RAW data formats
    - Supported on pass-through mode data path
    - Supported on bypass mode data path
  - Dual resizer engines: RSZ-A and RSZ-B:
    - Up to x20 upsampling and x1/4096 downsampling on both engines
    - Up to 304-MHz pixel throughput on both resizer engines
    - Programmable data rate control to smooth the peak memory bandwidth
  - RSZ-A: Horizontal resolution of up to 8K pixels on RSZ-A
  - RSZ-B: Horizontal resolution of up to 8K pixels on RSZ-B
  - Independent Y and Cb/Cr phases on horizontal and vertical axis:
    - Enables to take care of different YUV4:2:0 phases used in different video formats
    - Enables frame division mode: Images can be stitched together with the right phase.
  - Rescaling: two modes supported:
    - Normal mode for upscale and downscale: Higher flexibility but lower downscale quality
    - Downscale mode for downscale only: Lower flexibility but higher downscale quality
  - Filtering: two modes supported:
    - Independent settings for the horizontal and vertical directions
    - 3-tap low-pass filter with 2-tap linear interpolation
    - 4-tap cubic interpolation
  - Flip support of the output image:

    - Horizontal flip
    - Vertical flip
  - Pixel duplication on the top/bottom, left/right sides: Avoids losing pixels at the image boundaries because of the filtering
  - Support pass-through and bypass modes: Resizer engines bypassed:
    - Pass-through mode
      - RAW and YUV4:2:2 data support
      - Lower power consumption mode to transfer data to memory
      - Can transfer images larger than 8K pixels to memory
    - Bypass mode
    - RAW and YUV4:2:2 data support
    - Input buffer used. Can benefit from additional buffering in case the BL module memory is not big enough and back pressure occurs.
- Slave data interface: VP interface:
  - Two VP interfaces: The programming model selects which VP is used to input data to the RSZ module. Both VPs cannot be active simultaneously.
    - VP 1: Typically connected to the IPIPE module.
    - VP 2: Typically connected to the IPIPEIF module.
  - Up to 304-MHz pixel clock
- Master data interface:
  - Two interfaces to the BL module:
    - Up to 304 MHz
    - 32-bit-wide, 32-byte-long requests
    - Accesses are aligned on 32-byte boundaries.
    - Used to transfer data to memory
    - Each interface is dedicated to a single output image.
  - Addressing modes:
    - Linear
    - Circular
- Configuration interface:
  - Up to 152 MHz
  - 32 bits wide
  - Used to configure the resizer registers
- Power management: Independent clock domains for the two resizers (Each resizer engine can be gated off separately)
- Error management: FIFO overflow detection on the input buffers

Figure 8-173 show the RSZ module connections to other submodules of the ISP.

Figure 8-173. ISS ISP RSZ High-Level Diagram



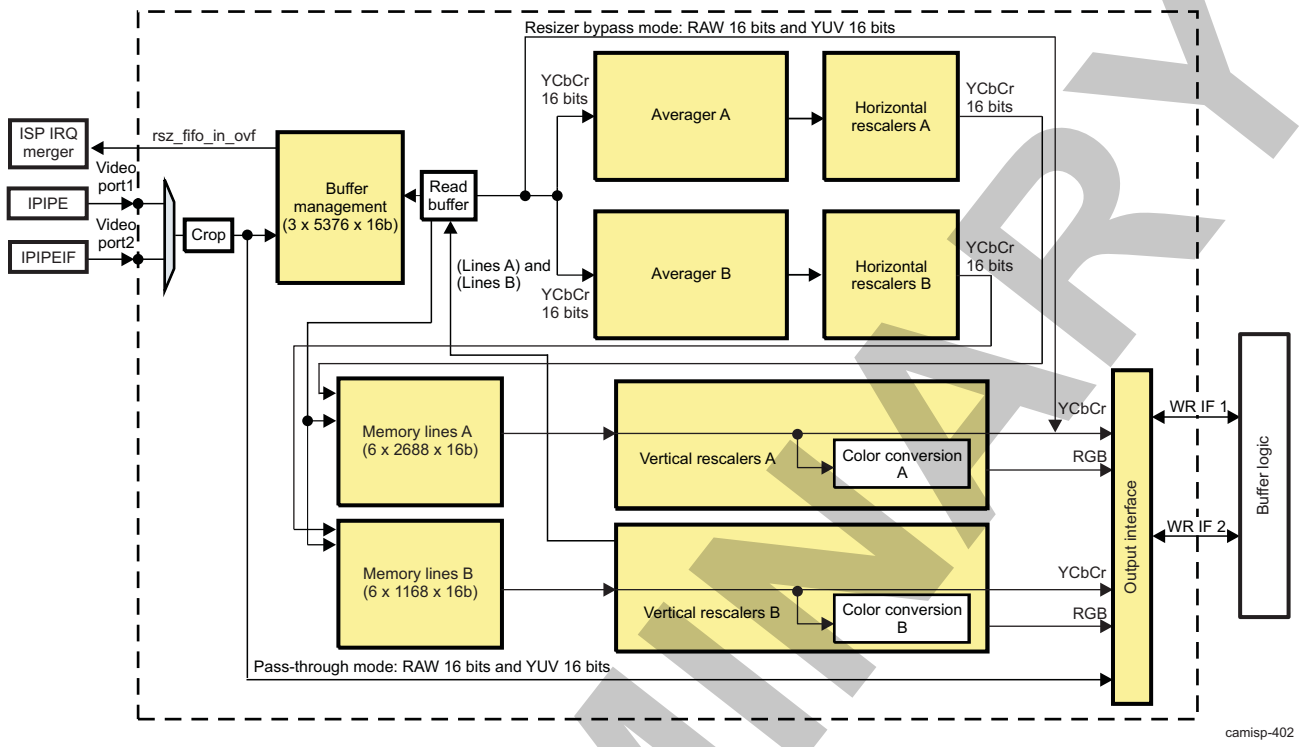
8.3.3.4.2 ISS ISP RSZ Top-Level Block Diagram

Figure 8-174 is the top-level block diagram of the RSZ module. The RSZ module comprises the following submodules: cropping, input data buffering, data requestor, averager, data saturation, and resizer interpolation (comprised of horizontal rescaler, vertical rescaler, color conversion, and output interface) (see the following sections for more information).

The RSZ module comprises two independent resizer engines with the same capabilities (except for the memory line size). The input data can come from VP 1 or VP 2. Software must determine and control which interface is selected.

The RSZ module includes one VBUSP slave port, which is used to control the RSZ registers. It also includes two MTC master ports, which are used to pass the pixels to the BL. The BL in turn creates the burst requests to the memory subsystem (see Section 8.3.3.4.3, *ISS ISP RSZ Interfaces*).

Figure 8-174. ISS ISP RSZ Top-Level Block Diagram



8.3.3.4.3 ISS ISP RSZ Interfaces

The RSZ module has the following data interfaces:

- One 32-bit read/write point-to-point pending VBUSP interface
- Two slave VP interfaces for transport YUV and RAW data
- Two MTC interfaces to BL for RSZ-A and RSZ-B, with only write capabilities

8.3.3.4.3.1 ISS ISP RSZ VBUSP Interface

The VBUSP interface is a 32-bit read/write capable interface. The VBUSP interface must be programmed in a way that back-to-back requests are possible for read and write. The RSZ_GCK_MMR[0] MMR bit enables the memory register access from the VBUSP interface to enable transfer and signal such as MMR request, direction, enable write/read data can be enabled.

8.3.3.4.3.2 ISS ISP RSZ Video Port Interfaces

The VP interfaces are slave interfaces; one is connected to IPIPE, and the other to IPIPEIF. These interfaces are for data transfer. Table 8-430 lists the format supported across IPIPE/IPIPEIF and RSZ. Signals coming from IPIPE and IPIPEIF can be write-enable signals. The RSZ_SRC_MODE[1] WRT bit is set whether or not the write enable signals are considered. This is a line-valid qualifier. This signal is sampled on the rising edge of HD, and the value is used for the full line.

Table 8-430. ISS ISP RSZ VP Supported Formats

	VP Signals: From IPIPE and IPIPEIF Modules (dat[15:0] Register)															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAW16	R15	R14	R13	R12	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0
YUV4:2:2 16 bits	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0

Table 8-430. ISS ISP RSZ VP Supported Formats (continued)

YUV4:2:0 Y data	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Low	Low	Low	Low	Low	Low	Low	Low
YUV4:2:0 Cb/Cr data	Low	Low	Low	Low	Low	Low	Low	Low	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0

NOTE: The formats are set from the IPIPE and IPIPEIF registers. For more information, see Section 8.3.3.3, *ISS ISP IPIPE Functional Description*, and Section 8.3.3.2, *ISS ISP IPIPEIF Functional Description*.

8.3.3.4.3.3 ISS ISP RSZ MTC Interfaces

The RSZ module includes two write-only MTC interfaces. Their implementation enables passing a maximum of eight 32-byte requests in 10 clock cycles. The RSZ must be programmed to obtain smooth and average bandwidth to buffer logic module by setting a minimum interval between two successive requests (set the RSZ_DMA_RZA[15:0] RZA and RSZ_DMA_RZB[15:0] RZB bit fields for the A and B resizers as appropriate). This setting is not expected to be dynamic. It can be a fixed setting from request to request and frame to frame. When the bandwidth is set appropriately, between the first valid translated pixel and the EOF signal sent to buffer logic, the RSZ_DMA_STA[0] STATUS bit can be seen, and it is high if the transfer over the MTC interfaces is active. Figure 8-175 shows how RSZ_DMA_RZx for resizers A and B affects the MTC data request generator.

Figure 8-175. ISS ISP RSZ MTC DMA Bandwidth Control

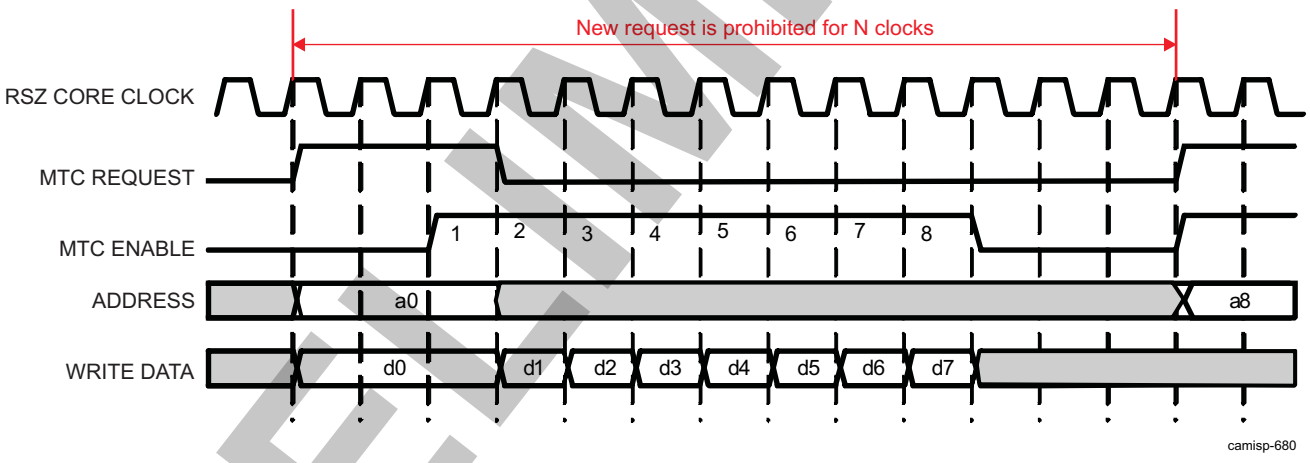


Figure 8-176 shows the pixel order in memory written by the MTC. The arrows do not represent the order in which data is written. Data are always written from left to right, whether horizontal reversal is enabled or not.

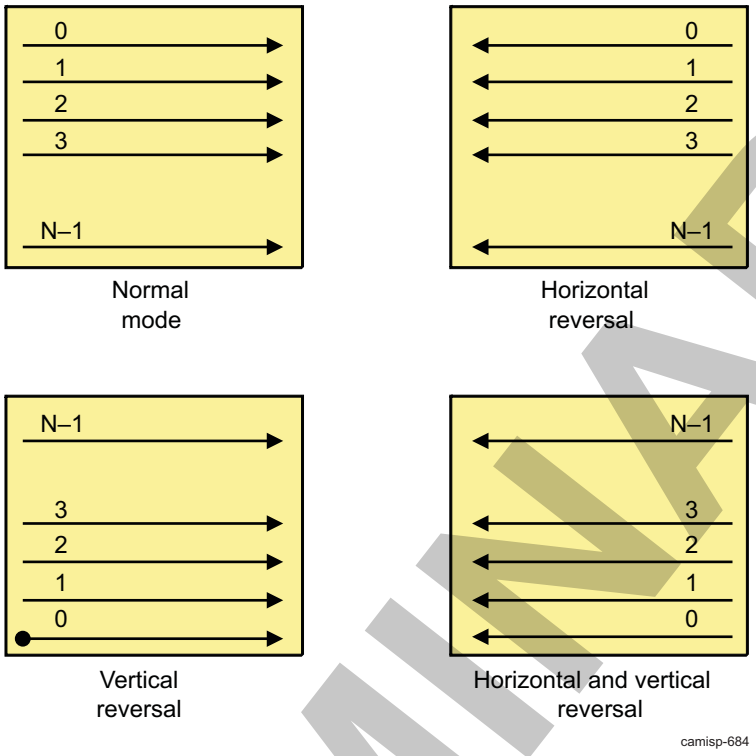
Figure 8-176. ISS ISP RSZ MTC Image Data Storage Pixel Order

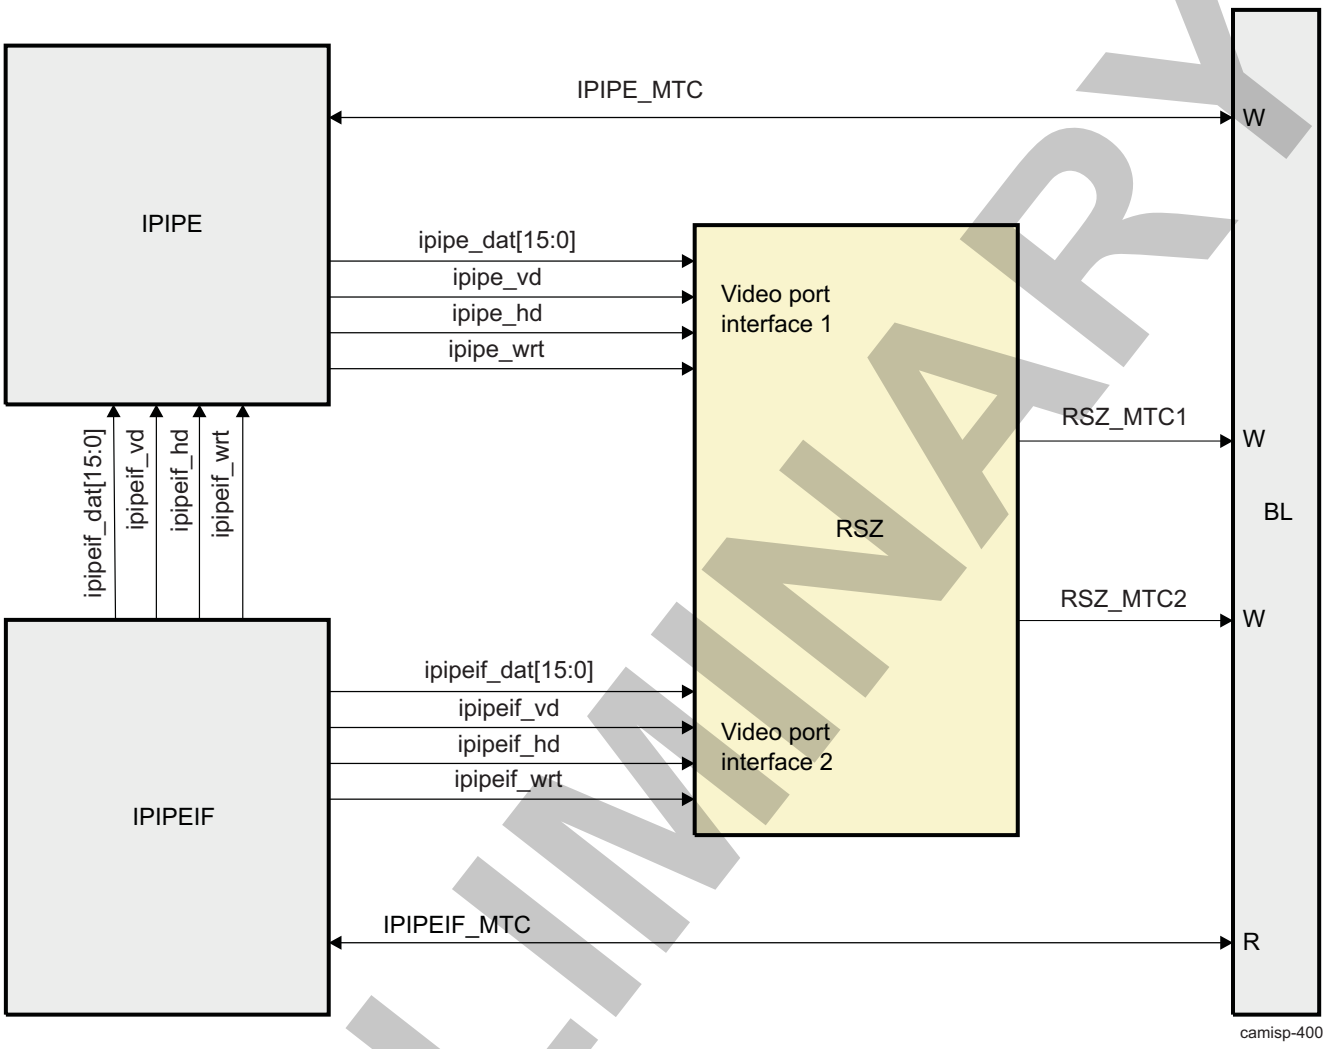


The RSZ MTC interfaces can be stalled by the input MTC STALL signal. The assertion of the MTC STALL signal is a result of a hardware mechanism that monitors the CBUFF module to prevent its overflow. When this signal is asserted, the current 32-byte MTC request is finished and then the RSZ MTC output ports are stalled. For further details on the output ports, see Section 8.3.3.4.5.7, *ISS ISP RSZ Output Interface*.

8.3.3.4.4 ISS ISP RSZ Integration

Figure 8-177 shows how the VP and interfaces of the RSZ module are connected to surrounding modules at the ISP level. The RSZ module gets data from the IPIPEIF module or IPIPE module.

Figure 8-177. ISS ISP RSZ Typical Module Integration: High-Level Summary



The following constraints apply to the RSZ module:

- The data coming from the IPIPEIF module can be RAW or YUV4:2:2 data. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 2. It is possible to bypass the resizer engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).
- The data coming from the IPIPE module can be RAW or YUV4:2:2 data. Eventually, YUV4:2:0 data can be sent through this path, but the data must be sent in two passes. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 1. It is possible to bypass the resizer engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).

VP 2 provides a way to bypass the IPIPE module when YUV4:2:2 data is received from the images sensor or when YUV4:2:2 is read back from memory with the CCP2 RX or ISIF module.

Table 8-431 summarizes the different RSZ configuration possibilities as a function of the input data format.

Table 8-431. ISS ISP RSZ Data Flow vs. Input Data Format Constraints

VP 1 Data Format	VP 2 Data Format	RSZ-A Configuration	RSZ-B Configuration	Comments
RAW	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode

Table 8-431. ISS ISP RSZ Data Flow vs. Input Data Format Constraints (continued)

VP 1 Data Format	VP 2 Data Format	RSZ-A Configuration	RSZ-B Configuration	Comments
N/A	RAW	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Enabled	Disabled	One output image
YUV4:2:2	N/A	Disabled	Enabled	One output image
YUV4:2:2	N/A	Enabled	Enabled	Two output images
N/A	YUV4:2:2	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
N/A	YUV4:2:2	Enabled	Disabled	One output image
N/A	YUV4:2:2	Disabled	Enabled	One output image
N/A	YUV4:2:2	Enabled	Enabled	Two output images

8.3.3.4.5 ISS ISP RSZ Functional Description

To start up, the RSZ configuration can be set from the RSZ_SYSCONFIG register, which provides enabling the RSZ-A and RSZ-B clocks. The RSZ module does not have stand-alone reset and status check. Software reset must be done at the ISP level. Moreover, when enabled, the RSZ module can control the input data buffer, and when the rsz_stall_input signals are set from the RSZ_IN_FIFO_CTRL register, the RSZ module generates a stall signal that can be used by the master module sending data to the RSZ module when the data threshold is too high.

The RSZ_SRC_EN[0] EN bit starts the resizer processing. If the processing mode is set to one shot (one run and then turn off) from the RSZ_SRC_MODE[0] OST bit, the EN bit is cleared to 0.

The RSZ module can be configured to be bypassed in certain cases (see Figure 8-177 for the module constraints) from the RSZ_SRC_FMT0[1] BYPASS bit. The data can be sent directly from here to the output interface (bypass mode) or imported to the module buffer, but not manipulated and sent to the output interface (pass-through mode). The master device sending data to the RSZ can be switched between IPIPEIF and IPIPE using the RSZ_SRC_FMT0[0] SEL bit. The RSZ understanding of the data input is set from the RSZ_SRC_FMT1 register (for more information, see Table 8-433). The RSZ_SEQ.VRVX and RSZ_SEQ.HRVX registers can be set to flip the image horizontally or vertically, respectively (see Figure 8-176).

Depending on the mode to which the RSZ is set, the core clock can be enabled from the RSZ_GCK_SDR register. Table 8-432 summarizes the behavior of the RSZ module for the different settings.

Table 8-432. ISS ISP RSZ Module Modes: Register Settings

Configuration Number	RSZ_SRC_EN	RZA_EN	RZA_CLK_EN	RZB_EN	RZB_CLK_EN	RSZ_GCK_SDR.CORE	RSZ_SRC_FMT0.BYPASS	Comments
0	0	X	X	X	X	X	X	Data cannot go through the RSZ module.
								Interrupts are not issued.
1	1	0	X	0	X	1	0	RSZ-A is disabled.
								RSZ-B is disabled.
								It is best to have RZA_EN = RZB_EN = 0 to save power, but RZA_EN = RZB_EN = 1 is also supported.
								This configuration is supported but does not make sense because data cannot go through the module.
2	1	1	1	0	X	1	0	RSZ-A is enabled.
								RSZ-B is disabled.

Table 8-432. ISS ISP RSZ Module Modes: Register Settings (continued)

								It is best to have RZB_EN = 0 to save power, but RZB_EN = 1 is supported as well.
3	1	0	X	1	1	1	0	RSZ-A is disabled.
								RSZ-B is enabled.
								It is best to have RZA_EN = 0 to save power, but RZA_EN = 1 is also supported.
4	1	1	1	1	1	1	0	Resizer A is enabled.
								Resizer B is enabled.
5	1	X	X	X	X	0	0	Bypass mode is enabled.
								Resizer core functional clock is disabled.
6	1	X	X	X	X	0	1	Pass-through mode enabled.
								Resizer core functional clock is disabled.
7	1	X	X	X	X	1	1	Pass-through mode is enabled.
								Resizer core functional clock is enabled.
								Not a preferred configuration. Configuration 6 saves power.

Table 8-433. ISS ISP RSZ Module Input Control: Register Settings

RSZ_SRC_FMT1.IN420	RSZ_SRC_FMT1.COL	Comments
0	X	YUV4:2:2 input. Chroma is co-sited.
1	0	YUV4:2:0 input. Valid data is Y, C is dummy. On the VP, YUV4:2:2 data is always assumed.
1	1	YUV4:2:0 input. Valid data is C, Y is dummy. On the VP, YUV4:2:2 data is always assumed.

The RSZ_YUV_PHS[0] POS bit sets the Chroma output. The RSZ module does not change the relative position of the Chroma samples versus the Luma samples between the input and output, and the Chroma position at the output of the IPIPE module and at the output of the RSZ module must be identical. In other words, RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS.

Settings are common for both resizer engines inside the RSZ module. Each engine (RSZ-A or RSZ-B) can be enabled from the RZx_EN register: select the mode from RZx_MODE, and select the input and output in the YUV color scheme from the RZx_420 register (valid only if YUV4:2:2 is the input set from RSZ_SRC_FMT1.IN420). Table 8-434 summarizes the combination of settings available in the RZx_420 register.

Table 8-434. ISS ISP RSZ-A/RSZ-B Output Format Selection

RZx_420.YEN	RZx_420.CEN	Comments
0	0	Input is YUV4:2:2. Output is YUV4:2:2 if RZX_RGB_EN = 0 and RGB if RZB_RGB_EN = 1.
0	1	Input is YUV4:2:2. Output is the Chroma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: First/second pass
1	0	Input is YUV4:2:2. Output is the Luma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: Second/first pass
1	1	Input is YUV4:2:2. Output is YUV4:2:0. RZX_RGB_EN is ignored.

8.3.3.4.5.1 ISS ISP RSZ Operating Modes

The RSZ module offers two basic rescaling modes. These modes are not built-in but are particular configurations, which means that other hybrid modes can be programmed. The normal mode provides more flexibility (the rescale ratio granularity is smaller) than downscale mode, but downscale mode produces better image quality (averager performs anti-aliasing):

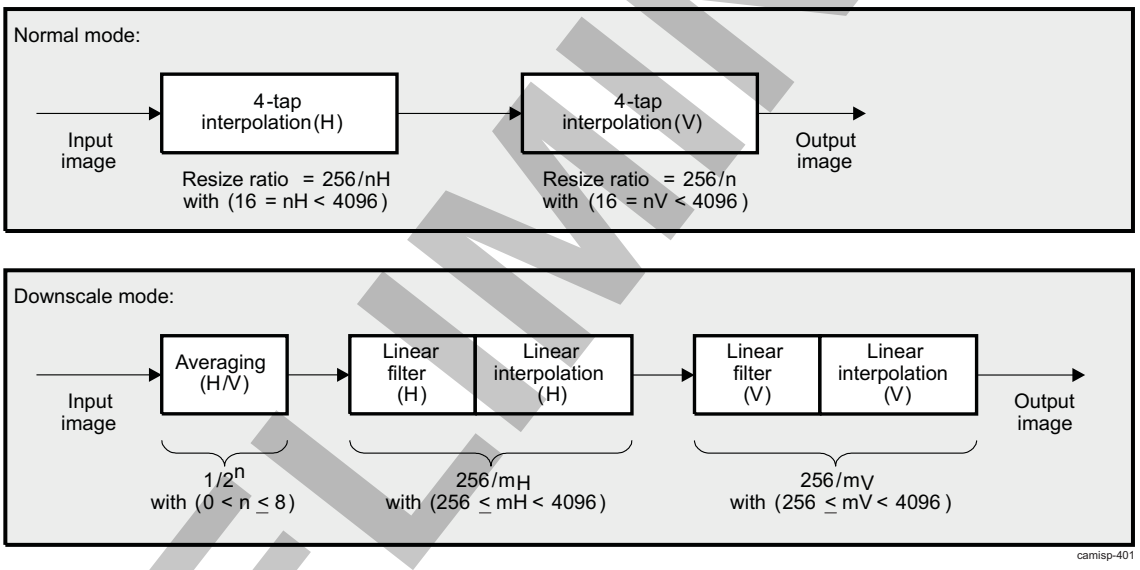
- Normal mode: The scaling process is carried out using interpolation with a 4-tap filter. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The user controls the type of interpolation that is used. The possible rescale ratios range from 1/16x to 20x.
- Downscale mode: The scaling process is the same as for normal mode, but an averaging function is placed before. It enables reaching much higher reduction factors while avoiding anti-aliasing artifacts. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The possible rescale ratios range from 1/4096x to 1x.

NOTE: The selection of the mode is independent for each resizer engine. One resizer engine can be configured in normal mode, while another is configured in downscale mode.

The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same. The RSZ output image sizes are limited to RSZ_GNC[12:0] RSZA_MEM_LINE_SIZE pixels/line for RSZ-A (5376 pixels/line) and RSZB_MEM_LINE_SIZE[28:16] for RSZ-B (2336 pixels/line).

Figure 8-178 shows the RSZ operating modes. Nothing prevents the use of linear interpolation in normal mode or bicubic interpolation in downscale mode; similarly, it is possible to mix the interpolation modes for horizontal and vertical filtering. This is fully programmable.

Figure 8-178. ISS ISP RSZ Operating Modes



8.3.3.4.5.1.1 ISS ISP RSZ Operating Modes and Maximum Input Clock

The maximum output pixel clock on both resizers is 304 MHz (OPP_NOM); that is, a pixel throughput of 304 MPix/s. Moreover, hardware takes care of the following constraints:

- When both resizer engines are configured to perform downscaling, there is no particular constraint on the VP pixel clock. The VP pixel clock can be as high as 304 MHz.
- When one resizer engine is configured to perform upscaling and the second resizer engine is configured to perform downscaling, the VP pixel clock must be limited. The VP must be lower than:

clk_pix <= (304 MHz/(Vertical Upscale Ratio × Horizontal Upscale Ratio)) (5)

For example, if a 4x upscale ratio happens horizontally and vertically, then the input pixel clock must be lower than 304/(4 × 4) = 19 MHz.

It is the reason why it is not possible to perform digital zoom upscaling on the fly. It is necessary to acquire the pixels to memory first and to read them back at a pace that does not exceed the previously discussed constraints. At the ISS level, data can be read back from memory from the CCP2 RX or ISIF module.

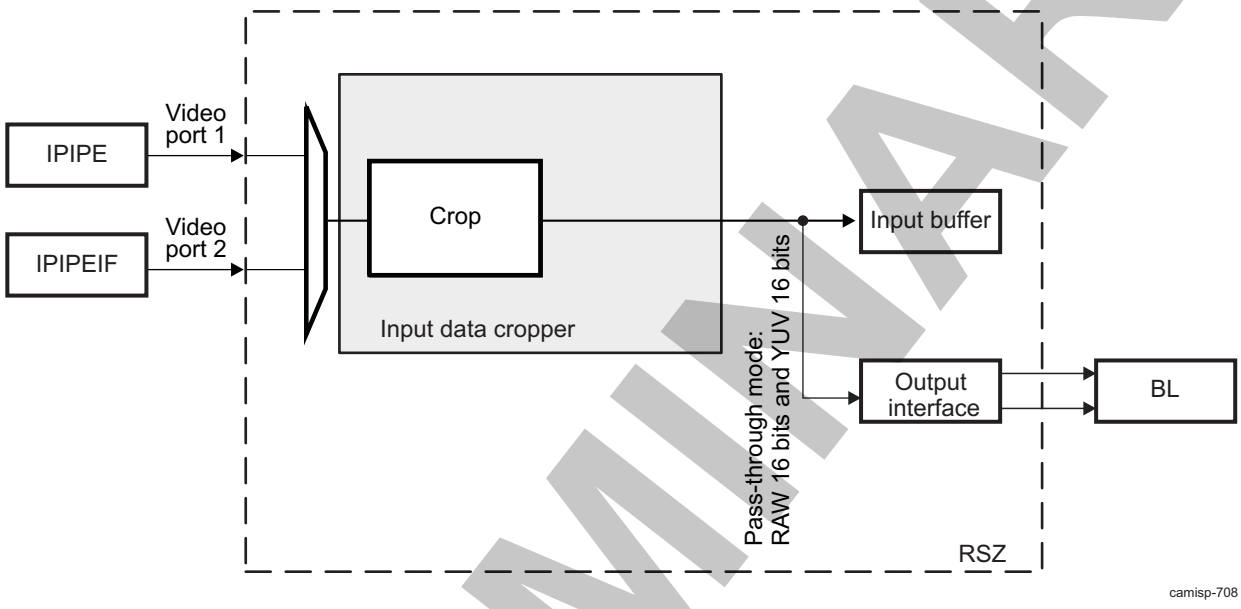
- When the two resizer engines are configured to perform upscaling, the VP pixel clock must be limited.

In that case, the VP frequency is limited by the resizer engine having the larger rescale ratios.

8.3.3.4.5.2 ISS ISP RSZ Input Data Cropper

The data coming from the VPs into the RSZ module can be cropped: this applies to RAW and YUV4:2:2 data. It is mandatory to crop the data as early as possible in the RSZ processing pipeline to reduce power consumption. It is mandatory to crop the data before storing it in the input data buffer. Figure 8-179 is the block diagram of the RSZ input data cropper.

Figure 8-179. ISS ISP RSZ Input Data Cropper Block Diagram



The input data are in YUV4:2:2 interleaved format or RAW format.

For YUV4:2:2 format, the data come as Cb0, Y0, Cr0, Y1, Cb2, Y2, Cr2, Y3, etc. Y denotes the Luma component value and Cb/Cr denotes the Chroma component values. There are as many Y components as Cb/Cr components per line.

Figure 8-180 shows input data cropping. Only the cropped data is stored in the input data buffer. The names used in the figure correspond to the register names. If no cropping is desired, the RSZ_SRC_HPS and RSZ_SRC_VPS registers, which set the horizontal and vertical positions, respectively, must be set to 0; the start size from the RSZ_SRC_HSZ register must be set to the input image width minus 1, and the RSZ_SRC_VSZ register must be set to the input image height minus 1. These are common settings for both resize engines inside the RSZ module. After setting, more flexibility is present through the RZx_i_VPS and RZx_i_HPS registers for vertical and horizontal positioning, respectively, of the input/output (where x = A or B, i = I or O).

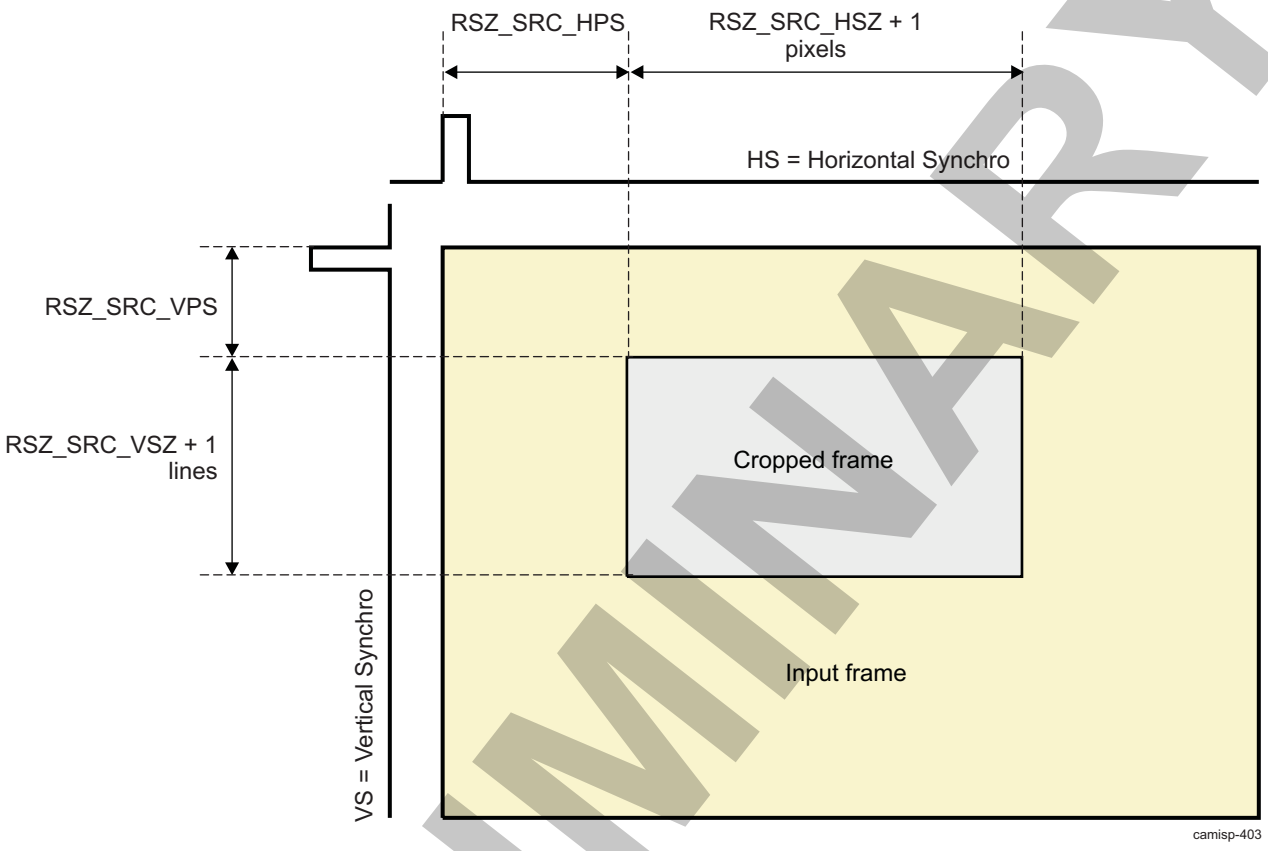
NOTE: After the RSZ second level cropping (defined by RZA_I_VPS and RZB_I_VPS register settings), the height of the image frame must be two lines or larger. A one-line image is not allowed.

Depending on the input data format, different constraints apply to the registers that set the cropping parameters:

- For YUV4:2:2 format, the vertical start positions of the cropped frame can be even or odd. However, the horizontal start position must be even: the reason is to always start with the same pattern: Cb_{2n}, Y_{2n}, Cr_{2n}, Y_{2n+1},etc. For the same reason, the horizontal size of the cropped frame (RSZ_SRC_HSZ + 1) must be an even number. Finally, the vertical size of the cropped frame can be odd or even.
- For RAW format, the vertical start position of the cropped frame can be even or odd. The vertical size can be even or odd. The horizontal resolution must be even.

These features and constraints are common for both resizer engines inside the RSZ module. Figure 8-180 shows the input data cropping.

Figure 8-180. ISS ISP RSZ Input Data Cropping



8.3.3.4.5.3 ISS ISP RSZ Averager

8.3.3.4.5.3.1 ISS ISP RSZ Use Cases

The two resizer engines can have independent averager settings:

- Both resizers can use the averager.
- One resizer can bypass it and the other can use the averager.
- Both resizers can bypass the averager.

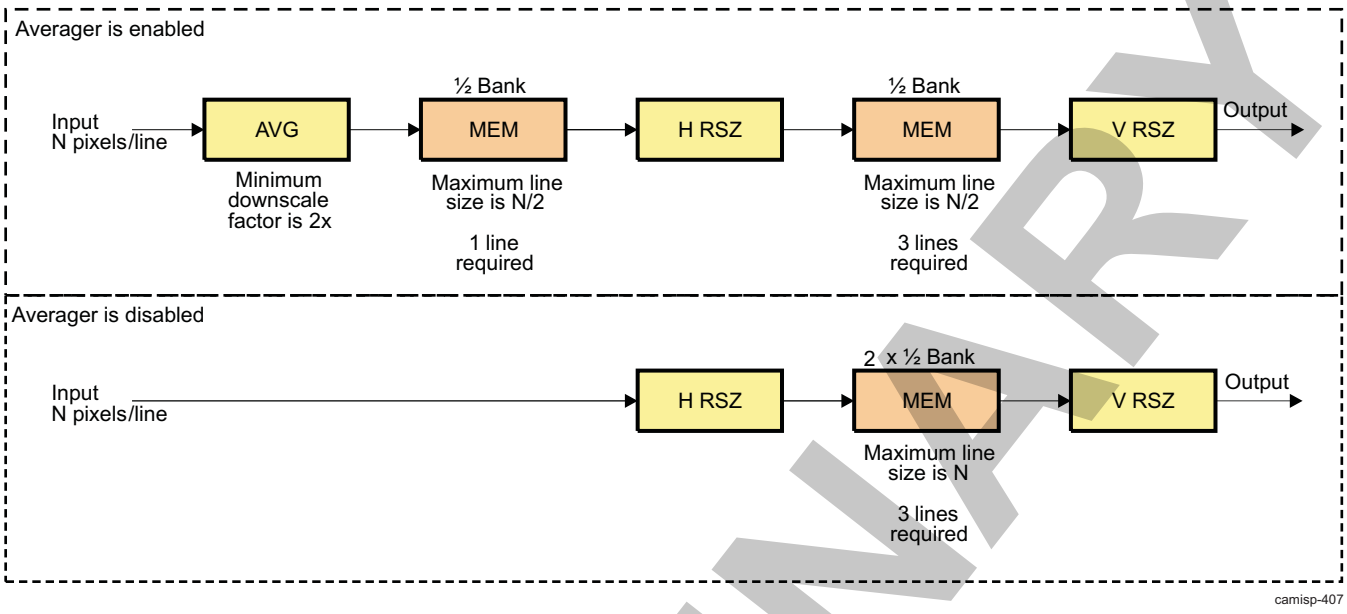
8.3.3.4.5.3.2 ISS ISP RSZ Memory Use

Vertical averaging requires memory to perform pixel data accumulation. It shares the vertical memory lines that are used for vertical filtering: this is the reason why the vertical memory lines are organized as two banks of half lines.

- The averagers output lines that are at most half the size of the input image in one memory bank.
- The horizontal resizers write their output data in the second memory banks.

Figure 8-181 shows the use of memory when the averager is enabled or disabled.

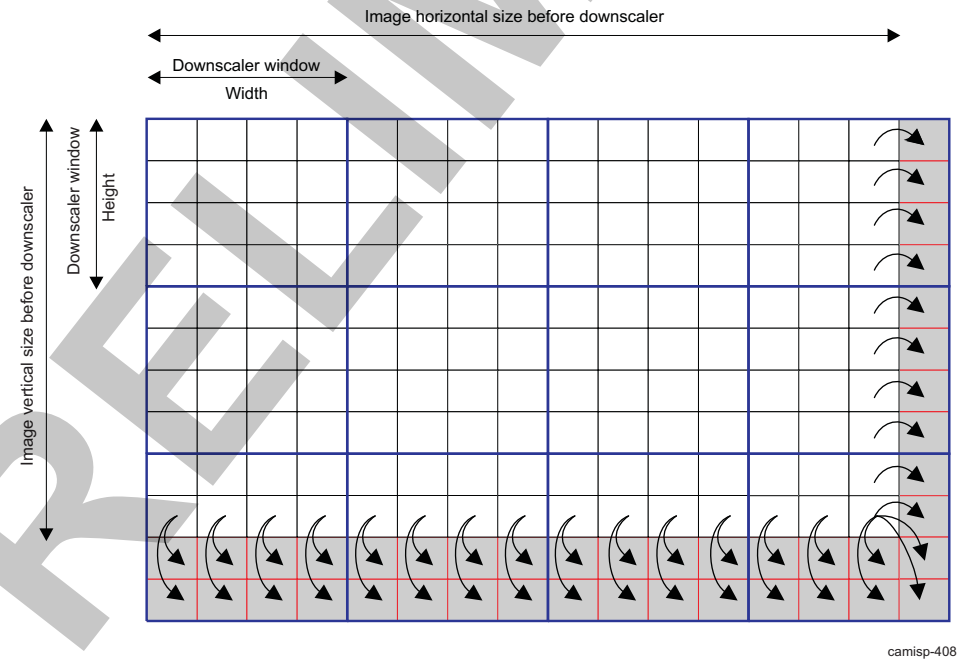
Figure 8-181. ISS ISP RSZ Averager Memory Utilization



8.3.3.4.5.3.3 ISS ISP RSZ Border Conditions

Figure 8-182 shows the averager behavior for border conditions. If the input image is not big enough, border duplication must occur.

Figure 8-182. ISS ISP RSZ Averager Border Conditions



Downscaling is enabled from the RZi_DWN_EN register. Moreover, the vertical averaging size is set by the RZA_DWN_AV[5:3] V bit field. The actual downscale ratio is given by $1/2^{(RZA\_DWN\_AV[5:3]\ V\ +1)}$. The range is from 1/2 to 1/256 in power of 2. The horizontal averaging size is set by the RZA_DWN_AV[0:2] H bit field. The actual downscale ratio is given by $1/2^{(RZA\_DWN\_AV[5:3]\ H\ +1)}$. The equations are the same for RSZ-B. The range goes from 1/2 to 1/256 in power of 2.

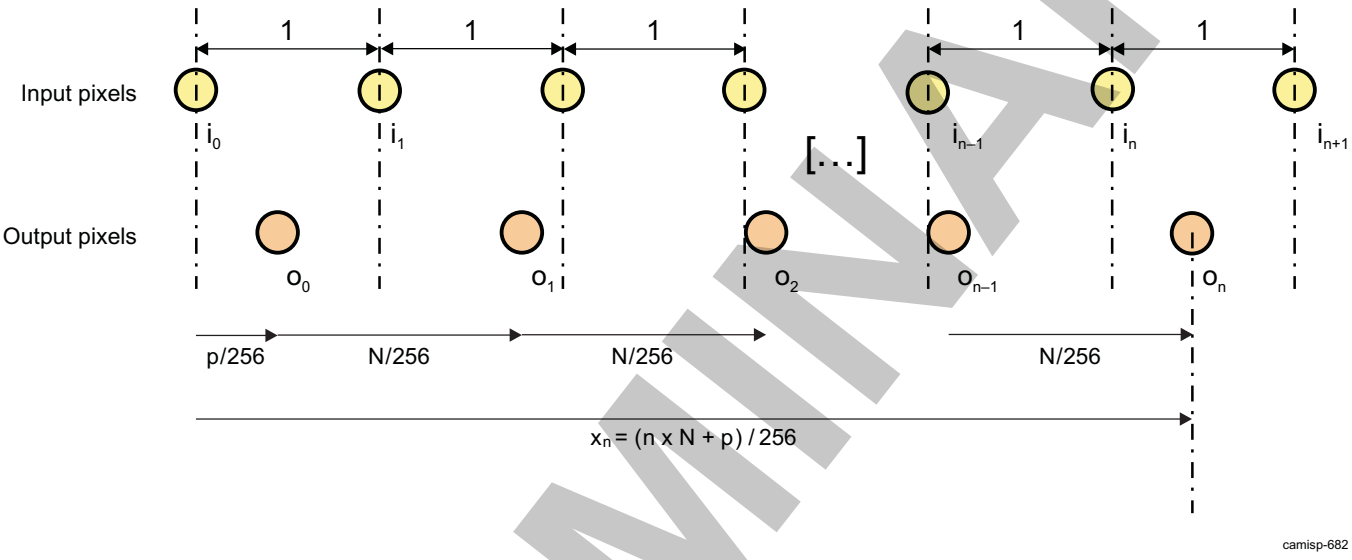
8.3.3.4.5.4 ISS ISP RSZ Interpolation

Figure 8-183 shows the basic interpolation method used in the RSZ module. The following assumptions are made:

- The distance between each input pixel is 1.
- The magnification ration is given by 256/N and p/256 is the initial phase of the output data.

The output pixels are also evenly spaced. The distance between each output pixel is given by N/256. In the example in Figure 8-183, N is greater than 256. The position of the n^{th} output pixel is given by (n × N + p) / 256.

Figure 8-183. ISS ISP RSZ Basic Interpolation Method



Assuming the intensity of input pixels is i_0, i_1, i_2, etc. and the resized (output) pixels are o_0, o_1, o_2, etc., the n^{th} output pixel (o_n) is determined using the nearest 4 input pixels as follows:

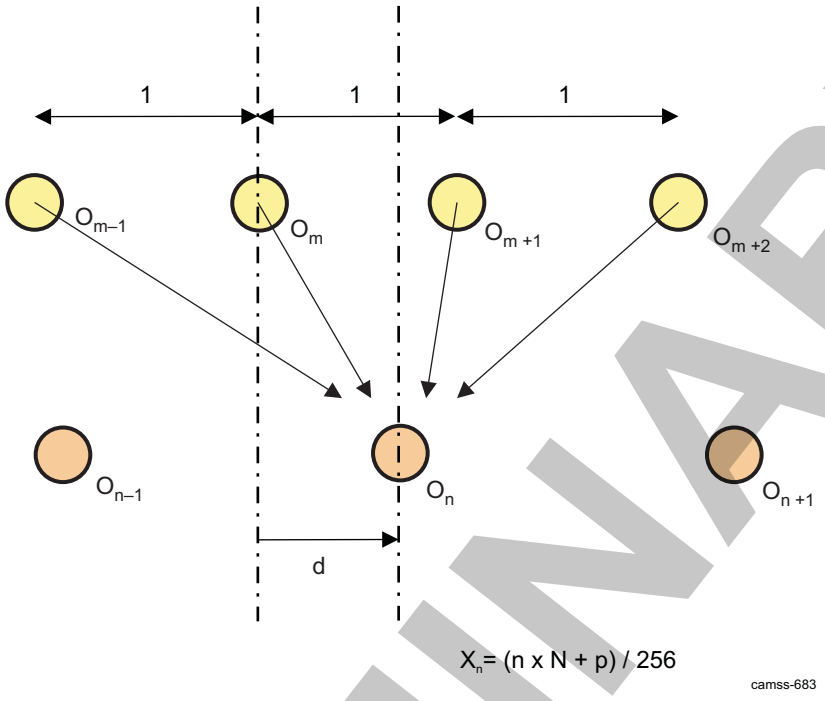
$o_n = h(1 + d) \times i_1 + h(d) \times i_m + h(d - 1) \times i_{m+1} + h(d - 2) \times i_{m+2}$

In the previous equation h(x) is the interpolation main function. The RSZ module supports linear and bicubic convolution interpolation functions.

Figure 8-184 shows the interpolation principle at the n^{th} output pixel (o_n) at position x_n. Furthermore, the m and d parameters are as follows:

m = floor((n × N + p) / 256) and d = ((n × N + p) / 256) – m

Figure 8-184. ISS ISP RSZ Interpolation Filtering



For each resizer (RSZ-A or RSZ-B), and for Chroma and Luma, the interpolation method for vertical interpolation can be a 2-tap linear interpolation or a 4-tap cubic convolution (default) method. The choice is made in RZi_V_TYP[0] Y for Luma and RZi_V_TYP[1] C for Chroma, where i = A or B and is the resizer number. It is similar for horizontal interpolation from RZi_H_TYP[0] Y for Luma and RZi_H_TYP[1] C for Chroma, where i = A or B and is the resizer number.

8.3.3.4.5.4.1 ISS ISP RSZ Liner Interpolation Input Data

Before data interpolation, a low pass filtering (LPF) operation is required on the input data. The following equation gives the LPF function. The equation is evaluated at pixel position d_i but neighbor pixels d_{i-1} and d_{i+1} are required. The gain value g is set up by the register RZi_V_LPF and RZi_H_LPF. Different gains are possible horizontally and vertically as well as for Luma and Chroma.

$LPF_g (d_{i-1}, d_i, d_{i+1}) = d_i + g \times (d_{i-1} - 2d_{i+1} + d_{i+2})/128$

8.3.3.4.5.4.1.1 ISS ISP RSZ Cubic Convolution Mode

The input data is not modified in bicubic mode. The input is equal to the output.

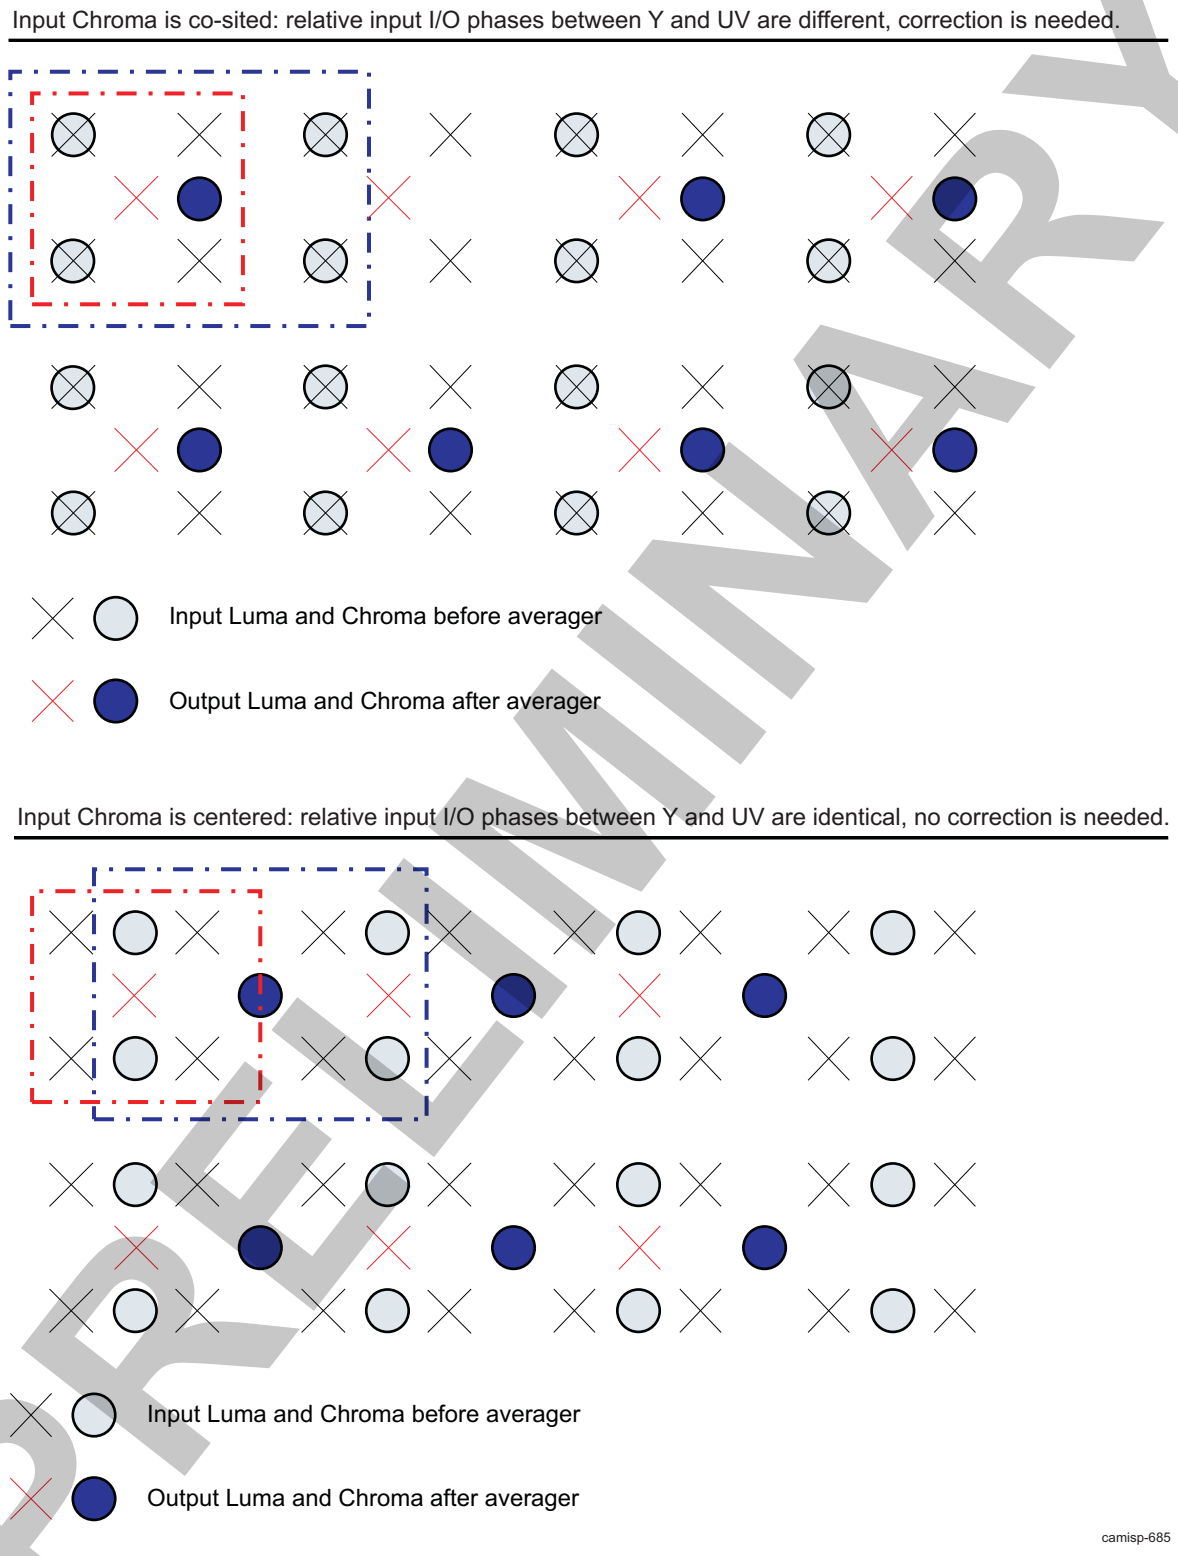
8.3.3.4.5.4.1.2 ISS ISP RSZ Phase Settings

The initial value for the phase value for vertical resizing is set by the RZi_V_PHS_Y for Luma and RZi_V_PHS_C for Chroma. These values are in the U14Q8 fractional format (values in the range [0 – 63.996]). When YUV4:2:2 data are output, the phase value for Luma and Chroma must be aligned; that is, RZi_V_PHS_Y = RZi_V_PHS_C.

The following constraint equation applies: | RZi_V_PHS_Y –RZx_V_PHS_C | <= RZi_V_DIF. This constraint means that at most the distance between the initial phases for Luma and Chroma is not expected to exceed the distance between two Luma pixels. The absolute value is used; therefore, the initial Luma phase can be greater than the initial Chroma phase or vice versa. As a reminder, the distance between two output pixels for Luma is given by RZi_V_DIF.

The initial value for the phase value for horizontal resizing is set by the RZi_H_PHS register. The RZi_H_PHS_ADJ register enables adjusting the horizontal phase for the Luma component when averaging is enabled (the averager disrupts the relative sampling point between Luma and Chroma when YUV4:2:2 co-sited data is input). The relative phase between Luma and Chroma is different before and after the horizontal averager. The vertical phase is not affected by the averager. Figure 8-185 shows the effect of the averager on the phases. RZi_H_PHS_ADJ is expected to be equal to 0 if the averager is disabled.

Figure 8-185. ISS ISP RSZ-A/RSZ-B Phase Averager Effect



8.3.3.4.5.5 ISS ISP RSZ Data Saturator

After vertical rescaling and before color conversion, the output data is saturated (clipped) to programmable values that are given by the following registers:

- RSZ_YUV_Y_MIN
- RSZ_YUV_Y_MAX
- RSZ_YUV_C_MIN
- RSZ_YUV_C_MAX

The maximum Y value is set up with the RSZ_YUV_Y_MAX register. If the input Y value is greater than the MAX value, it is clipped to MAX.

The minimum Y value is set up with the RSZ_YUV_Y_MIN register. If the input Y value is smaller than the MIN value, it is clipped to MIN.

The maximum Cb/Cr value is set up with the RSZ_YUV_C_MAX register. If the input Cb/Cr value is greater than the MAX value, it is clipped to MAX.

The minimum Cb/Cr value is set up with the RSZ_YUV_C_MIN register. If the input Cb/Cr value is smaller than the MIN value, it is clipped to MIN.

8.3.3.4.5.6 ISS ISP RSZ Color Converter

As mentioned previously, the resizer can support RAW, YUV4:2:0, and YUV4:2:2 formats. The resizer engines can also support RGB output: RGB5:6:5 and ARGB32.

The RGB5:6:5 data is 16 bits wide and consists of 5 bits for red, 6 bits for green, and 5 bits for blue.

The following table shows the way RGB5:6:5 is stored to memory. This data format is compatible with the display controller. Only the little-endian memory representation is supported.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R1					G1						B1					R0					G0							B0				

The ARGB32 data is 32 bits wide and consists of 8 bits for alpha, 8 bits for red, 8 bits for green, and 8 bits for blue. The alpha value is global and is set for the entire frame; registers control the alpha value: the RZx_RGB_BLD register controls the alpha values of resizer A and resizer B.

The following table shows the way ARGB32 is stored to memory. This data format is compatible with the display controller. This representation is endiannism invariant: it is the same for little endian and big endian.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A								R								G								B							

The RGB output is enabled by setting the RZx_RGB_EN[0] RGB_EN bit to 1.

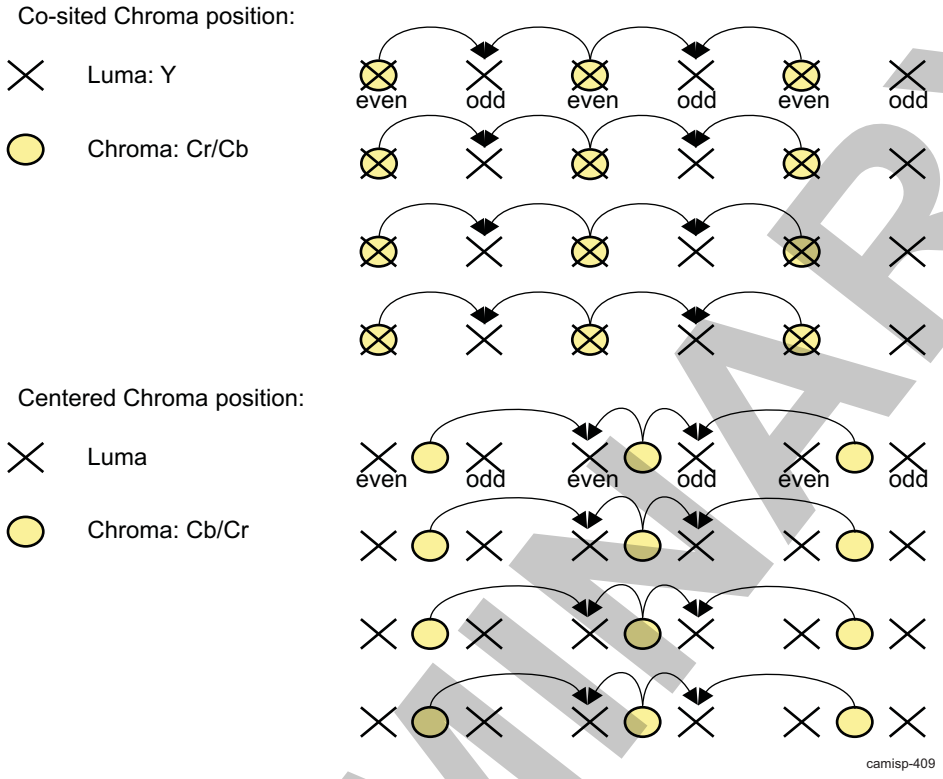
The RGB format is set by the RZx_RGB_TYP[0] TYP bit (0 for ARGB32 format and 1 for RGB5:6:5).

To handle the horizontal border conditions, the left-most Chroma sample or the right-most Chroma sample is duplicated on the left or the right.

Software must make it possible to remove 2 pixels on the left and/or right to take care of the issues that Chroma duplication introduces on the borders. The RZx_RGB_TYP[1] MSK0 and RZx_RGB_TYP[2] MSK1 bits control this feature.

Figure 8-186 shows the ISS ISP RSZ chroma position and upsampling.

Figure 8-186. ISS ISP RSZ Chroma Position and Upsampling



NOTE: In case Cb/Cr in the input image is flipped, the RSZ_SRC_FMT1[3] CHR bit must be set to 1 to assure correct color conversion. This setting restores the right order in YUV to RGB conversion, and generates correct RGB colors.

8.3.3.4.5.7 ISS ISP RSZ Output Interface

The output interface receives the data generated by the two resizer engines and generates the addresses and the port requests to the BL module.

- The port 1 interface is dedicated to the RSZ-A module. If the RSZ module is set up in pass-through mode, then the data is output on the port 1 interface. This interface can transfer RAW, YUV4:2:2, YUV4:2:0, and RGB data
- The port 2 interface is dedicated to the RSZ-B module. This interface can transfer RAW, YUV4:2:2, YUV4:2:0, and RGB data.

The YUV4:2:0 data format is handled differently from the other formats because the output data are written at two different memory locations: Luma in one buffer and Chroma in a second buffer. For all other formats the data are written in the same buffer.

Each data format must be stored in memory in a dedicated manner, which is summarized in Table 8-435.

Table 8-435. ISS ISP RSZ Output Interface: Data Formats

Output Format	Bytes per Pixel	Output Buffers per Image	Interface Supporting the Data Format
RAW	2	1	MTC port 1
YUV4:2:2	2 average	1	MTC port 1 port 2
YUV4:2:0	1.5 average	2	MTC port 1 port 2
RGB16	2	1	MTC port 1 port 2
ARGB32	4	1	MTC port 1 port 2

8.3.3.4.5.7.1 ISS ISP RSZ Circular Buffer

Figure 8-187 shows the parameters that are required to set up the circular buffers. As mentioned previously, there can be up to four circular buffers in case the two resizer engines are outputting YUV4:2:0 data.

The circular buffer management requires the following parameters (RSZ-A or RSZ-B A or B,Chroma or Luma Y or C, low or high part of the address, L or H. Sets the base address of the circular buffer):

- Baseline address (BAD, in registers, where x is the resizer A or B, and i is Y or C)
- Start address (SAD, in RZx_SDR_i_SAD_j registers)
- Start pointer (PTR_S, in RZx_SDR_i_PTR_S registers)
- End pointer (PTR_E, in RZx_SDR_i_PTR_E registers)
- Line offset (OFT, in RZx_SDR_i_OFT registers)

Table 8-436. ISS ISP RSZ Circular Buffer

Circular Buffer Parameter	Register (for RSZ-A and RSZ-B)	Description
Baseline address	RZA_SDR_Y_BAD_H RZA_SDR_Y_BAD_L RZA_SDR_C_BAD_H RZA_SDR_C_BAD_L RZB_SDR_Y_BAD_H RZB_SDR_Y_BAD_L RZB_SDR_C_BAD_H RZB_SDR_C_BAD_L	Sets the base address of the circular buffer
Start address	RZA_SDR_Y_SAD_H RZA_SDR_Y_SAD_L RZA_SDR_C_SAD_H RZA_SDR_C_SAD_L RZB_SDR_Y_SAD_H RZB_SDR_Y_SAD_L RZB_SDR_C_SAD_H RZB_SDR_C_SAD_L	Sets the start address of the circular buffer. The first data output is written to this address. If the first line of a frame must be written at the beginning of the circular buffer memory, then SAD = BAD and PTR_S = 0.
Start pointer	RZA_SDR_Y_PTR_S RZA_SDR_C_PTR_S RZB_SDR_Y_PTR_S RZB_SDR_C_PTR_S	Sets the initial value of the circular buffer internal counter. It must be set up as PTR_S = (SAD – BAD)/OFT. PTR_S is expressed in the number of lines.
End pointer	RZA_SDR_Y_PTR_E RZA_SDR_C_PTR_E RZB_SDR_Y_PTR_E RZB_SDR_C_PTR_E	Sets the size of the circular buffer. PTR_E is expressed in the number of lines. The circular buffer can contain up to PTR_E lines.
Line offset	RZA_SDR_Y_OFT RZA_SDR_C_OFT RZB_SDR_Y_OFT RZB_SDR_C_OFT	This is the offset expressed in bytes between two lines in the circular buffer. Here: Line 0 = SAD, Line 1 = SAD + 1 × OFT, Line 2 = SAD + 2 × OFT, etc. OFT does not necessarily correspond to the size of a line in a frame; it can be bigger.

More generally, the following equations hold:

- SAD = BAD + (PTR_S × OFT) and PTR_S < PTR_E

Interrupts can be triggered every time a certain number of lines are written to the circular buffer. There are independent settings for each RSZ and for each possible output of each RSZ.

Figure 8-187. ISS ISP RSZ and Circular Buffer Settings

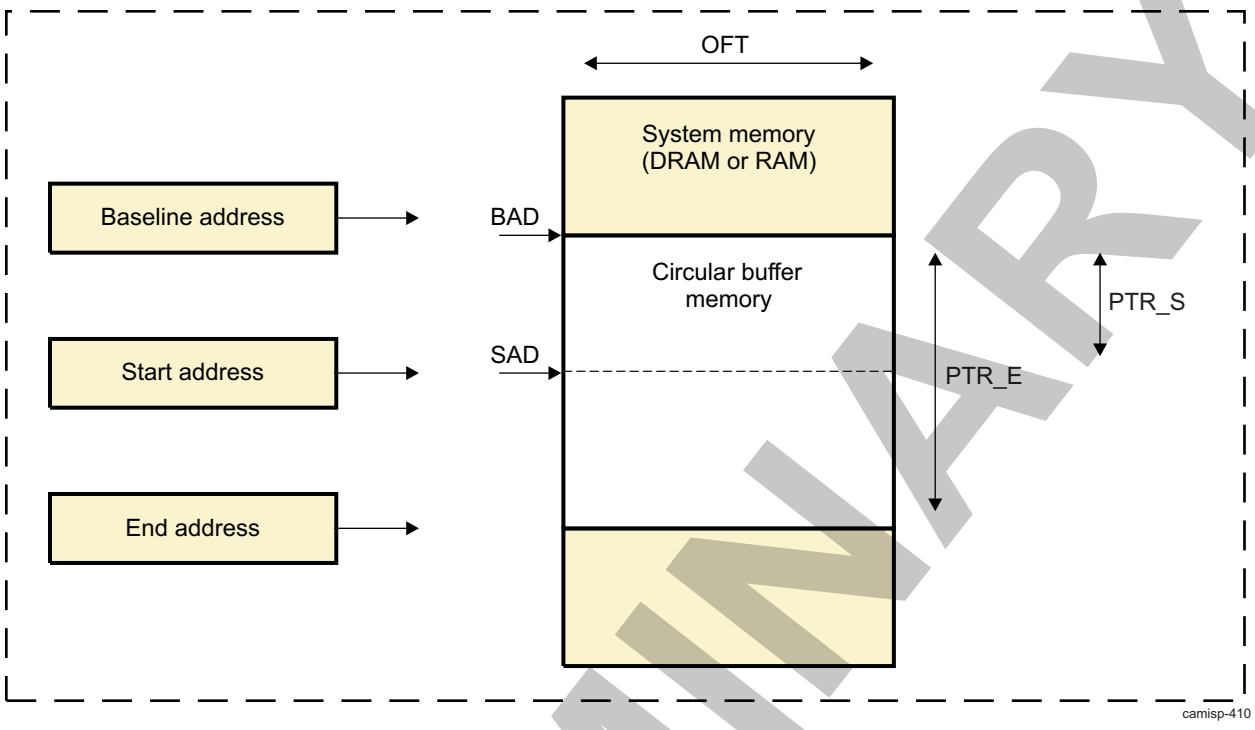


Figure 8-188 shows how the data are stored in the circular buffer over time when vertical flip is disabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

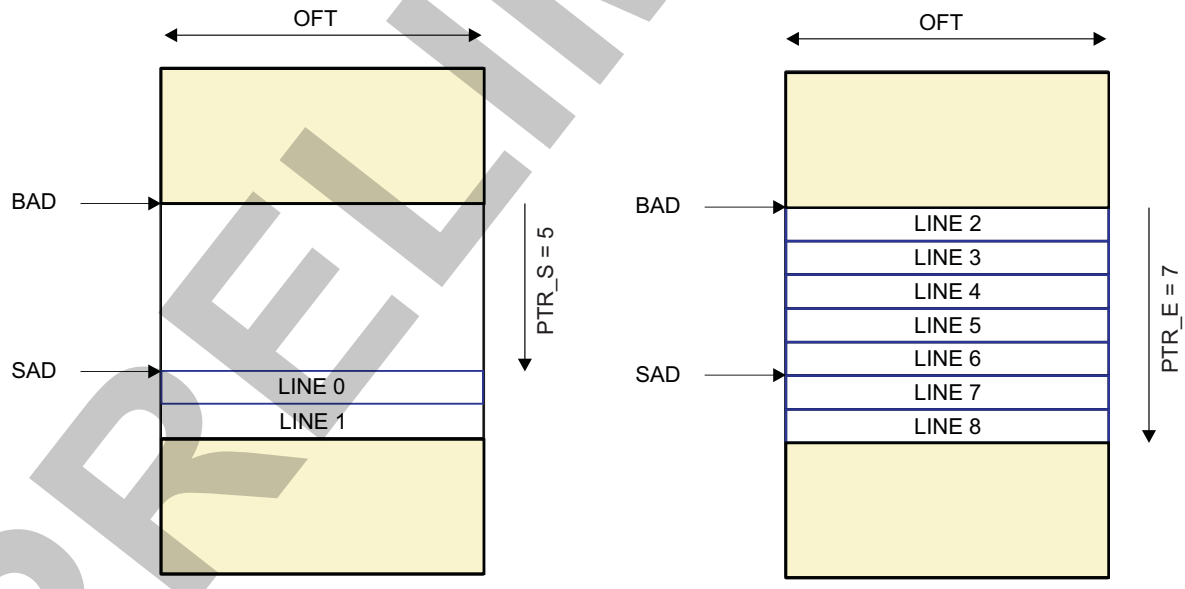
Figure 8-188. ISS ISP RSZ and Circular Buffer Settings – Example 1



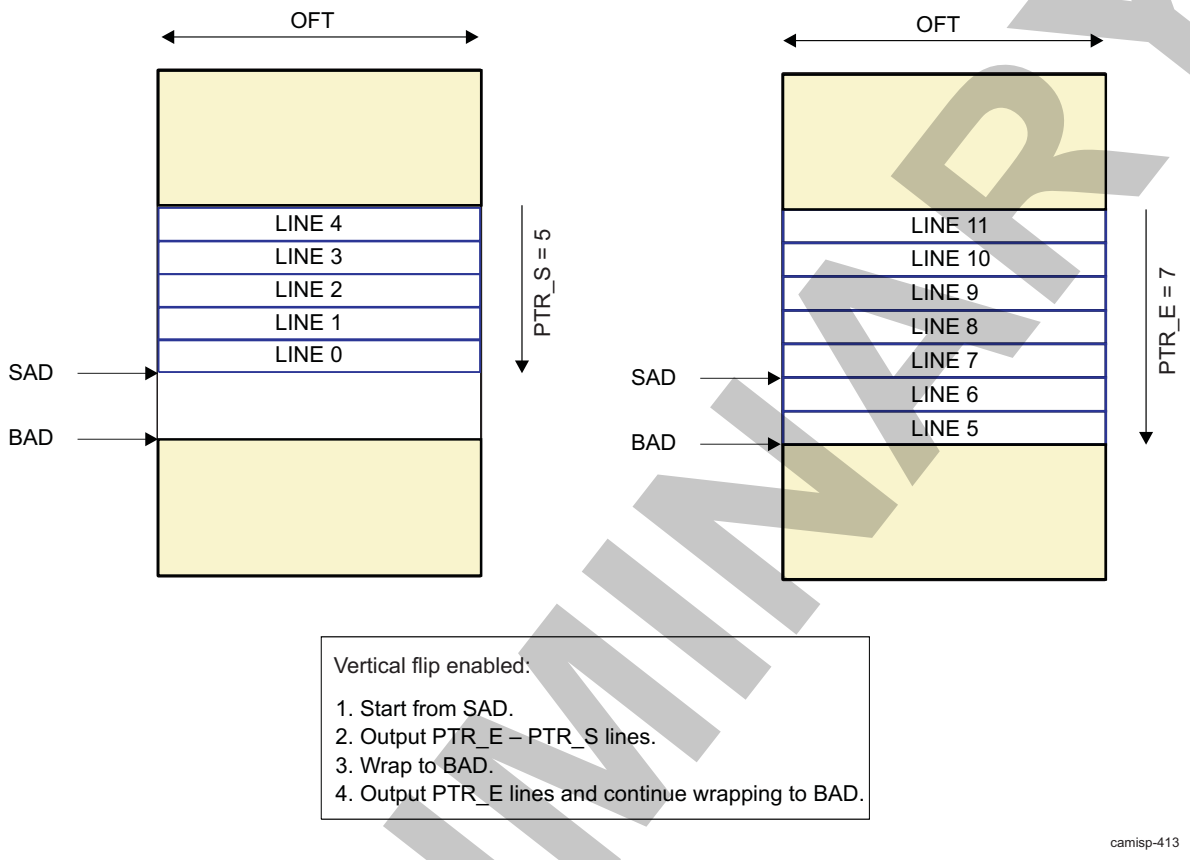
Vertical flip enabled:

1. Start from SAD.
2. Output PTR_E – PTR_S lines.
3. Wrap to BAD.
4. Output PTR_E lines and continue wrapping to BAD.

camisp-412

Figure 8-189 shows how the data are stored in the circular buffer over time when vertical flip is enabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

Figure 8-189. ISS ISP RSZ and Circular Buffer Settings – Example 2



8.3.3.5 ISS ISP H3A Functional Description

8.3.3.5.1 ISS ISP H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:

  The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:

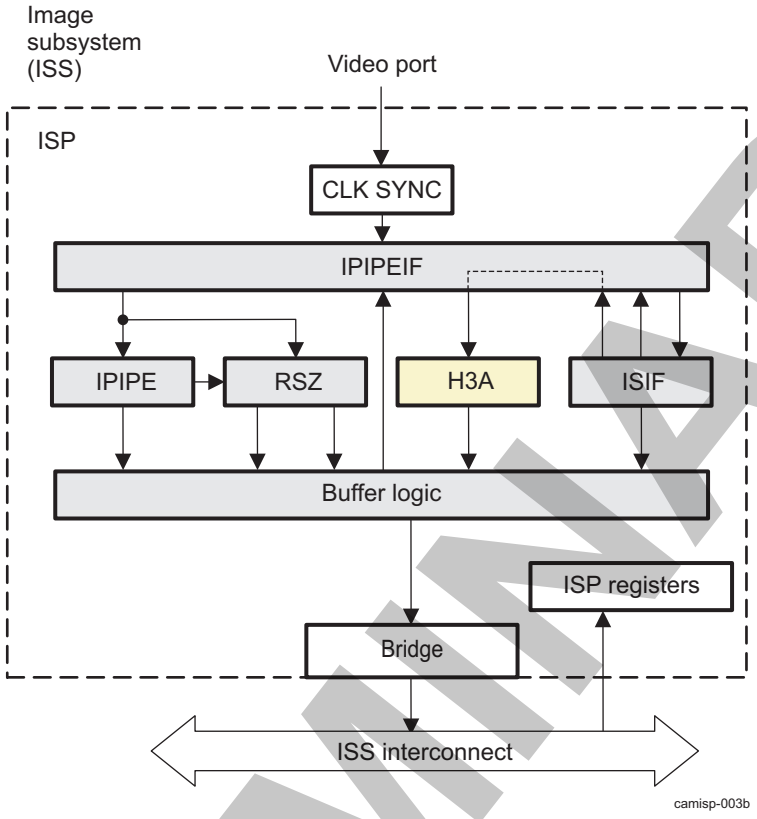
  – Peak mode in a paxel: Accumulation of the maximum focus value (FV) of each line in a paxel
  – Accumulation mode in a paxel
  – Accumulation of horizontal and vertical focus value in a paxel
  – Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
  – Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
  – Programmable width and height for the paxel/window
  – Programmable red, green, and blue position within a 2 × 2 matrix
  – Separate horizontal start for paxel and filtering
  – Programmable vertical and horizontal line increments within a paxel

  - Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame on which to focus.
  - Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:

  The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:
  - Accumulate clipped pixels along with all nonsaturated pixels in each window per color
  - Accumulate the sum of squared pixels in each window per color
  - Minimum and maximum pixel values in each window per color
  - Support for up to 36 horizontal windows with sum + { sum_sq or min+max} output
  - Support for up to 56 horizontal windows with sum output
  - Support for up to 128 vertical windows
  - Programmable width and height for the windows. All windows in the frame are the same size.
  - Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
  - Programmable horizontal sampling points in a window
  - Programmable vertical sampling points in a window
- Maximum pixel throughput of 304 MPix/s
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 3008 pixels.

Figure 8-190 shows the H3A module connections to other submodules of the ISP.

Figure 8-190. ISS ISP H3A High-Level Diagram



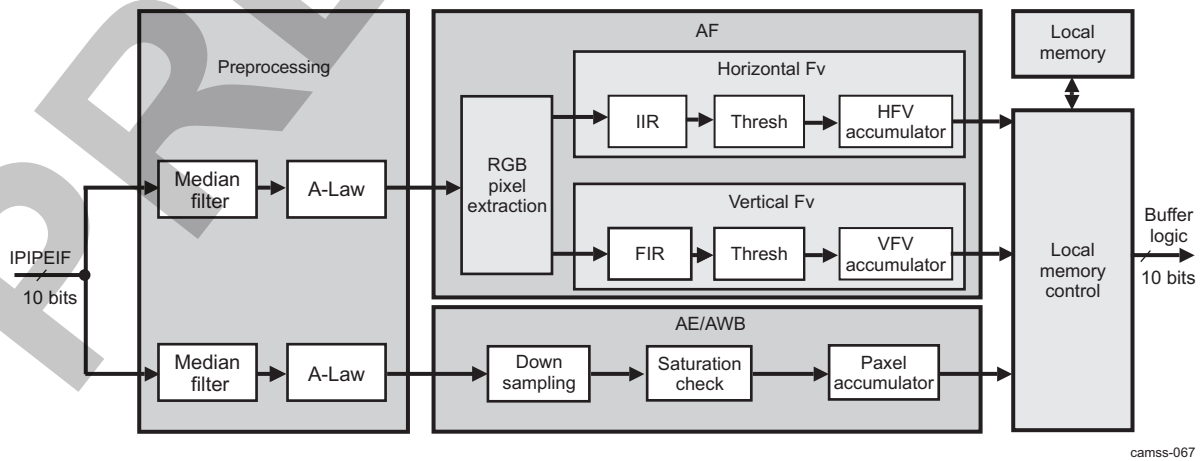
8.3.3.5.2 ISS ISP H3A Top-Level Block Diagram

The block diagram in Figure 8-191 shows the process of the AF and AE/AWB data paths through the H3A module.

The data flow before H3A is:

1. Data comes from the VP or BL.
2. The data is processed by the ISIF.
3. The data is processed by the IPIPEIF.
4. The data is 10 bits from the IPIPEIF at H3A input.

Figure 8-191. ISS ISP H3A Top-Level Block Diagram

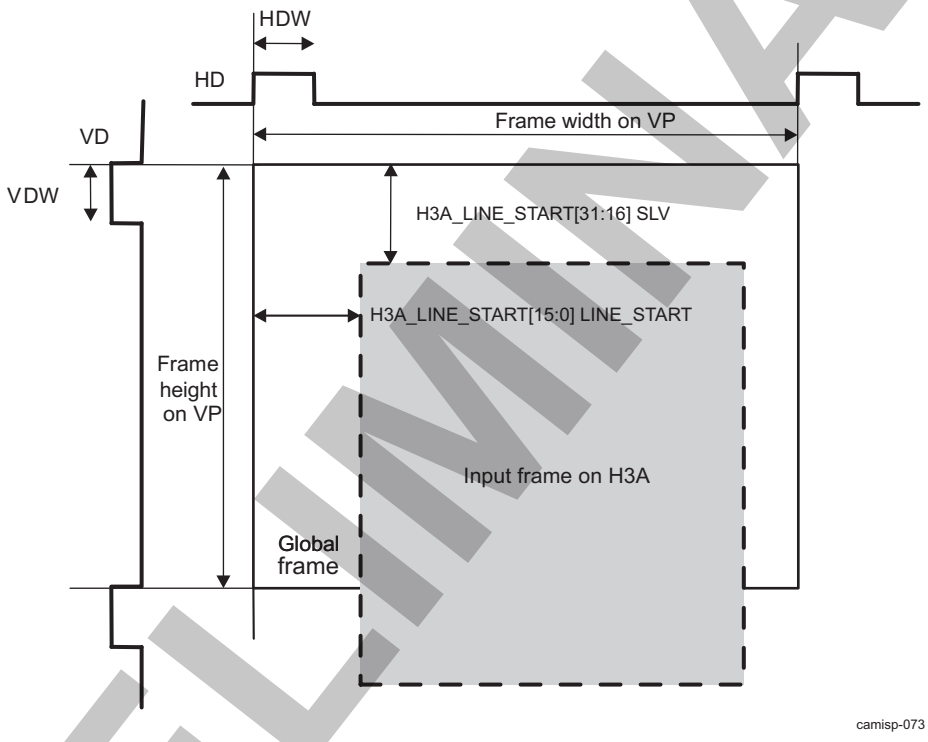


8.3.3.5.3 ISS ISP H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the H3A_LINE_START register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 3008 pixels. After 3008 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 3008 clock cycles, then the active region ends immediately and the counter waits for the H3A_LINE_START register count to be reached again. For the vertical position the H3A_LINE_START[31:16] SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 8-192 shows the ISS ISP H3A frame format settings.

Figure 8-192. ISS ISP H3A Frame Format Settings



NOTE: (Frame width on VP) - (H3A_LINE_START[15:0] LINE_START) must be less than or equal to 3008, because the H3A memory lines are limited to 3008 pixels.

8.3.3.5.4 ISS ISP H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the H3A_PCR[1] AF_ALAW_EN bit) and the AE/AWB engine (the H3A_PCR[17] AEW_ALAW_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the H3A_PCR[2] AF_MED_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel (i) and pixel (i – 2), and between the current pixel (i) and pixel (i + 2). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel (i – 2) and pixel (i + 2) replaces pixel (i). The threshold of the horizontal median filter can be set in the H3A_PCR[10:3] MED_TH bit field.

8.3.3.5.5 ISS ISP H3A Autofocus Engine

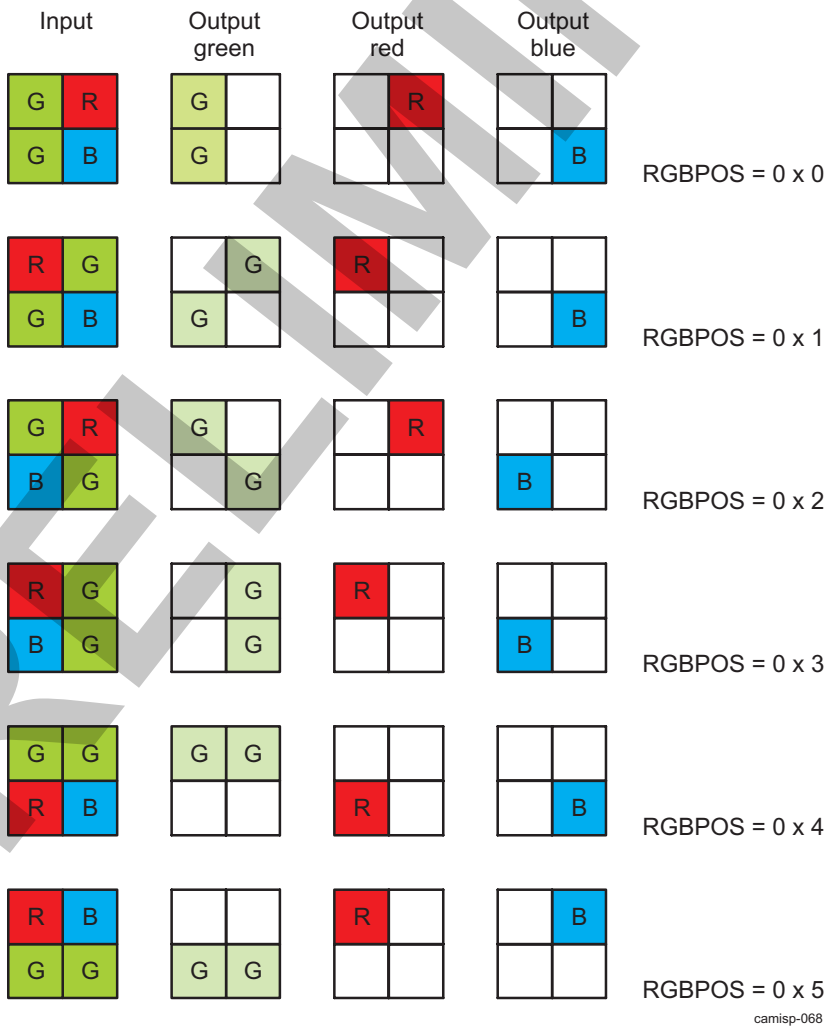
The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV^2 are produced. The FV and FV^2 values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

8.3.3.5.5.1 ISS ISP H3A Paxel Extraction

From the paxel starting coordinate (the H3A_AFPAXSTART[27:16] PAXSH and H3A_AFPAXSTART[11:0] PAXSV bit fields) specifies the starting point of the paxel grid, with respect to first pixel of the input image frame.

The paxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if H3A_PCR[20] AF_VF_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the H3A_PCR[13:11] RGBPOS bit field to extract the correct colors from the input stream. Figure 8-193 shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2 × 2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

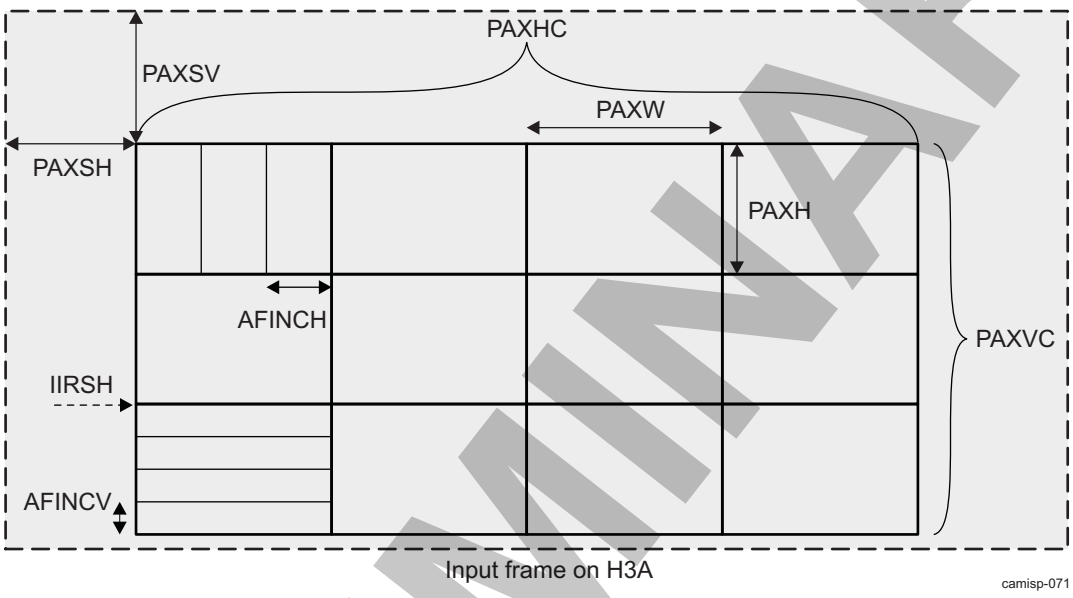
Figure 8-193. ISS ISP H3A Red, Green, and Blue Pixel Extraction Examples



Each paxel is H3A_AFPAX1[23:16] PAXW × H3A_AFPAX1[7:0] PAXH (width × height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every H3A_AFPAX2[16:13] AFINCV lines. Vertical FV can skip columns, operating on one every H3A_AFPAX2[20:17] AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) >= 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column H3A_AFIIRSH[11:0] IIRSH.

Figure 8-194 shows the ISS ISP H3A horizontal/vertical fv paxel configuration.

Figure 8-194. ISS ISP H3A Horizontal/Vertical FV Paxel Configuration



NOTE: (H3A_AFPAXSTART[27:16] PAXSH) + (H3A_AFPAX2[5:0] PAXHC) × (H3A_AFPAX1[23:16] PAXW) <= [(Frame width on VP) – (H3A_LINE_START[15:0] LINE_START)] <= 3008

Table 8-437 lists the bit fields that configure the size and number of paxels.

Table 8-437. ISS ISP H3A Paxel Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AFPAX1[23:16] PAXW	8	Paxel width (in pixels)
H3A_AFPAX1[7:0] PAXH	8	Paxel height (in lines)
H3A_AFPAX2[5:0] PAXHC	6	Paxel count for horizontal direction
H3A_AFPAX2[12:6] PAXVC	7	Paxel count for vertical direction
H3A_AFPAX2[16:13] AFINCV	4	Line increments in a paxel
H3A_AFPAX2[20:17] AFINCH	4	Column increments in a paxel
H3A_AFPAXSTART[27:16] PAXSH	12	Paxel start position H
H3A_AFPAXSTART[11:0] PAXSV	12	Paxel start position V
H3A_AFIIRSH[11:0] IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the H3A_ADVANCED[31:15] ID bit field, then H3A_ADVANCED[0] AF_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF paxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV_1 and HFV_2.

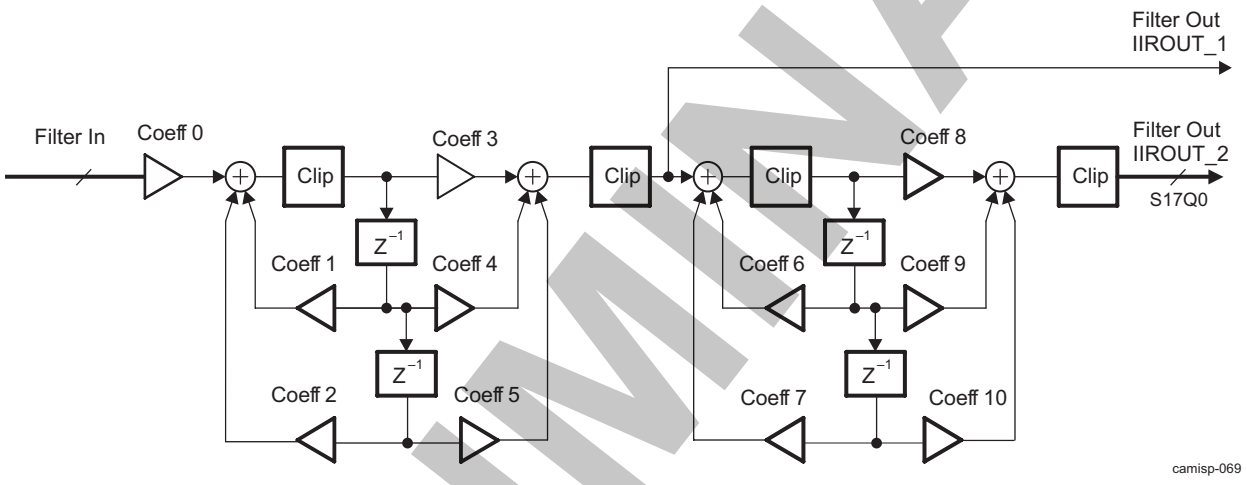
8.3.3.5.5.2 ISS ISP H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range –128 to 127 or –512 to 511.

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 (H3A_AFCOEF010 to H3A_AFCOEF0010 for SET0, and H3A_AFCOEF110 to H3A_AFCOEF1010 for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the H3A_AFIIRSH[11:0] IIRSH bit field). The absolute values of the output (16 bits wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is m bits (signed) and the required output value is n bits, clipping transforms the input to between -2^1 and 2^1. Values lower than -2^1 are set to -2^1, and values higher than 2^1 are set to 2^1.

Figure 8-195 shows the IIR filter model.

Figure 8-195. ISS ISP H3A IIR Filter Model



8.3.3.5.5.3 ISS ISP H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 8-437 lists the register fields that configure the size and number of paxels:

- In peak mode (H3A_PCR[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode (H3A_PCR[14] FVMODE = 0x0), all HFV_n are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV_n (HFV_n_peak for peak mode or HFV_n_sum for sum mode)
- HFV_count_n
- HFV_sq_n (HFV_sq_n_peak for peak mode or HFV_sq_n_sum for sum mode)

n = 1 or 2 for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on paxel rows
{
 rowpeak_n = 0;

 for (l=0; l<PAXW; l++) // Loop on values within a row
 {
 aIIRout_n = ABS(IIRout_n);
```

```
if (aIIRout_n >= threshold_n)
{
hfval = aIIRout_n - threshold_n;
HFV_count_n++;
}
else hfval = 0;
if (hfval > rowpeak_n)
{
rowpeak_n = HFV_n;
}
HFV_n_sum += hfval;
HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
} // Finished looping on values in a row
HFV_n_peak += rowpeak_n;
HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;

}
```

- threshold_n is H3A_HVF_THR[15:0] HTHR1 and H3A_HVF_THR[31:16] HTHR2, respectively.
- IIRout_n is the IIRout_1 and IIRout_2 outputs, respectively.
- HFV_count_n and HFV_sq_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
  - HFV_n = HFV_n_sum
  - HFV_sq_n = HFV_sq_n_sum
- In peak mode:
  - HFV_n = HFV_n_peak
  - HFV_sq_n = HFV_sq_n_peak

8.3.3.5.5.4 ISS ISP H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1_x, where x = 0 to 4, in the H3A_VFV_CFG1 and H3A_VFV_CFG2 registers for FIR 1, and VCOEF2_x, where x = 0 to 4, in the H3A_VFV_CFG3 and H3A_VFV_CFG4 registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and takes an absolute value to produce a 16-bit unsigned value. This is then sent to threshold H3A_VFV_CFG2[31:16] VTHR1 for FIR 1, and H3A_VFV_CFG4[31:16] VTHR2 for FIR 2, and square logic to produce VFV_n and VFV_sq_n.

8.3.3.5.5.5 ISS ISP H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 8-437 lists the bitfields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV_n
- VFV_count_n
- VFV_sq_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;
```

```
if (aFIRout_n >= threshold_n)
{
 VFV_n = aFIRout_n - threshold_n
 VFV_count_n++;
}
else VFV_n = 0;

VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold_n is H3A_VFV_CFG2[31:16] VTHR1 and H3A_VFV_CFG4[31:16] VTHR2, respectively.
- FIRout_n is the FIRout_1 and FIRout_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

8.3.3.5.6 ISS ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2 × 2 blocks. For each subsampled 2 × 2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2 × 2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the H3A_AEWCFG[9:8] AEFMT bit field:

- Sum of square mode: H3A_AEWCFG[9:8] AEFMT = 0x0
- Min/max mode: H3A_AEWCFG[9:8] AEFMT = 0x1
- Sum-only mode: H3A_AEWCFG[9:8] AEFMT = 0x2

8.3.3.5.6.1 ISS ISP H3A Subsampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in Figure 8-196. Each window is further sampled down to a set of 2 × 2 blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in Figure 8-196.

Figure 8-196. ISS ISP H3A AE/AWB Window Configurations

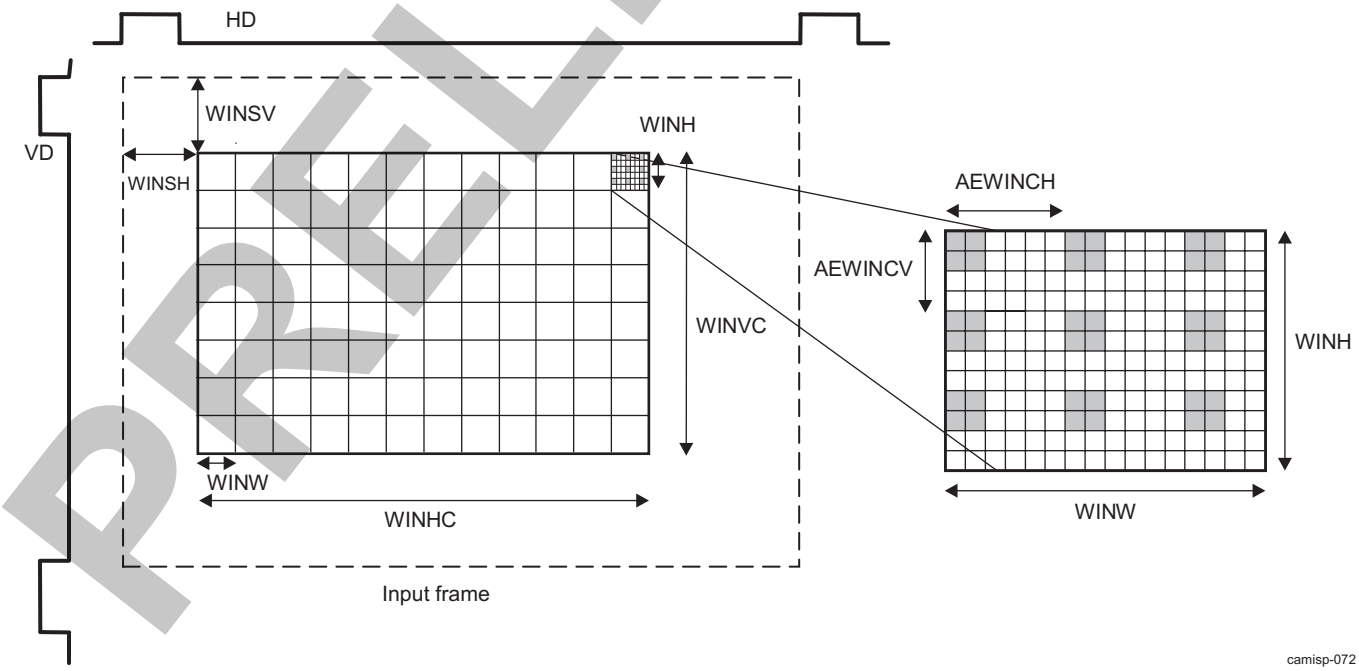


Table 8-438 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 8-438. ISS ISP H3A AE/AWB Window Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H
H3A_AEWINSTART[27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

8.3.3.5.6.2 ISS ISP H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the H3A_AEWINBLK[27:16] WINSV bit field, and the height is specified in the H3A_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 8-197 shows a black row of windows before rows of windows.

Figure 8-197. ISS ISP H3A Black Row of Windows Before Regular Rows of Windows

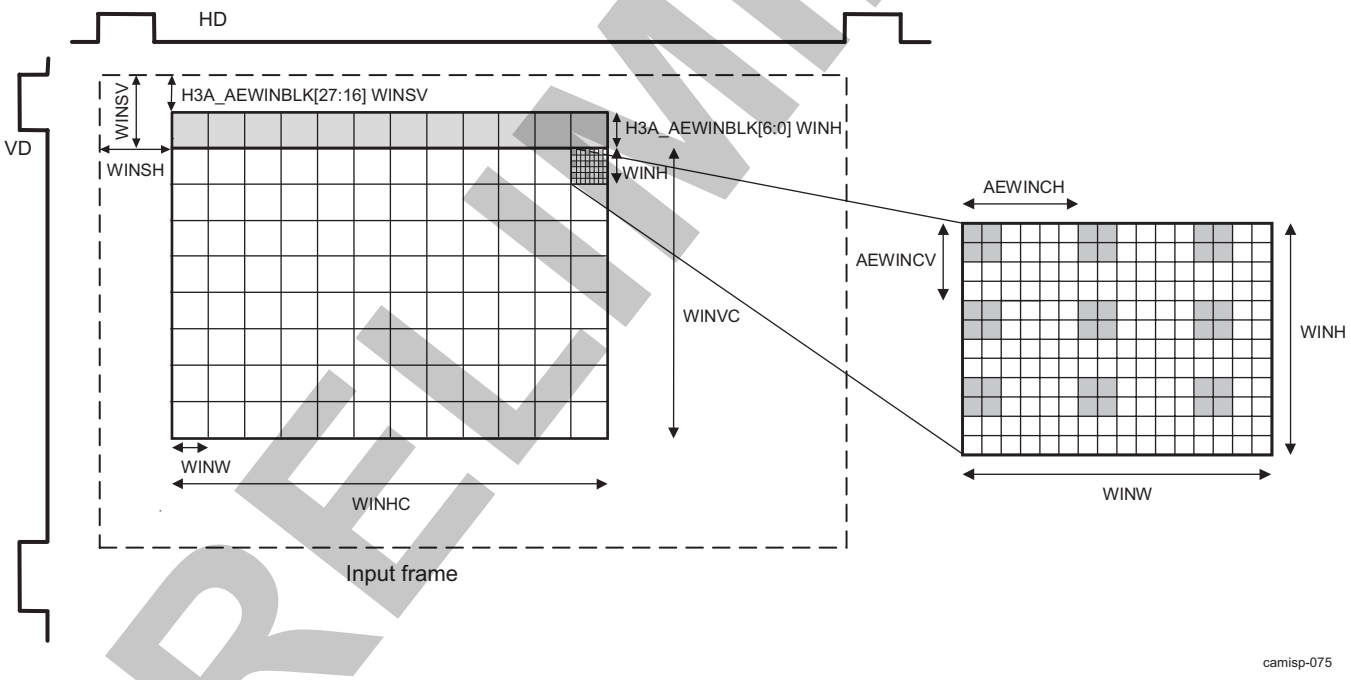

Table 8-439 lists the bit fields that configure the window and block sizes, counts, and starting positions.

Table 8-439. ISS ISP H3A AE/AWB Window With Additional Black Row Register Field Descriptions

Bit Field	Bit Width	Description
H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H

Table 8-439. ISS ISP H3A AE/AWB Window With Additional Black Row Register Field Descriptions (continued)

Bit Field	Bit Width	Description
H3A_AEWINSTART[27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples
H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

8.3.3.5.6.3 ISS ISP H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the H3A_PCR[31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

8.3.3.5.6.4 ISS ISP H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color (R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See Section 8.3.3.5.4 for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the H3A_AEWCFG[3:0] SUMSHFT bit field.

8.3.3.5.7 ISS ISP H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the H3A_AFBUFST[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the H3A_AEWBUFST[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of paxels or windows. This requires that each horizontal row of paxels or windows starts and ends on a 32-byte boundary. If a horizontal row of paxels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the eighth consecutive window.

Table 8-440 lists the packet formats for AF with vertical AF disabled.

Table 8-440. ISS ISP H3A AF Packet Format With Vertical AF Disabled

Buffer Start Address (Byte Address) H3A_AFBUFST	31 16	15 0
	Sum of pixel values used in HFV	(Paxel 0)
	HFV_1 (peak or sum)	(Paxel 0)
	HFV_2 (peak or sum)	(Paxel 0)
	Zeroes	(Paxel 0)
	Sum of pixel values used in HFV	(Paxel 0)

Table 8-440. ISS ISP H3A AF Packet Format With Vertical AF Disabled (continued)

Buffer Start Address (Byte Address) H3A_AFBUFST	31 16	15 0
	HFV_1 (peak or sum)	(Paxel 0)
	HFV_2 (peak or sum)	(Paxel 0)
	Zeroes	(Paxel 0)
	Sum of pixel values used in HFV	(Paxel 0)
	HFV_1 (peak or sum)	(Paxel 0)
	HFV_2 (peak or sum)	(Paxel 0)
	Zeroes	(Paxel 0)
	Sum of pixel values used in HFV	(Paxel 1)

8.3.3.5.8 ISS ISP H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine (ISR) does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the ISR does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and ISR execution.

The H3A_PCR[15] BUSYAF and/or H3A_PCR[18] BUSYAEAWB status bits are set when the start of frame occurs (if the H3A_PCR[0] AF_EN and/or H3A_PCR[16] AEW_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The H3A_PCR[15] BUSYAF and/or H3A_PCR[18] BUSYAEAWB status bits may be polled to determine the end of frame status.

8.3.3.6 ISS ISP ISIF Functional Description

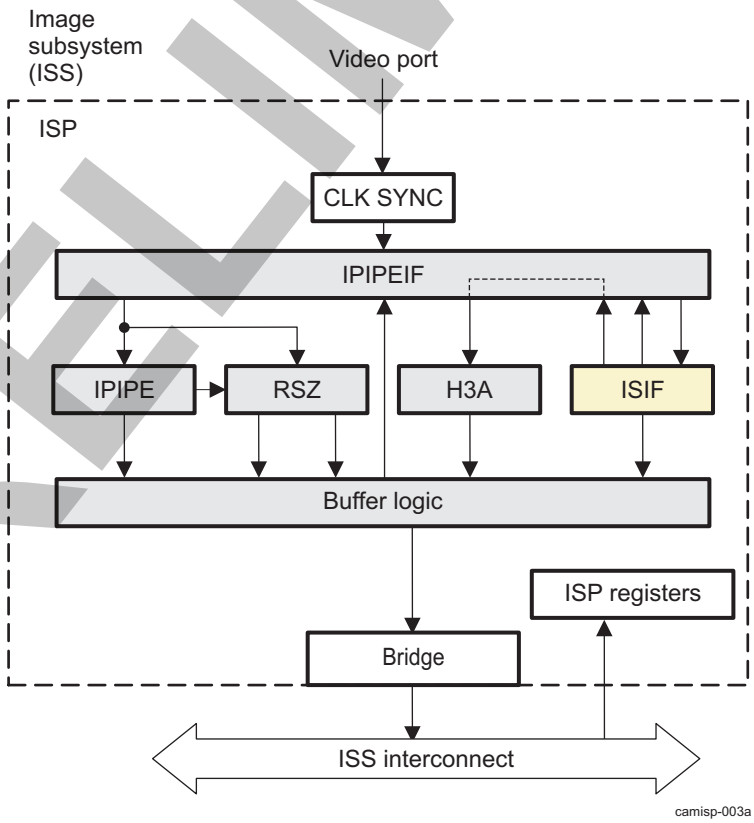
8.3.3.6.1 ISS ISP ISIF Overview

The ISIF module receives RAW or YUV4:2:2 data from the IPIPEIF module. The module outputs data back to the IPIPEIF module and can also output data to memory though the BL module. The ISIF module can process the incoming data and supports the following functions:

- Maximum supported image size is 32,768 × 32,768
- Supports up to 16-bit analog front end
- Sensor data linearization
- Supports Bayer and Foveon® input data format (RGB and CMYG color support)
- Supports VGA read out mode
- Supports various image data format
- Color space conversion
- Digital clamp with horizontal/vertical offset drift compensation
- Vertical line defect correction
- Programmable 2D-matrix LSC
- Gain and offset control
- Programmable horizontal/vertical culling pattern
- Maximum pixel rate clock of 304 MPix/s on the VP interface.
- 10-to-8-bit A-Law compression table inside
- 12-bit pack supported when written to memory

Figure 8-199 show the ISIF module connections to other submodules of the ISP.

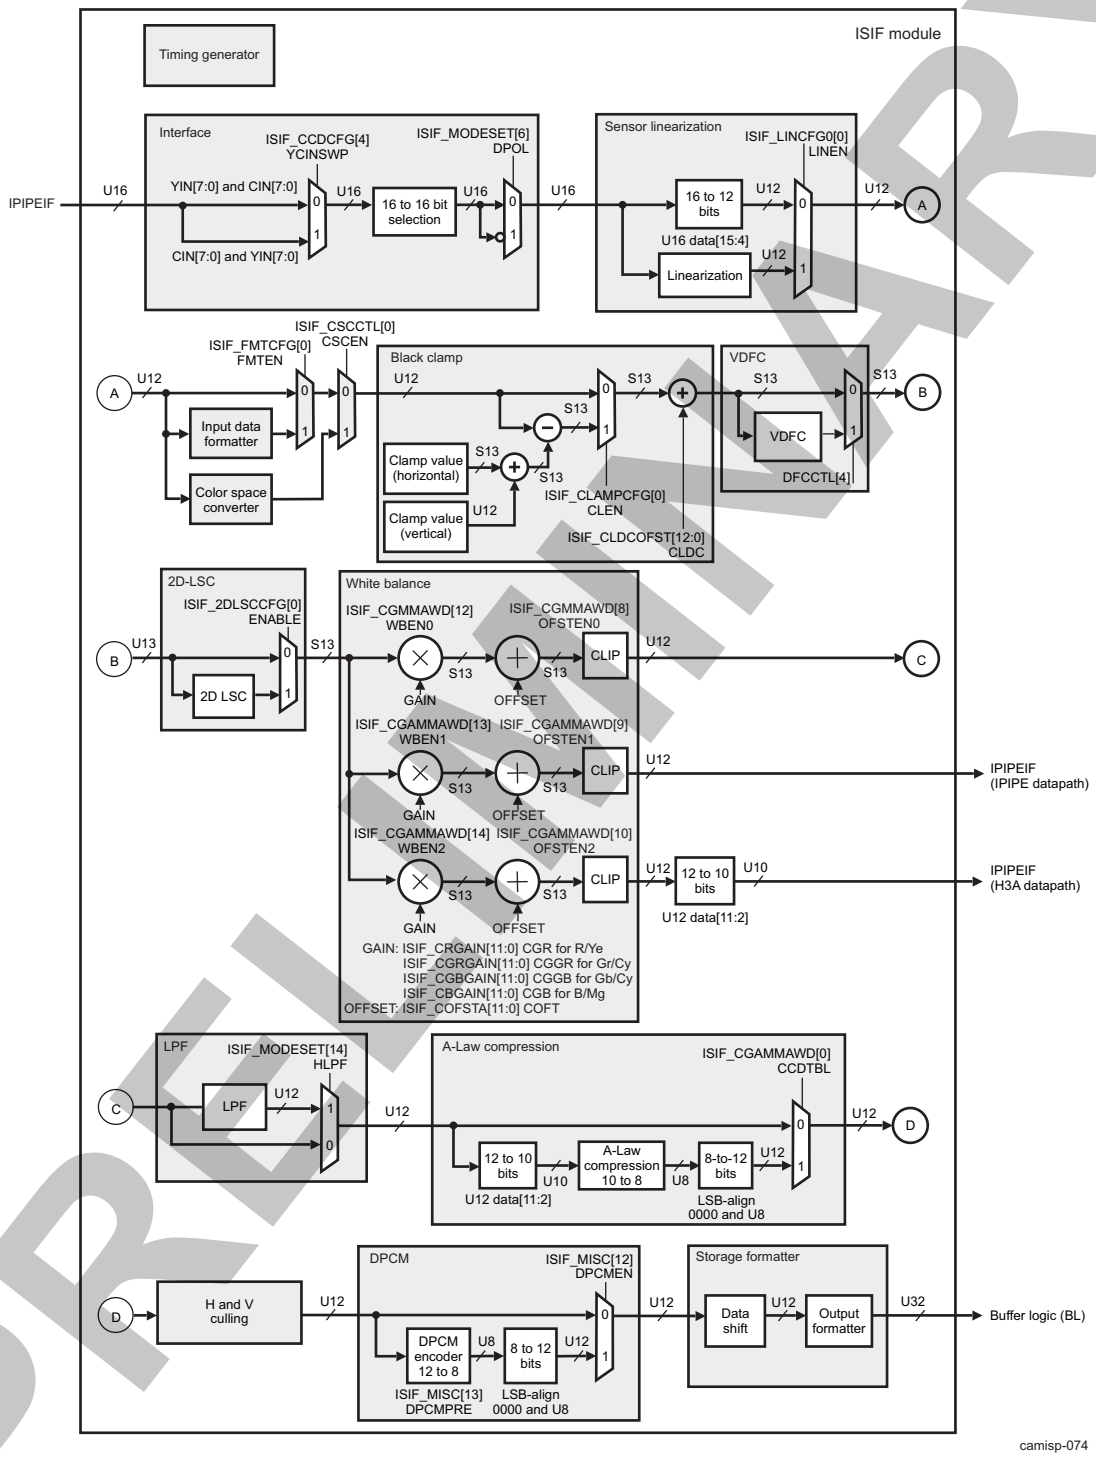
Figure 8-199. ISS ISP ISIF High-Level Diagram



8.3.3.6.2 ISS ISP ISIF Top-Level Block Diagram

Figure 8-200 shows the different blocks of the ISIF module.

Figure 8-200. ISS ISP ISIF Top-Level Block Diagram



The following sections describe the blocks in the ISIF module.

8.3.3.6.3 ISS ISP ISIF Input Interface

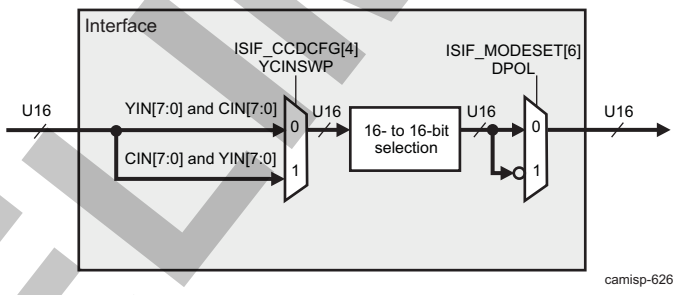
The input interface is a video interface. It comprises the horizontal (HD) and vertical (VD) synchronization signal, pixel clock (PCLK), and data (DATA). Table 8-445 gives more information about these different signals. The ISIF uses the HD and VD signals provided by the sensor through the VP and IPIPEIF. The pixel clock clocks data into the ISIF at a maximum rate of 304 MHz.

Table 8-445. ISS ISP ISIF Input Interface Signals

Name	I/O	Function
VD	I	Vertical sync signal
HD	I	Horizontal sync signal
PCLK	I	Pixel clock. This signal is the pixel clock used to load image data into the ISIF. The clock controller can configure to trigger on the rising or falling edge of the PCLK signal.
DATA	I	Data. The data interface is a 16-bit interface. When the ISIF is configured to write data to SDRAM, the write-enable signal allows an external device to control which data is to be written to SDRAM. The data input can be configured from the ISIF_MODESET.INPMOD register where it can be set to RAW, YCbCr (16 bits and 8 bits). The polarity of the data can be changed from the ISIF_MODESET.DPOL as shown in Figure 8-201.

8.3.3.6.4 ISS ISP ISIF Interface

Figure 8-201. ISS ISP ISIF Interface Block Diagram



The ISIF supports 8- to 16-bit-wide RAW data signals and 8-/16-bit YCbCr signals, as described in Table 8-446. The interface can be set in the three different modes from the ISIF_MODESET[13:12] INPMOD bit field. The ISIF_CCDCFG[11] Y8POS bit selects the y signal positioning whenever YUV4:2:2 is input. Moreover, if CCIR656 input is used the width of selected bit can be set through the ISIF_CCDCFG[5] BT656 bit.

Table 8-446. ISS ISP ISIF Data Input Formats

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
YI7	C_DATA15	Y7	
YI6	C_DATA14	Y6	
YI5	C_DATA13	Y5	
YI4	C_DATA12	Y4	
YI3	C_DATA11	Y3	
YI2	C_DATA10	Y2	
YI1	C_DATA9	Y1	
YI0	C_DATA8	Y0	

Table 8-446. ISS ISP ISIF Data Input Formats (continued)

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
CI7	C_DATA7	Cb7,Cr7	Y7,Cb7,Cr7
CI6	C_DATA6	Cb6,Cr6	Y6,Cb6,Cr6
CI5	C_DATA5	Cb5,Cr5	Y5,Cb5,Cr5
CI4	C_DATA4	Cb4,Cr4	Y4,Cb4,Cr4
CI3	C_DATA3	Cb3,Cr3	Y3,Cb3,Cr3
CI2	C_DATA2	Cb2,Cr2	Y2,Cb2,Cr2
CI1	C_DATA1	Cb1,Cr1	Y1,Cb1,Cr1
CI0	C_DATA0	Cb0,Cr0	Y0,Cb0,Cr0

Y and C input signals can be swapped through the ISIF_CCDCFG[4] YCINSWP bit.

In case of RAW data at ISIF input, a 16- to-16-bit selection can be done: when the number of RAW data lines is less than 16, data can be connected to the upper or lower lines of C_DATA[15:0]. Lines not connected must be tied low. As shown in Table 8-447, the ISIF_CGAMMAWD[4:1] GWDI bit field must be configured correctly so that the MSB of the input is connected to the MSB of the 16-bit data bus in ISIF.

Table 8-447. ISS ISP ISIF Raw Data Connection: Selects MSB Position of Input Data

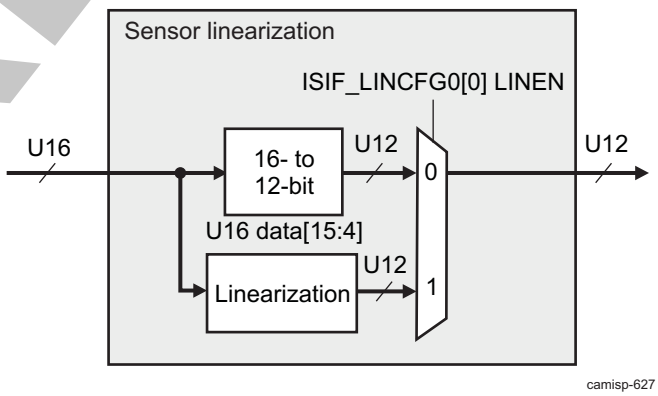
ISIF_CGAMMAWD[4:1] GWDI	16-to-16-bit Selection
0	C_DATA[15:0] = C_DATA[15:0]
1	C_DATA[15:0] = C_DATA[14:0] &0
2	C_DATA[15:0] = C_DATA[13:0] &00
3	C_DATA[15:0] = C_DATA[12:0] &000
4	C_DATA[15:0] = C_DATA[11:0] &0000
5	C_DATA[15:0] = C_DATA[10:0] &00000
6	C_DATA[15:0] = C_DATA[9:0] &000000
7	C_DATA[15:0] = C_DATA[8:0] &0000000
8	C_DATA[15:0] = C_DATA[7:0] &00000000

The polarity of the input image data can be switched through the ISIF_MODESET[6] DPOL bit.

8.3.3.6.5 ISS ISP ISIF Sensor Linearization

NOTE: For the memory access locations of the sensor linearization table, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

Figure 8-202. ISS ISP ISIF Sensor Linearization Block Diagram



The sensor linearization module can correct for the nonlinear response of image sensors. A LUT is programmed with an offset value to add to the original pixel value based on the original pixel value.

The LUT is a sampling of the linearization correction curve based on calibration of the image sensor. Intermediate values between sampling points are computed using linear interpolation. The entire correction curve is divided into seven regions, as listed in Table 8-448. The regions for the darkest part and the brightest part of the response curve have dense sampling. The linearization mode can be a uniform or a nonuniform sampling and can be set through the ISIF_LINCFG0[1] LINMD bit.

Table 8-448. ISS ISP ISIF Linearization LUT

Region	Number of Sample Points	LUT Address
table_in[15:11] == 00000	32	table_in[10:6]
table_in[15:11] == 00001	4	table_in[10:9] + 32
table_in[15:12] == 0001	4	table_in[11:10] + 36
table_in[15:13] == 001	4	table_in[12:11] + 40
table_in[15:14] == 01	4	table_in[13:12] + 44
table_in[15:14] == 10	16	table_in[13:10] + 48
table_in[15:14] == 01	128	table_in[13:7] + 64

The LUT has 192 entries and is split into two 96 × 10-bit memories, as shown in Figure 8-203. Table 8-449 is mapped in the memory map. The LUT entries are interleaved between memory 0 and memory 1.

Figure 8-203. ISS ISP ISIF Linearization LUT Memories

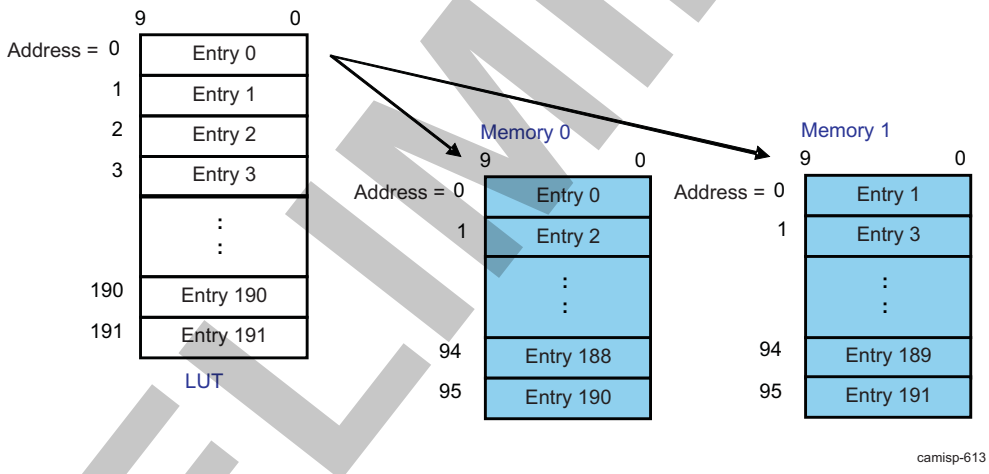


Table 8-449. ISS ISP ISIF LUT Memory Region

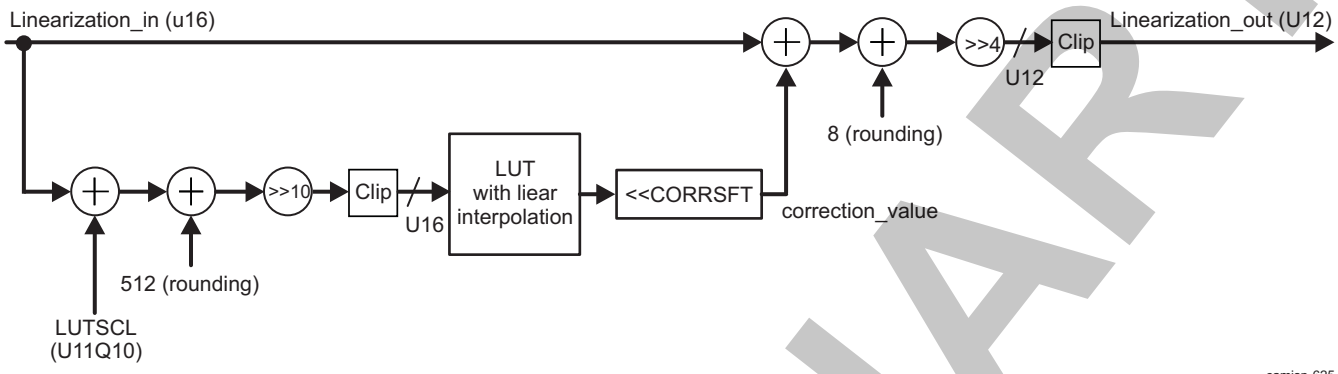
Memory Region	Address Range	Description
Memory 0	0xC000 – 0xC17F	ISIF linearity compensation LUT 0
Memory 1	0xC400 – C57F	ISIF linearity compensation LUT 1

A scale factor is applied to the input before lookup through the ISIF_LINCFG1[10:0] LUTSCL bit field. The LUT entries are signed 10-bit data (u16). After linear interpolation, the correction value is left-shifted by a programmable amount (the ISIF_LINCFG0[6:4] CORRSFT bit field), and then added to the input. This is then converted to unsigned 12-bit by right shift, followed by clipping.

Figure 8-204. ISS ISP ISIF Linearization Block Diagram



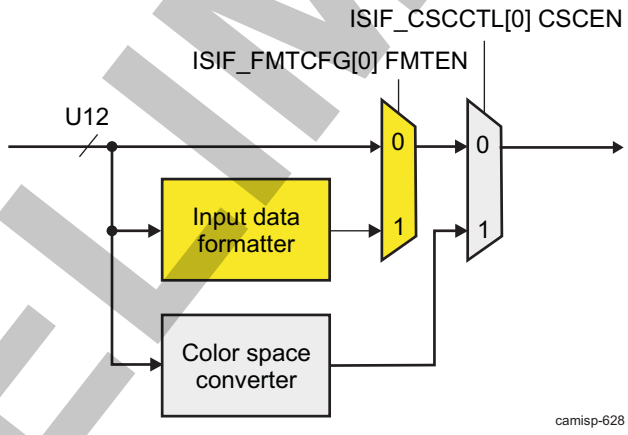
To enable the linearization module, set the ISIF_LINCFG0[0] LINEN bit to 1.

If the linearization module is disabled (ISIF_LINCFG0[0] LINEN = 0x0), a 16- to-12-bit transformation is done, and the upper 12 bits of U16 input are sent to the next block.

8.3.3.6.6 ISS ISP ISIF Input Data Formatter

Figure 8-205 shows the ISS ISP ISIF input data formatter block diagram.

Figure 8-205. ISS ISP ISIF Input Data Formatter Block Diagram



There are two functional blocks: input data formatter and color space converter, which use two 5376 × 12-bit memories (corresponds to one line of maximum 5376 pixels with each pixel equal to 12 bits). Only one of the function blocks can be enabled.

The input data formatter block allows the ISIF to handle a wide variety of current and future readout schemes other than Bayer format. Two line memories and a programmable address generator are used to translate those patterns into a standard Bayer pattern (or any other pattern). This allows the back-end processing (noise filters, interpolation, histogram, 3A statistics) to remain unchanged.

The input data formatter block also supports divided input lines. In case an input line is divided into multiple lines and fed to the ISIF, the formatter gathers the divided lines and organizes a single line. Up to four divided lines can be supported.

The input data formatter is enabled through the ISIF_FMTCFG[0] FMTEN bit.

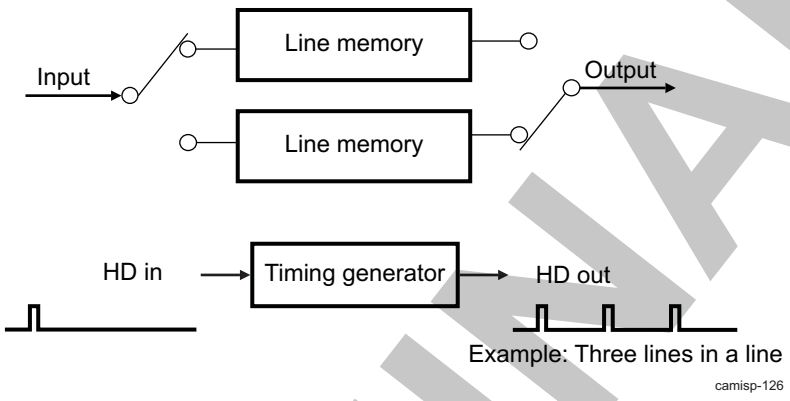
The input data formatter can split an input line into one, two, three, or four output lines, or can combine the divided by one, two, three, or four input lines into a single line.

- Set the ISIF_FMTCFG[1] FMTCBL bit to 0 for split mode.
- Set the ISIF_FMTCFG[1] FMTCBL bit to 1 for combine mode.
- Select the number of lines in the ISIF_FMTCFG[5:4] LNUM bit field.

The input data formatter can work in normal or line alternative mode. The choice is done through the ISIF_FMTCFG[2] LNALT bit.

Figure 8-206 shows an example of generating three output lines from an input line with a new, internally generated HD signal.

Figure 8-206. ISS ISP ISIF Splits an Input Line Into Three Output Lines



This HD signal then gates the downstream processing rather than the original sensor HD signal. Descriptions of how to configure the formatter are provided in the following sections.

Because the size of the line memories is 5376 × 12 bits, the following restrictions apply for the data formatter:

- Split mode:
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into one output line is 5376.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into two output lines is 2688.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into three output lines is 1792.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into four output lines is 1344.
- Combine mode:
  - The maximum number of pixels that can be supported in an input line if one input line is transformed into an output line is 5376.
  - The maximum number of pixels that can be supported in an input line if two input lines are transformed into an output line is 2668.
  - The maximum number of pixels that can be supported in an input line if three input lines are transformed into an output line is 1792.
  - The maximum number of pixels that can be supported in an input line if four input lines are transformed into an output line is 1344.

8.3.3.6.6.1 ISS ISP ISIF Formatter Area Settings

As shown in Figure 8-207, the following registers are used to set the formatter area:

- ISIF_FMTSPH
- ISIF_FMTLNH
- ISIF_FMTLSV
- ISIF_FMTLNV

Figure 8-207. ISS ISP ISIF Input Data Formatter Area Settings

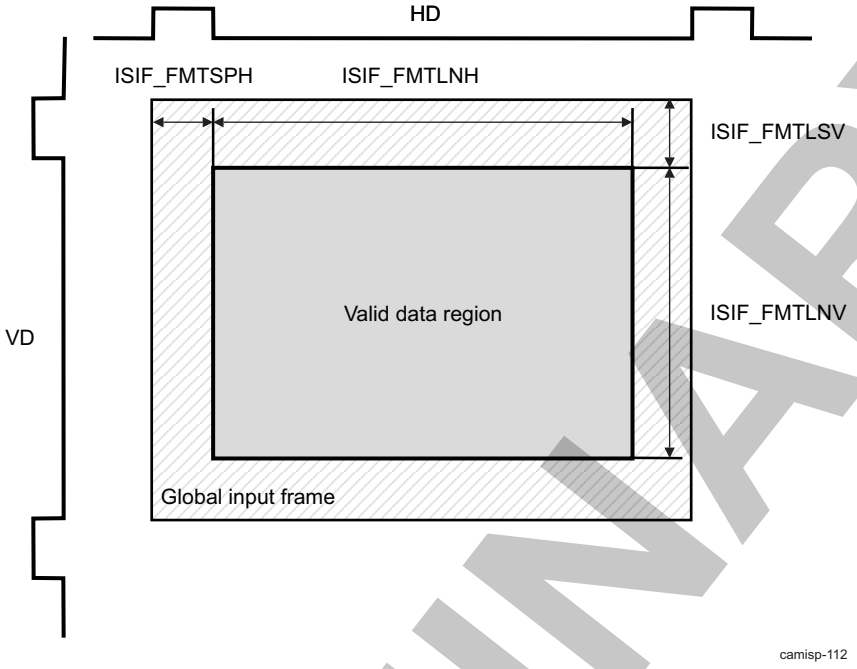


Table 8-450 and Table 8-451 describe these registers. The input line is input to the formatter, and the output line is output from the formatter.

Table 8-450. ISS ISP ISIF Input Data Formatter Area Setting Registers

Register	Description
ISIF_FMTSPH	The first valid pixel of an input line
ISIF_FMTLNH	Valid length of a input line = FMTLNH + 1
ISIF_FMTLSV	The first valid input line
ISIF_FMTLNV	The number of the valid input lines = FMTLNV + 1

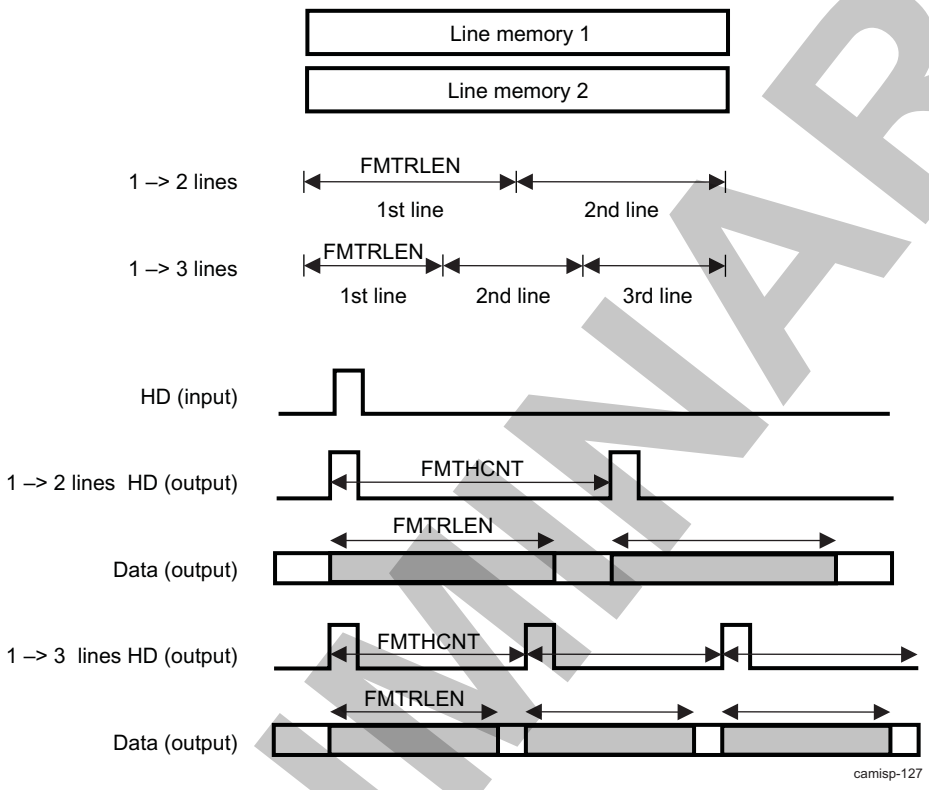
Table 8-451. ISS ISP ISIF Output Data Formatter Area Setting Registers

Register	Description
ISIF_FMTRLEN	The length of an output line
ISIF_FMTHCNT	HD interval for output lines
ISIF_SPH	The first pixel in an output line to be stored to SDRAM
ISIF_LNH	The number of pixels in an output line to be stored to SDRAM = LNH + 1
ISIF_LNV	The number of the output lines to be stored to SDRAM = LNV + 1

The number of pixels in an output line must be set to the ISIF_FMTRLEN register, and the HD output interval must be set to the ISIF_FMTHCNT register. It is not necessary to set the ISIF_FMTHCNT register if multiple input lines are combined into a single line.

Figure 8-208 shows an example of splitting an input line into two or three output lines.

Figure 8-208. ISS ISP ISIF Data Formatter Output Control Example



8.3.3.6.6.2 ISS ISP ISIF Formatter Programming

The data formatter derives its flexibility by supporting up to 16 different addresses and a program that can contain up to 32 entries.

Address pointer

There are 16 address pointer registers (ISIF_FMTAPTR0 to ISIF_FMTAPTR15), which contain:

- The ISIF_FMTAPTRx[14:13] LINE bit field: 2-bit line number to specify the output line to which it belongs: 0, 1, 2, or 3. It is valid only for the line splitting.
- The ISIF_FMTAPTRx[12:0] INIT bit field: 13-bit initial address for pointer x (where x = 0 to 15)

Each address value is auto-incremented or auto-decremented by a programmable value (the ISIF_FMTCFG[11:8] FMTAINC bit field).

Program

There are 32 program entry registers, which contain:

- In the ISIF_FMTPGMVF0 and ISIF_FMTPGMVF1 registers: The PGMxxEN fields set the program entry valid flag (where xx = 00 to 31) .
- In the ISIF_FMTPGMAPS0 to ISIF_FMTPGMAPS7 registers: The PGMxxAPTR fields specify the program xx address pointer (where xx = 00 to 31).
- In the ISIF_FMTPGMAPU0 and ISIF_FMTPGMAPU1 registers: The PGMxxUPDT fields set the program xx address update (increment or decrement) (where xx = 00 to 31).

Because each program entry has a valid flag, the formatter can also support images larger than the memory limit (length: 4480) by not choosing some of the entries.

The total program memory of 32 entries is divided into two or four sets:

- Program memory of 16 entries each for odd and even lines to split the line:
  - SET0 for even input line: Program entry 015
  - SET1 for odd input line: Program entry 1631
- Program memory of eight entries for up to four input lines to combine the lines:
  - SET0 for first input line: Program entry 07
  - SET1 for second input line: Program entry 815
  - SET2 for third input line: Program entry 1623
  - SET3 for fourth input line: Program entry 2431

The number of program entries per set must be specified by the ISIF_FMTPLEN register as follows:

- Number of program entries for SET0: ISIF_FMTPLEN[3:0] FMTPLEN0
- Number of program entries for SET1: ISIF_FMTPLEN[7:4] FMTPLEN1
- Number of program entries for SET2: ISIF_FMTPLEN[10:8] FMTPLEN2
- Number of program entries for SET3: ISIF_FMTPLEN[14:12] FMTPLEN3

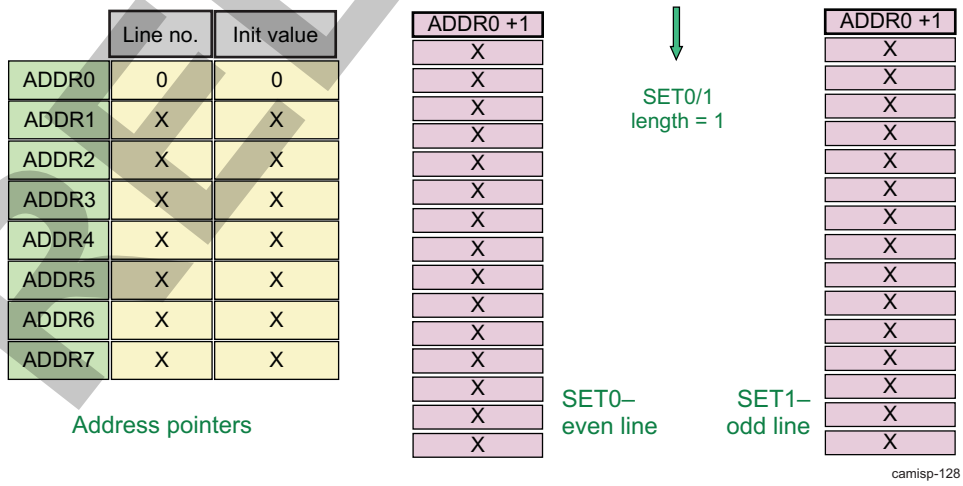
The program entry must be set from the lower registers within a set. For instance, start from program entry 16 for odd input lines.

The following examples show the programmability of the data formatter:

- Register settings:
  - ISIF_FMTCFG[0] FMTEN = 0x1
  - ISIF_FMTCFG[1] FMTCBL = 0x0
  - ISIF_FMTCFG[11:8] FMTAINC = 0x0 (add or subtract 1)
- 1 input line –> 1 output line

NOTE: ADDR0 is set to an example value. Addresses with no value in the following example are marked with X.

Figure 8-209. ISS ISP ISIF Conventional Read-Out Pattern

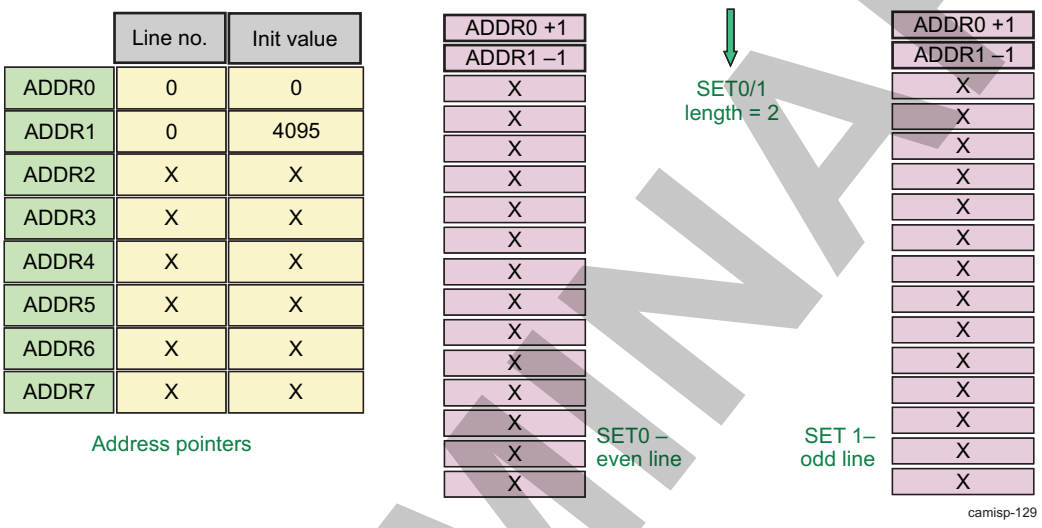


The following examples show the programmability of the data formatter with a 2-tap analog front end (AFE):

- Register settings:
  - ISIF_FMTCFG[0] FMTEN = 0x1

  - ISIF_FMTCFG[1] FMTCBL = 0x0
  - ISIF_FMTCFG[11:8] FMTAINC = 0x0 (add or subtract 1)
  - ISIF_FMTCFG[5:4] LNUM = 0x0
- One input line (4096): one output line with left and right read-out
- Input: First pixel, last pixel, first pixel + 1, last pixel – 1, and so on
- Input: 0, 4095, 1, 4094, 2, 4093, 3, 4092, ..., 2047 and 2048
- Output: 0, 1, 2, 3, ..., 4094 and 4095

Figure 8-210. ISS ISP ISIF Conventional Read-Out Pattern With 2-tap AFE



8.3.3.6.6.3 ISS ISP ISIF Combine the Divided Input Lines

The formatter can gather the divided input lines and organize a single line. Figure 8-211 shows an example generating a single output line from three input lines and masking two out of three HD input pulses.

Figure 8-211. ISS ISP ISIF Combine Three Input Lines Into Single Line

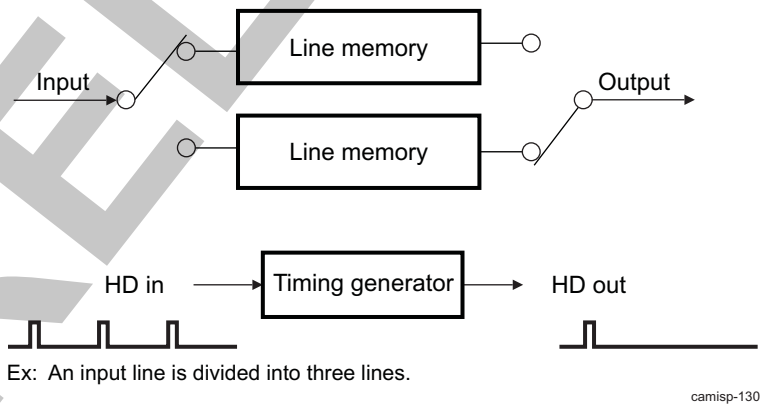


Figure 8-212 is an example that shows the register setting.

- Multiple input lines combined into one output line (use three input lines to one output line in this example)
- Input: 4, 5, 10, 11, ..., 2, 3, 8, 9, ..., 0, 1, 6, 7, ... (three lines read from sensor)
- Output: 0, 1, 2, 3, ... (1 line output)
- Register settings:

- ISIF_FMTCFG[0] FMTEN = 0x1
- ISIF_FMTCFG[1] FMTCBL = 0x1
- ISIF_FMTCFG[11:8] FMTAINC = 0x5 (add or subtract 6)
- ISIF_FMTCFG[5:4] LNUM = 0x2
- Sets recycled based on LNUM

Figure 8-212. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line

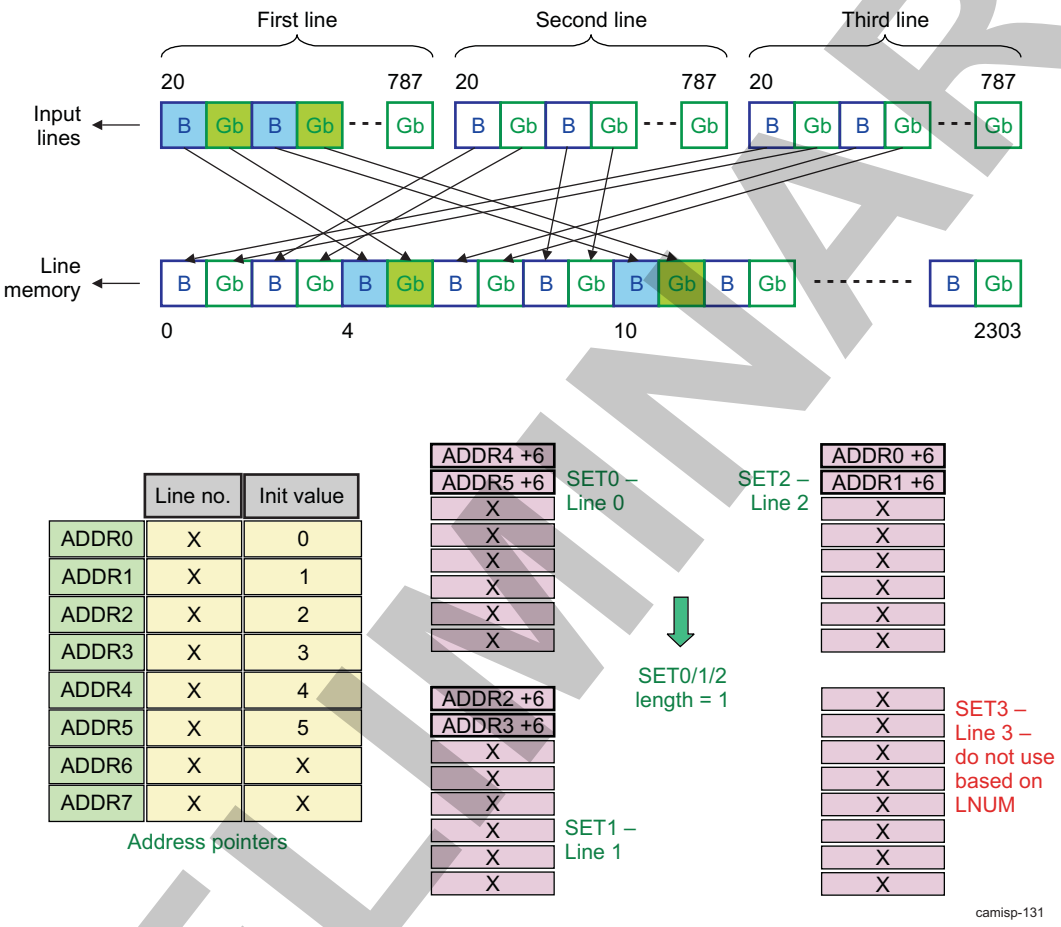

Table 8-452 lists an example of the ISS ISP ISIF combining three input lines into a single line.

Table 8-452. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line: Register Setting Example

Step	Configuration Required	Size
Formatter enable	ISIF_FMTCFG[0] FMTEN	1
Combine input lines.	ISIF_FMTCFG[1] FMTCBL	1
Address increment = FMTAINC + 1 = 6	ISIF_FMTCFG[11:8] FMTAINC	5
The first valid pixel of a divided line	ISIF_FMTSPH[12:0] FMTSPH	20
Valid length of a divided line = FMTLNH + 1 = 768	ISIF_FMTLNH[12:0] FMTLNH	767
The first valid divided line	ISIF_FMTLSV[12:0] FMTSLV	16
The number of the valid divided lines = FMTLNV + 1 = 4590	ISIF_FMTLNV[14:0] FMTLNV	4589
The length of an organized line = (FMTLNH + 1) x (LNUM + 1) = 2304	ISIF_FMTRLEN[12:0] FMTRLEN	2304
Split/combine line number = LNUM + 1 = 3	ISIF_FMTCFG[5:4] LNUM	2
Number of PGM entries for SET0 = FMTPLEN0 + 1 = 2	ISIF_FMTPLEN[3:0] FMTPLEN0	1

Table 8-452. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line: Register Setting Example (continued)

Step	Configuration Required	Size
Number of PGM entries for SET1 = FMTPLEN1 + 1 = 2	ISIF_FMTPLEN[7:4] FMTPLEN1	1
Number of PGM entries for SET2 = FMTPLEN2 + 1 = 2	ISIF_FMTPLEN[10:8] FMTPLEN2	1
Address pointer 0, INIT = 0	ISIF_FMTAPTR0[12:0] INIT	0

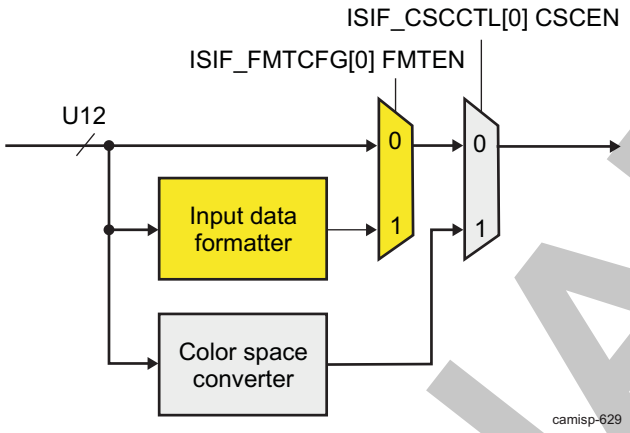
8.3.3.6.7 ISS ISP ISIF Color Space Converter

Figure 8-213 shows the ISS ISP ISIF Color Space Converter Block Diagram.

Figure 8-213. ISS ISP ISIF Color Space Converter Block Diagram

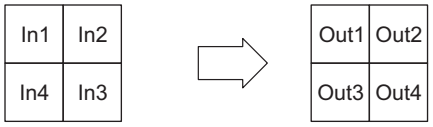


The color space converter (CSC) includes four 8-bit × 12-bit multipliers and one adder for the color space conversion. These multiplier/adder units are used for the operation described in Figure 8-214. Data are taken from two input lines during the operation.

Coefficients are signed 8-bit (decimal is 5 bits). Coefficients are set through the following registers:

- Coefficient M00: ISIF_CSCM0[7:0] CSCM00
- Coefficient M01: ISIF_CSCM0[15:8] CSCM01
- Coefficient M02: ISIF_CSCM1[7:0] CSCM02
- Coefficient M03: ISIF_CSCM1[15:8] CSCM03
- Coefficient M10: ISIF_CSCM2[7:0] CSCM10
- Coefficient M11: ISIF_CSCM2[15:8] CSCM11
- Coefficient M12: ISIF_CSCM3[7:0] CSCM12
- Coefficient M13: ISIF_CSCM3[15:8] CSCM13
- Coefficient M20: ISIF_CSCM4[7:0] CSCM20
- Coefficient M21: ISIF_CSCM4[15:8] CSCM21
- Coefficient M22: ISIF_CSCM5[7:0] CSCM22
- Coefficient M23: ISIF_CSCM5[15:8] CSCM23
- Coefficient M30: ISIF_CSCM6[7:0] CSCM30
- Coefficient M31: ISIF_CSCM6[15:8] CSCM31
- Coefficient M32: ISIF_CSCM7[7:0] CSCM32
- Coefficient M33: ISIF_CSCM7[15:8] CSCM33

Figure 8-214. ISS ISP ISIF Color Space Converter Operation



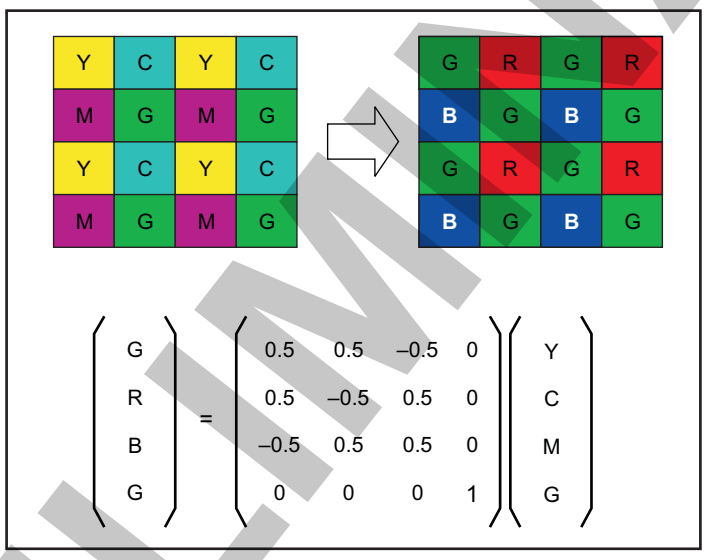
$$\begin{pmatrix} Out1 \\ Out2 \\ Out3 \\ Out4 \end{pmatrix} = \begin{pmatrix} M00 & M01 & M02 & M03 \\ M10 & M11 & M12 & M13 \\ M20 & M21 & M22 & M23 \\ M30 & M31 & M32 & M33 \end{pmatrix} \begin{pmatrix} In1 \\ In2 \\ In3 \\ In4 \end{pmatrix}$$

M00–M33: Signed 8-bit data with 5-bit decimal
the value range –4=< Mxx<4

camisp-618

The CSC can convert CMYG filtered CCD data to Bayer matrix (RGBG) data, as shown in Figure 8-215.

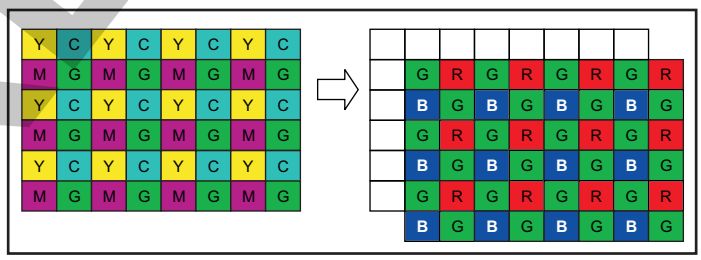
Figure 8-215. ISS ISP ISIF Color Space Converter Operation: CMYG to RGBG



camisp-113

Figure 8-216 through Figure 8-218 show which input pixels are used for the operation. There is 1line latency between the input and the output.

Figure 8-216. ISS ISP ISIF Color Space Conversion Example



camisp-114

Figure 8-217. ISS ISP ISIF First Pixel/First Line Generation

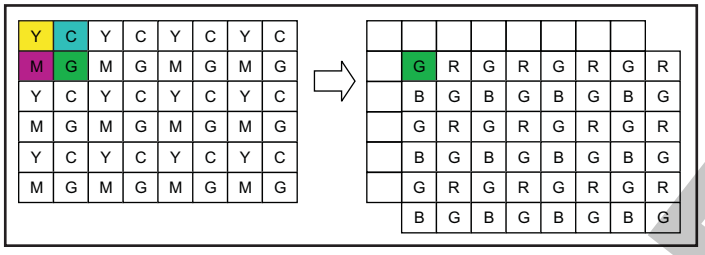


Figure 8-218. ISS ISP ISIF Second Pixel/First Line Generation

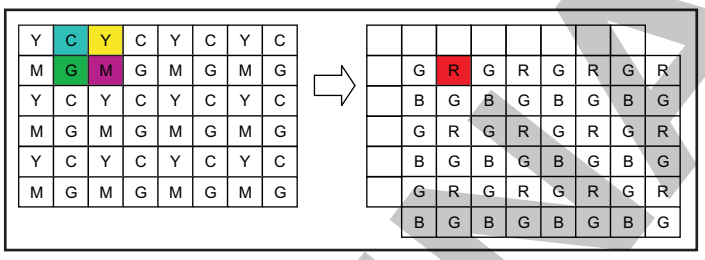

As shown inFigure 8-219 through Figure 8-222, the operation for the last pixel and the second last pixel uses the same input data.

Figure 8-219. ISS ISP ISIF Second Last Pixel/First Line Generation

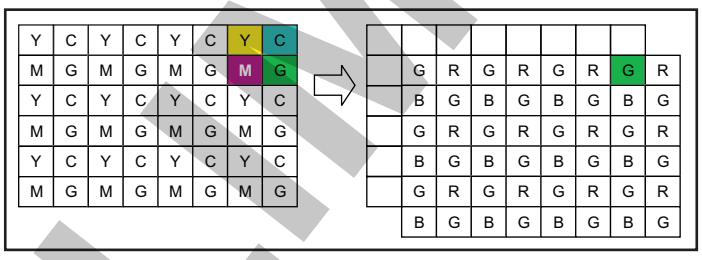

Figure 8-220. ISS ISP ISIF Last Pixel/First Line Generation

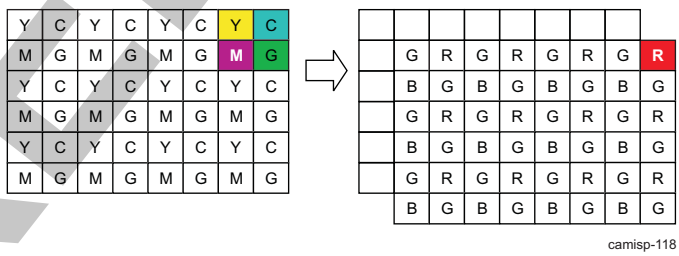

Figure 8-221. ISS ISP ISIF First Pixel/Last Line Generation

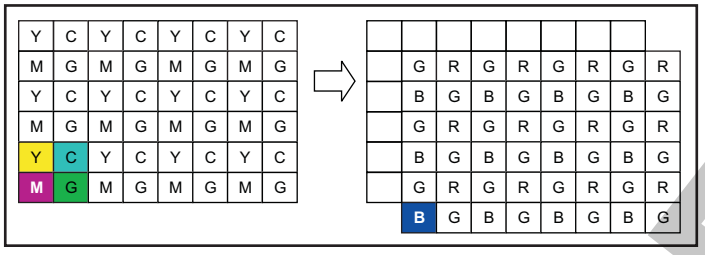

Figure 8-222. ISS ISP ISIF Second Pixel/Last Line Generation

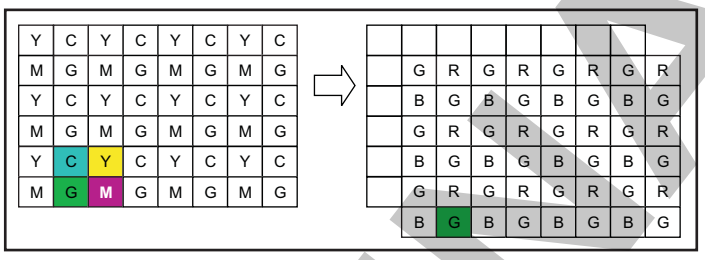

Also, the operation for the last line and the second last line uses the same input data (see Figure 8-223 and Figure 8-224).

Figure 8-223. ISS ISP ISIF Second Last Pixel/Last Line Generation

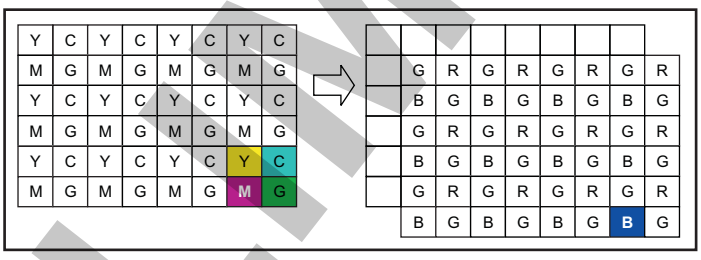

Figure 8-224. ISS ISP ISIF Last Pixel/Last Line Generation

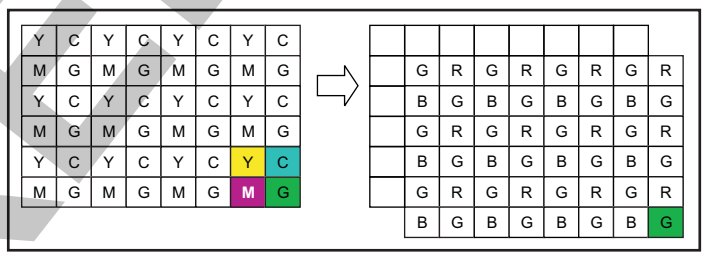


In addition to the registers specific to the CSC, some of the registers are shared with the input data formatter to configure the valid area:

- ISIF_FMTSPH
- ISIF_FMTLNH
- ISIF_FMTLSV
- ISIF_FMTLNV

There must be at least 1 invalid pixel at the end of the line and one invalid line at the end of the frame.

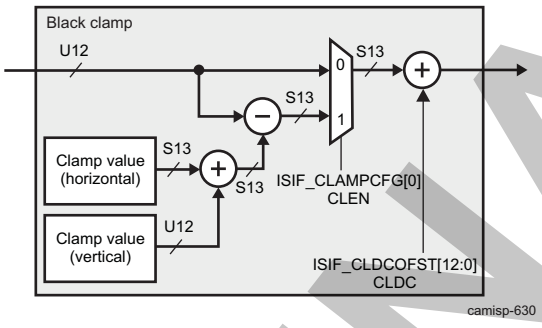
To enable the color space conversion, set the ISIF_CSCCTL[0] CSCEN bit to 1.

8.3.3.6.8 ISS ISP ISIF Black Clamp

NOTE: For the memory access locations of the ISIF clamp, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

Figure 8-225 shows the ISS ISP ISIF black clamp block diagram.

Figure 8-225. ISS ISP ISIF Black Clamp Block Diagram



The clamp value is calculated based on the pixel value of the OB region of the sensor. The clamp value is calculated separately for horizontal and vertical directions to compensate the offset drift in the horizontal and vertical directions. The sum of the horizontal and vertical clamp values is subtracted from the image data, and then the additional DC offset is added (the ISIF_CLDCOFST[12:0] CLDC bit field, an S13Q0 value). This value is added whether the black clamp module is enabled or not.

The horizontal clamp is disabled through the ISIF_CLAMPCFG[2:1] CLHMD bit field.

To enable the black clamp module, set the ISIF_CLAMPCFG[0] CLEN bit to 1. The ISIF_PPLN[15:0] PPLN bit field sets the pixel per line, and the number of pixel clock periods in one line HD period equals PPLN + 1 pixel clock. The ISIF_PPLN[15:0] bit field is not used when the input is are already HD/VD.

8.3.3.6.8.1 ISS ISP ISIF Clamp Value for Horizontal Direction

The clamp value for horizontal direction is calculated using the pixel values at the upper OB region.

The maximum pixel value to be used for the clamp value calculation can be limited to 1023 if the pixel value limitation is enabled (ISIF_CLHWIN0[6] CLHLMT = 1).

Clamp value calculation for horizontal direction can be disabled if there is no upper OB region. The operating modes are:

- The horizontal clamp value calculation is enabled. The calculated horizontal clamp value is subtracted from the image data along with the vertical clamp value (ISIF_CLAMPCFG[2:1] CLHMD = 0x1).
- The horizontal clamp value is not updated. The horizontal clamp value used for the previous image is subtracted from the image data along with the vertical clamp value (ISIF_CLAMPCFG[2:1] CLHMD = 0x2).
- The horizontal clamp value is not updated. Only the vertical clamp value is subtracted from the image data (ISIF_CLAMPCFG[2:1] CLHMD = 0x0).

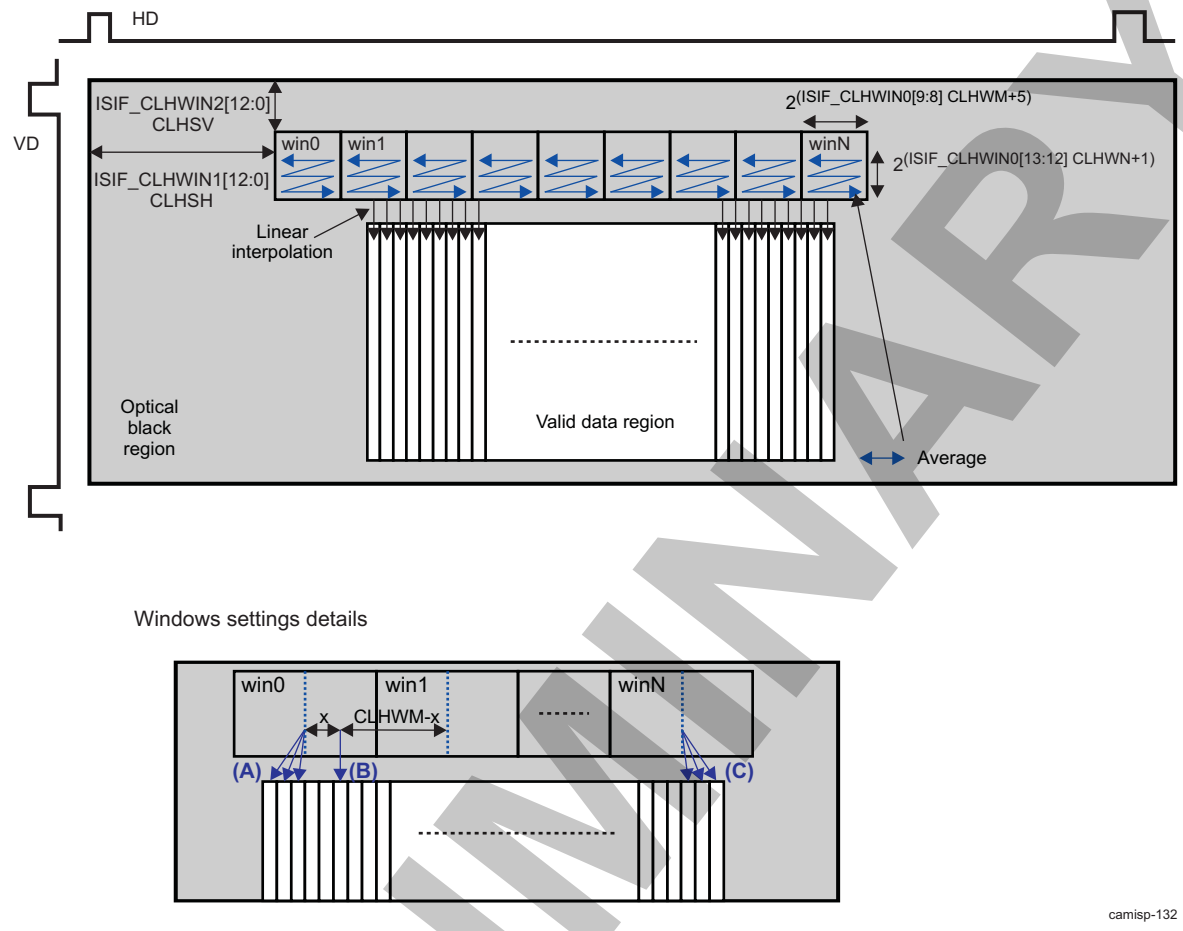
The number of windows in a row is set with the ISIF_CLHWIN0[4:0] CLHWC bit field.

Up to 32 windows in a row can be set for clamp value calculation. All the windows have the same size in a format [$2^{(ISIF\_CLHWIN0[9:8]\ CLHWM+5)}$] pixels by [$2^{(ISIF\_CLHWIN0[13:12]\ CLHWN+1)}$] lines.

The ISIF_CLHWIN2[12:0] CLHSV and ISIF_CLHWIN1[12:0] CLHSH bit fields enable setting the position of the first optical black clamp window in the frame. The pixel and line offset are in a range 0 to 8191. The ISIF_HDW register sets the width of the HD.

Figure 8-226 shows the ISS ISP ISIF clamp value for the horizontal direction.

Figure 8-226. ISS ISP ISIF Clamp Value for Horizontal Direction



The clamp value for horizontal direction calculation steps is:

1. Calculate the average of the pixel value in each window (ave_win_0 to ave_win_N).

Calculation Steps	win0	win1	win2	...	wini	wini + 1	...	winN
Average of the pixel value	ave_win_0	ave_win_1	ave_win_2		ave_win_i	ave_win_{i+1}		ave_win_N

2. Set the average of the left-most window or the right-most window as the base value B_V:
   - B_V = ave_win_0 (if ISIF_CLHWIN0[5] CLHWBS = 0x0, case 1)
   - B_V = ave_win_N (if ISIF_CLHWIN0[5] CLHWBS = 0x1, case 2)
3. Subtract the base value from the average of each window. Use this value as a clamp value for each window.

Calculation Steps	win0	...	wini	wini+1	...	winN
Clamp value for each window	$clamp\_win_0 = ave\_win_0 - B\_V$		$clamp\_win_i = ave\_win_i - B\_V$	$clamp\_win_{i+1} = ave\_win_{i+1} - B\_V$		$clamp\_win_N = ave\_win_N - B\_V$

4. Acquire the horizontal distance (X and CLHWM – X) from the valid pixel to be processed to the center of the closest two windows.
5. Calculate the clamp value of the valid pixel by linear interpolation, using the clamp value of the closest two windows (i and i + 1).
   - Case 1: $interpolated\_clamp\_win_X = (clamp\_win_{i+1} - clamp\_win_i) \times X / CLHWM$
   - Case 2: $interpolated\_clamp\_win_X = (clamp\_win_i - clamp\_win_N) \times (CLHWM - X) / CLHWM +$

$(clamp\_win_{i+1} – clamp\_win_N) \times X / CLHWM$

6. If the valid pixel is on the left of the center of the left-most window, the clamp value of the left-most window is applied. If the valid pixel is on the right of the center of the right-most window, the clamp value of the right-most window is applied.

The clamp values calculated (A), (B), and (C) are:

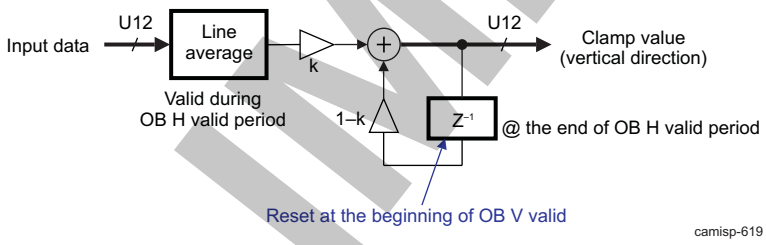
- Case1: Base is win_0 (Left-most window: ISIF_CLHWIN0[5] CLHWBS = 0x0)
  - (A): zero
  - (B): $(clamp\_win_{i+1} – clamp\_win_i) \times X / CLHWM$
  - (C): $(clamp\_win_N – clamp\_win_0)$
- Case2: Base is win_N (Right-most window: ISIF_CLHWIN0[5] CLHWBS = 0x1)
  - (A): $(clamp\_win_0 – clamp\_win_N)$
  - (B): $(clamp\_win_i – clamp\_win_N) \times (CLHWM – X) / CLHWM + (clamp\_win_{i+1} – clamp\_win_N) \times X / CLHWM$
  - (C): zero

Each interpolated value $interpolated\_clamp\_win_X$ is then subtracted to the associated column.

8.3.3.6.8.2 ISS ISP ISIF Clamp Value for Vertical Direction

The clamp value for vertical direction is calculated using the pixel values at the left or right OB region. Line average is calculated for the OB H valid period ($2^{(ISIF\_CLVWIN0[2:0]\ CLVOBH\ +\ 1)}$). The averages for the previous lines are also added back to reduce the difference between the lines, as shown in Figure 8-227.

Figure 8-227. ISS ISP ISIF Clamp Value for Vertical Direction Calculation



- Clamp Value (V_n) = Line Average (V_n) * k + Clamp Value (V_1) * (1-k)
- k = ISIF_CLVWIN0[15:8] CLVCOEF

The position of the first vertical black clamp window is set with the ISIF_CLVWIN2[12:0] CLVSV and ISIF_CLVWIN1[12:0] CLVSH bit fields. The number of vertical windows is set with the ISIF_CLVWIN3[12:0] CLVOBV bit field. ISIF_VDW sets the width of the VD.

The accumulator, which holds the vertical clamp value for the previous line, is reset at the beginning of the OB V valid. The reset value can be selected through the ISIF_CLVWIN0[5:4] CLVRVSL bit field:

- ISIF_CLVWIN0[5:4] CLVRVSL = 0x0: The base value is calculated for horizontal direction (left-most window win_0 or right-most win_n set with ISIF_CLHWIN0[5] CLHWBS).
- ISIF_CLVWIN0[5:4] CLVRVSL = 0x1: The base value is set through the configuration register (ISIF_CLVRV[11:0] CLVRV).
- ISIF_CLVWIN0[5:4] CLVRVSL = 0x2: No update (same as the previous image)

The following figures show the OB valid settings and associated vertical clamp value calculation when OB region is at the left (see Figure 8-228) and when OB region is at the right (see Figure 8-229). Each line average value is subtracted from the associated line valid region data.

Figure 8-228. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Left

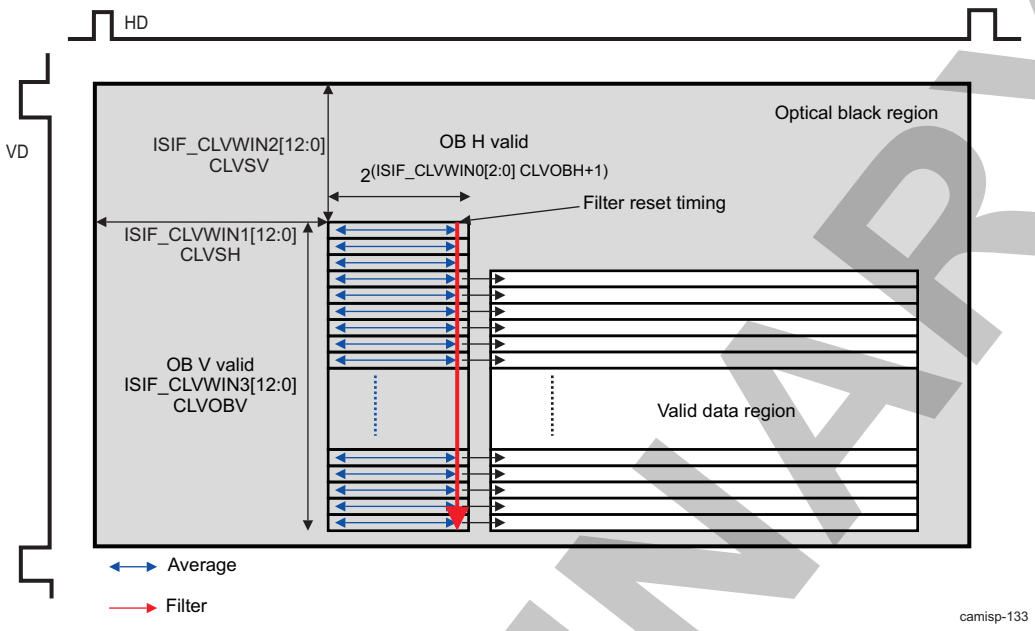


Figure 8-229. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Right

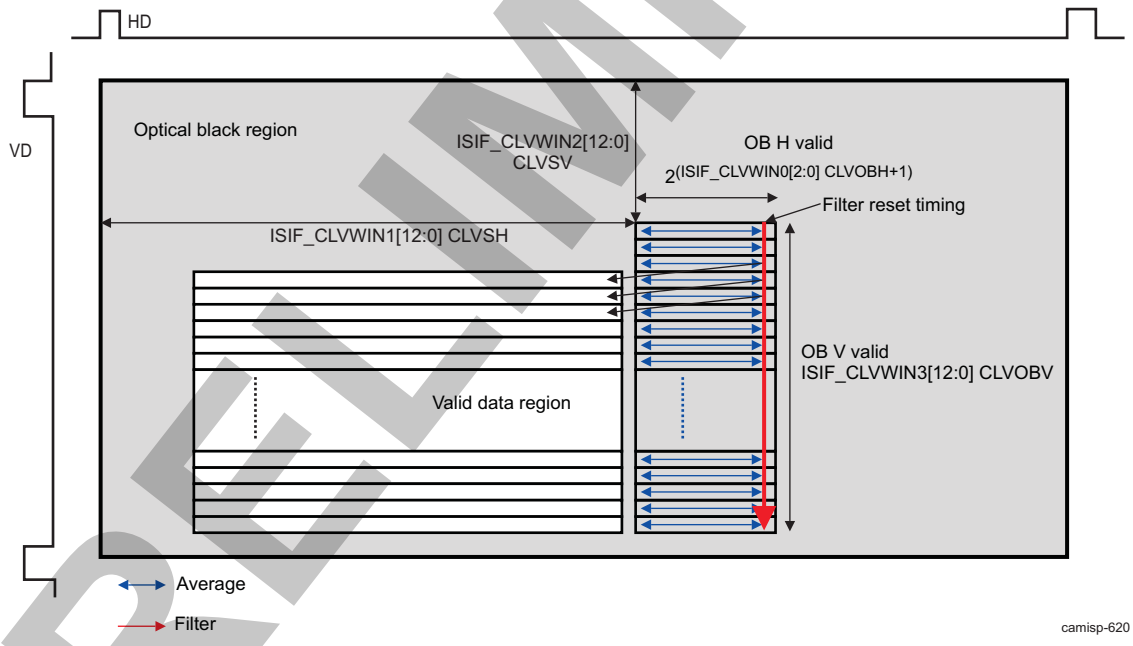
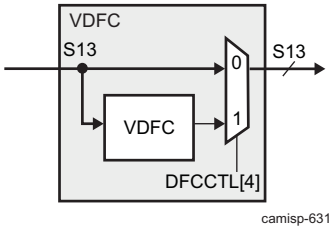


8.3.3.6.9 ISS ISP ISIF Vertical Line Defect Correction (VDFC)

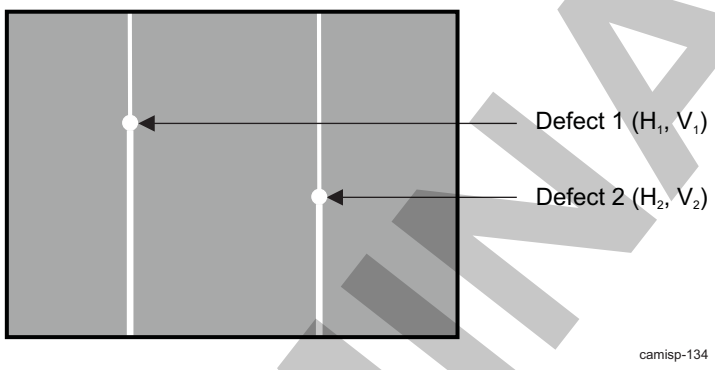
Figure 8-230 shows the block diagram of the vertical line defect (VDFC) correction.

Figure 8-230. ISS ISP ISIF Vertical Line Defect Correction Block Diagram



The VDFC block can correct up to eight vertical line defects (see Figure 8-231).

Figure 8-231. ISS ISP ISIF Vertical Line Defects



The correction method is common to all the defects and can be selected through the ISIF_DFCCTL[6:5] VDFCSL bit field.

There are two different methods to correct vertical line defects (ISIF_DFCCTL[6:5] VDFCSL):

- Method 1: Data is replaced by an average (ISIF_DFCCTL[6:5] VDFCSL = 0x2):
  - The defect is replaced by the average of pixel (i – 2) and pixel (i + 2).
- Method 2: Data is subtracted by a defect level (ISIF_DFCCTL[6:5] VDFCSL = 0x0 or 0x1):
  - A saturation level is defined in the ISIF_VDFSATLV[11:0] VDFSLV bit field.
  - The coordinates of the defect:
    - Are defined in the ISIF_DFCMEM0[12:0] DFCMEM0 and ISIF_DFCMEM1[12:0] DFCMEM1 bit fields
    - Are 13 bits wide for horizontal and vertical direction, so an image size up to 8192 × 8192 is supported
  - If the data is not saturated (data < VDFSLV):
    - The defect is corrected by subtracting the defect level. A different defect level is defined for:
      - The point of the defect (V = Vdefect): SUB1 defect level is defined in the ISIF_DFCMEM2[7:0] DFCMEM2 bit field.
      - The pixels lower than the defect (V < Vdefect): SUB2 defect level is defined in the ISIF_DFCMEM3[7:0] DFCMEM3 bit field.
      - The pixels above the defect (V > Vdefect): Defect level is defined in the ISIF_DFCMEM4[7:0] DFCMEM4 bit field.
    - Each defect level (value to be subtracted from the data) described previously can be up-shifted through the ISIF_DFCCTL[10:8] VDFLSFT bit field.
    - Vertical line defect correction for upper pixels can be disabled through the ISIF_DFCCTL[7] VDFCUDA bit.
  - If the data is saturated (VDFSLV), there are two possibilities:
    - ISIF_DFCCTL[6:5] VDFCSL = 0x0: Data is simply fed through (not subtracted).
    - ISIF_DFCCTL[6:5] VDFCSL = 0x1: Horizontal interpolation ((i 2) + (i + 2)) / 2 (data is replaced

by interpolation or data is subtracted with interpolation)

The ISIF_LPFR register sets the number of half lines per frame or field: VD period = (L PFR+ 1) / 2 lines. LPFR is not used when HD and VD are inputs.

The following paragraphs concern only method 2 correction.

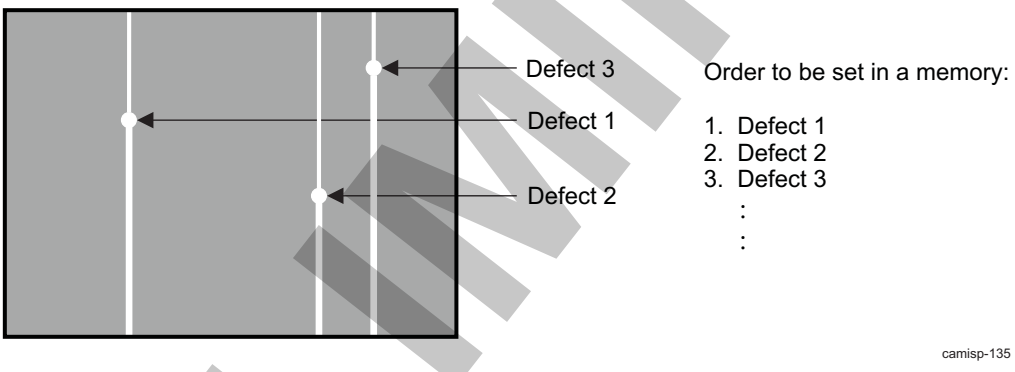
The coordinates of the defects and the defect levels to be subtracted from the data must be set to the processing listed in Table 8-453.

Table 8-453. ISS ISP ISIF Vertical Line Defect Table in Memory

Bit	Defect Information
12:0	Vertical position of the defects
25:13	Horizontal position of the defects
33:26	Defect level of the vertical line defect position (V = Vdefect)
41:34	Defect level of the pixels above the vertical line defect (V < Vdefect)
49:42	Defect level of the pixels below the vertical line defect (V > Vdefect)

The defect must be set from left to right, as shown in Figure 8-232.

Figure 8-232. ISS ISP ISIF Vertical Line Defects



Vertical line defect correction is enable by setting the ISIF_DFCCTL[4] VDFCEN bit to 1, but the procedure in Section 8.3.3.6.9.1, *ISS ISP ISIF Vertical Line Defect Table Update Procedure*, must be followed.

8.3.3.6.9.1 ISS ISP ISIF Vertical Line Defect Table Update Procedure

This procedure must be followed to write the vertical line defect table in memory.

1. ISIF_DFCMEMCTL[4] DFCMCLR = 0x1
2. Ensure that ISIF_DFCCTL[4] VDFCEN is disabled (0x0).
3. Write the V coordinate of the first defect to the ISIF_DFCMEM0[12:0] DFCMEM0 bit field.
4. Write the H coordinate of the first defect to the ISIF_DFCMEM1[12:0] DFCMEM1 bit field.
5. Set the defect level to:
   - ISIF_DFCMEM2[7:0] DFCMEM2
   - ISIF_DFCMEM3[7:0] DFCMEM3
   - ISIF_DFCMEM4[7:0] DFCMEM4
6. Set the ISIF_DFCMEMCTL[0] DFCMWR bit to 1 with the ISIF_DFCMEMCTL[2] DFCMARST bit set to 1.
7. Wait until the ISIF_DFCMEMCTL[0] DFCMWR bit is cleared.
8. Write the next data to:
   - ISIF_DFCMEM0[12:0] DFCMEM0

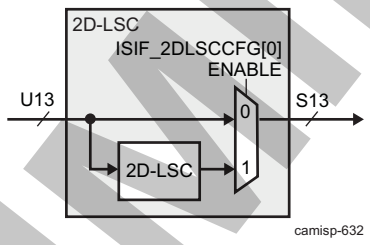
- ISIF_DFCMEM1[12:0] DFCMEM1
- ISIF_DFCMEM2[7:0] DFCMEM2
- ISIF_DFCMEM3[7:0] DFCMEM3
- ISIF_DFCMEM4[7:0] DFCMEM4

9. Set the ISIF_DFCMEMCTL[0] DFCMWR bit to 1 with the ISIF_DFCMEMCTL[2] DFCMARST bit cleared.
10. Repeat four or five times until all entries (up to eight) are written to the vertical line defect table.
11. If the defect entry is less than eight, an extra write cycle is required to fill the next table location with a certain value.
12. Clear the ISIF_DFCMEM0[12:0] DFCMEM0 bit field to all 0's, set the ISIF_DFCMEM1[12:0] DFCMEM1 to all 1's, and set the ISIF_DFCMEMCTL[0] DFCMWR bit to 1 with the ISIF_DFCMEMCTL[2] DFCMARST bit cleared.
13. Enable VDFC by setting the ISIF_DFCCTL[1] VDFCEN bit.

8.3.3.6.10 ISS ISP ISIF Lens Shading Correction Module (2D-LSC)

NOTE: For the memory access locations of the 2D-LSC table, see Section 8.3.3.8, *ISS ISP Memory Mapping*.

Figure 8-233. ISS ISP ISIF 2D-LSC Block Diagram



Lens shading correction (LSC) is useful for correcting optical artifacts that cause image brightness to decrease starting at the center of the image and going to the edges.

The LSC implements a per-pixel offset and gain adjustment in the RAW Bayer domain (2 × 2 color pattern).

- In 8-bit gain mode, when the ISIF_2DLSCCFG[6] GAIN_RANGE bit is set to 0, the offset is applied before gain multiplication.
- In 16-bit gain mode, when the ISIF_2DLSCCFG[6] GAIN_RANGE bit is set to 1, the offset function is disabled, and the loaded offset value is used to constitute the lower 8 bits of the 16-bit gain table offset table.

The offset and gains are stored in a LUT, which is stored in SDRAM and is loaded in real time. The submodule prefetches the data from SDRAM such that no underflow occurs. Underflow occurs when the offset and gain data required for the current pixel are not available.

The data stored in the LUT is downsampled; that is, there is no gain or offset per pixel. The downsampling factor is programmable. High downsampling ratios lead to a smaller LUT, lower accuracy, and lower memory bandwidth. A low downsampling ratio leads to a bigger LUT, higher accuracy, and higher memory bandwidth.

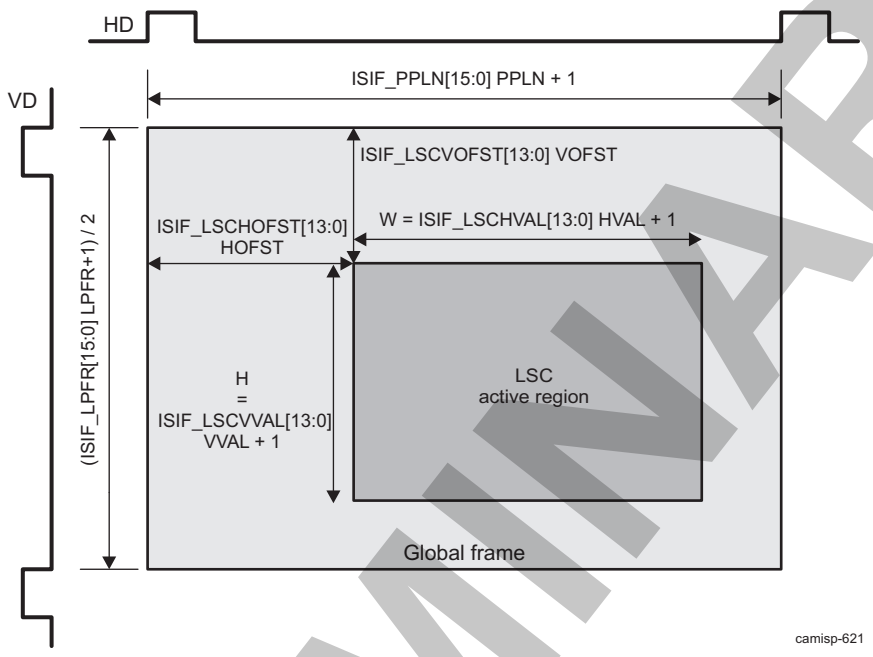
When the offset and gain values are loaded, they are upscaled to the incoming image resolution. The missing table values are computed through bilinear interpolation.

To enable the 2D-LSC module, set the ISIF_2DLSCCFG[0] ENABLE bit to 1.

8.3.3.6.10.1 ISS ISP ISIF 2D-LSC Active Region Settings

The gain and offset maps are internally upsampled to full resolution before being applied to the image. To account for all the possible cropping schemes and zoom ratios, the 2D-LSC can be configured to store a single gain map in memory that maps to sensor lens. Figure 8-234 shows the 2D-LSC active region.

Figure 8-234. ISS ISP ISIF 2D-LSC Active Region for ISIF Input Frame



8.3.3.6.10.1.1 ISS ISP ISIF 2D-LSC Gain and Offset Tables

The gain and offset map are M × N downsampled:

- M is the horizontal sampling factor.
- N is the vertical sampling factor.
- M and N are {8, 16, 32, 64, 128} independently.
- N = M. M is set in the ISIF_2DLSCCFG[14:12] GAIN_MODE_M bit field.
- N is set in the ISIF_2DLSCCFG[10:8] GAIN_MODE_N bit field.

The starting point of the preconfigured lens shading map can be modified in software to align with the ISIF input image frame. The location of the gain and offset mask data in memory is specified as follows:

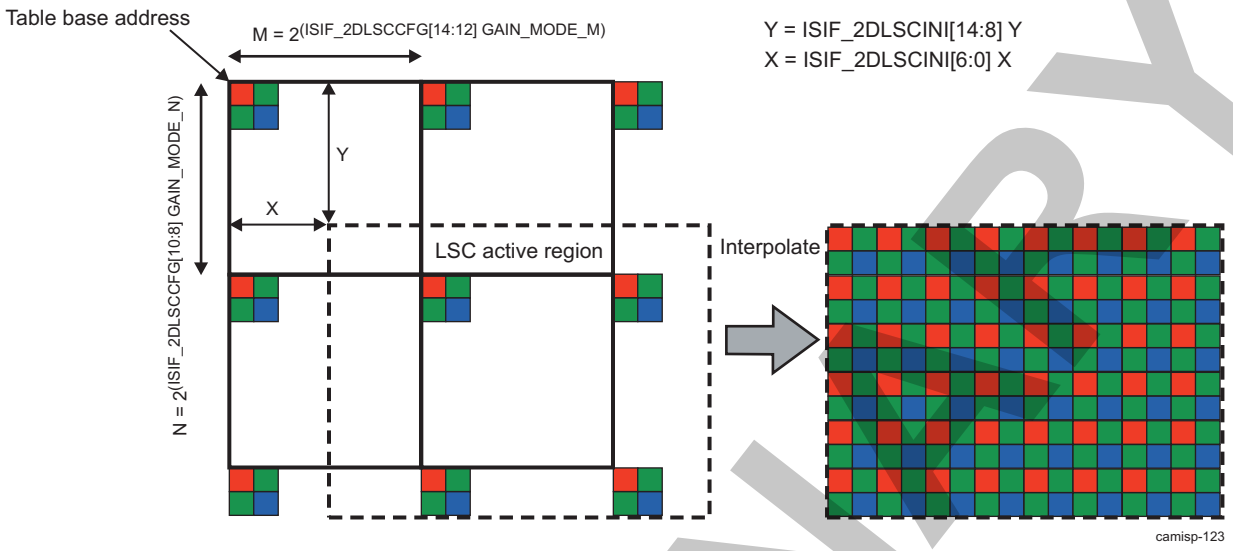
- For gain map:
  - Table base address: ISIF_2DLSCGRBU[15:0] BASE31_16 and ISIF_2DLSCGRBL[15:0] BASE15_0
- For offset map:
  - Table base address: ISIF_2DLSCORBU[15:0] BASE and ISIF_2DLSCORBL[15:0] BASE

The input address must be aligned to a 4-byte boundary.

In the full resolution case, the address is set to the beginning of the map. When the LSC active region is defined over a cropped region of the full image, the SDRAM input address can be set to the upper-left corner of the grid closest to the beginning of the active region, and the ISIF_2DLSCINI[6:0] X and ISIF_2DLSCINI[14:8] Y bit fields mark the offset into the upsampled gain and offset map where the active region begins. Figure 8-235 shows the LSC active region with respect to the gain and offset map grid. Because (X, Y) deals with the pixel phase inside a gain and offset map grid, X and Y must each be less than M and N, respectively.

Before applying the gain or offset table, the table is internally upsampled and interpolated back to full resolution via bilinear interpolation.

Figure 8-235. ISS ISP ISIF Gain and Offset Mask Upsampling via Bilinear Interpolation



The gain table format is set in the ISIF_2DLSCCFG[4:1] GAIN_FORMAT bit field. Eight-bit entries are supported in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with an optional base of 1.0 to shift the range up).

Eight-bit entries are supported in the offset map (in S8Q0 format). An optional shifting up for offsets is possible. The shift-up value is selected through the ISIF_2DLSCOFST[6:4] OFSTSFT bit field. A scaling factor for offsets is defined in the ISIF_2DLSCOFST[15:8] OFSTSF bit field.

A 16-bit gain map is supported by combining the gain map and offset map (in U16Q16, U16Q15, U16Q14, U16Q13, U16Q12, U16Q11, U16Q10, and U16Q9 format with an optional base of 1.0 to shift the range up). This function is exclusive to offset control function, and can be configured through the ISIF_2DLSCCFG[6] GAIN_RANGE bit.

The offset control in the 2D-LSC module can be enabled or disabled through the ISIF_2DLSCOFST[0] OFSTEN bit.

For an LSC active region size of W × H (the output and input are the same size), and the gain and offset maps are M × N downsampled, a table with the following values is needed:

- (ceil[(X + W) / M] + 1) x (ceil[(Y + H) / N] + 1) × 4 bytes data in external memory organized as:
  - (ceil[(InitX + W) / M] +1) lines of data
  - Each line having at least (ceil[(InitY + H) / N] + 1) × 4 data points

  Extra data at end of each line can be skipped by the line offset register parameter:
  - For gain map:
    - Line offset: ISIF_2DLSCGROF[15:0] OFFSET
  - For offset map:
    - Line offset: ISIF_2DLSCOROF[15:0] OFFSET
  - Each line offset must start at a 32-bit aligned boundary.

8.3.3.6.10.1.2 ISS ISP ISIF 2D-LSC Gain and Offset Table Upsampling

Upsampling of the pixel-by-pixel gains is performed by locating the four same-color anchors for each destination gain value and applying bilinear interpolation.

The gain and offset mask function is neutral to color pattern. The starting color of the gain and offset mask must be consistent with the starting color of the image, and can be any color. To align starting colors, the X and Y values must be even. The 2D-LSC engine upsamples each phase of the mask data as a separate plane and applies the upsampled mask to the image with the same color phasing. In other words, the red gains are interpolated with red gains, and applied to the red input pixels. The same process is done for the other three colors in the color pattern. The 2D-LSC module is designed to work with Bayer CFA data, having the R/Gr/Gb/B color pattern. For the purpose of functional description, assume red is the starting color, but any other starting color or other 2 × 2 pattern can be used by placing color gains in the appropriate order.

8.3.3.6.10.1.3 ISS ISP ISIF Application of Gain and Offset to Image Pixels

The gain value interpolated for each pixel is multiplied with a corresponding input pixel. An offset is applied before the gain. The product is rounded to the nearest integer and then clipped or saturated to the valid range of 13 bits.

The following equation describes the operation of the LSC in terms of offset and gain:

$$out[x,y] = (in[x,y] + a \times (ofst[x,y] << T)) \times gain[x,y] \quad (6)$$

- in[x, y] are the input pixels, 13 bits signed.
- ofst[x, y] are the upsampled offset points.
- T is the upshift value applied to the result of the offset interpolation points (0–5) set through the ISIF_2DLSCOFST[6:4] OFSTSFT bit field.
- a is the offset gain value in U8Q7 format set through the ISIF_2DLSCOFST[15:8] OFSTSF bit field.
- gain[x, y] are the upsampled gain points.
- out[x, y] are the resulting output pixels, 13 bits signed.

8.3.3.6.10.1.4 ISS ISP ISIF Enabling and Disabling the 2D-LSC Module

LSC operates on a single frame or continuously, depending on the firmware programming.

Upon power-on reset (POR), the 2D-LSC module is disabled and input pixels are copied to the output, thus bypassing any shading operation.

When enabling or disabling the 2D-LSC, caution must be taken on the timing of register modifications. To avoid causing a prefetch error or other unexpected behavior, the following safeguards must be implemented:

1. While configuring the 2D-LSC registers, the input clock into the ISIF should be toggling.
2. All of the 2D-LSC registers must be configured appropriately before enabling the ISIF_2DLSCCFG[0] ENABLE bit.
3. After setting the ENABLE bit to 1, the hardware immediately begins fetching the first two rows of gain and offset data entries from external memory. When this is complete, the ISIF_2DLSCIRQST[2] PREFETCH_COMPETED status flag is set.

NOTE: If the ENABLE bit is disabled before the ISIF_2DLSCIRQST[3] SOF status flag is set, the ISIF_2DLSCIRQST[1] PREFETCH_ERROR flag is set and the state of the 2D-LSC module may lead to unexpected errors. Therefore, the ENABLE bit must not be disabled until after the ISIF_2DLSCIRQST[3] SOF status flag is set.

4. Appropriate gains and offsets are applied to the image pixels. Pixels outside the LSC active region are passed through unaltered. When the 2D-LSC operation on the active region completes, the ISIF_2DLSCIRQST[0] DONE status flag is set.
5. At this point:
   - If the ENABLE bit is still set to 1, the hardware immediately begins to prefetch the gain and offset data entries for the next frame and waits for the active region of the next frame to arrive.
   - If the ENABLE bit is set to 0, it stops LSC operation once the active region is passed, and goes into idle mode until the ENABLE bit is reset to 1.

NOTE: To provide a mechanism for firmware to recover from the LSC module waiting indefinitely for the input image, if the LSC_ENABLE bit is set to 0 after it has started gain/offset map prefetching, but before the LSC gets to the next active region, the LSC operation is aborted and turned idle, and any prefetched gain/offset entries are discarded. This can happen before or after the next start-of-frame.

NOTE: Therefore, because of the constraints set in point 3, the ENABLE bit must be disabled only after the ISIF_2DLSCIRQST[3] SOF status flag is set and before the ISIF_2DLSCIRQST[0] DONE status flag is set for that same frame.

It is suggested that when the 2D-LSC or the whole ISIF must be disabled for switching modes, the ISIF_2DLSCIRQST[3] SOF interrupt be enabled so that software knows when it is safe to disable the 2D-LSC. Then the ISIF can be disabled after the ISIF_2DLSCIRQST[0] DONE status signal is set for that frame.

NOTE: The LSC_ENABLE bit, once set to 1, must not be cleared until at least one vpi_clk clock cycle after start-of-frame, to ensure correct processing.

8.3.3.6.10.1.5 ISS ISP ISIF 2D-LSC Events and Status Checking

The 2D-LSC module can generate events on a single interrupt line. These events are further remapped at the ISP level in the ISP5_IRQENABLE_SET_i[3] ISIF_INT_3 bit, where i = 0 to 3.

Four 2D-LSC events can be generated:

- DONE: LSC done. This event triggers when the LSC submodules transition from ACTIVE state to IDLE state.
- PREFETCH_ERROR: Gain table prefetch error. This event triggers when the tables stored in SDRAM are read too slowly. After this event is asserted, the LSC disables the LSC computation until the beginning of the next frame.
- PREFETCH_COMPLETE: Gain table prefetch complete. This event triggers when data prefetching from SDRAM completes. Data prefetching must complete by the time the first pixel of a frame arrives. The event triggers when the buffer contains three full rows of data.
- SOF: This event signals the start of the LSC valid region. The LSC configuration registers for the next frame can be updated after the LSC SOF triggers.

The ISIF_2DLSCIRQEN register can be configured to select which events are masked and which are propagated to the LSC interrupt signal. The ISIF_2DLSCIRQST register can be read and cleared to identify which events have occurred.

In addition, the 2D-LSC module provides the following status bit:

- BUSY: This indicates that LSC has entered the active region vertically. This bit remains on during horizontal blanking, and turns off only after the entire active region of the current frame is processed.

8.3.3.6.10.1.6 ISS ISP ISIF Supported On-the-Fly 2D-LSC Configurations

The 2D-LSC prefetch memory is equal to 2 × 1536 × 32 bits. This memory is sized to fetch three lines of 8-bit gain and 8-bit offset × four color components per paxel. Given an image sensor of horizontal resolution H, there are floor [(H / ISIF_2DLSCCFG[14:12] GAIN_MODE_M) + 1] paxels per line, where M is the horizontal LSC paxel size.

Table 8-454 shows the LSC horizontal paxel size, which can be supported for different image sensor resolutions. When M = 8, some resolutions cannot be supported on the fly (orange-shaded cells in the table); the way to process such large images is to use vertical frame division.

Table 8-454. ISS ISP ISIF Supported On-the-Fly LSC Configurations

MPix	Aspect Ratio		Line Size	Horizontal LSC Paxel Size: M = 2[ISIF_2DLSCCFG[14:12] GAIN_MODE_M]				
				8	16	32	64	128
Maximum	–	–	5376	2019	1011	507	255	129
16	16	9	5333	2003	1003	503	253	128
16	4	3	4619	1735	869	436	220	111
16	3	2	4899	1840	922	462	233	118
12	16	9	4619	1735	869	436	220	111
12	4	3	4000	1503	753	378	191	97

8	4	3	3266	1228	615	309	156	80
8	3	2	3464	1302	653	328	165	84

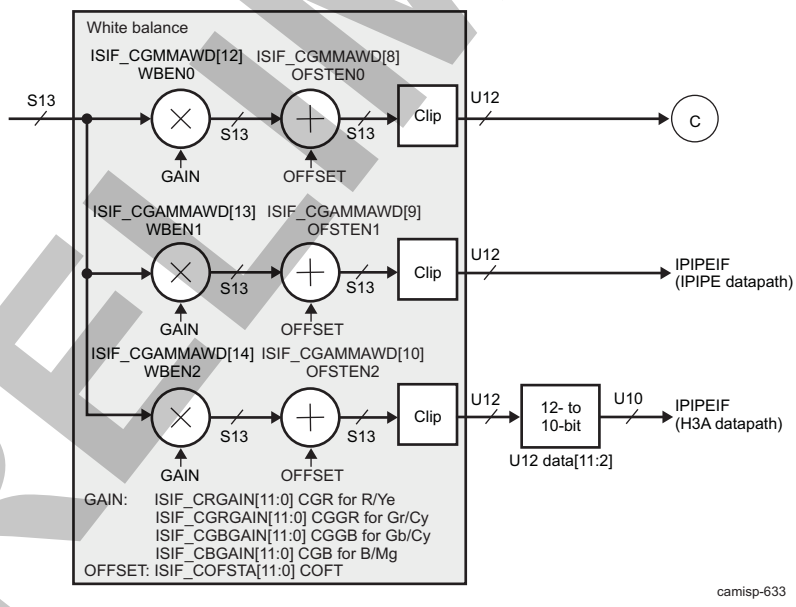
8.3.3.6.10.1.7 ISS ISP ISIF Bandwidth Requirements on BL Read Port

For details, see Section 8.3.3.6.18.2, *ISS ISP ISIF Read Port*.

8.3.3.6.11 ISS ISP ISIF White Balance

Figure 8-236 shows the white balance block diagram.

Figure 8-236. ISS ISP ISIF White Balance Block Diagram



Color pattern settings are set through the ISIF_CCOLP register. Moreover, through this register the pixel position from 0 to 3 can be set to the needed Bayer universal camera filter color pattern (RGB/CYGM).

The CFA pattern can be in two modes, stripe or mosaic, and is set through the ISIF_CGAMMAWD[5] CFAP bit.

There are color-dependent gain controls for the three outputs:

- BL output
- IPIPEIF (IPIPE path) output

- IPIPEIF (H3A path) output

The gain applied to each data is selected according to the pixel position and the color pattern settings. Gain factors are common for the three data paths. Gain is in U11Q9 format, which ranges from 0 to 3 + 511/512. The gain factor is set through the following registers:

- R/Ye gain: ISIF_CRGAIN[11:0] CGR
- Gr/Cy gain: ISIF_CGRGAIN[11:0] CGGR
- Gb/Cy gain: ISIF_CGBGAIN[11:0] CGGB
- B/Mg gain: ISIF_CBGAIN[11:0] CGB

Gain control can be enabled or disabled individually for each path.

- Enable or disable gain for the BL path: ISIF_CGAMMAWD[12] WBEN0
- Enable or disable gain for the IPIPEIF (IPIPE) path: ISIF_CGAMMAWD[13] WBEN1
- Enable or disable gain for the IPIPEIF (H3A) path: ISIF_CGAMMAWD[14] WBEN2

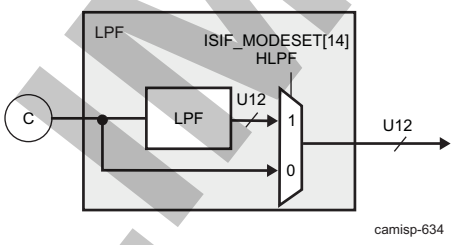
After the gain control, a single offset value can be added to each path individually. This offset is common for the three paths and is set through the ISIF_COFSTA[11:0] COFT bit field. The offset value is U12, which ranges from 0 to 4095. Data (S13) are then truncated to U12.

- Enable or disable offset for the BL path: ISIF_CGAMMAWD[8] OFSTEN0
- Enable or disable offset for the IPIPEIF (IPIPE) path: ISIF_CGAMMAWD[9] OFSTEN1
- Enable or disable offset for the IPIPEIF (H3A) path: ISIF_CGAMMAWD[10] OFSTEN2

8.3.3.6.12 ISS ISP ISIF Low-Pass Filter

Figure 8-237 shows the low-pass filter (LPF) block diagram.

Figure 8-237. ISS ISP ISIF Low-Pass Filter Block Diagram



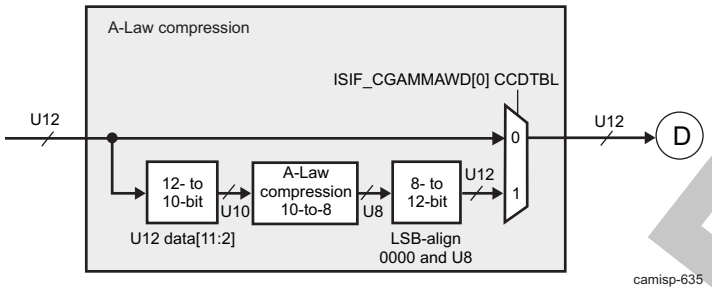
An optional horizontal low-pass anti-aliasing filter (LPF) can be applied (the ISIF_MODESET[14] HLPF bit) after reframing. The LPF consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled (ISIF_MODESET[14] HLPF = 0x0).

8.3.3.6.13 ISS ISP ISIF A-Law Compression

Figure 8-238 shows the A-Law compression block diagram.

Figure 8-238. ISS ISP ISIF A-Law Compression Block Diagram



An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (the ISIF_CGAMMAWD[0] CCDTBL bit) as the final processing stage. Using this compression causes the data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (the ISIF_CGAMMAWD[4:1] GWDI bit field).

The IPIPEIF module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: Do not use A-Law compression (ISIF_CGAMMAWD[0] CCDTBL = 0) with YUV data.

Figure 8-239 shows the A-Law table diagram, and Figure 8-240 shows the A-Law table values.

Figure 8-239. ISS ISP ISIF A-Law Table Diagram

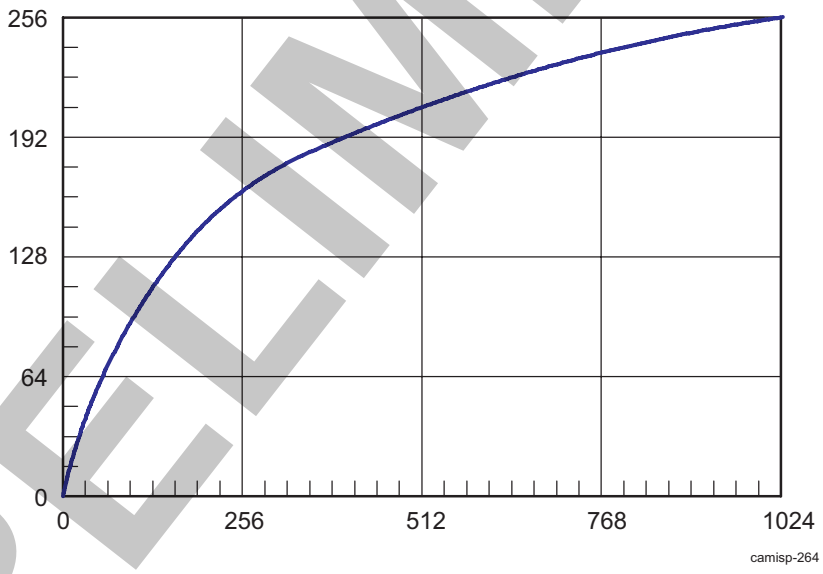


Figure 8-240. ISS ISP ISIF A-Law Table Values

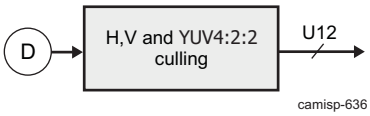
8.3.3.6.14 ISS ISP ISIF Culling

Figure 8-241 shows the culling block diagram.

Figure 8-241. ISS ISP ISIF Culling Block Diagram



The culling block performs a programmable decimation function for horizontal, vertical, and YUV4:2:2 data directions. The horizontal and vertical decimation of image data can be controlled by two registers.

The horizontal culling operation allows selected pixel data to be culled (deleted) from a line. The ISIF_CULH register specifies the horizontal culling pattern for even and odd lines:

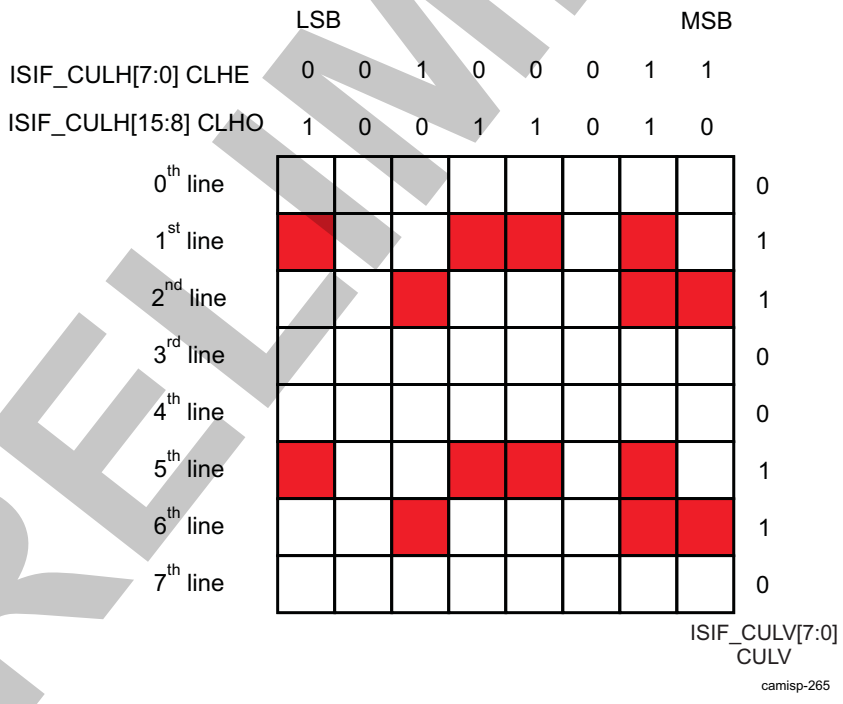
- Even lines: ISIF_CULH[15:8] CLHE
- Odd lines: ISIF_CULH[16:0] CLHO

The vertical culling operation allows selected lines to be culled from a frame. The ISIF_CULV register specifies the pattern for the vertical direction. The LSBs of CULV represent the top line of the CCD; the MSB is the seventh line.

Figure 8-242 is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, CULH = 0x59C4 and CULV = 0x0066.

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV4:2:2 output format.

Figure 8-242. ISS ISP ISIF Example for Decimation Pattern



8.3.3.6.15 ISS ISP ISIF 12-to-8-Bit DPCM Compression Block

In the ISIF, a DPCM compression block is between the culling module and the storage formatter module. This block can compress 12-bit image data to 8 bits for bandwidth reduction in transmission between the ISIF and SDRAM. An 8-to-12-bit DPCM decoder at the IPIPEIF decompresses data for IPIPE processing.

Two different predictors are used for the compression system. The first predictor is simple (simple predictor), and the second predictor is slightly more complex (advanced predictor). Because the advanced predictor gives a slightly better prediction for the pixel value, the image quality can be improved using it. Because the simple predictor is very basic, the processing power and memory requirements are reduced using it, when the image quality is already sufficiently high.

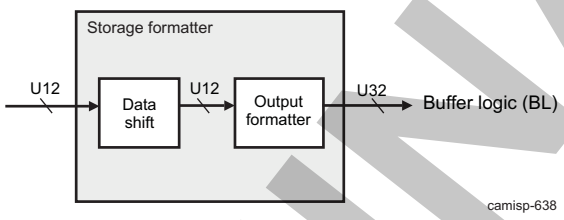
- Advanced predictor: This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- This predictor uses four previous pixel values when the prediction value is evaluated. This means that the other color component values are also used when the prediction value is defined.

The function is controlled from the ISIF_MISC[12] DPCMEN and ISIF_MISC[13] DPCMPRE bits.

8.3.3.6.16 ISP ISIF Storage Formatter

Figure 8-243 shows the storage formatter block diagram.

Figure 8-243. ISS ISP ISIF Storage Formatter Block Diagram



Data are stored to the lower bits of a 16-bit SDRAM word, or can be 8- or 12-bit packed. The ISIF_HSIZE[11:0] HSIZE bit field can specify the memory address offsets between lines of memory (offset in 32-byte units). If set, the ISIF_HSIZE[12] ADCR bit can decrement the memory address line and the line can be horizontally flipped in memory.

In case of RAW data, a data shift module is used: data to be stored can be right-shifted according to the value set at the ISIF_MODESET[10:8] CCDW bit field, as described in Table 8-455.

Table 8-455. ISS ISP ISIF RAW Data Shifting

ISIF_MODESET[10:8] CCDW	Output Format	
	MSB	LSB
000	0000 &U12 data[11:0]	
001	00000 &U12 data[11:1]	
010	000000 &U12 data[11:2]	
011	0000000 &U12 data[11:3]	
100	00000000 &U12 data[11:4]	

Table 8-456 shows the format where data are stored to the lower bits of a 16-bit word and the format where data are packed to 8 bits. The unused bits are filled with zeros.

Table 8-456. ISS ISP ISIF SDRAM Data Format

	Upper Word				Lower Word			
	MSB(31)			LSB(16)	MSB(15)			LSB(0)
12 bit	0	Pixel 1			0	Pixel 0		
11 bit	0	Pixel 1			0	Pixel 0		
10 bit	0	Pixel 1			0	Pixel 0		
9 bit	0	Pixel 1			0	Pixel 0		
8 bit	0	Pixel 1			0	Pixel 0		
8-bit packed	Pixel 3	Pixel 2			Pixel 1	Pixel 0		

Table 8-457 shows the format where data are packed to 12 bits.

Table 8-457. ISS ISP ISIF SDRAM Data Format for 12-bit Packed

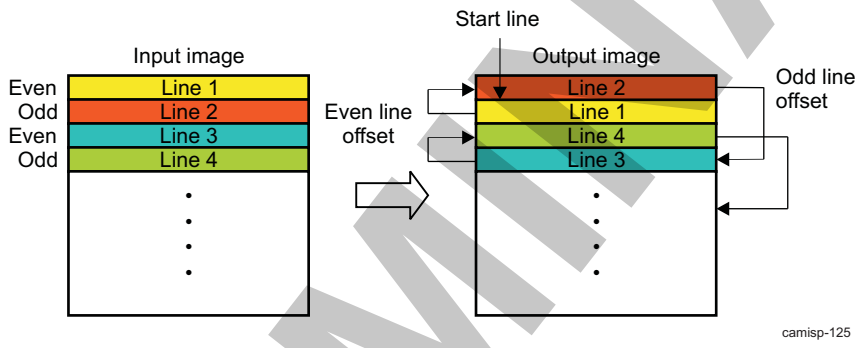
	Upper Word				Lower Word			
	MSB(31)			LSB(16)	MSB(15)			LSB(0)
12 bit	Pixel2[7:0]	Pixel1			Pixel 0			
	Pixel5[3:0]	Pixel4			Pixel3			Pixel2[11:8]
	Pixel7		Pixel6			Pixel5[11:4]		

In case of YUV, YUV data is stored in memory in packed YUV4:2:2 mode, using 2 pixels per 32 bits, as shown in Table 8-458.

The output formatter can configure to any image format by using the SDRAM line offset register and offset control registers. Figure 8-244 shows how to construct a frame format in SDRAM. The ISIF_CADU[10:0] CADU bit field specifies the memory destination (upper 11 bits) to SDRAM (the address is the value of the set bit multiplied by 32 bytes). On the other hand, the ISIF_CADL[15:0] CADL bit field sets the memory destination to SDRAM (lower 16 bits) (the address is the value of the set bit multiplied by 32 bytes).

- ISIF_SPH defines the first pixel in a line to be stored to memory.
- ISIF_LNH defines the number of pixels in an line to be stored to memory.
- ISIF_LNV defines the number of lines to be stored to memory.
- ISIF_SLV0 sets line at which data output to SDRAM will begin.
- ISIF_SLV1 sets line at which data output to SDRAM will begin, measured from the start of VD.
- ISIF_SDOFST, ISIF_MODESET[15] MDFS, and ISIF_MODESET[4] FIPOL sets the setting for line FID polarity and the offset of even/odd lines in SDRAM.

Figure 8-244. ISS ISP ISIF Frame Image Format Conversion



8.3.3.6.17 ISS ISP ISIF YCbCr Signal Processing

The ISIF accepts 4:2:2 sampled YCbCr input data. The Luma and color difference signals are 8 bits each, scaled 0 to 255. The color difference signals are multiplexed into one 8-bit bus beginning with a Cb sample. The Y and CbCr buses can be input parallel (16-bit mode) or time-multiplexed and input as a single bus (8-bit mode).

The 16- or 8-bit YCbCr data is stored in SDRAM as 4:2:2 format. Table 8-458 lists the data format in SDRAM. Y data typically has a range of 16 to 235; however, it is possible to subtract a DC value from the Y signal.

Table 8-458. ISS ISP ISIF Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

8.3.3.6.18 ISS ISP ISIF Expected Bandwidth on BL Ports

The ISIF has a write port and a read port connected to the BL. This section summarizes the expected bandwidth on these ports.

8.3.3.6.18.1 ISS ISP ISIF Write Port

The write port is used to write pixels to memory after the data have passed through the storage formatter. Data storage to SDRAM is controlled by the ISIF_SYNCEN[1] DWEN bit. The ISIF allows writing the data as 16, 12, and 8 bpp. The bit width is controlled by the ISIF_CCDCFG[1:0] SDRPACK bit field.

The write port generates a burst of 32 bytes on the MTC interface. The delay between consecutive bursts is proportional to the input pixel clock. Hence, the write port does not request peak bandwidth traffic.

Table 8-459 lists the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3_MAIN clock is 200 MHz.

Table 8-459. ISP ISIF ISIF Module: Write Port Bandwidth

Pixel Clock	Maximum Bandwidth 2 Bytes/s Pixel MB/s	Expected Delay Between MTC Requests
200	400	16 cycles = 80 ns
100	200	32 cycles = 160 ns
10	20	320 cycles = 1600 ns

8.3.3.6.18.2 ISS ISP ISIF Read Port

The read port is used to read gain and offset data from SDRAM required for the LSC computation. When LSC is enabled, 8-bit gain values are read and 8-bit offset values can optionally also be read. The LSC gain computation can be enabled or disabled by setting the ISIF_2DLSCCFG[0] ENABLE bit. The LSC offset computation can be enabled by setting the ISIF_2DLSCOFST[0] OFSTEN bit.

LSC fetches four 8-bit gain values per paxel and optionally four 8-bit offset values per paxel. This is a maximum 8 bytes per paxel.

The bandwidth that is generated by the LSC module is also proportional to the paxel size. The paxel size is set up by the ISIF_2DLSCCFG[14:12] GAIN_MODE_M and ISIF_2DLSCCFG[10:8] GAIN_MODE_N bit fields. The possible values are 8, 16, 32, 64, and 128. Smaller values lead to higher memory bandwidth requirements. Hence, the worst case is achieved by setting an 8 × 8 paxel size.

When LSC is enabled it automatically prefetches two lines of gain values and two lines of offset values (if this is enabled). When the first VD comes, it again requests one line of gain values and one line of offset values (if this is enabled). Then, it again fetches one line of gain values and one line of offset values (if this is enabled) after ISIF_2DLSCCFG[10:8] GAIN_MODE_N lines. It continues to do so until the last row of paxels. For the last row of paxels, it fetch two lines of gain values and two lines of offset values (if this is enabled), which are used for the following frame.

By default, LSC creates peak bandwidth requirements. To avoid this, the MTC bandwidth limiter must be used to space the request over time.

The MTC bandwidth limiter must be used to smooth the bandwidth requirements of the LSC module. The MTC bandwidth limiter can be set with the ISP5_BL_MTC_1.ISIF_R register.

The principle is that instead of reading the gain and offset data as fast as possible, use the time that it takes for ISIF_2DLSCCFG[10:8] GAIN_MODE_N lines to pass through the ISP to read the data.

Table 8-460 gives the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3_MAIN clock at 200 MHz.

Table 8-460. ISS ISP ISIF Read Port Bandwidth

Pixel Clock	Max Bandwidth MB/s	Expected Delay Between MTC Requests
200	25.07	255 cycles = 1275 ns
100	12.5	510 cycles = 2550 ns
10	1.25	5103 cycles = 2515 ns

When the bandwidth limiter is used, ensure that there is enough time for the data prefetching.

- LSC must be enabled at least 2 × ISIF_2DLSCCFG[10:8] GAIN_MODE_N lines before the first VD.
- There must be at least ISIF_2DLSCCFG[10:8] GAIN_MODE_N lines of blanking. If there is not enough blanking, multiply the bandwidth requirement by 2 (that is, ensure two lines of gain and offset data can be fetched within the time of ISIF_2DLSCCFG[10:8] GAIN_MODE_N lines.

8.3.3.6.19 ISS ISP ISIF Events and Status Checking

The ISIF module can generate four different interrupts: VDINT0, VDINT1, VDINT2, and 2DLSCINT. The ISIF_SYNCEN[0] SYEN bit must be enabled to receive any of the ISIF interrupts.

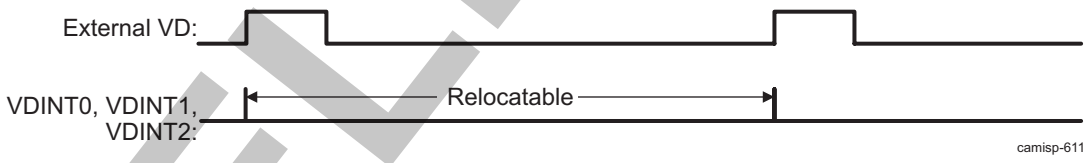
8.3.3.6.19.1 ISS ISP ISIF VDINT0, VDINT1, and VDINT2 Interrupts

As shown in Figure 8-245, the VDINT0, VDINT1, and VDINT2 interrupts occur relative to the VD pulse. The trigger timing is selected by using the ISIF_MODESET[2] VDPOL bit setting. VDINT0, VDINT1, and VDINT2 occur after receiving the number of horizontal lines (HD pulse signals) set in the ISIF_VDINT0[14:0] CDV0, ISIF_VDINT1[14:0] CDV1, and ISIF_VDINT2[14:0] CDV2 register fields, respectively.

NOTE: In the case of BT.656 input mode, there is a VD at the beginning of each field. Therefore, there are two interrupts for each frame (that is, one for each field).

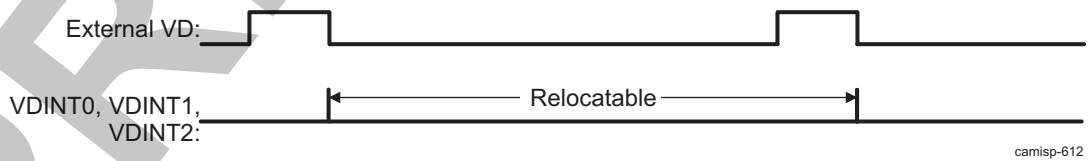
If the ISIF_MODESET[2] VDPOL bit is set to 0, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the rising edge of the external VD.

Figure 8-245. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 0



If the ISIF_MODESET[2] VDPOL bit is set to 1, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the falling edge of the external VD.

Figure 8-246. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 1



8.3.3.6.19.2 ISS ISP ISIF 2DLSCINT Interrupt

For more information, see Section 8.3.3.6.10.1.5, *ISS ISP ISIF 2D-LSC Events and Status Checking*.

8.3.3.6.19.3 ISS ISP ISIF Status Checking

The ISIF_MODESET[15] MDFS bit is set when the field status is on an even field, and it is cleared when the field status is on an odd field.

The 2D-LSC has a register that monitors the status of the LSC. For more information, see Section 8.3.3.6.10.1.5, ISS ISP ISIF 2D-LSC Events and Status Checking.

8.3.3.7 ISS ISP BL Functional Description

8.3.3.7.1 ISS ISP BL Overview

The BL module arbitrates and merges the memory requests of the ISP master module. The BL module also generates interrupts upon frame completion for the following modules. The interrupt generation is delayed until the transfer completes (acknowledge signal is returned). The following interrupts are delayed by the BL module:

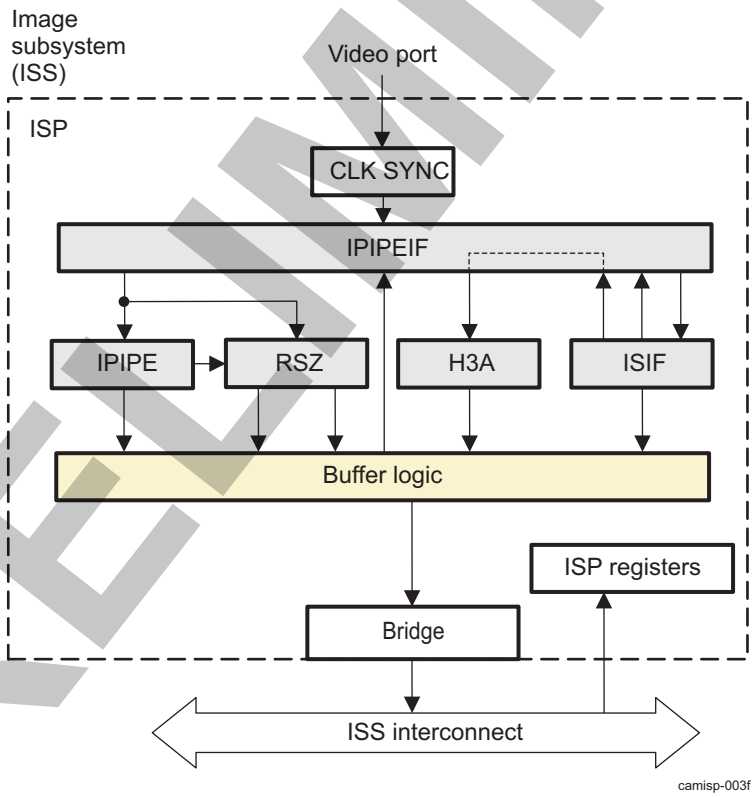
- RSZ module resizer RSZ-A EOF
- RSZ module resizer RSZ-B EOF
- H3A module EOF
- IPIPE module EOF

The BL uses two different types of interfaces:

- MTC protocol is used between the ISP modules and the BL.
- VBUSM is use on the BL master port interface.

Figure 8-247 show the BL module connections to other submodules of the ISP.

Figure 8-247. ISS ISP BL High-Level Diagram



8.3.3.7.2 ISS ISP BL Functional Description

The BL merges the memory requests of the ISP master module to memory (read/write). The BL interfaces with all the ISP modules through a 32-bit-wide bus.

The ISP modules make memory requests of 32 bytes. Additional signals, SOF for read and EOF for write, are included to deal with boundary conditions in frame transitions.

The BL arbitration is divided into two parts: a bus hog and a fixed priority arbitration. Bus hog refers to the property of the buffer logic that gives higher priority to the module that last sent or received data. RSZ module MTC write port 0 and RSZ module MTC write port 1 are excluded from the bus hog.

The buffer logic is to be programmed to maximize the memory bandwidth: it makes maximum burst requests of 128 bytes (8 × 128 bits) for reads and writes. The BL can generate burst sizes of 2 × 128, 4 × 128, 6 × 128, and 8 × 128 bits.

NOTE: The ISP interface supports burst sizes of only 1, 2, 4, and 8 × 128 bits. If the BL generates a 6 × 128-bit request, it is divided into a 4 × 128-bit request, followed by a 2 × 128-bit request.

To use the memory bandwidth efficiently, the BL interfaces with the memory through a high-bandwidth bus (128 bits wide).

The BL handles memory requests for the following modules:

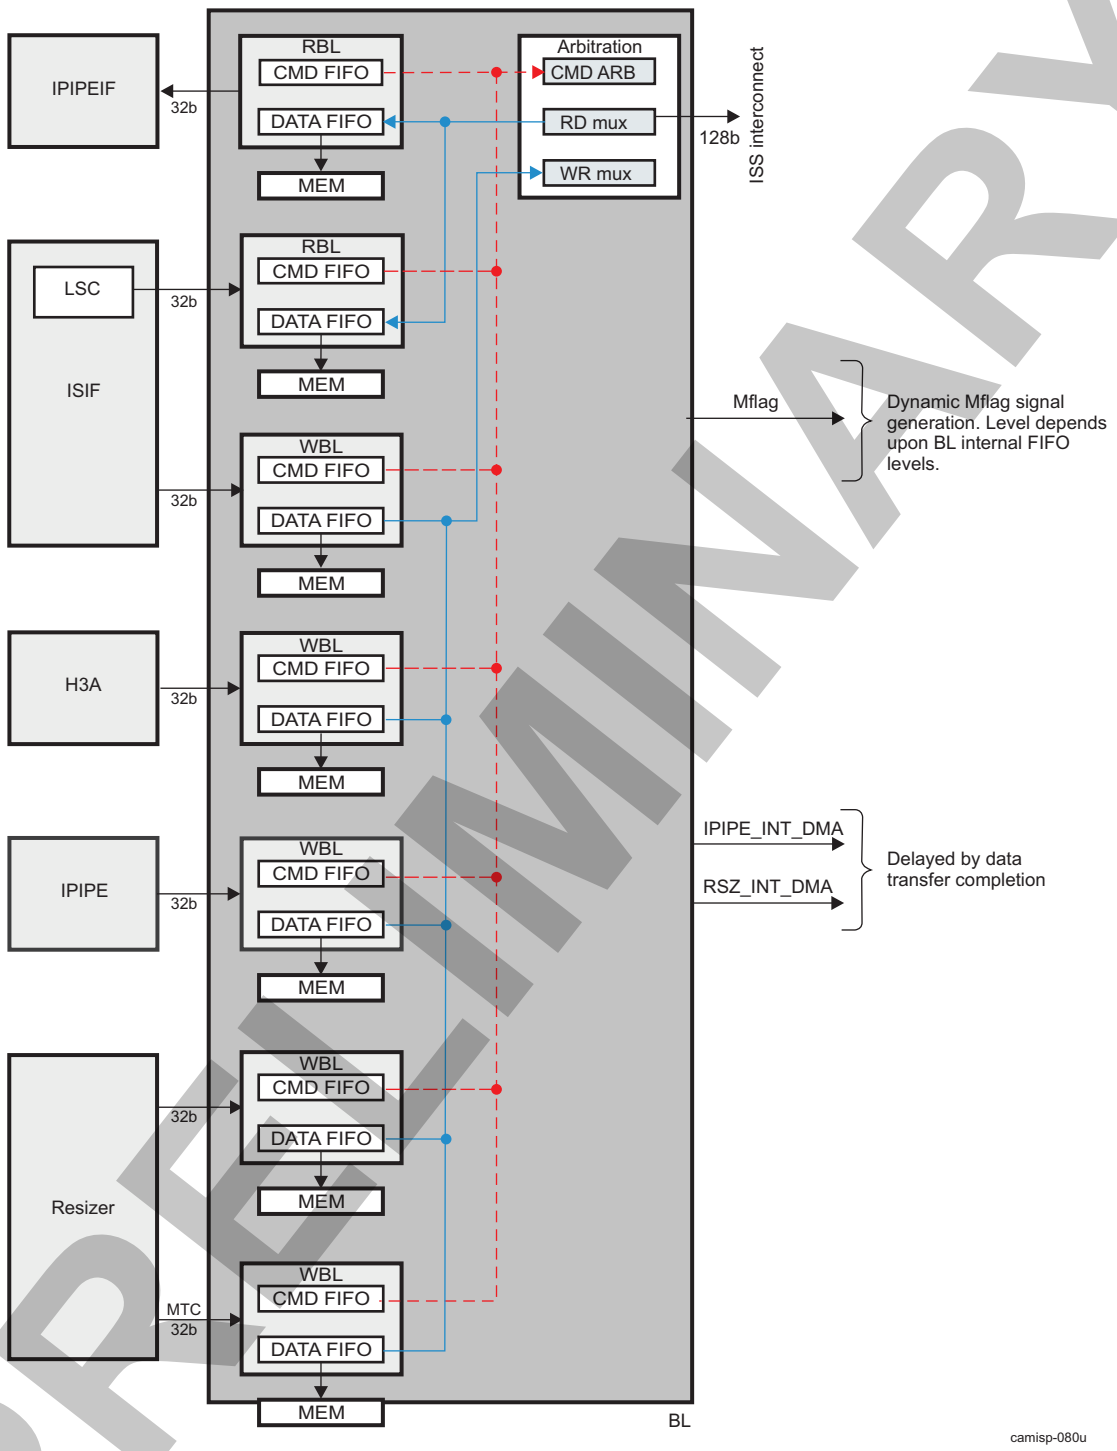
- IPIPEIF module read port
- ISIF-LSC module read port
- ISIF module write port
- IPIPE-BOXCAR module write port
- H3A module write port
- RSZ module write port 0
- RSZ module write port 1

From a use case point of view, the following sharing and priority arrangement is used. All reads have higher priority than writes; for reads: IPIPEIF > ISIF-LSC, and for writes: ISIF > IPIPE-BOXCAR > RSZ 0 > RSZ 1 > H3A.

NOTE: The BL can generate a static or a dynamic MFlag signal. The MFlag signal is used by the ISS arbitration to consider the urgency of the requests coming from the ISP. The dynamic MFlag feature is enabled from the ISP5_CTRL[21] MFLAG bit.

Figure 8-248 shows the BL top-level block diagram. The figure highlights the two clock domains that are used.

Figure 8-248. ISS ISP BL Block Diagram



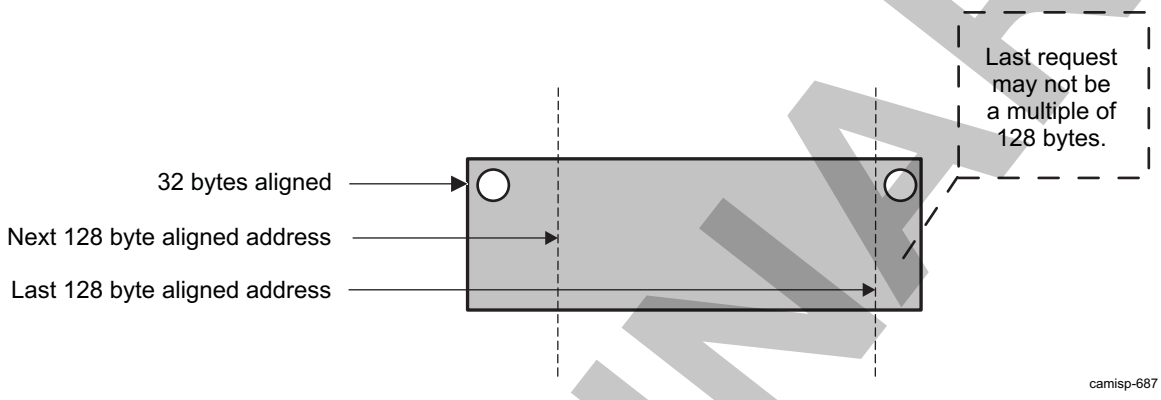
NOTE: The BL module has no registers. The configurations come from the top level of the ISP. See Table 8-501 for register details.

8.3.3.7.3 ISS ISP BL Address Alignment

The BL module ensures maximum memory efficiency by realigning data to a 128-byte address boundary. In all cases, the BL accesses are 32-byte-aligned: address [4:0] is always 0.

This is required when the input address is a multiple of 32 bytes, not 128 bytes. The BL issues a nonaligned burst until it reaches a 128-byte boundary, and then keeps making a 128-byte request until the end of the line. Eventually, although the last burst in a line may not be a multiple of 128 bytes, it will always be a multiple of 32 bytes, as shown in Figure 8-249.

Figure 8-249. ISS ISP BL Address Alignment



8.3.3.7.4 ISS ISP BL Out-of-Order Responses

BL supports out-of-order responses. The out-of-order response is handled by having up to 16 outstanding CIDs (reads and writes). The maximum number of outstanding CIDs is set up by the ISP5_CTRL[7:4] VBUSM_CIDS bit field. There is one outstanding request per CID.

If any of the CIDs are not outstanding, a command is accepted from the highest prioritized buffer with a request. The CID availability is cleared when status complete is received. The outstanding commands can be all reads or all writes or any combination. The CID that is allocated is the lowest number of the 16 that are available when the command is accepted. As soon as a CID is released it is used if a command is available.

The VBUSM2OCP module transforms the VBUMS CIDs into OCP MFlag signals. There can be only one outstanding CID per tag. It is not authorized to make a new request on a tag which is already waiting for a response.

8.3.3.7.5 ISS ISP BL Stalling

The BL can stall the requests from the initiator modules for reads and writes

8.3.3.7.5.1 ISS ISP BL Stalling Write Requests

One reason for the BL to stall write requests is that because back pressure usually exists on the system memory and requests cannot be issued as fast as required. In that case the BL must stall requests from the initiator modules. The BL module cannot know whether stalling the request will lead to an initiator overflow or not. The RSZ module can support back pressure from the BL module when it is configured in bypass mode. The input buffer memory can be used to store data from the IPIPE and IPIPEIF modules. If the RSZ input buffer overflows, an interrupt is issued.

8.3.3.7.5.2 ISS ISP BL Stalling Read Requests

The BL may also stall read requests from the ISIF-LSC and IPIPEIF modules. When data comes from an image sensor, there is no way to stop the sensor. If the read request is stalled too long, the LSC module may eventually underflow. When the IPIPEIF reads all its data from memory, the IPIPEIF stalls transfers to successive modules by masking the clock.

8.3.3.7.6 ISS ISP BL Dynamic and Static MFlag Generation

NOTE: The following applies when ISP5_CTRL[21] MFLAG = 1. The MFlag value is static.

The BL outputs cpriority[2:0] and cepriority[2:0] signals on its VBUS master port interface. On the VBUSM side, these signals are aligned with the request (creq). Both values actually repeat register input signals. The lower value (0) corresponds to the higher priority.

The MFlag signal does not need to be aligned with the request. The signal can change value anytime.

In the ISP VBUSM2 interface bridge, the cepriority signal is ignored and only the cpriority signal is used. Because the priority value is set up by a register setting, the value is not dynamically modified. Table 8-461 shows how the cpriority values are mapped to the interface MFlag signal, which is present on the ISP master interface and set in the ISP5_CTRL[3:1] VBUSM_CPRIORITY bit field.

Table 8-461. ISS ISP BL cpriority to MFlag With ISP5_CTRL[21] MFLAG = 1

MFlag[1:0]	Description
00	Normal priority cpriority[2:0] = 4, 5, 6, 7
01	Medium priority cpriority[2:0] = 2, 3
10	Reserved
11	High priority cpriority[2:0] = 0, 1

NOTE: The following applies when the ISP5_CTRL[21] MFLAG = 0. The MFlag value is dynamic.

This feature is enabled at reset. The purpose for dynamic MFlag generation is to monitor the FIFO levels. Thresholds are used to increase or decrease the MFlag values. There are different implementations for read and write requestors.

An individual MFlag value is generated for each FIFO and then ORed altogether and exported at the BL boundary. The MFlag signal generation does not affect the BL arbitration scheme.

- Writes: To prevent overflows in the BL, dynamic MFlag signal generation gives higher priority to FIFOs that are almost full:
  - Low FIFO level = 50 percent
  - High FIFO level = 75 percent
  - FIFOs with more than 75 percent fill level have high priority: MFlag = 11
  - FIFOs between 50 and 75 percent fill level have medium priority: MFlag = 01
  - FIFOs below 50 percent fill level have low priority: MFlag = 00

Table 8-462 gives the low- and high-level priority thresholds for write initiators.

Table 8-462. ISS ISP BL MFlag Write Low- and High-Level Priority Thresholds

	ISIF	H3A	IPIPE	RSZ
Access type	Write	Write	Write	Write
Buffer size	64 × 128	64 × 128	48 × 128	64 × 136
50% low level	32 × 128	32 × 128	24 × 128	32 × 136
75% high level	48 × 128	48 × 128	36 × 128	48 × 128

- Reads: The dynamic MFlag signal generation depends on the reserved data units in the initiator data FIFO. The reserved data units correspond to read commands waiting to be sent on the interface bus, plus the read commands that have been sent on the interface bus and for which data responses have not yet arrived.
- The total FIFO size in bytes can be expressed as reserved data units (bytes) + data bytes stored (bytes) + empty space (bytes). By definition, empty space is lower than a burst size (128 bytes).
  - Low FIFO level = 25 percent

– High FIFO level = 50 percent
– Data bytes stored + empty space (bytes) = 50 percent of FIFO size: MFlag = 00
– Data bytes stored + empty space (bytes) = 50 percent of FIFO size: MFlag = 01
– Data bytes stored + empty space (bytes) = 25 percent of FIFO size: MFlag = 11

Table 8-463 gives the low- and high-level priority thresholds for read initiators

Table 8-463. ISS ISP BL MFlag Read Low- and High-Level Priority Thresholds

	IPIPEIF	ISIF-LSC
Access type	Read	Read
Buffer size	64 × 128	32 × 128
25% buffer size	16 × 128	8 × 128
50% buffer size	32 × 128	16 × 128

8.3.3.7.7 ISS ISP BL VBUSM2OCP Last Beat Command Delay

The VBUSM2OCP module bridge implements the following function to work around a limitation of the BL module, which does not send back-to-back requests to the ISS, thereby leading to possible situations where the ISP loses arbitration at the ISS level.

To fully benefit from dynamic MFlag generation (see Section 8.3.3.7.6, *ISS ISP BL Dynamic and Static MFlag Generation*), the following function is present in the VBUSM2OCP module bridge:

- The delay occurs only if BL MFflag = ISP5_BL_VBUSM[5] MFLAG_THRES.
- The MFlag value used is whatever is available when the last beat comes on the interface bus.
- The last beat of the interface request (read or write) is held until one cycle before a new command (read or write). This is achieved by masking the last beat of the interface command at the ISP interface.

  The last beat is unmasked on the first event of one cycle before a new interface command, or the delay counter that uses the value counter of the ISP5_BL_VBUSM[4:0] LASTCMD_DLY bit field expires (has decremented to 0). The ISP5_BL_VBUSM[4:0] LASTCMD_DLY bit field must be set before the request on the BL starts. If the value of the ISP5_BL_VBUSM[4:0] LASTCMD_DLY bit field is changed during the pending requests, the delay counter is not updated.

8.3.3.7.8 ISS ISP BL Peak Memory Bandwidth Reduction

To limit the peak memory bandwidth generated by the IPIPEIF (read port), ISIF (read port), and H3A (write port) modules, a bandwidth limiter is placed between the modules and the BL. The RSZ module has this function built in and therefore does not need a bandwidth limiter.

The bandwidth limiter enables control of the minimum interval between two consecutive memory requests.

This function is controlled by the ISP5_BL_MTC_1 and ISP5_BL_MTC_2 registers. When the registers are set to 0, the function is not modified (that is, the bandwidth limiter is disabled). For the RSZ module, it is controlled by the RSZ_DMA_RZA and RSZ_DMA_RZB registers.

8.3.3.8 ISS ISP Memory Mapping

A total of 64 KiB is reserved for the ISP registers and memories. Table 8-464 describes the memory map.

Table 8-464. ISS ISP Memory Mapping

Memory Mapping	Start	End	Size	Comments
ISS ISP5 SYS1	0x5201 0000	0x5201 009F	160	ISP5 configuration registers (set 1)
ISS ISP5 SYS2	0x5201 00A0	0x5201 03FF	864	ISP5 configuration registers (set 2)
ISS RESIZER registers	0x5201 0400	0x5201 07FF	1024	RSZ configuration registers

Table 8-464. ISS ISP Memory Mapping (continued)

Memory Mapping	Start	End	Size	Comments

8.3.4 ISS ISP Programming Model

NOTE: The preferred way to perform memory-to-memory processing with ISP is to use the CCP2 receiver module at the ISS level (see Section 8.2.1, *ISS Interfaces*). It is possible to use the IPIPEIF read port for memory-to-memory processing, but it is not the preferred way because it does not provide enough granularity on the fractional clock divider for up to 20x digital zoom.

8.3.4.1 ISS ISP ISIF Programming Model

This section discusses issues related to the software control of the ISIF. It lists the registers that must be programmed in different modes, describes how to enable and disable the ISIF and how to check the status of the ISIF, discusses the different register access types, and enumerates several programming constraints.

8.3.4.1.1 ISS ISP ISIF Hardware Setup/Initialization

This section discusses the configuration of the ISIF required before image processing can begin.

8.3.4.1.1.1 ISS ISP ISIF Reset Behavior

Upon hardware reset of the ISP, all of the registers in the ISIF, except the defect table registers, are reset to their reset values. Because the defect table registers are stored in internal RAM, they do not have reset values. If the reset is a chip-level POR (reset after power is applied), the values of the defect table register are unknown. If the reset is an ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

8.3.4.1.1.2 ISS ISP ISIF Register Setup

Before enabling the ISIF, the hardware must be properly configured through register writes. Figure 8-250 and Figure 8-251 show the sequence to be used for RAW and YUV data before enabling the ISIF. The register settings for each process in the following sequence are described in Table 8-465.

Figure 8-250. ISS ISP ISIF Initialization Flow Chart – Part One

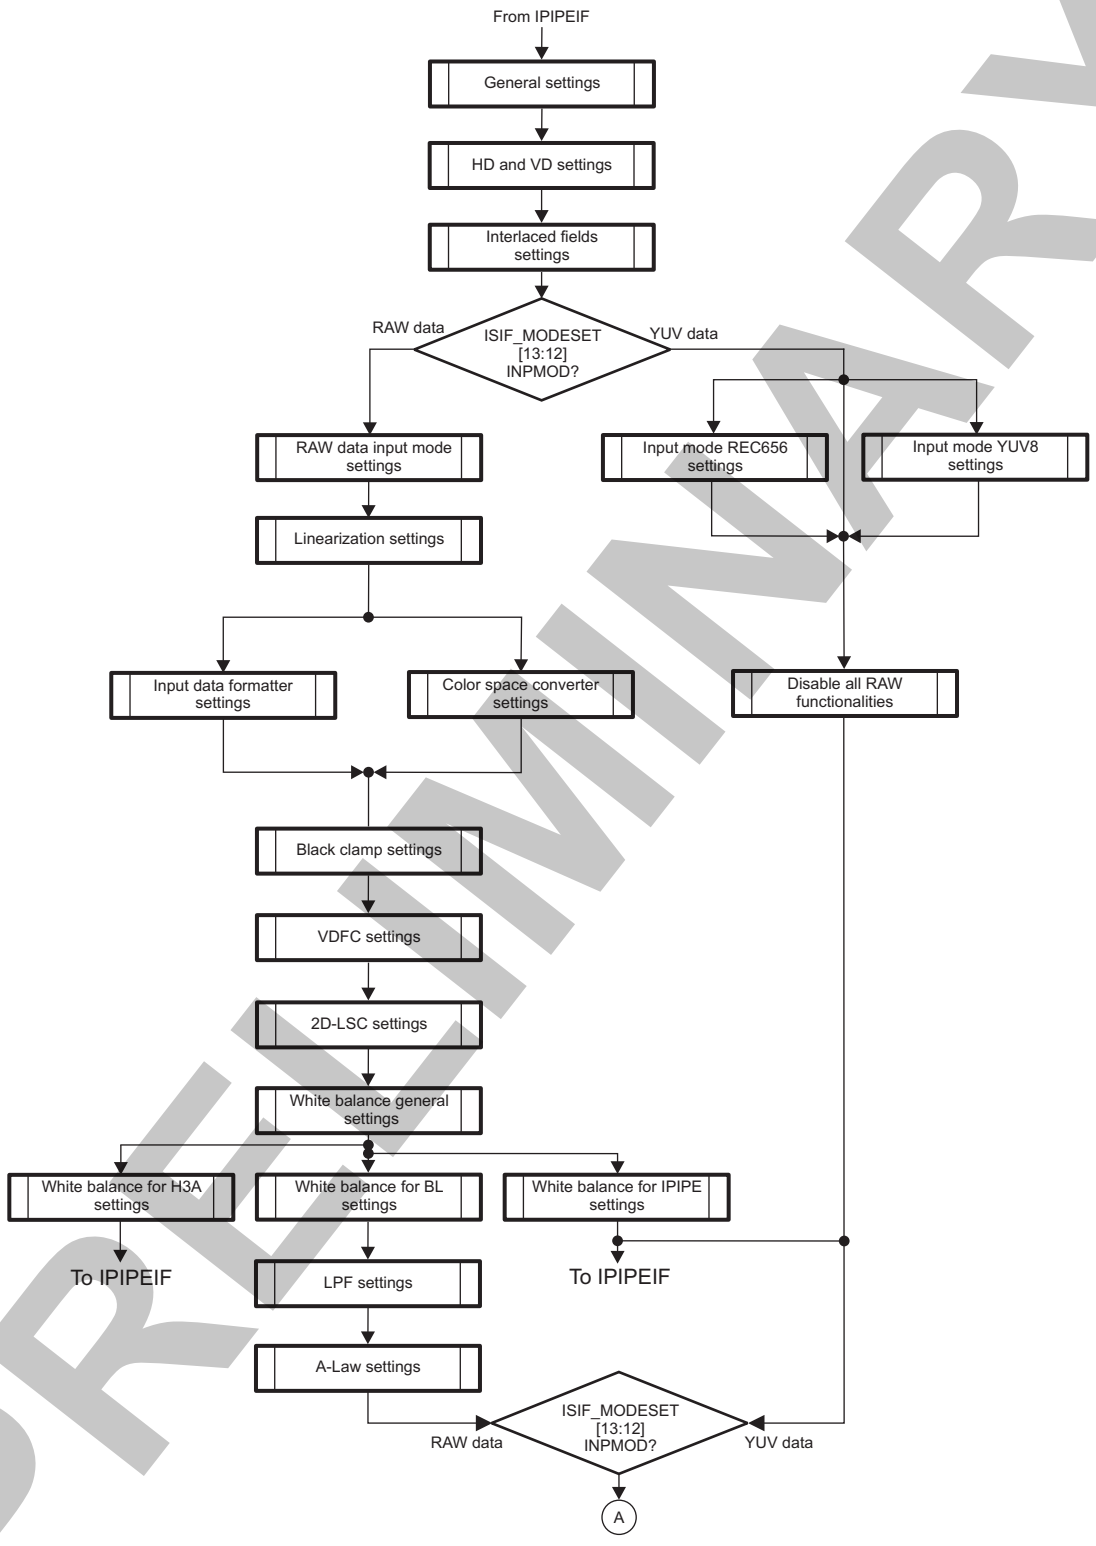

Figure 8-251. ISS ISP ISIF Initialization Flow Chart – Part Two

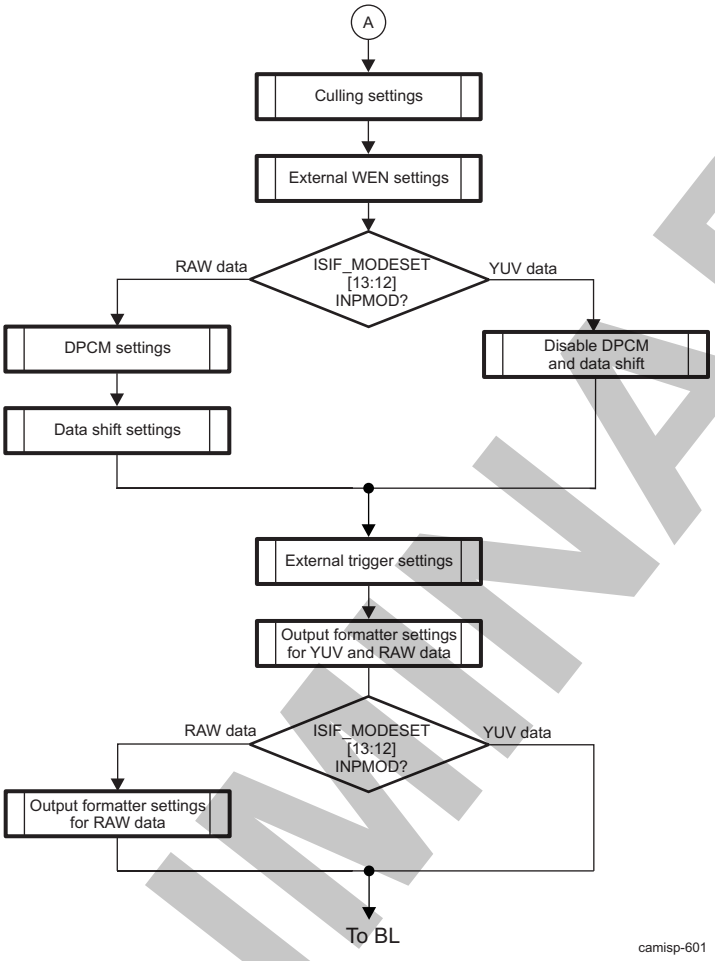

Table 8-465. ISS ISP ISIF Required Configuration Parameters

Step	Configuration Required	Value
General settings		
Set the Field Indicator signal direction.	ISIF_MODESET[1] FIDD	
Set the VD signal polarity.	ISIF_MODESET[2] VDPOL	
Set the HD signal polarity.	ISIF_MODESET[3] HDPOL	
Set the Field Indicator signal polarity.	ISIF_MODESET[4] FIPOL	
HD and VD settings		
Set the HD and VD signal directions.	ISIF_MODESET[0] HDVDD	
If: HD and VD are set as output (HDVDD = 0x1):		
Set the HD width.	ISIF_HDW[11:0] HDW	
Set the VD width.	ISIF_VDW[11:0] VDW	
Set the HD period.	ISIF_PPLN[15:0] PPLN	
Set the VD period.	ISIF_LPFR[15:0] LPFR	
End		
Interlaced fields settings		
Select the type of image sensor (progressive or interlaced)	ISIF_MODESET[7] CCDMD	
Input mode settings		
Set the data input mode.	ISIF_MODESET[13:12] INPMOD	

Table 8-465. ISS ISP ISIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Input mode settings for REC656 data		
Select CCIR Rec.656 interface or not.	ISIF_REC656IF[1] R656ON	
If: Input is REC656 (R656ON = 0x1)		
Set error correction of FVH code.	ISIF_REC656IF[0] ECCFVH	
Select bit width of CCIR656.	ISIF_CCDCFG[5] BT656	
End		
Input mode settings for YCC 8 bit data (if INPMOD = 0x2)		
Selects Y position signal	ISIF_CCDCFG[11] Y8POS	
RAW data processing: input settings		
Enable or disable MSB inverse of CIN port (YUV format).	ISIF_CCDCFG[13] MSBINVI	
Select Y and C swapping.	ISIF_CCDCFG[4] YCINSWP	
Select MSB position of input data (16 bits to 16 bits)	ISIF_CGAMMAWD[4:1] GWDI	
Set the image sensor data polarity.	ISIF_MODESET[6] DPOL	
Select the CFA pattern mode.	ISIF_CGAMMAWD[5] CFAP	
Specifies the color pattern	ISIF_CCOLP[7:6] CP0_F0	
	ISIF_CCOLP[5:4] CP1_F0	
	ISIF_CCOLP[3:2] CP2_F0	
	ISIF_CCOLP[1:0] CP3_F0	
Linearization settings		
Enable linearization or not.	ISIF_LINCFG0[0] LINEN	
If: Linearization enabled (LINEN = 0x1)		
Select linearization mode.	ISIF_LINCFG0[1] LINMD	
Select the shift value.	ISIF_LINCFG0[6:4] CORRSFT	
Set the scale factor for LUT.	ISIF_LINCFG1[10:0] LUTSCL	
Set up linearization LUT.		
End		
Input data formatter settings		
Enable data formatter or not.	ISIF_FMTCFG[0] FMTEN	
If: Data formatter is enabled (FMTEN = 0x1)		
Select the combine input lines.	ISIF_FMTCFG[1] FMTCBL	
Select the mode normal or alternative.	ISIF_FMTCFG[2] LNALT	
Select the split/combine number of lines.	ISIF_FMTCFG[5:4] LNUM	
Set the address increment.	ISIF_FMTCFG[11:8] FMTAINC	
Set the number of program entries per set.	ISIF_FMTPLEN[3:0] FMTPLEN0	
	ISIF_FMTPLEN[7:4] FMTPLEN1	
	ISIF_FMTPLEN[10:8] FMTPLEN2	
	ISIF_FMTPLEN[14:12] FMTPLEN3	
Set the first pixel in a line.	ISIF_FMTSPH[12:0] FMTSPH	
Set the number of pixels in a line.	ISIF_FMTLNH[12:0] FMTLNH	
Set the start line vertical.	ISIF_FMTLSV[12:0] FMTSLV	
Set the number of lines in a vertical.	ISIF_FMTLNV[14:0] FMTLNV	
Set the number of pixels in an output line.	ISIF_FMTRLEN[12:0] FMTRLEN	
Set the HD interval for output lines.	ISIF_FMTHCNT[12:0] FMTHCNT	
Set up to 16 address pointers.	ISIF_FMTAPTRx[14:13] LINE (x = 0 to 15)	
	ISIF_FMTAPTRx[12:0] INIT (x = 0 to 15)	

Table 8-465. ISS ISP ISIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Set the 32 possible program entry valid flag.	ISIF_FMTPGMVF0	
	ISIF_FMTPGMVF1	
Set the 32 possible address pointers.	ISIF_FMTPGMAPS0	
	ISIF_FMTPGMAPS1	
	ISIF_FMTPGMAPS2

End		
Black clamp settings		
Enable or disable black clamp.	ISIF_CLAMPCFG[0] CLEN	
If: Black clamp is enabled (CLEN = 0x1)		
Set the DC offset for black clamp.	ISIF_CLDCOFST[12:0] CLDC	
[Horizontal Black Clamp]		
Set the horizontal clamp mode.	ISIF_CLAMPCFG[2:1] CLHMD	
Set the vertical dimension of a window.	ISIF_CLHWIN0[13:12] CLHWN	
Set the horizontal dimension of a window.	ISIF_CLHWIN0[9:8] CLHWM	
Enable or disable limitation for horizontal.	ISIF_CLHWIN0[6] CLHLMT	
Select base window.	ISIF_CLHWIN0[5] CLHWBS	
Set the window count per color.	ISIF_CLHWIN0[4:0] CLHWC	
Set the window start position (H).	ISIF_CLHWIN1[12:0] CLHSH	
Set the window start position (V).	ISIF_CLHWIN2[12:0] CLHSV	
[Vertical Black Clamp]		
Set the black clamp start position.	ISIF_CLSV[12:0] CLSV	
Set the vertical black clamp reset value.	ISIF_CLVRV[11:0] CLVRV	
Set the line average coefficient.	ISIF_CLVWIN0[15:8] CLVCOEF	
Select the reset value for the clamp value of the previous line.	ISIF_CLVWIN0[5:4] CLVRVSL	
Select the optical black H valid.	ISIF_CLVWIN0[2:0] CLVOBH	
Set the window start position (H).	ISIF_CLVWIN1[12:0] CLVSH	
Set the window start position (V).	ISIF_CLVWIN2[12:0] CLVSV	
Select the optical black V valid.	ISIF_CLVWIN3[12:0] CLVOBV	

Table 8-465. ISS ISP ISIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
End		
Set the DC offset for black clamp (RAW data only).	ISIF_CLDCOFST[12:0] CLDC	DC offset available for YUV
Vertical line defect correction (VDFC) settings		
Disable vertical line defect correction.	ISIF_DFCCTL[4] VDFCEN	0x0
If: Vertical line defect correction will be enabled (VDFCEN = 0x1)		
Select the mode.	ISIF_DFCCTL[6:5] VDFCSL	
Select upper pixels correction enable or disable.	ISIF_DFCCTL[7] VDFCUDA	
Set the shift value.	ISIF_DFCCTL[10:8] VDFLSFT	
Set the saturation level.	ISIF_VDFSATLV[11:0] VDFSLV	
Clear memories.	ISIF_DFCMEMCTL[4] DFCMCLR	0x1
Vertical line defect table update procedure	See Section 8.3.3.6.9.1 for details.	
	Use the following registers:	
	ISIF_DFCMEMCTL[2] DFCMARST	
	ISIF_DFCMEMCTL[0] DFCMWR	
	ISIF_DFCMEM0	
	ISIF_DFCMEM1	
	ISIF_DFCMEM2	
	ISIF_DFCMEM3	
	ISIF_DFCMEM4	
End		
Enable vertical line defect correction.	ISIF_DFCCTL[4] VDFCEN	0x1
2D Lens Shading Compensation (LSC) settings		
Disable lens shading compensation.	ISIF_2DLSCCFG[0] ENABLE	0x0
If: 2D-LSC will be enabled (ENABLE = 0x1)		
Set the H direction data offset.	ISIF_LSCHOFST[13:0] HOFST	
Set the V direction data offset.	ISIF_LSCVOFST[13:0] VOFST	
Set the number of valid pixels in H direction.	ISIF_LSCHVAL[13:0] HVAL	
Set the number of valid lines in V direction.	ISIF_LSCVVAL[13:0] VVAL	
Define the horizontal dimension of a paxel.	ISIF_2DLSCCFG[14:12] GAIN_MODE_M	
Define the vertical dimension of a paxel.	ISIF_2DLSCCFG[10:8] GAIN_MODE_N	
Set gain format table.	ISIF_2DLSCCFG[4:1] GAIN_FORMAT	
Enable or disable offset control.	ISIF_2DLSCOFST[0] OFSTEN	
Select shift up value for offsets.	ISIF_2DLSCOFST[6:4] OFSTSFT	
Set scaling factor for offset.	ISIF_2DLSCOFST[15:8] OFSTSF	
Set the initial Y position.	ISIF_2DLSCINI[14:8] Y	
Set the initial X position.	ISIF_2DLSCINI[6:0] X	
Set the gain table base address.	ISIF_2DLSCGRBU[15:0] BASE31_16	
	ISIF_2DLSCGRBL[15:0] BASE15_0	
Set the gain table offset (length of one row).	ISIF_2DLSCGROF[15:0] OFFSET	
Set the offset table base address.	ISIF_2DLSCORBU[15:0] BASE	
	ISIF_2DLSCORBL[15:0] BASE	
Set the offset table offset (length of one row).	ISIF_2DLSCOROF	

Table 8-465. ISS ISP ISIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Enable useful interrupts.	ISIF_2DLSCIRQEN[3] SOF	
	ISIF_2DLSCIRQEN[2] PREFETCH_COMPLETED	
	ISIF_2DLSCIRQEN[1] PREFETCH_ERROR	
	ISIF_2DLSCIRQEN[0] DONE	
Set up LSC gain table and offset table in SDRAM. See Figure 8-237 for details.		
Wait seven clock periods before enabling LSC.		
Enable lens shading compensation.	ISIF_2DLSCCFG[0] ENABLE	0x1
End		
White balance color settings		
Set R/Ye gain.	ISIF_CRGAIN[11:0] CGR	
Set Gr/Cy gain.	ISIF_CGRGAIN[11:0] CGGR	
Set Gr/Cy gain.	ISIF_CGBGAIN[11:0] CGGB	
Set B/Mg gain.	ISIF_CBGAIN[11:0] CGB	
Set offset.	ISIF_COFSTA[11:0] COFT	
[For BL output]		
Enable or disable white balance for BL path.	ISIF_CGAMMAWD[12] WBNEN0	
Enable or disable offset control for BL path.	ISIF_CGAMMAWD[8] OFSTEN0	
[For IPIPE (through IPIPEIF) output]		
Enable or disable white balance for IPIPE path.	ISIF_CGAMMAWD[13] WBEN1	
Enable or disable offset control for IPIPE path.	ISIF_CGAMMAWD[9] OFSTEN1	
[For H3A (through IPIPEIF) output]		
Enable or disable white balance for H3A path.	ISIF_CGAMMAWD[14] WBEN2	
Enable or disable offset control for H3A path.	ISIF_CGAMMAWD[10] OFSTEN2	
LPF settings (for BL output only) (RAW data only)		
Enable or disable low-pass filter.	ISIF_MODESET[14] HLPF	
A-Law compression settings (for BL output only) (RAW data only)		
Enable or disable A-Law compression.	ISIF_CGAMMAWD[0] CCDTBL	
Culling settings (for BL output only) (RAW or YUV data)		
Set the culling pattern in odd lines.	ISIF_CULH[15:8] CLHO	
Set the culling pattern in even lines.	ISIF_CULH[7:0] CLHE	
Set the culling pattern in vertical lines.	ISIF_CULV[7:0] CULV	
External WEN settings (for BL output only)		
Select external WEN use or not.	ISIF_MODESET[5] SWEN	
If: External WEN is used (SWEN = 0x1):		
Specifies the CCD valid area	ISIF_CCDCFG[8] WENLOG	
End		
DPCM settings (for BL output only) (RAW data only)		
Select the predictor for DPCM encoder.	ISIF_MISC[13] DPCMPRE	

Table 8-465. ISS ISP ISIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Enable or disable DPCM encoding.	ISIF_MISC[12] DPCMEN	
Data shift settings (for BL output only) (RAW data only)		
Select the data shift value when image is written to memory.	ISIF_MODESET[10:8] CCDW	
External trigger settings (for BL output only)		
If: External trigger is selected (EXTRG = 0x1):		
Select the trigger source signal.	ISIF_CCDCFG[9] TRGSEL	
End		
Output formatter (for BL output only) RAW and YUV		
Set the memory address decrement.	ISIF_HSIZE[12] ADCR	
Set the memory address offset between lines.	ISIF_HSIZE[11:0] HSIZE	
Set the first pixel in a line to be stored in memory.	ISIF_SPH[14:0] SPH	
Set the number of pixels in a line to be stored in memory.	ISIF_LNH[14:0] LNH	
Set the start line vertical for field 0.	ISIF_SLV0[14:0] SLV0	
Set the start line vertical for field 1.	ISIF_SLV1[14:0] SLV1	
Set the number of lines to be stored in memory.	ISIF_LNV[14:0] LNV	
Enable or disable the storage of image in memory.	ISIF_SYNCEN[1] DWEN	
Set the memory destination address.	ISIF_CADU[10:0] CADU	
	ISIF_CADL[10:0] CADL	
Enable or disable MSB inverse of COUT port.	ISIF_CCDCFG[14] MSBINVO	
Enable or disable byte swap when SDRAM capturing.	ISIF_CCDCFG[12] BSWD	
Select Y and C swapping.	ISIF_CCDCFG[2] YCOUNTSWP	
Select SDRAM pack mode.	ISIF_CCDCFG[1:0] SDRPACK	
Enable or disable VD/HD output.	ISIF_SYNCEN[0] SYEN	

8.3.4.1.2 ISS ISP ISIF Enable/Disable Hardware

The ISIF is enabled by setting the ISIF_SYNCEN[0] SYEN bit. This is done after all the required registers discussed in the previous section are programmed.

With respect to the write-enable bit and output address, the following procedure must be followed:

1. Set the data output address (ISIF_CADU and ISIF_CADL).
2. Enable HD and VD and WEN at the same time (ISIF_MODESET[1] DWEN and ISIF_SYNCEN[0] SYEN).

If the ISIF_SYNCEN[0] SYEN bit is written before the output address and the SDRAM write-enable bit (not recommended but may be required for a particular mode), data begins to be written to the old address value and not the one recently programmed. The desired response can be achieved if the following procedure is followed:

1. Enable HD and VD (ISIF_SYNCEN[0] SYEN).
2. Set the output address (ISIF_CADU and ISIF_CADL).
3. Wait for the next VD.

4. Enable WEN (ISIF_MODESET[1] DWEN).

The ISIF always operates in continuous mode. In other words, after enabling the ISIF, it continues to process sequential frames until software clears the ISIF_SYNCEN[0] SYEN bit. When this happens, the frame being processed is disabled immediately and does not continue to process the current frame.

When the HD and VD signals are set to outputs (ISIF_MODESET[0] HDVDD = 0x1), fetching and processing of the frame begin immediately upon setting the ISIF_SYNCEN[0] SYEN bit.

When the HD and VD signals are set to inputs (ISIF_MODESET[0] HDVDD = 0x0), processing of the frame is dependent on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the ISIF must be enabled before data transmission from the external device. In this way, the ISIF waits for data from the external device.

8.3.4.1.3 ISS ISP ISIF Register Accessibility During Frame Processing

There are two types of register access in the ISIF:

- Shadowed registers (event latched registers)

  Shadowed registers are those that can be read and written at any time. However, the written values take effect (are latched) only at certain times based on some event. Reads still return the most-recent write even though the settings are not used until the specific event occurs.

- Busy-writable registers

  These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantly.

The following registers/fields can be set as shadow registers, or optionally set as busy-writable registers. When the ISIF_CCDCFG[15] VDLC bit is set to 0, these registers are shadowed; when the ISIF_CCDCFG[15] VDLC bit is set to 1, these registers are busy-writable. All other ISIF registers not included in this list are always busy-writable.

ISIF_SYNCEN[1] DWEN		ISIF_CGRGAIN	ISIF_FMTLSV
ISIF_MODESET[14] HLPF	ISIF_CULH	ISIF_CGBGAIN	ISIF_FMTLNV
ISIF_HDW	ISIF_CULV	ISIF_CBGAIN	ISIF_LSCHOFST
ISIF_VDW	ISIF_HSIZE	ISIF_COFSTA	ISIF_LSCVOFST
ISIF_PPLN		ISIF_CLAMPCFG[0] CLEN	ISIF_DFCCTL
ISIF_LPFR	ISIF_CADU	ISIF_MISC	ISIF_VDFSATLV
ISIF_SPH	ISIF_CADL	ISIF_CGAMMAWD	
ISIF_LNH	ISIF_CCOLP	ISIF_FMTSPH	
	ISIF_CRGAIN	ISIF_FMTLNH	
ISIF_SLV0	ISIF_SLV1	ISIF_SDOFST	

8.3.4.1.4 ISS ISP ISIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because the ISIF_SYNCEN[1] DWEN bit and the memory pointer registers are shadowed, these modifications can occur any time before the end of the frame and the data will be latched in for the next frame. Likewise, the 2D-LSC registers can be changed after receiving the LSC SOF interrupt but before it starts to prefetch the gain values for the next frame (the end of the LSC active region is reached). The host controller can perform these changes when it receives an interrupt.

8.3.4.1.5 ISS ISP ISIF Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the ISIF. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- PCLK cannot be higher than 304 MHz.

- If SDRAM output port is enabled:
  - The memory output line offset and address must be on 32-byte boundaries.
  - ISIF_LNH[14:0] LNH – 1 must be a multiple of 32 bytes.
  - ISIF_SPH, ISIF_LNH, ISIF_SLV0, ISIF_SLV1, and ISIF_LNV must be cleared to 0 within the same VD period in which the ISIF_SYNCEN[1] DWEN bit is cleared to 0.
  - ISIF_SPH, ISIF_LNH, ISIF_SLV0, ISIF_SLV1, and ISIF_LNV must be set from 0 to the appropriate values within the same VD period in which the ISIF_SYNCEN[1] DWEN bit is set to 1.
- In RAW input mode: The ISIF_CCDCFG[4] YCINSWP must be set to 0.
- If DPCM compression is enabled: The horizontal culling must not be used. Use the input formatter instead.
- For 2D-LSC:
  - N <= M (where M = horizontal downsampling factor, N = vertical downsampling factor)
  - The ISIF_2DLSCINI register values must be even numbers.
  - Maximum widths with respect to selected M value (see Table 8-466)

Table 8-466. ISS ISP ISIF Maximum Line Width Versus M Value

M	Maximum Line Width
8	2040
16	4080
32	8160
64	16,320
128	16,384

8.3.4.2 ISS ISP IPIPEIF Programming Model

This section discusses issues related to the software control of the IPIPEIF module. It lists the registers that are required to be programmed in different modes, describes how to enable and disable the IPIPEIF module and how to check the status of the IPIPEIF module, discusses the different register access types, and enumerates several programming constraints.

8.3.4.2.1 ISS ISP IPIPEIF Hardware Setup/Initialization

This section discusses the configuration of the IPIPEIF module required before image processing can begin.

8.3.4.2.1.1 ISS ISP IPIPEIF Reset Behavior

Upon hardware reset of the ISP (ISP5_SYSCONFIG[1] SOFTRESET = 0x1), all the registers in the IPIPEIF are reset to their reset values.

8.3.4.2.1.2 ISS ISP IPIPEIF Register Setup

Before enabling the IPIPEIF, the hardware must be properly configured through register writes. Table 8-467 identifies the register parameters that must be programmed before enabling the IPIPEIF module (depending on the functions needed).

Table 8-467. ISS ISP IPIPEIF Required Configuration Parameters

Step	Configuration Required	Value
General settings		
Select the input sources for IPIPEIF.	IPIPEIF_CFG1[15:14] INPSRC1	
	IPIPEIF_CFG1[3:2] INPSRC2	
Select VD sync polarity.	IPIPEIF_CFG2[2] VDPOL	
Select HD sync polarity.	IPIPEIF_CFG2[1] HDPOL	

Table 8-467. ISS ISP IPIPEIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Select the interrupt source.	IPIPEIF_CFG2[0] INTSW	
Select the input clock source.	IPIPEIF_CFG1[10] CLKSEL	
Set the clock divider value.	IPIPEIF_CLKDIV[15:0] CLKDIV	
Set the data type: YUV or RAW.	IPIPEIF_CFG2[3] YUV16	
Settings to perform if data is from BL		
Set HD setting.	IPIPEIF_PPLN[12:0] PPLN	
Set VD setting.	IPIPEIF_LPFR[12:0] LPFR	
Set the number of valid pixels in a line.	IPIPEIF_HNUM[12:0] HNUM	
Set the number of valid lines.	IPIPEIF_VNUM[12:0] VNUM	
Set memory address information.	IPIPEIF_ADDRU[10:0] ADDRU	
	IPIPEIF_ADDRL[15:0] ADDRL	
	IPIPEIF_ADOFS[11:0] ADOFS	
Set one-shot mode, if needed.	IPIPEIF_CFG1[0] ONESHOT	
Use SYNCOFF function only for double-buffering. See Section 8.3.3.2.3.2.1 for details.	IPIPEIF_ENABLE[1] SYNCOFF	
Settings to perform for RAW data from ISIF or BL		
Select the unpack function.	IPIPEIF_CFG1[9:8] UNPACK	
Settings to perform for YUV data from ISIF		
Set the data type to YUV.	IPIPEIF_CFG2[3] YUV16	
If YUV16 = 0x1, enables or not the conversion from 8 bits to 16 bits	IPIPEIF_CFG2[6] YUV8	
If YUV16 = 0x1, set the way the data is unpacked.	IPIPEIF_CFG2[7] YUV8P	
DPCM function	RAW data from BL	
Enable or disable DPCM decompression.	IPIPEIF_DPCM[0] ENA	
Select DPCM prediction mode.	IPIPEIF_DPCM[1] PRED	
Select DPCM bit mode.	IPIPEIF_DPCM[2] BITS	
Select inverse A-Law function.	IPIPEIF_CFG1[9:8] UNPACK	
Select SDRAM read data shift. - For RAW data - DPCM enabled and A- Law disabled - or DPCM disabled	IPIPEIF_CFG1[13:11] DATASFT	
Dark frame subtraction (DFS) function	RAW data from (VP, BL, SDRAM) or ISIF	
Set defect pixel correction (DPC1) for VP or ISIF inputs.	IPIPEIF_DPC1[12] ENA	
Set the associated threshold for DPC1.	IPIPEIF_DPC1[11:0] TH	
Set defect pixel correction (DPC2) for BL inputs.	IPIPEIF_DPC2[12] ENA	
Set the associated threshold for DPC1.	IPIPEIF_DPC2[11:0] TH	
Set the direction of subtraction.	IPIPEIF_CFG2[5] DFSDIR	
Set the averaging filter, horizontal pixel decimator, and gain function for IPIPE data path.		
Enable averaging filter function.	IPIPEIF_CFG1[7] AVGFILT	
Enable horizontal pixel decimation function.	IPIPEIF_CFG1[1] DECIM	
Set horizontal resizing value.	IPIPEIF_RSZ[6:0] RSZ	
Set the resizer initial position.	IPIPEIF_INIRSZ[13] ALNSYNC	
	IPIPEIF_INIRSZ[12:0] INIRSZ	

Table 8-467. ISS ISP IPIPEIF Required Configuration Parameters (continued)

Step	Configuration Required	Value
Set the data gain (only for RAW data).	IPIPEIF_GAIN[9:0] GAIN	
Set the output clipping value.	IPIPEIF_OCLIP[11:0] OCLIP	
Set the averaging filter and horizontal pixel decimator function for H3A data path.		
Enable averaging filter function.	IPIPEIF_RSZ3A[8] AVGFILT	
Enable horizontal pixel decimation function.	IPIPEIF_RSZ3A[9] DECIM	
Set horizontal resizing value.	IPIPEIF_RSZ3A[6:0] RSZ	
Set the resizer initial position.	IPIPEIF_RSZ3A[13] ALNSYNC	
	IPIPEIF_RSZ3A[12:0] INIRSZ	

For information about YUV data coming and unpacking from the ISIF module, see Section 8.3.3.2.13, *ISS ISP IPIPEIF YUV4:2:2 8-bit Packed Data Input Coming From ISIF Module*.

8.3.4.2.2 ISS ISP IPIPEIF Enable/Disable Hardware

When IPIPEIF_CFG1[15:14] INPSRC1 or IPIPEIF_CFG1[3:2] INPSRC2 = 0, the IPIPEIF does not need to be enabled: it receives data from the VP and pushes it to the ISIF, H3A, IPIPE, and RESIZER modules.

If IPIPEIF_CFG1[15:14] INPSRC1 or IPIPEIF_CFG1[3:2] INPSRC2 ≠ 0, the IPIPEIF module begins to fetch data from the BL by setting the IPIPEIF_ENABLE[0] ENABLE bit. Writing the enable bit must be the last step of the configuration.

When the input source is the BL, the IPIPEIF can optionally operate in one-shot mode or continuous mode by setting the IPIPEIF_CFG1[0] ONESHOT bit. If one-shot mode is enabled, then after enabling the IPIPEIF, the IPIPEIF_ENABLE[0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begins immediately upon setting the IPIPEIF_ENABLE[0] ENABLE bit.

When the input source is the ISIF, processing of the frame depends on the timing of the ISIF. To ensure that data from the ISIF is not missed, the IPIPEIF must be enabled before the ISIF. In this way, the IPIPEIF waits for data from the ISIF.

When the IPIPEIF is in continuous mode, it can be disabled by clearing the IPIPEIF_ENABLE[0] ENABLE bit after processing of the last frame. The disable occurs immediately because it is a busy-writable register.

An EOF interrupt can indicate to other modules that the frame treatment is finished. For more information, see Section 8.3.3.2.15, *ISS ISP IPIPEIF Module Events and Status Checking*.

8.3.4.2.3 ISS ISP IPIPEIF Register Accessibility During Frame Processing

There are two types of register accesses in the IPIPEIF:

- Shadow registers

  These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame (VD rising edge). Reads still return the most-recent write even though the settings are not used until the next start of frame. The following are the shadowed registers in the IPIPEIF:

IPIPEIF_PPLN
IPIPEIF_HNUM
IPIPEIF_VNUM
IPIPEIF_GAIN
IPIPEIF_RSZ3A[6:0] RSZ
IPIPEIF_ADDRU
IPIPEIF_ADOFS
IPIPEIF_ENABLE[1] SYNCOFF
IPIPEIF_RSZ3A[9] DECIM
IPIPEIF_CFG1[1] DECIM
IPIPEIF_CFG1[7] AVGFILT
IPIPEIF_RSZ
IPIPEIF_RSZ3A[8] AVGFILT

- Busy-writable registers

  These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occurs instantaneously. Registers that are not shadowed are busy-writable.

Only for busy-writable registers, the ideal procedure for changing the IPIPEIF registers is if (PCR.BUSY == 0) or if (EOF interrupt occurs):

1. Disable IPIPEIF (IPIPEIF_ENABLE[0] ENABLE = 0x0).
2. Change registers.
3. Enable IPIPEIF (IPIPEIF_ENABLE[0] ENABLE = 0x1).

8.3.4.2.4 ISS ISP IPIPEIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because several of the registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The host controller can perform these changes when it receives an interrupt.

When reading input data from the BL, the host must check IPIPEIF_DTUF or the ISP5_IRQSTATUS_RAW2_i[1] IPIPEIF_UDF bit (if this event is enabled and mapped to the ISP IRQ lines) during vertical blanking to see if an underflow occurred.

If an underflow occurs it means the system is congested because too much bandwidth is being generated. Most likely, the scenario being passed is too memory bandwidth-intensive. If the bit is set, software must clear the bit. If the process is taking place from memory-to-memory, software may try to reinitiate the data flow. Software must decide the sequence to execute after an underflow.

8.3.4.2.5 ISS ISP IPIPEIF Summary of Constraints

Adhere to the following list of register configuration constraints when programming the IPIPEIF module. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If BL is the source for the IPIPEIF:
  - The memory output line offset and address must be on 32-byte boundaries.
  - In DFS block, IPIPEIF_LPFR must be > 0, because the first line cannot be fetched.
  - IPIPEIF_PPLN > IPIPEIF_HNUM
  - IPIPEIF_LPFR > IPIPEIF_VNUM + 1
- There are restrictions on IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 combinations. See Table 8-422 for details.

8.3.4.3 ISS ISP IPIPE Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the ISS ISP IPIPE module.

8.3.4.3.1 Global Initialization

8.3.4.3.1.1 Surrounding Modules Global Initialization

This initialization of surrounding modules is based on the integration of the ISS ISP.

8.3.4.3.1.2 ISS ISP IPIPE Global Initialization

8.3.4.3.1.2.1 Main Sequence – ISS ISP IPIPE Global Initialization

The procedure in Table 8-468 initializes the ISS ISP IPIPE modules after a POR or software reset.

Table 8-468. ISS Global Initialization

Step	Register/Bit Field/Programming Model	Value
Set the IPIPE processing modes.	IPIPE_SRC_MODE[0] OST	0x-
Select the IPIPEIF module as a source.	IPIPE_SRC_MODE[1] WRT	0x1
Set the vertical start position of the window to process.	IPIPE_SRC_VPS[15:0] VAL	0x-
Set the horizontal start position of the window to process.	IPIPE_SRC_HPS[15:0] VAL	0x-
Set the vertical size of the processing area.	IPIPE_SRC_VSZ[12:0] VAL	0X-
Set the horizontal size of the processing area.	IPIPE_SRC_HSZ[12:1] VAL	0x-
Enable clk_arm_g0.	IPIPE_GCK_MMR[0] REG	0x-
Enable clk_pix_g3.	IPIPE_GCK_PIX[3] G3	0x-
Enable clk_pix_g2.	IPIPE_GCK_PIX[2] G2	0x-
Enable clk_pix_g1.	IPIPE_GCK_PIX[1] G1	0x-
Enable clk_pix_g0.	IPIPE_GCK_PIX[0] G0	0x-
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

8.3.4.3.1.2.2 Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization

8.3.4.3.1.2.2.1 Subsequence – ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

The procedure in Table 8-469 initializes the ISS ISP IPIPE LUT defect pixel correction (LUT DPC).

Table 8-469. ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

Step	Register/Bit Field/Programming Model	Value
Set the address of the first valid data in the LUT.	IPIPE_DPC_LUT_ADR[9:0] ADR	0x-
Set the LUT type.	IPIPE_DPC_LUT_SEL[1] TBL	0x-
Set the size of the LUT.	IPIPE_DPC_LUT_SIZ[9:0] SIZ	0x-
Set the dot replacement correction method.	IPIPE_DPC_LUT_SEL[0] DOT	0x-
Enable LUT DPC.	IPIPE_DPC_LUT_EN[0] EN	0x1

8.3.4.3.1.2.3 Subsequence – ISS ISP IPIPE White Balance Initialization

The procedure in Table 8-470 initializes the ISS ISP IPIPE white balance.

Table 8-470. ISS ISP IPIPE White Balance Initialization

Step	Register/Bit Field/Programming Model	Value
Set the offset before white balance.	IPIPE_WB2_OFT_R[11:0] VAL IPIPE_WB2_OFT_GR[11:0] VAL IPIPE_WB2_OFT_GB[11:0] VAL IPIPE_WB2_OFT_B[11:0] VAL	0x-
Set the white balance gain.	IPIPE_WB2_WGN_R[12:0] VAL IPIPE_WB2_WGN_GR[12:0] VAL IPIPE_WB2_WGN_GB[12:0] VAL IPIPE_WB2_WGN_B[12:0] VAL	0x-

8.3.4.3.1.2.4 Subsequence – ISS ISP IPIPE RGB2RGB Blending Module Initialization

The procedure in Table 8-471 initializes the ISS ISP IPIPE RGB2RGB blending module.

Table 8-471. ISS ISP IPIPE RGB2RGB Blending Module Initialization

Step	Register/Bit Field/Programming Model	Value
Set gain range.	IPIPE_RGB1_MUL_RR[11:0] VAL IPIPE_RGB1_MUL_GR[11:0] VAL IPIPE_RGB1_MUL_BR[11:0] VAL IPIPE_RGB1_MUL_RG[11:0] VAL IPIPE_RGB1_MUL_GG[11:0] VAL IPIPE_RGB1_MUL_BG[11:0] VAL IPIPE_RGB1_MUL_RB[11:0] VAL IPIPE_RGB1_MUL_GB[11:0] VAL IPIPE_RGB1_MUL_BB[11:0] VAL	0x-
Se the offset range for each component.	IPIPE_RGB1_OFT_OR[12:0] VAL IPIPE_RGB1_OFT_OG[12:0] VAL IPIPE_RGB1_OFT_OB[12:0] VAL	0x-

8.3.4.3.1.2.5 Subsequence – ISS ISP IPIPE Gamma Correction Module Initialization

The procedure in Table 8-472 initializes the ISS ISP IPIPE gamma correction module.

Table 8-472. ISS ISP IPIPE Gamma Correction Module Initialization

Step	Register/Bit Field/Programming Model	Value
Select the gamma table.	IPIPE_GMM_CFG[4] TBL	0x-
Set the size of the gamma table.	IPIPE_GMM_CFG[6:5] SIZ	0x-
(optional) Insert bypass bit for each color.	IPIPE_GMM_CFG[0] BYPR IPIPE_GMM_CFG[1] BYPG IPIPE_GMM_CFG[2] BYPB	0x1

8.3.4.3.1.2.6 Subsequence – ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization

The procedure in Table 8-473 initializes the Second ISS ISP IPIPE RGB2RGB conversion matrix.

Table 8-473. ISS ISP IPIPE Second RGB2RGB Conversion Matrix Initialization

Step	Register/Bit Field/Programming Model	Value
Set the gain range.	IPIPE_RGB2_MUL_RR[10:0] VAL IPIPE_RGB2_MUL_GR[10:0] VAL IPIPE_RGB2_MUL_BR[10:0] VAL IPIPE_RGB2_MUL_RG[10:0] VAL IPIPE_RGB2_MUL_GG[10:0] VAL IPIPE_RGB2_MUL_BG[10:0] VAL IPIPE_RGB2_MUL_RB[10:0] VAL IPIPE_RGB2_MUL_GB[10:0] VAL IPIPE_RGB2_MUL_BB[10:0] VAL	0x-
Set the offset.	IPIPE_RGB2_OFT_OR[10:0] VAL IPIPE_RGB2_OFT_OG[10:0] VAL IPIPE_RGB2_OFT_OB[10:0] VAL	0x-

8.3.4.3.1.2.7 Subsequence – ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization

The procedure in Table 8-474 initializes the ISS ISP IPIPE RGB2YCbCr conversion matrix.

Table 8-474. ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization

Step	Register/Bit Field/Programming Model	Value
Set the brightness control.	IPIPE_YUV_ADJ[15:8] BRT	0x-
Set the contrast control.	IPIPE_YUV_ADJ[7:0] CRT	0x-

Table 8-474. ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Configure the gain range.	IPIPE_YUV_MUL_RY[11:0] VAL IPIPE_YUV_MUL_GY[11:0] VAL IPIPE_YUV_MUL_BY[11:0] VAL IPIPE_YUV_MUL_RCB[11:0] VAL IPIPE_YUV_MUL_GCB[11:0] VAL IPIPE_YUV_MUL_BCB[11:0] VAL IPIPE_YUV_MUL_RCR[11:0] VAL IPIPE_YUV_MUL_GCR[11:0] VAL IPIPE_YUV_MUL_BCR[11:0] VAL	0x-
Set the output offset value for Y.	IPIPE_YUV_OFT_Y[10:0] VAL	0x-
Set the output offset value for Cr.	IPIPE_YUV_OFT_CR[10:0] VAL	0x-
Set the output offset value for Cb.	IPIPE_YUV_OFT_CB[10:0] VAL	0x-

8.3.4.3.1.2.8 Subsequence – ISS ISP IPIPE 4:2:2 Conversion Module Initialization

The procedure in Table 8-475 initializes the ISS ISP IPIPE 4:2:2 conversion module.

Table 8-475. ISS ISP IPIPE 4:2:2 Conversion Module Initialization

Step	Register/Bit Field/Programming Model	Value
If: RAW BAYER data set as an input?	IPIPE_SRC_FMT[1:0] FMT	= 0x0
Select the Y and Cb/Cr sampling point.	IPIPE_YUV_PHS[0] POS	0x-
Enable 4:2:2 conversion module.	IPIPE_YUV_PHS[1] PLF	0x-
ELSE		

8.3.4.3.1.2.9 Subsequence – ISS ISP IPIPE 2D Edge-Enhancer Initialization

The procedure in Table 8-476 initializes the ISS ISP IPIPE 2D edge enhancer.

Table 8-476. ISS ISP IPIPE 2D Edge-Enhancer Initialization

Step	Register/Bit Field/Programming Model	Value
Set the merging method.	IPIPE_YEE_TYP[0] SEL	0x-
Set the downshift length of HPF in the edge-enhancer.	IPIPE_YEE_SHF[3:0] SHF	0x-
Set the edge-enhancer lower threshold before referring to the LUT.	IPIPE_YEE_THR[5:0] VAL	0x-
Set the multiplier coefficient in the HPF.	IPIPE_YEE_MUL_00[9:0] VAL IPIPE_YEE_MUL_01[9:0] VAL IPIPE_YEE_MUL_02[9:0] VAL IPIPE_YEE_MUL_10[9:0] VAL IPIPE_YEE_MUL_11[9:0] VAL IPIPE_YEE_MUL_12[9:0] VAL IPIPE_YEE_MUL_20[9:0] VAL IPIPE_YEE_MUL_21[9:0] VAL IPIPE_YEE_MUL_22[9:0] VAL	0x-
Set the edge sharpener HPF value lower limit.	IPIPE_YEE_E_THR_1[11:0] VAL	0x-
Set the edge sharpener HPF value upper limit.	IPIPE_YEE_E_THR_2[5:0] VAL	0x-
Set the edge sharpener gain value on gradient.	IPIPE_YEE_G_GAN[7:0] VAL	0x-
Set the edge sharpener gain value.	IPIPE_YEE_E_GAN[7:0] VAL	0x-
Set the edge sharpener offset value on gradient.	IPIPE_YEE_G_OFT[5:0] VAL	0x-
Enable the 2D edge-enhancer.	IPIPE_YEE_EN[0] EN	0x1

8.3.4.3.1.2.10 Subsequence – ISS ISP IPIPE Histogram Initialization

The procedure in Table 8-477 initializes the ISS ISP IPIPE histogram.

Table 8-477. ISS ISP IPIPE Histogram Initialization

Step	Register/Bit Field/Programming Model	Value
Select input source.	IPIPE_HST_SEL[2] SEL	0x-
Select the Bayer mode.	IPIPE_HST_SEL[1:0] TYP	0x-
Set the number of bins.	IPIPE_HST_PARA[13:12] BIN	0x-
Enable region(area) 0.	IPIPE_HST_PARA[0] RGN0	0x-
Enable region(area) 1.	IPIPE_HST_PARA[1] RGN1	0x-
Enable region(area) 2.	IPIPE_HST_PARA[2] RGN2	0x-
Enable region(area) 3.	IPIPE_HST_PARA[3] RGN3	0x-
Set the vertical position of region 0.	IPIPE_HST_0_VPS[12:1] VAL	0x-
Set the vertical position of region 1.	IPIPE_HST_1_VPS[12:1] VAL	0x-
Set the vertical position of region 2.	IPIPE_HST_2_VPS[12:1] VAL	0x-
Set the vertical position of region 3.	IPIPE_HST_3_VPS[12:1] VAL	0x-
Set the horizontal position of region 0.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 1.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 2.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 3.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the vertical size of region 0.	IPIPE_HST_0_VSZ[12:1] VAL	0x-
Set the vertical size of region 1.	IPIPE_HST_1_VSZ[12:1] VAL	0x-
Set the vertical size of region 2.	IPIPE_HST_2_VSZ[12:1] VAL	0x-
Set the vertical size of region 3.	IPIPE_HST_3_VSZ[12:1] VAL	0x-
Set the horizontal size of region 0.	IPIPE_HST_0_HSZ[12:1] VAL	0x-
Set the horizontal size of region 1.	IPIPE_HST_1_HSZ[12:1] VAL	0x-
Set the horizontal size of region 2.	IPIPE_HST_2_HSZ[12:1] VAL	0x-
Set the horizontal size of region 3.	IPIPE_HST_3_HSZ[12:1] VAL	0x-
Enable selection of the color pattern 0 (R).	IPIPE_HST_PARA[4] COL0	0x-
Enable selection of the color pattern 1 (G).	IPIPE_HST_PARA[5] COL1	0x-
Enable selection of the color pattern 2 (B).	IPIPE_HST_PARA[6] COL2	0x-
Enable selection of the color pattern 3 (Y).	IPIPE_HST_PARA[7] COL3	0x-
Set the shift length of the input data.	IPIPE_HST_PARA[11:8] SHF	0x-
Enable/disable histogram memory clear.	IPIPE_HST_TBL[1] CLR	0x-
Select table for store the histogram data.	IPIPE_HST_TBL[1] CLR	0x-
IF: Is input from noise filter?	IPIPE_HST_SEL[2] SEI	0x0
Gain for color for R.	IPIPE_HST_MUL_R[7:0] GAIN	0x-
Gain for color for GR.	IPIPE_HST_MUL_GR[7:0] GAIN	0x-
Gain for color for GB.	IPIPE_HST_MUL_GB[7:0] GAIN	0x-
Gain for color for B.	IPIPE_HST_MUL_B[7:0] GAIN	0x-
ENDIF		
Select processing mode.	IPIPE_HST_MODE[0] OST	0x-
Enable histogram.	IPIPE_HST_EN[0] EN	0x1

8.3.4.3.1.2.11 Subsequence – ISS ISP IPIPE Boxcar Initialization

The procedure in Table 8-478 initializes the ISS ISP IPIPE boxcar.

Table 8-478. ISS ISP IPIPE Boxcar Initialization

Step	Register/Bit Field/Programming Model	Value
Select the processing mode.	IPIPE_BOX_MODE[0] OST	0x-
Set the size of blocks.	IPIPE_BOX_TYP[0] SEL	0x-
Set the higher 16 bits of the first address of output in memory.	IPIPE_BOX_SDR_SAD_H[15:0] VAL	0x-
Set the lower 16 bits of the first address of output in memory.	IPIPE_BOX_SDR_SAD_L[15:5] VAL	0x-
Set the downshift value.	IPIPE_BOX_SHF[2:0] VAL	0x-
Enable boxcar.	IPIPE_BOX_EN[0] EN	0x1

8.3.4.3.2 ISS ISP IPIPE Operational Modes Configuration

8.3.4.3.2.1 ISS ISP IPIPE Processing Path: Case 1 Configuration

Table 8-479 lists the ISS ISP IPIPE processing path: case 1 configuration procedures.

Table 8-479. ISS ISP IPIPE Processing Path: Case 1 Configuration

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 1	IPIPE_SRC_FMT[1:0] FMT	0x0
Configure IPIPE DPC.	See Section 8.3.4.3.1.2.2, *Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization*.	
Configure IPIPE white balance.	See Section 8.3.4.3.1.2.3, *Subsequence – ISS ISP IPIPE White Balance Initialization*.	
Configure IPIPE RGB2RGB blending module.	See Section 8.3.4.3.1.2.4, *Subsequence – ISS ISP IPIPE RGB2RGB Blending Module Initialization*.	
Configure IPIPE gamma correction module.	See Section 8.3.4.3.1.2.5, *Subsequence – ISS ISP IPIPE Gamma Correction Module Initialization*.	
Configure IPIPE second RGB2RGB conversion matrix.	See Section 8.3.4.3.1.2.6, *Subsequence – ISS ISP IPIPE Second RGB2RGB Conversion Matrix Initialization*.	
Configure IPIPE RGB2YCbCr conversion matrix.	See Section 8.3.4.3.1.2.7, *Subsequence – ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization*.	
Configure IPIPE 2D edge-enhancer.	See Section 8.3.4.3.1.2.9, *Subsequence – ISS ISP IPIPE 2D Edge Enhancer Initialization*.	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

8.3.4.3.2.2 ISS ISP IPIPE Processing Path: Case 2 Configuration

Table 8-480 lists the ISS ISP IPIPE processing path: case 2 configuration procedures.

Table 8-480. ISS ISP IPIPE Processing Path: Case 2 Configuration

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 2.	IPIPE_SRC_FMT[1:0] FMT	0x1
Configure IPIPE DPC.	See Section 8.3.4.3.1.2.2, *Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization*.	
Configure IPIPE white balance.	See Section 8.3.4.3.1.2.3, *Subsequence – ISS ISP IPIPE White Balance Initialization*.	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

8.3.4.3.2.3 ISS ISP IPIPE Processing Path: Case 3 Configuration

Table 8-481 lists the ISS ISP IPIPE processing path: case 3 configuration procedures.

Table 8-481. ISS ISP IPIPE Processing Path: Case 3 Configuration

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 3.	IPIPE_SRC_FMT[1:0] FMT	0x3
Configure IPIPE 2D edge enhancer.	See Section 8.3.4.3.1.2.9, *Subsequence - ISS ISP IPIPE 2D Edge Enhancer Initialization*.	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

8.3.4.3.2.4 ISS ISP IPIPE Processing Path: Case 4 Configuration

Table 8-482 lists the ISS ISP IPIPE processing path: case 4 configuration procedures.

Table 8-482. ISS ISP IPIPE Processing Path: Case 4 Configuration

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 4.	IPIPE_SRC_FMT[1:0] FMT	0x2
Configure IPIPE boxcar.	See Section 8.3.4.3.1.2.11, *Subsequence – ISS ISP IPIPE Boxcar Initialization*.	
Configure IPIEE histogram.	See Section 8.3.4.3.1.2.10, *Subsequence – ISS ISP IPIPE Histogram Initialization*.	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

8.3.4.4 ISS ISP RSZ Programming Model

This section discusses programming configuration steps related to software control of the RSZ. It lists the registers that must be programmed in different modes, describes how to enable and disable the RSZ and how to check the status of the image resizing procedure, and discusses the different register access types and several programming constraints.

8.3.4.4.1 ISS ISP RSZ Hardware Setup/Initialization

This section discusses the configuration of the RSZ required before image processing can begin.

8.3.4.4.1.1 ISS ISP RSZ Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the RSZ module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the RSZ. For more information, see Section 8.3.3.4.4, *ISS ISP RSZ Integration.*

Table 8-483 lists the ISS ISP RSZ surrounding modules global initialization.

Table 8-483. ISS ISP RSZ Surrounding Modules Global Initialization

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. RSZ is part of ISP, which is part of ISS. To enable the clocks for ISS, see Chapter 3, *Power, Reset, and Clock Management*. Also see Section 8.3.2.1.1, *ISS ISP Clocks*.
(optional) MPU/IPU INTC	The MPU/IPU INTC must be configured to enable interrupts from the RSZ. For information about how to configure the local ISS interrupt channels, see Section 8.3.2.2, *ISS ISP Interrupt Tree*, and Section 8.1.2.1.1, *ISS Interrupt Merger*. Then, to configure the outside ISS boundary channels, see Chapter 17, *Interrupt Controllers*.
(optional) IPIPE	Configure the IPIPE module to process and pass data to the RSZ module. See Section 8.3.4.3, *ISS ISP IPIPE Programming Model*.
(optional) IPIPEIF	Configure the IPIPEIF module to process and pass data to the RSZ module. See Section 8.3.4.2, *ISS ISP IPIPEIF Programming Model*.

Table 8-483. ISS ISP RSZ Surrounding Modules Global Initialization (continued)

Surrounding Modules	Comments
(optional) BL	Configure the BL for reading back data from memory. See Section 8.3.4.6, *ISS ISP BL Programming Model*.
(optional) CSI2	If the data comes from the sensor, configure the CSI2-A interface. See Section 8.2.5.4, *ISS CSI2 Programming Model*.
(optional) CCP2	If the data comes from the sensor, configure the CCP2 interface. See Section 8.2.4.4, *ISS CCP2 Programming Model*.

NOTE: The MPU/IPU INTC configurations are necessary if the interrupt-based communication modes are used. The IPIPE or IPIPEIF configuration is also necessary for putting data into the RSZ. Moreover, if data comes from memory, the BL must be configured. If data comes from the image sensor CSI2 or CCP2, the interface must be configured.

8.3.4.4.1.2 ISS ISP RSZ Initial Register Setup

Before enabling the RSZ, the hardware must be properly configured through register writes. Table 8-484 identifies the sequence to be used before enabling the hardware.

Table 8-484. ISS ISP RSZ Initial Register Setup

Step	Register/Bit Field/Programming Model	Value
Set the MMR clock to enable RSZ register read/write access.	RSZ_GCK_MMR[0] MMR	0x1
Determine whether or not a bypass mode will be used and set the RSZ core functional clock accordingly.	RSZ_GCK_SDR[0] CORE	0x-
IF: Is the core clock enabled?	RSZ_GCK_SDR[0] CORE	= 0x1
Enable RSZ engine clocks.	RSZ_SYSCONFIG[8] RSZA_CLK_EN RSZ_SYSCONFIG[9] RSZB_CLK_EN	0x1
ELSE: The input data buffer is not used?	RSZ_GCK_SDR[0] CORE	= 0x0
Set the bypass mode accordingly.	RSZ_SRC_FMT0[1] BYPASS	0x-
ENDIF		
Enable the RSZ core clock.	RSZ_GCK_SDR[0] CORE	0x1
Determine the upscale ratio and functional clock, and adjust the fractional clock divider as appropriate.	RSZ_FRACDIV[15:0] RSZ_FRACDIV	0x-
Set the low threshold of the RSZ input data buffer as appropriate.	RSZ_IN_FIFO_CTRL[28:16] THRLD_LOW	0x-
Set the high threshold of the RSZ input data buffer as appropriate.	RSZ_IN_FIFO_CTRL[12:0] THRLD_HIGH	0x-
Determine whether IPIPE or IPIPEIF will be the source of input and set this bit accordingly.	RSZ_SRC_FMT0[0] SEL	0x-
Determine whether the RSZ will process as long as data is present in the input buffer, or whether it will wait for a WEN signal from the input source (IPIPE or IPIPEIF) to process lines arrived only during WEN high state.	RSZ_SRC_MODE[1] WRT	0x-
Select the processing mode (one shot or free running). This bit controls the RSZ module. There are also additional mode settings for the two RSZ engines within. After RSZ reset, the mode is automatically set to free running.	RSZ_SRC_MODE[0] OST	0x-

Table 8-484. ISS ISP RSZ Initial Register Setup (continued)

Step	Register/Bit Field/Programming Model	Value
Configure the number of interrupt intervals for writing lines into CBUFF for the two RSZ engines.	RSZ_IRQ_RZA[12:0] RZA RSZ_IRQ_RZB[12:0] RZB	0x-
Enable the RSZ module.	RSZ_SRC_EN[0] EN	0x1
Enable resizer engine A.	RZA_EN[0] EN	0x1
Enable resizer engine B.	RZB_EN[0] EN	0x1

NOTE: RSZ-A or RSZ-B must be enabled after setting all needed configuration parameters.

8.3.4.4.1.3 ISS ISP RSZ Reset Behavior

Because the RSZ module has no software reset, software can issue one at the ISP level. Moreover, upon hardware reset, all the registers in the RSZ are reset to their reset values. Table 8-485 identifies the proper software sequence before and after RSZ reset issues at the ISP level.

Table 8-485. ISS ISP RSZ Reset Behavior

Step	Register/Bit Field/Programming Model	Value
ELSE IF: Is FIFO overflow or blanking error present?	ISP5_IRQSTATUS_i[18] RSZ_FIFO_IN_OVF or ISP5_IRQSTATUS_i[19] RSZ_FIFO_IN_BLK_ERR	= 0x1
Clear the FIFO blanking event.	ISP5_IRQENABLE_CLR_i[19] RSZ_FIFO_IN_BLK_ERR	0x1
Clear the overflow event.	ISP5_IRQENABLE_CLR_i[18] RSZ_FIFO_IN_OVF	0x1
ELSE: No FIFO overflow or blanking error is present?		
Wait until there is no DMA process and the module ready for reset.	ISP5_SYSCONFIG[1] SOFTRESET and ISP5_IRQSTATUS_i[15] RSZ_INT_DMA	= 0x0
ENDIF		
Disable the source data.	RSZ_SRC_EN[0] EN	0x0
Reset the RSZ at the ISP level.	ISP5_SYSCONFIG[1] SOFTRESET	0x1
Check whether the RSZ has been reset properly.	ISP5_SYSCONFIG[1] SOFTRESET	0x-

8.3.4.4.2 ISS ISP RSZ Global Image Processing Settings

This section discusses the configuration of the RSZ global settings before and during image frame processing. Table 8-486 identifies the global RSZ functional sequence, which includes global control, frame settings, bandwidth control, and reversal output image frames.

Table 8-486. ISS ISP RSZ Global Image Processing Settings

Step	Register/Bit Field/Programming Model	Value
Initialize the RSZ module.	See Section 8.3.4.4.1.	
Determine input data type and configure the source parameters.	See Section 8.3.4.4.2.1.	
Determine if vertical flip of the output image will be performed by the two resizer engines and set accordingly.	RSZ_SEQ[1] VRVA RSZ_SEQ[3] VRVB	0x-

Table 8-486. ISS ISP RSZ Global Image Processing Settings (continued)

Step	Register/Bit Field/Programming Model	Value
Determine if horizontal flip of the output image will be performed by the two resizer engines and set accordingly.	RSZ_SEQ[0] HRVA	0x-
	RSZ_SEQ[2] HRVB	
Set the baseline address of the RSZ output to CBUFF. Best performance can be achieved by assigning address on a 128-byte boundary.	RZA_SDR_Y_BAD_H[15:0] Y_BAD_H	0x-
	RZA_SDR_Y_BAD_L[15:0] Y_BAD_L	
	RZB_SDR_Y_BAD_H[15:0] Y_BAD_H	
	RZB_SDR_Y_BAD_L[15:0] Y_BAD_L	
	RZA_SDR_C_BAD_H[15:0] C_BAD_H	
	RZA_SDR_C_BAD_L[15:0] C_BAD_L	
	RZB_SDR_C_BAD_H[15:0] C_BAD_H	
	RZB_SDR_C_BAD_L[15:0] C_BAD_L	
Set the start address of the RSZ output to CBUFF. The first data output will be written to this address. If the first line of a frame is written at the beginning of the CBUFF memory, then SAD = BAD and PTR_S = 0. It is strongly advised to set up this address on a 128-byte boundary, which leads to the best performance.	RZA_SDR_Y_SAD_H[15:0] Y_SAD_H	0x-
	RZA_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZB_SDR_Y_SAD_H[15:0] Y_SAD_H	
	RZB_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZA_SDR_C_SAD_H[15:0] C_SAD_H	
	RZA_SDR_C_SAD_L [15:0] C_SAD_L	
	RZB_SDR_C_SAD_H[15:0] C_SAD_H	
	RZB_SDR_C_SAD_L[15:0] C_SAD_L	
Set the start pointer of the CBUFF internal counter. It must be set up as PTR_S = (SAD – BAD) / OFT. PTR_S is expressed in number of lines.	RZA_SDR_Y_PTR_S[12:0] Y_PTR_S	0x-
	RZB_SDR_Y_PTR_S[12:0] Y_PTR_S	
	RZA_SDR_C_PTR_S[12:0] C_PTR_S	
	RZB_SDR_C_PTR_S[12:0] C_PTR_S	
Set the end pointer of the CBUFF internal counter. PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines.	RZA_SDR_Y_PTR_E[12:0] Y_PTR_E	0x-
	RZB_SDR_Y_PTR_E[12:0] Y_PTR_E	
	RZA_SDR_C_PTR_E[12:0] C_PTR_E	
	RZB_SDR_C_PTR_E[12:0] C_PTR_E	
Set the line of offset expressed in bytes between two lines in the CBUFF (Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT). PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines. Note: OFT does not necessarily correspond to the size of a line in a frame; it can be much bigger. The line offset must be a multiple of 128 bytes.	RZA_SDR_Y_OFT[16:0] Y_OFT	0x-
	RZB_SDR_Y_OFT[16:0] Y_OFT	
	RZA_SDR_C_OFT[16:0] C_OFT	

Table 8-486. ISS ISP RSZ Global Image Processing Settings (continued)

Step	Register/Bit Field/Programming Model	Value
	RZB_SDR_C_OFT[16:0] C_OFT	
Determine output data type, whether it will be flipped, and configure the output memory addresses.	See Section 8.3.4.4.2.2.	

NOTE: When data output is 4:2:2 or 4:2:0-Y only, the following values are not needed:

- RZx_SDR_C_BAD_x
- RZx_SDR_C_SAD_x
- RZx_SDR_C_PTR_S
- RZx_SDR_C_PTR_E
- RZx_SDR_C_OFT

When output is 4:2:0-C only, the following values are not needed:

- RZx_SDR_Y_BAD_x
- RZx_SDR_Y_SAD_x
- RZx_SDR_Y_PTR_S
- RZx_SDR_Y_PTR_E
- RZx_SDR_Y_OFT

8.3.4.4.2.1 ISS ISP RSZ Global Image Processing Settings – Subsequence 1

The procedure shown in Figure 8-252 determines which of the RSZ engines is enabled and the type of input data, and configures the source data parameters.

Figure 8-252. ISS ISP RSZ Global Image Processing Settings – Subsequence 1

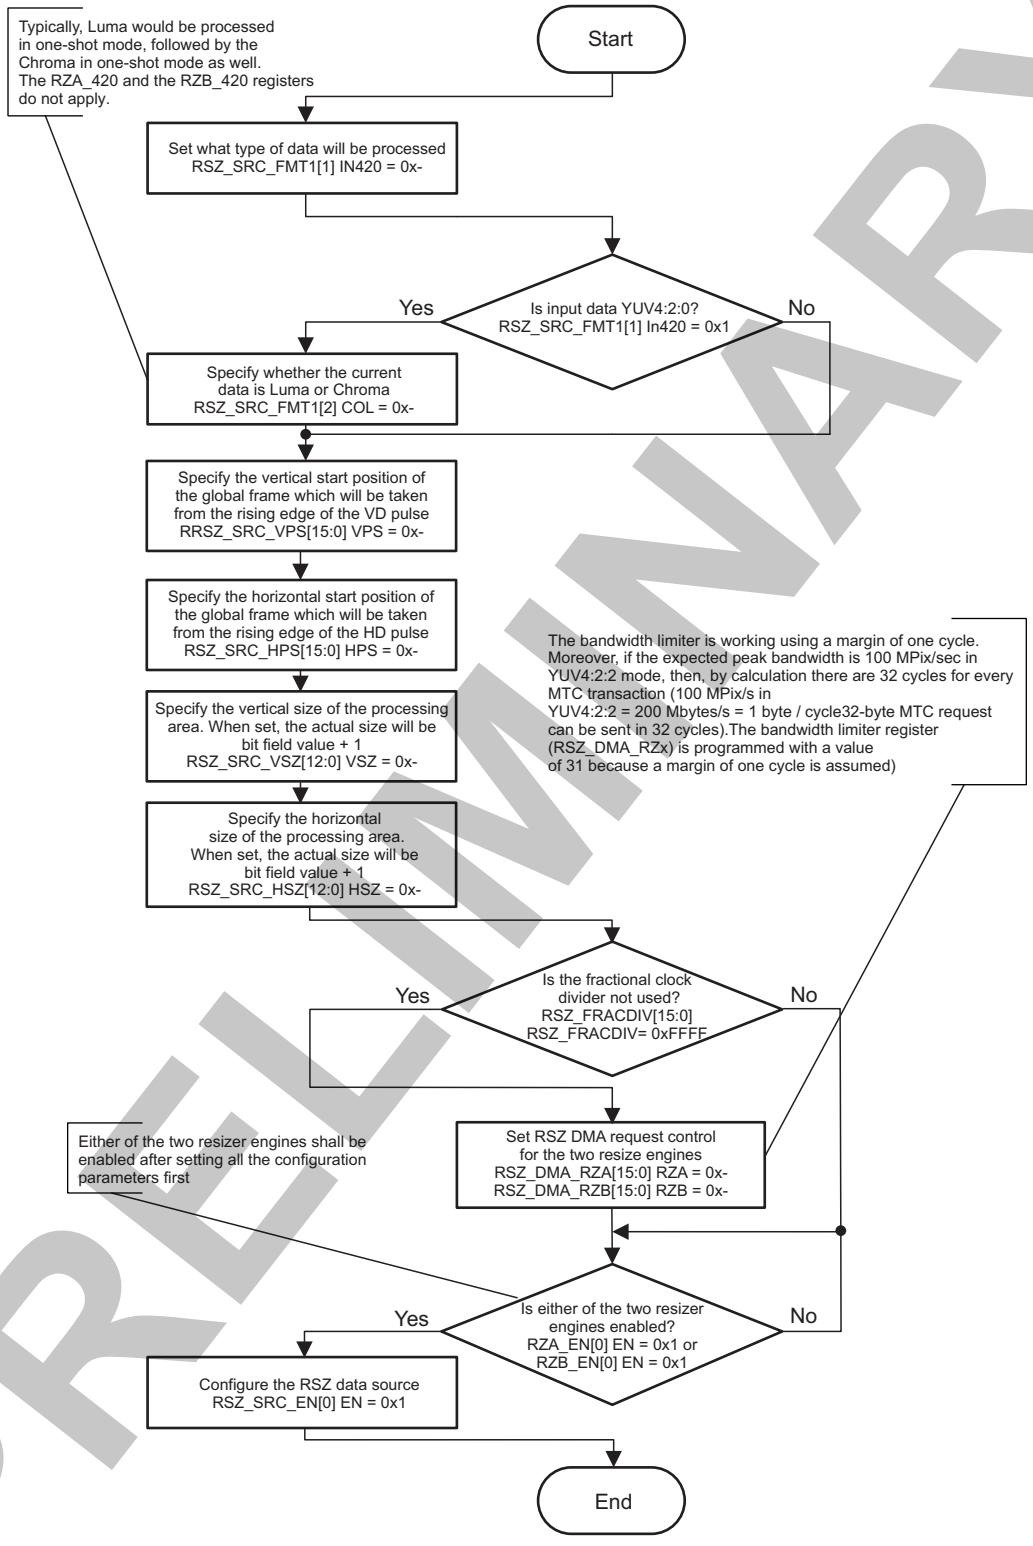

Table 8-487. Register Call Summary for ISS ISP RSZ Global Image Processing Settings – Subsequence 1

Register Name	Register Name	Register Name

8.3.4.4.3 ISS ISP RSZ Engines Interframe Image Processing Settings

This section discusses the configuration of the RSZ interframe image processing. Table 8-489 identifies the setup sequence for the two different engines within the RSZ module.

Table 8-489. ISS ISP RSZ Engines Interframe Image Processing Settings

Step	Register/Bit Field/Programming Model	Value
IF: Is the RSZ module set to free-running mode?	RSZ_SRC_MODE[0] OST	= 0x0
Set either of the engines to free-running mode to keep popping data out of the internal buffer. Otherwise, it will lead to an overflow event after the first frame.	RZA_MODE[0] MODE RZB_MODE[0] MODE	0x0
ELSE: Is the RSZ module set to one-shot mode?		
Set both resizer engines to one-shot mode.	RZA_MODE[0] MODE RZB_MODE[0] MODE	0x1
ENDIF		
Set the output format. See Table 8-434.	RZA_420[0] YEN RZA_420[1] CEN RZB_420[0] YEN RZB_420[1] CEN	0x-
On the side of the RSZ_SRC_VPS, RSZ_SRC_HPS, RSZ_SRC_VSZ, and RSZ_SRC_HSZ registers, set the engine complementary function to crop within the global frame and assign proper vertical start position (start line) of the input frame.(1)	RZA_I_VPS[12:0] VPS RZB_I_VPS[12:0] VPS	0x-
Assign proper horizontal start position (start pixel) of the input frame.	RZA_I_HPS[12:0] HPS RZB_I_HPS[12:0] HPS	0x-
Assign proper vertical size of the output frame.	RZA_O_VSZ[12:0] VPS RZB_O_VSZ[12:0] VPS	0x-
Assign proper horizontal size of the output frame.	RZA_O_HSZ[12:1] HPS RZB_O_HSZ[12:1] HPS	0x-
Set the phase position for the Chroma and Luma element and configure the averager.	See Section 8.3.4.4.3.1	
Set the vertical resize value for the two engines (vertical resize ration = 256 / RZx_V_DIF).	RZA_V_DIF[13:0] V RZB_V_DIF[13:0] V	0x-
Set the horizontal resize value for the two engines (horizontal resize ration = 256 / RZx_H_DIF).	RZA_H_DIF[13:0] H RZB_H_DIF[13:0] H	0x-
Select vertical method of resizing filtering (linear or cubic interpolation) for the Luma and Chroma elements.	RZA_V_TYP[0] Y RZB_V_TYP[0] Y RZA_V_TYP[1] C RZB_V_TYP[1] C	0x-
Select horizontal method of resizing filtering (linear or cubic interpolation) for the Luma and Chroma elements.	RZA_H_TYP[0] Y RZB_H_TYP[0] Y RZA_H_TYP[1] C RZB_H_TYP[1] C	0x-
IF: Is the interpolation method linear?	RZx_V_TYP[0] Y and RZx_V_TYP[1] C RZx_H_TYP[0] Y and RZx_H_TYP[1] C	= 0x1
Set the needed vertical LPF intensity for the Luma and Chroma elements.	RZA_V_LPF[5:0] Y RZA_V_LPF[11:6] C RZB_V_LPF[5:0] Y RZB_V_LPF[11:6] C	0x-
Set the needed horizontal LPF intensity for the Luma and Chroma elements.	RZA_H_LPF[5:0] Y RZA_H_LPF[11:6] C RZB_H_LPF[5:0] Y RZB_H_LPF[11:6] C	0x-
ENDIF		
Set the Chroma saturation MAX and MIN values.	RSZ_YUV_C_MAX[7:0] MAX RSZ_YUV_C_MIN[7:0] MIN	0x-
Set the Luma saturation MAX and MIN values.	RSZ_YUV_Y_MAX[7:0] MAX RSZ_YUV_Y_MIN[7:0] MIN	0x-

(1) The size of the frame (height of the image) after the cropping must be two lines or larger.

Table 8-489. ISS ISP RSZ Engines Interframe Image Processing Settings (continued)

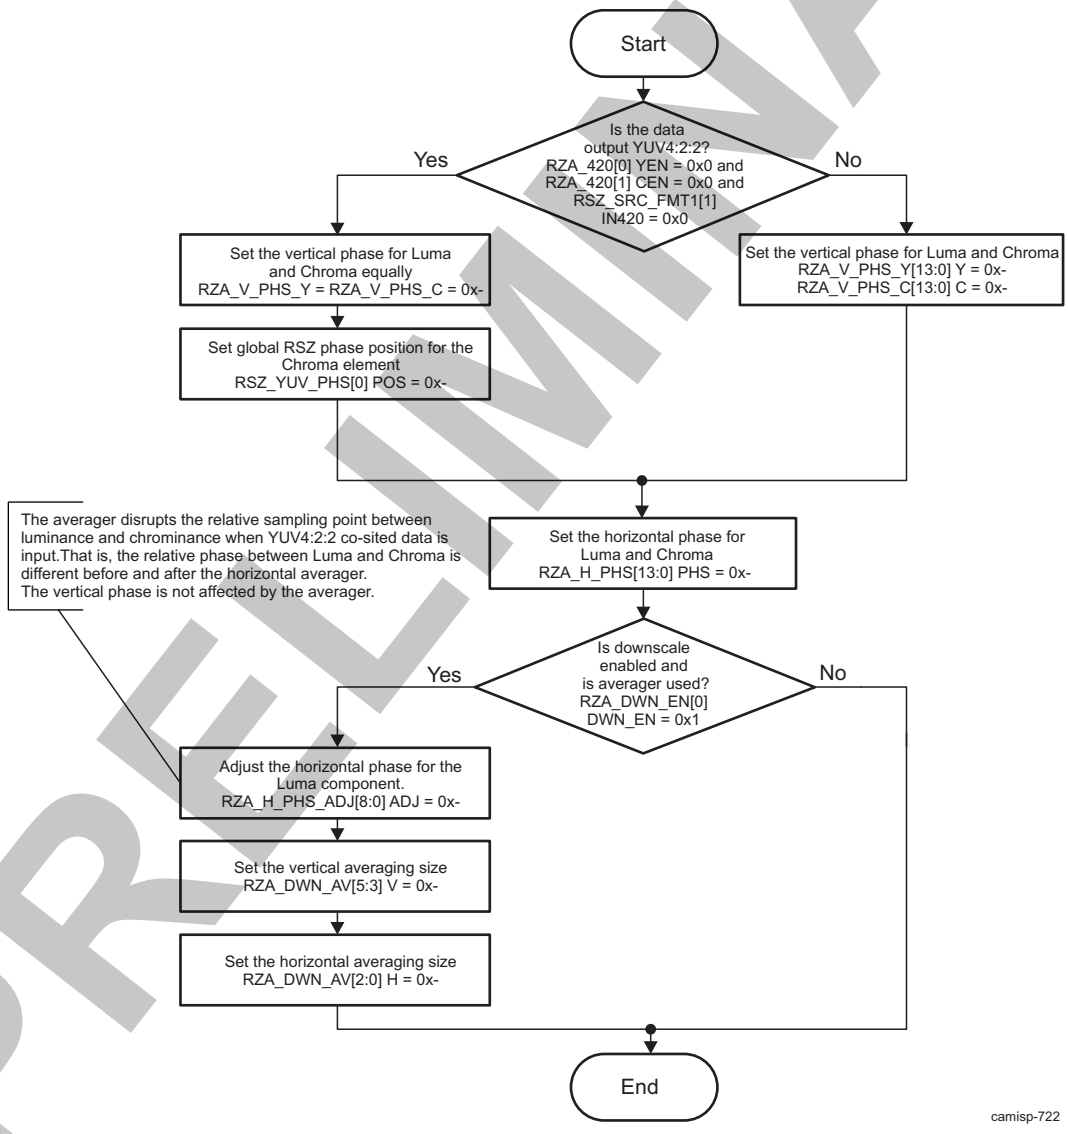
Step	Register/Bit Field/Programming Model	Value
(optional) Set the mode to RGB conversion, configure the alpha value, and set additional pixel masking.	See Section 8.3.4.4.3.2.	

8.3.4.4.3.1 ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1

The procedure shown in Figure 8-254 sets the phase position for the Chroma and Luma elements and configures the averager.

NOTE: This procedure configures RSZ-A. The procedure for RSZ-B is identical.

Figure 8-254. ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1



NOTE: When masking is used, boundaries affect the leftmost/rightmost 2 pixels in up-conversion.

Table 8-490. Register Call Summary for ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1

8.3.4.4.4 ISS ISP RSZ Programming Constraints

The RSZ module contains shadowed and nonshadowed registers. Shadowed registers can be updated anytime during the resizing operation, but the new setting does not take effect until the next rsz_int_reg event. Shadowed registers can be updated for the next frame after the rsz_int_reg event triggers.

Nonshadowed registers must be programmed before enabling the RSZ module or between frames (that is, after the rsz_int_dma and the entire frame have come on the VPORT interface, and before the VD of the next frame). Table 8-492 lists the nonshadowed registers.

Table 8-492. ISS ISP RSZ Nonshadowed Registers

8.3.4.5 ISS ISP H3A Programming Model

This section discusses issues related to the software control of the H3A module. It lists the registers that must be programmed in different modes, how to enable and disable the H3A, how to check the status of the H3A, discusses the different register access types, and enumerates several programming constraints.

8.3.4.5.1 ISS ISP H3A Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

8.3.4.5.1.1 ISS ISP H3A Reset Behavior

Upon hardware reset of the ISP, all the registers in the H3A are reset to their reset values.

8.3.4.5.1.2 ISS ISP H3A Register Setup

For register configuration purposes, the AF and AEW engines of the H3A can be configured independently. Because there are separate enable bits for each engine, this section is divided into the AF engine and the AEW engine.

8.3.4.5.1.2.1 ISS ISP H3A AF Engine

Before enabling the AF engine, the hardware must be properly configured through register writes. Table 8-493 lists the register parameters that must be programmed before enabling the AF engine of the H3A.

Table 8-493. ISS ISP H3A AF Engine Required Configuration Parameters

Step	Configuration Required	Value
AF optional preprocessing settings		
Note: A suggestion is to use the averaging filter in the IPIPEIF to reduce noise before generating AF statistics.		
Enable or disable the median filter.	H3A_PCR[2] AF_MED_EN	
Set the median filter threshold, if the filter is enabled.	H3A_PCR[10:3] MED_TH	
Enable or disable A-Law compression.	H3A_PCR[1] AF_ALAW_EN	
Set AF general settings.		
Set the focus value accumulation mode.	H3A_PCR[14] FVMODE	
Set the input start information.	H3A_LINE_START[31:16] SLV H3A_LINE_START[15:0] LINE_START	
Set the output SDRAM destination start address.	H3A_AFBUFST[31:5] AFBUFST	
RGB pixel extraction and paxel settings		
Set the RGB positions in the pixel.	H3A_PCR[13:11] RGBPOS	
Set the paxel width.	H3A_AFPAX1[23:16] PAXW	
Set the paxel height.	H3A_AFPAX1[7:0] PAXH	
Set the paxel horizontal start position.	H3A_AFPAXSTART[27:16] PAXSH	
Set the paxel vertical start position.	H3A_AFPAXSTART[11:0] PAXSV	
Set the column increment.	H3A_AFPAX2[20:17] AFINCH	
Set the line increment.	H3A_AFPAX2[16:13] AFINCV	
Set the vertical paxel count.	H3A_AFPAX2[12:6] PAXVC	
Set the horizontal paxel count.	H3A_AFPAX2[5:0] PAXHC	
Horizontal focus value calculator settings		
Set the horizontal threshold for the two IIR.	H3A_HVF_THR[31:16] HTHR2 H3A_HVF_THR[15:0] HTHR1	
Set the IIR horizontal start position.	H3A_AFIIRSH[11:0] IIRSH	
Set the coefficients for the SET 0 IIR.	H3A_AFCOEF010 H3A_AFCOEF032 H3A_AFCOEF054 H3A_AFCOEF076 H3A_AFCOEF098 H3A_AFCOEF0010	
Set the coefficients for the SET 1 IIR.	H3A_AFCOEF110 H3A_AFCOEF132 H3A_AFCOEF154 H3A_AFCOEF176 H3A_AFCOEF198 H3A_AFCOEF1010	
Vertical focus value calculator settings		
Enable or disable vertical AF focus value calculation.	H3A_PCR[20] AF_VF_EN	
Set the vertical FIR 1 coefficients and threshold.	H3A_VFV_CFG1 H3A_VFV_CFG2	
Set the vertical FIR 2 coefficients and threshold.	H3A_VFV_CFG3 H3A_VFV_CFG4	

The following references offer guidelines on how to program the filter coefficients and make use of the H3A output.

8.3.4.5.1.2.2 ISS ISP H3A AEW Engine

Before enabling the AEW engine, the hardware must be properly configured through register writes. Table 8-494 lists the register parameters that must be programmed before enabling the AEW engine of the H3A.

Table 8-494. ISS ISP H3A AEW Engine Required Configuration Parameters

Step	Configuration Required	Value
AEW optional preprocessing settings		
Enable or disable the median filter.	H3A_PCR[19] AEW_MED_EN	
Set the median filter threshold.	H3A_PCR[10:3] MED_TH	
Enable or disable A-Law compression.	H3A_PCR[17] AEW_ALAW_EN	
Set AEW general settings.		
Set the saturation limit.	H3A_PCR[31:22] AVE2LMT	
Set the AE/AWB output format.	H3A_AEWCFG[9:8] AEFMT	
Set the AE/AWB shift value for sum of pixels.	H3A_AEWCFG[3:0] SUMFST	
Set the input start information.	H3A_LINE_START[31:16] SLV H3A_LINE_START[15:0] LINE_START	
Set the output SDRAM destination start address.	H3A_AEWBUFST[31:5] AEWBUFST	
Set the AE/AWB window configuration settings.		
Set the window width (in pixels).	H3A_AEWWIN1[20:13] WINW	
Set the window height (in lines).	H3A_AEWWIN1[31:24] WINH	
Set the window count for horizontal direction.	H3A_AEWWIN1[5:0] WINHC	
Set the window count for vertical direction.	H3A_AEWWIN1[12:6] WINVC	
Set the window start position H.	H3A_AEWINSTART[11:0] WINSH	
Set the window start position V.	H3A_AEWINSTART[27:16] WINSV	
Set the horizontal distance between subsamples.	H3A_AEWSUBWIN[3:0] AEWINCH	
Set the vertical distance between subsamples.	H3A_AEWSUBWIN[11:8] AEWINCV	
Set the vertical start position for single black line of windows.	H3A_AEWINBLK[27:16] WINSV	
Set the height for the single black line of windows.	H3A_AEWINBLK[6:0] WINH	

8.3.4.5.2 ISS ISP H3A Enable/Disable Hardware

Setting the H3A_PCR[0] AF_EN bit enables the AF engine, and setting the H3A_PCR[16] AEW_EN bit enables the AEW engine. This is done after all of the required registers discussed in the previous section are programmed.

The H3A operates in continuous mode. Processing of the frame is dependent on the timing of the IPIPEIF. To ensure that data from the IPIPEIF is not missed, the H3A must be enabled before the IPIPEIF. In this way, the H3A waits for data from the IPIPEIF. The AF engine or the AEW engine can be disabled by clearing the H3A_PCR[0] AF_EN or H3A_PCR[16] AEW_EN bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

8.3.4.5.3 ISS ISP H3A Register Accessibility During Frame Processing

There are two types of register accesses in the H3A module:

- Shadow registers

  These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads still return the most-recent write even though the settings are not used until the next start of frame.

  The only shadowed registers in the H3A module are:

  – H3A_AFPAX1
  – H3A_AFPAX2
  – H3A_AFPAXSTART
  – H3A_AFIIRSH
  – H3A_AEWWIN1
  – H3A_AEWINSTART
  – H3A_AEWINBLK
  – H3A_AEWSUBWIN
  – H3A_AEWCFG
  – H3A_AEWBUFST

- Busy-lock registers

  All other registers, except those described previously, belong to this category.

  Busy-lock registers cannot be written when the module is busy (H3A_PCR[15] BUSYAF == 1 or H3A_PCR[18] BUSYAEAWB == 1). Writes are allowed to occur, but no change occurs in the registers (blocked writes from the hardware perspective, but allowed write from the software perspective). Once the busy bit in the H3A_PCR register (H3A_PCR[15] BUSYAF or H3A_PCR[18] BUSYAEAWB bit) is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the H3A registers if (H3A_PCR[15] BUSYAF == 0 or H3A_PCR[18] BUSYAEAWB == 0) or if (EOF interrupt occurs) is:

1. Disable AF or AE/AWB.
2. Change registers.
3. Enable AF or AE/AWB.

8.3.4.5.4 ISS ISP H3A Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the H3A_PCR register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data will be latched in for the next frame. The host controller can perform these changes upon receiving an interrupt.

8.3.4.5.5 ISS ISP H3A Summary of Constraints

Adhere to the following list of register configuration constraints when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The output addresses (H3A_AFBUFST[31:5] AFBUFST) must be on 64-byte boundaries.
- Each horizontal row of paxels () or windows () starts on a 32-byte boundary.
- If the pixel clock frequency is less than ISP_FCLK / 2 and vertical focus is enabled, the constraints listed in Table 8-495 apply.

Table 8-495. ISS ISP H3A Constraints When PCLK < ISP_FCLK / 2 and Vertical Focus Enabled

Field	Constraint
H3A_AEWWIN1[20:13] WINW	>7
H3A_AFPAX1[23:16] PAXW	>7
H3A_AFIIRSH[11:0] IIRSH	None
H3A_AFPAXSTART[27:16] PAXSH	>= H3A_AFIIRSH[11:0] IIRSH + 2
H3A_AFPAX2[20:17] AFINCH	None
H3A_AFPAX2[5:0] PAXHC	<=11

- If the pixel clock frequency is less than ISP_FCLK / 2 and vertical focus is disabled, the constraints listed in Table 8-496 apply.

Table 8-496. ISS ISP H3A Constraints When PCLK < ISP_FCLK / 2 and Vertical Focus Disabled

Field	Constraint
H3A_AEWWIN1[20:13] WINW	>7
H3A_AFPAX1[23:16] PAXW	>7
H3A_AFIIRSH[11:0] IIRSH	Must be even
H3A_AFPAXSTART[27:16] PAXSH	>= H3A_AFIIRSH[11:0] IIRSH + 2 and must be even
H3A_AFPAX2[20:17] AFINCH	(1+ H3A_AFPAX1[23:16] PAXW / H3A_AFPAX2[20:17] AFINCH) * H3A_AFPAX2[5:0] PAXHC must be between 4 and 384
H3A_AFPAX2[5:0] PAXHC	<=35

- If the pixel clock frequency is greater than or equal to ISP_FCLK / 2 and vertical focus is enabled, the constraints listed in Table 8-497 apply.

Table 8-497. ISS ISP H3A Constraints When PCLK >= ISP_FCLK / 2 and Vertical Focus Enabled

Field	Constraint
H3A_AEWWIN1[20:13] WINW	>15
H3A_AFPAX1[23:16] PAXW	>15
H3A_AFIIRSH[11:0] IIRSH	None
H3A_AFPAXSTART[27:16] PAXSH	>= H3A_AFIIRSH[11:0] IIRSH + 2
H3A_AFPAX2[20:17] AFINCH	None
H3A_AFPAX2[5:0] PAXHC	<= 11

- If the pixel clock frequency is greater than or equal to ISP_FCLK / 2 and vertical focus is disabled, the constraints in Table 8-498 apply.

Table 8-498. ISS ISP H3A Constraints When PCLK >= ISP_FCLK / 2 and Vertical Focus Disabled

Field	Constraint
H3A_AEWWIN1[20:13] WINW	>15
H3A_AFPAX1[23:16] PAXW	>15
H3A_AFIIRSH[11:0] IIRSH	Must be even
H3A_AFPAXSTART[27:16] PAXSH	>= H3A_AFIIRSH[11:0] IIRSH + 2 and must be even
H3A_AFPAX2[20:17] AFINCH	(1 + H3A_AFPAX1[23:16] PAXW / H3A_AFPAX2[20:17] AFINCH) * H3A_AFPAX2[5:0] PAXHC must be between 4 and 384 and H3A_AFPAX2[20:17] AFINCH modulo H3A_AFPAX1[23:16] PAXW !=1

Table 8-498. ISS ISP H3A Constraints When PCLK >= ISP_FCLK / 2 and Vertical Focus Disabled (continued)

Field	Constraint
H3A_AFPAX2[5:0] PAXHC	<= 35

AF engine

- The paxel horizontal start value must be greater than or equal to the IIR horizontal start position.
- The paxel start/end and IIR filter start positions must not be set within the first 2 and the last 2 pixels (to check).
- The width (H3A_AFPAX1[23:16] PAXW) and height (H3A_AFPAX1[7:0] PAXH) of the paxels must be an even number.
- The minimum width of the paxel (H3A_AFPAX1[23:16] PAXW) must be 16 pixels, if pixel clock is half or less of the ISP_FCLK clock. If pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The value of H3A_AFPAX2[20:17] AFINCH bit-field should be higher than 0, irrespective of the ratio of the pixel clock to the ISP_FCLK.
- The number of columns to increment in a paxel (H3A_AFPAX2[20:17] AFINCH) must be even and is restricted to 2 to 32.
- The number of lines to increment in a paxel (H3A_AFPAX2[16:13] AFINCV) must be even and is restricted to 0 to 30.
- The maximum number of vertical paxels in a frame (H3A_AFPAX2[12:6] PAXVC) must not exceed 128.
- The number of paxels in the horizontal direction (H3A_AFPAX2[5:0] PAXHC) has a valid range from 1 to 35.
- If vertical mode is enabled:
  - The paxel horizontal start position (H3A_AFPAXSTART[27:16] PAXSH) must be even.
  - The lower bit of the H3A_AFPAXSTART[27:16] PAXSH bit field and the lower bit of the H3A_AFIIRSH[11:0] IIRSH bit field must be equal.
  - The H3A_AFPAXSTART[11:0] PAXSV bit field must be >= 8.
- If vertical mode is not enabled, the H3A_AFIIRSH[11:0] IIRSH bit field must be even.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW engine

- The width (H3A_AEWWIN1[20:13] WINW) and height (H3A_AEWWIN1[31:24] WINH) of the windows must be an even number.
- The minimum width of the window (H3A_AEWWIN1[20:13] WINW) must be 16 pixels, if the pixel clock is half or less of the ISP_FCLK clock. If the pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The window height (H3A_AEWWIN1[31:24] WINH) has a valid range from 2 to 512.
- The maximum number of vertical windows in a frame (H3A_AEWWIN1[12:6] WINVC) must not exceed 128.
- The number of horizontal windows (H3A_AEWWIN1[5:0] WINHC) has a valid range from 1 to 35.
- The vertical and horizontal window start position (H3A_AEWWINSTART) has a valid range from 0 to 4095.
- The vertical window start position for single black lines (H3A_AEWINBLK[27:16] WINSV) has a valid range from 0 to 4095.
- The horizontal window start position for single black lines (H3A_AEWINBLK[6:0] WINH) must be even and has a valid range from 2 to 256.
- The subsampling windows can start only on even numbers.

- The vertical and horizontal sampling point increment (H3A_AEWSUBWIN) has a valid range from 2 to 32.

8.3.4.6 ISS ISP BL Programming Model

The procedure listed in Table 8-499 initializes the buffer logic.

Table 8-499. ISS ISP BL Settings

Step	Register/Bit Field/Programming Model	Value
Set the memory access priority registers.	ISP5_MPSR	
Set the minimum interval between two memory requests for ISIF read port.	ISP5_BL_MTC_1[31:16] ISIF_R	
Set the minimum interval between two memory requests for IPIPEIF read port.	ISP5_BL_MTC_1[15:0] IPIPEIF_R	
Set the minimum interval between two memory requests for H3A write port.	ISP5_BL_MTC_1[31:16] H3A_W	
Set the maximum number of CIDs/tags that the BL can use.	ISP5_CTRL[7:4] VBUSM_CIDS	
Set the BL VBUSM priority setting.	ISP5_CTRL[3:1] VBUSM_CPRIORITY	
Set write-posted/nonposted.	ISP5_CTRL[0] OCP_WRNP	
Enable the BL clock.	ISP5_CTRL[15] BL_CLK_ENABLE	0x1

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0000000
5:4	STANDBYMODE	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 0x1: No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 0x3: Reserved 0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module must not generate (initiator-related) wake-up events. Generation of the MStandby signal must be initiated by the firmware by writing ISP5_CTRL.MSTANDBY = 1.	RW	0x2
3:2	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
1	SOFTRESET	Software reset. The soft reset will cause the MStandby to be asserted as the reset value of the ISP5_CTRL.MSTANDBY bit is 1. After a soft reset, the software must ensure not to perform any access for 16 clock cycles (OCP-slave port frequency) after writing this bit. The OCP slave port is running at half the frequency of the functional clock. Before issuing a soft reset, the software must ensure that no more traffic is being generated by the ISP. Basically, it means that the camera module must be stopped from sending data and/or that the ISP modules are disabled. The last interrupt triggered by the ISP design upon completion of the frame processing is rsz_int_dma. This rsz_int_dma event must be used to enable clean termination of the processing. The software must wait a few hundred cycles to trigger the soft reset after upon assertion of the rsz_int_dma, this is to ensure that the BL is completely drained. Software must set the ISP in standby mode before issuing the soft reset: Set ISP5_SYSCONFIG.STANDBYMODE = 2 (smart standby). Set ISP5_CTRL.MSTANDBY to 1. Poll for ISP5_CTRL.MSTANDBY_WAIT = 1. Then, the soft reset can be applied (ISP5_SYSCONFIG.SOFTRESET = 1). Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action	RW	0
0	AUTO_IDLE	Auto clock gating. Always enabled.	R	1

23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
21:20	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
18	RSZ_FIFO_OVF	This event signals that overflow happened in the input data buffering submodule. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. Depending on the mode being used, the overflow can happen at different places: 1. Bypass mode: overflow happened in the input circular buffer. 2. Pass through mode: overflow happened on the module output interface (MTC) 3. Normal resize mode: overflow happened in the input circular buffer. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0

Bits	Field Name	Description	Type	Reset
16	RSZ_INT_CYC_RZA	RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
15	RSZ_INT_DMA	This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next rsz_int_reg event. Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
12	H3A_INT	Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
11	AF_INT	Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0
10	AEW_INT	Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0

Bits	Field Name	Description	Type	Reset
9	IPIPEIF_IRQ	IPIPEIF module interrupt Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending	RW W1toSet	0

Table 8-511. Register Call Summary for Register ISP5_IRQSTATUS_RAW_i

ISS ISP

- ISS ISP5 SYS1 Register Summary: [0]

Table 8-512. ISP5_IRQSTATUS_i

Address Offset	0x0000 0028 + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 0028 + (0x10 * i)	**Instance**	ISS_ISP5_SYS1
Description	Per-event "enabled" interrupt status vector. Enabled status is not set unless event is enabled. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, that is, even if not enabled). The ISP outputs four interrupt lines, ISP_IRQ0 to ISP_IRQ3. Any internal ISP event can be merged on the four lines. A same event must be enabled on only one interrupt line.		
Type	RW

Bits	Field Name	Description	Type	Reset
31	OCP_ERR_IRQ	An OCP error has been received on the ISP master port. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
30	RESERVED		R	0
29	IPIPE_INT_DPC_RNEW1	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
28	IPIPE_INT_DPC_RNEW0	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
27	IPIPE_INT_DPC_INI	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
26	RESERVED		R	0
25	IPIPE_INT_EOF	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
24	H3A_INT_EOF	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
18	RSZ_FIFO_OVF	This event signals that overflow happened in the input data buffering submodule or in the RSZ output interface. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
16	RSZ_INT_CYC_RZA	RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
15	RSZ_INT_DMA	This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next rsz_int_reg event. Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
12	H3A_INT	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
11	AF_INT	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

9	IPIPEIF_IRQ	IPIPEIF module interrupt Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
8	IPIPE_INT_HST	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
7	IPIPE_INT_BSC	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
6	IPIPE_INT_DMA	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
5	IPIPE_INT_LAST_PIX	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
4	IPIPE_INT_REG	Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
3	ISIF_INT_3	LSC interrupt issued by 2D-LSC block. Four types of 2D-LSC can be generated and mapped to the INT_3 line. For more information, see Section 8.3.3.6.10.1.5, *ISS ISP ISIF 2D-LSC Events and Status Checking.* Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
2	ISIF_INT_2	VD interrupt 2 event. Read this bit to check the interrupt mapped to the INT_2 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
1	ISIF_INT_1	VD interrupt 1 event. Read this bit to check the interrupt mapped to the INT_1 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0
0	ISIF_INT_0	VD interrupt 0 event. Read this bit to check the interrupt mapped to the INT_0 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending	RW W1toClr	0

Table 8-513. Register Call Summary for Register ISP5_IRQSTATUS_i

ISS ISP

- ISS ISP RSZ Reset Behavior: [0] [1] [2]
- ISS ISP5 SYS1 Register Summary: [3]

NOTE: ISP submodule interrupts are mapped to ISP top-level lines. Moreover, ISP top-level lines are mapped to the ISS top interrupt merger level. For information about how IRQ lines are handled at the ISP level, see Table 8-419. For information about how IRQs are handled at the ISS top-level before the signals leave ISS boundaries, see Section 8.1.2.1.1, *ISS Interrupt Merger.*

Table 8-514. ISP5_IRQENABLE_SET_i

Address Offset	0x0000 002C + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 002C + (0x10 * i)	**Instance**	ISS_ISP5_SYS1
Description	Per-event interrupt enable bit vector. Write 1 to set (enable interrupt). Readout equal to corresponding _CLR register. The ISP outputs four interrupt lines, ISP_IRQ0 to ISP_IRQ3. Any internal ISP event can be merged on the four lines. A same event must be enabled on only one interrupt line.

23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0

Bits	Field Name	Description	Type	Reset
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
18	RSZ_FIFO_OVF	This event signals that overflow happened in the input data buffering submodule or in the RSZ output interface. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0

Bits	Field Name	Description	Type	Reset
16	RSZ_INT_CYC_RZA	RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
15	RSZ_INT_DMA	This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
14	RSZ_INT_LAST_PIX	This event is triggered when the last pixel of the valid area is received. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
13	RSZ_INT_REG	This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next rsz_int_reg event. Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
12	H3A_INT	Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
11	AF_INT	Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
10	AEW_INT	Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0

Bits	Field Name	Description	Type	Reset
9	IPIPEIF_IRQ	IPIPEIF module interrupt Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
8	IPIPE_INT_HST	Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0
7	IPIPE_INT_BSC	Write 0x0: No action Write 0x1: Enable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toSet	0

- ISS ISP5 SYS1 Register Summary: [33]

NOTE: Setting the ISP submodule interrupts and mapping them to the ISP lines requires a configuration to receive the IRQ events at a higher ISS interrupt merger level. For information about how IRQ lines are handled at the ISP level, see Table 8-419. For information about how IRQs are handled at the ISS top-level before the signals leave ISS boundaries, see Section 8.1.2.1.1, *ISS Interrupt Merger.*

Table 8-516. ISP5_IRQENABLE_CLR_i

Address Offset	0x0000 0030 + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 0030 + (0x10 * i)	**Instance**	ISS_ISP5_SYS1
Description	Per-event interrupt enable bit vector. Write 1 to clear (disable interrupt). Readout equal to corresponding _SET register. The ISP outputs four interrupt lines, ISP_IRQ0 to ISP_IRQ3. Any internal ISP event can be merged on the four lines. A same event must be enabled on only one interrupt line.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31	OCP_ERR_IRQ	An OCP error has been received on the ISP master port. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
30	RESERVED		R	0
29	IPIPE_INT_DPC_RNEW1	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
28	IPIPE_INT_DPC_RNEW0	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
27	IPIPE_INT_DPC_INI	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
26	RESERVED		R	0
25	IPIPE_INT_EOF	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW	0
24	H3A_INT_EOF	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW	0
23	RSZ_INT_EOF1	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW	0

Bits	Field Name	Description	Type	Reset
22	RSZ_INT_EOF0	RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW	0
21:20	RESERVED		R	0x0
19	RSZ_FIFO_IN_BLK_ERR	This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
18	RSZ_FIFO_OVF	RESIZER module event: This event signals that overflow happened in the input data buffering submodule or in the RSZ output interface.. This event would typically happen because the video port pixel clock is too high. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
17	RSZ_INT_CYC_RZB	RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
16	RSZ_INT_CYC_RZA	RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA. Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
15	RSZ_INT_DMA	RESIZER module event: This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and that the resizer core has returned to idle. rsz_int_dma is a true indication that all processing is finished for the particular frame on both resizer engines. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
14	RSZ_INT_LAST_PIX	RESIZER module event: This event is triggered when the last pixel of the valid area is received. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
13	RSZ_INT_REG	RESIZER module event: This event is triggered when the first pixel of the valid area is received. Shadowed registers can be updated at any time but the new value will take effect on the next rsz_int_reg event. Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
12	H3A_INT	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
11	AF_INT	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
10	AEW_INT	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
9	IPIPEIF_IRQ	IPIPEIF module interrupt Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
8	IPIPE_INT_HST	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
7	IPIPE_INT_BSC	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
6	IPIPE_INT_DMA	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
5	IPIPE_INT_LAST_PIX	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
4	IPIPE_INT_REG	Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
3	ISIF_INT_3	Set this bit to disable the LSC interrupt issued by the 2D-LSC block. Four types of 2D-LSC can be generated and mapped to the INT_3 line. For more information, see Section 8.3.3.6.10.1.5, *ISS ISP ISIF 2D-LSC Events and Status Checking.* Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
2	ISIF_INT_2	VD interrupt 2 event. Set this bit to disable the interrupt mapped to the INT_2 line. This interrupt is set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
1	ISIF_INT_1	VD interrupt 1 event. Set this bit to disable the interrupt mapped to the INT_1 line. This interrupt is set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0
0	ISIF_INT_0	VD interrupt 0 event. Set this bit to disable the interrupt mapped to the INT_0 line. This interrupt is set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.6.19.1, *ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.* Write 0x0: No action Write 0x1: Disable interrupt Read 0x1: Interrupt enabled Read 0x0: Interrupt disabled (masked)	RW W1toClr	0

Bits	Field Name	Description	Type	Reset
31:30	DMA3_CFG	This bit field selects the DMA transfer configuration which is used with the ISS_DRE_4 DMA request signal. This DMA request is generated from IPIPE_INT_LAST_PIXEL event. One can choose to use this DMA request to transfer the DPC initialization data, the gamma table, or both. 0x0: No DMA request associated with ISS_DREQ_4. 0x1: DPC DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 2 KiB in the range 0x8000-0x87FF. DPC_EVT_INI must be set to 0. 0x3: DPC + GAMMA DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 8 KiB in the range 0x8000-0x87FF and 0xA800-0xBFFF. DPC_EVT_INI must be set to 0. 0x2: GAMMA DMA request associated with ISS_DREQ_4. Expected DMA transfer size is 6 KiB in the range 0xA800-0xBFFF.	RW	0x0
29:28	RESERVED		R	0x0
27	RESERVED		R	0x0
26	HST_RD_CHK	When the HISTOGRAM computation is enabled and the HST DMA request is not used to read out the data, this register ensures that the data is read fast enough, else an interrupt ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR is triggered. The hardware sets automatically this bit to 1 when software can start reading the memory.	RW	0

CAUTION

Software must set this bit to 0 after reading the data. Once the MPU/IPU has read the histogram data, it must clear this register, else the ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR will occur.

Write 0x0: Clears the signal to avoid error generation.
The software must write this bit to 0 after the last data read.

Write 0x1: Reserved

Bits	Field Name	Description	Type	Reset
		Read 0x1: The MPU/IPU can read the data from the memory. Needs to complete fast enough to avoid the interrupt generation.		
		Read 0x0: No interrupt generation can happen		
25	DPC_EVT_INI	Select the IPIPE module event to be used to generate the DMA requests for the DPC submodule. 0x0: IPIPE_INT_LAST_PIX event is selected. 0x1: IPIPE_INT_DPC_INI event is selected.	RW	0
24	MSTANDBY	MStandby signal assertion and de-assertion control for power management transitions. After software reset, this bit is asserted. Write "1" to transition from normal mode to idle mode. The firmware needs to ensure that no more ISP processing is ongoing before setting up this bit. Write "0" to transition from idle mode to normal mode. The software should poll ISP5_CTRL.MSTANDBY_WAIT = 0 after writing ISP5_CTRL.MSTANDBY = 0 in a transition from idle to normal mode. 0x0: De-assert MStandby signal. May not be immediate due to power management handshaking btw the MStandby and Wait signals. 0x1: Assert MStandby signal	RW	1
23	VD_PULSE_EXT	VD pulse extension enable This bit enables or disables the VD extension bridge. By default, the bridge is enabled. At ISS level, it is expected that ISP5_CTRL.VD_PULSE_EXT = 1 when the VPORT gets data from the CSI2 RX module and ISP5_CTRL.VD_PULSE_EXT = 0 when the VPORT gets data from the parallel interface or the CCP2 RX module. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Disabled 0x1: Enabled	RW	1
22	PCLK_INV	Pixel clock inversion This bit enables or disables pixel clock inversion. The ISP always samples the data on the rising edge of the pixel clock. Enabling the inversion shifts the resampling period by 1/2 a pixel clock period. PCLK needs to be disabled at ISS level before setting to 0x1 this bit. This can be done through the proper ISS_CLKCTRL[] VPORTx_CLK register bit on ISS top level, depending on the interface (CCP2 or CSI2) that is sending data on the ISP video port. 0x0: Normal 0x1: Inversed	RW	0
21	MFLAG	MFlag signal generation control This bit controls how the OCP MFlag signal is generated on the ISS NOC. 0x0: The MFlag value is dynamic. 0x1: The MFlag value is static. The value is set with the ISP5_CTRL[3:1] VBUSM_CPRIORITY.	RW	0
20	MSTANDBY_WAIT	MStandby / Wait power management status bit. The power management framework of the ISP is based on the handshaking of the MStandby and Wait signals. The software is not supposed to write inside the ISP slave port and initiate traffic when ISP5_CTRL.MSTANDBY bit is written. The software can poll this bit to know when Wait signal is deasserted. Read 0x1: MStandby signal is asserted. Read 0x0: MStandby signal is deasserted.	R	-
19:16	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
15	BL_CLK_ENABLE	BL clock enable 0x0: Disable 0x1: Enable	RW	0
14	ISIF_CLK_ENABLE	ISIF clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Disable 0x1: Enable	RW	0
13	H3A_CLK_ENABLE	H3A clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0
12	RSZ_CLK_ENABLE	RESIZER clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0
11	IPIPE_CLK_ENABLE	IPIPE clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0
10	IPIPEIF_CLK_ENABLE	IPIPEIF clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable	RW	0
9	SYNC_ENABLE	PCLK Sync module enable. This bit may only be modified when the video port is not receiving data such as when data is read from the IPIPEIF module memory read port. 0x0: Disable 0x1: Enable	RW	0
8	PSYNC_CLK_SEL	PCLK Sync clock select. This bit selects the clock which is used to resynchronize the input pixel clock. 0x0: GCK_MMR. Can be used if the input pixel clock is always lower than 152 MHz. 0x1: ISP_FCLK. Must be used if the pixel clock is higher than 152 MHz.	RW	0
7:4	VBUSM_CIDS	BL MAX VBUSM CIDs The BL module supports up to 16 CIDs/tags. This bit field sets up the maximum number of CISs/tags that the BL can use. The actual number of CIDs/tags is setup by VBUSM_CIDS + 1. Tag number 0 to VBUSM_CIDS are used.	RW	0xF

Bits	Field Name	Description	Type	Reset
3:1	VBUSM_CPRIORITY	BL VBUSM priority setting 0x6: Normal Priority VBUSM cpriority[2:0] = 6 0x1: High Priority VBUSM cpriority[2:0] = 1 0x7: Normal Priority VBUSM cpriority[2:0] = 7 0x0: High Priority VBUSM cpriority[2:0] = 0 0x2: Medium Priority VBUSM cpriority[2:0] = 2 0x4: Normal Priority VBUSM cpriority[2:0] = 4 0x5: Normal Priority VBUSM cpriority[2:0] = 5 0x3: Medium Priority VBUSM cpriority[2:0] = 3	RW	0x4
0	OCP_WRNP	ISP OCP master port non-posted write control. 0x0: All writes are non posted. 0x1: All writes are posted.	RW	0

Table 8-524. ISP5_MPSR

Address Offset	0x0000 007C		
Physical Address	0x5201 007C	**Instance**	ISS_ISP5_SYS1
Description	ISP memory access register. One need to pay attention when setting the bit fields in this register such that there is no conflict between the CPU and module accesses. Usually, the ISP modules must have access to the memories and it is only when the ISP is idle (vertical blanking period or module disabled that the CPU can access the memories.

Description	BL VBUSM TUNING REGISTER The settings in the register are static and not expected to be modified dynamically.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																										MFLAG_THRES	LASTCMD_DLY				

Bits	Field Name	Description	Type	Reset
31:6	RESERVED		R	0x0000000
5	MFLAG_THRES	MFLAG Threshold value The value of this bit field is a threshold which is compared to the MFlag output of the ISP5. If the BL MFlag signal is greater or equal to this threshold the last beat of the VBUSM command is delayed by ISP5_BL_VBUSM[4:0] LASTCMD_DLY cycles. Only values 0, 1 are valid, the least significant bit is tied off to 1 to make a 2-bit field. 0x0: Thres = 1 0x1: Thres = 3	RW	1
4:0	LASTCMD_DLY	The value of this bit field represents a delay expressed in cycles (L3_MAIN clock). This value is used to delay the last beat of the VBUSM command such that the ISP does not loose arbitration at the ISS level because the BL does not generate back to back requests by default. The last beat is delayed until the counter expires or the new request is accepted. This delay is used when the MFlag output of the ISP is greater or equal to ISP5_BL_VBUSM[5] MFLAG_THRES. One can set this value to 0 to disable the last command beat delay.	RW	0x04

Table 8-551. ISP5_IRQENABLE_CLR2_i

Address Offset	0x0000 0024 + (0x10 * i)	**Index**	i = 0 to 3
Physical Address	0x5201 00C4 + (0x10 * i)	**Instance**	ISS_ISP5_SYS2
Description	Per-event interrupt enable bit vector. Write 1 to clear (disable interrupt). Readout equal to corresponding _SET register. Overflow / underflow errors are not recoverable at ISP level, a software reset is required at ISS level. The ISP outputs 4 interrupt lines ISP5_IRQ0 to ISP5_IRQ3. Any internal ISP event can be merged on the 4 lines. A same event must be enabled on only one interrupt line.

RESERVED																															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:0	RSZ_FRACDIV	Fractional clock divider value. The fractional clock divider gates the read requests made to the input data buffer such that the input data buffer is read at an average frequency equal to FFCLK instead of FCLK. The value of FFCLK depends upon the upscaling ratios as well as the input pixel clock: We have FFCLK = FCLK / FRACDIV MHz and RSZ_FRACDIV = 65536 / FRACDIV. When RSZ_ FRACDIV = 65536, we have: FFCLK = FCLK.	RW	0xFFFF

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:0	HPS	Horizontal Start Position The RSZ_SRC_HPS register has two functions: The first function is to compensate for possible delay between the HD pulse and the first valid data. It is possible for this delay to be different than 0 when the RESIZER module gets its input data from the VP connected to the IPIPEIF module (the offset value can be odd or even). When data are coming from the IPIPE module, it is not required to resynchronize HD and the first valid data. The second function is to crop the data in the horizontal direction. When used for cropping, only RSZ_SRC_HPS must be even or null.	RW	0x0000

Table 8-620. RZA_V_PHS_Y

Address Offset	0x0000 0094		
Physical Address	0x5201 0494	**Instance**	ISS_RESIZER
Description	RESIZER A - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV4:2:2 data are output, the phase values for luma and chroma should typically be equal, that is, RZX_V_PHS_Y= RZX_V_PHS_C. The following constraints apply when setting the initial vertical phases ABS(RZX_V_PHS_Y - RZX_V_PHS_C) RZX_V_DIF. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF.

Address Offset	0x0000 0124		
Physical Address	0x5201 0524	**Instance**	ISS_RESIZER
Description	RESIZER B - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV4:2:2 data are output, the phase values for luma and chroma should typically be equal, that is, RZX_V_PHS_Y= RZX_V_PHS_C. The following constraints apply when setting the initial vertical phases ABS(RZX_V_PHS_Y - RZX_V_PHS_C) RZX_V_DIF. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF.

RESERVED																Y_SAD_L															
R-0																RW-0															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:0	Y_SAD_L	Memory Start Address Sets the 16 lower bits of the 32-bit start address in memory. It is a byte address. For every frame, the first line of data will be written to this address. We have: SAD = BAD + (PTR_S x OFT) and PTR_S < PTR_E If the first line must be written at the beginning of the circular buffer memory then SAD = BAD and PTR_S = 0. YUV4:2:0 format (output data on 8 bits): The two least significant bits must be set to 00 when horizontal reversal mode is off. The two least significant bits must be set to 11 when horizontal reversal mode is on. RAW, RGB5:6:5 and YUV4:2:2 formats (output data on 16 bits): The two least significant bits must be set to 00 when horizontal reversal mode is off. The two least significant bits must be set to 11 when horizontal reversal mode is on. RGBA format (output data on 32 bits): The three least significant bits must be set to "000" when horizontal reversal mode is off. The three least significant bits must be set to "111" when horizontal reversal mode is on.	RW	0x0000

Table 8-911. IPIPE_YUV_PHS

Address Offset	0x0000 02C8		
Physical Address	0x5201 0AC8	**Instance**	ISS_IPIPE
Description	YUV4:2:2 down sampling register. This register controls the YUV4:4:4 to YUV4:2:2 chroma downsampling. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). IPIPE_YUV_PHS = 0 leads to pure subsampling, no filtering, cosited chroma output. IPIPE_YUV_PHS = 1 leads to (1, 1) >> 1 filtering, centered chroma output. IPIPE_YUV_PHS = 2 leads to (1, 2, 1) >> 1 filtering, cosited chroma output. IPIPE_YUV_PHS = 3 leads to (1, 3, 3, 1) >> 3 filtering, centered chroma output. When the chroma output is cosited, and that downsampling is enabled in the RESIZER module, one need to take care that the averager disrupts the relative phase for luma and chroma color components. The RZA_H_PHS_ADJ and RZB_H_PHS_ADJ registers need to be used to fix the disruption.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED														LPF	POS

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	LPF	121-LPF enable for chrominance samples. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). 0x0: off 0x1: on	RW	0
0	POS	This bit sets the output position of the chrominance sample with regards to the luma sample positions. One can choose between centered and cosited. This register is valid if IPIPE_SRC_FMT.FMT = 0 (RAW input and YUV output). The RESIZER module does not change the relative position of the chroma samples vs. the luma samples between the input and output and the chroma position at the output of the IPIPE module and at the output of the RESIZER module must be identical. In other words, we must have RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS. 0x0: Cosited = same position with luminance 0x1: Centered = middle of the luminance	RW	0

RESERVED																RESERVED														CLR	SEL

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	CLR	Histogram memory clear. The histogram can be cleared before the start of operations. However, the clear takes 512 cycles and therefore: + if line size > 512, the first line must not be used for histogram computation. + if line size < 512, ceil (512/line size) lines must not be used for histogram computation. It's the programmer's responsibility to set the histogram computation area outside the "clear" area. 0x0: Disable 0x1: Enable	RW	0
0	SEL	This bit must be used to select which memory is used to store the histogram data. By selecting alternatively one or the other bit, one can double buffer the histogram output buffer. The 4-KiB memory can either be read by the CPU or a DMA request. 0x0: Use Table 0 and 1 = 4 KiB in the memory ISP map. 0x1: Use Table 2 and 3 = 4 KiB in the memory ISP map.	RW	0

8.3.5.6.2 ISS ISIF Register Description

Table 8-1012. ISIF_SYNCEN

Address Offset	0x0000 0000		
Physical Address	0x5201 1000	**Instance**	ISS_ISIF
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED														DWEN	SYEN

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:2	RESERVED		R	0x0000
1	DWEN	Controls the storage of image sensor RAW data in memory. This bit is loaded with the timing of the internal VD signal: it becomes active starting at the lead of the VD signal that comes after 1 is written in this bit. 0x0: Disable 0x1: Enable	RW	0
0	SYEN	Controls ON/OFF of VD/HD output. Internal timing generator becomes active and VD/HD output starts when 1 is written in this bit. In case of input, VD/HD loading begins. 0: Disable 1: Enable	RW	0

Table 8-1014. ISIF_MODESET

Address Offset	0x0000 0004		
Physical Address	0x5201 1004	**Instance**	ISS_ISIF
Description			
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MDFS	HLPF	INPMOD		OVF	CCDW			CCDMD	DPOL	SWEN	FIPOL	HDPOL	VDPOL	FIDD	HDVDD

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	MDFS	Field Status This bit indicates the status of the current FLD signal when the ISIF module is in interlaced mode. Read 0x1: Even field Read 0x0: Odd field	R	0
14	HLPF	Low pass filter enable. When this bit is enabled, a 3-tap (1/4 + 1/2 Z^{-2} + 1/4 Z^{4}) filtering process is performed on the sensor data. 0x0: Disable 0x1: Enable	RW	0
13:12	INPMOD	Data input mode: 0x0: RAW data 0x1: YCbCr 16bit 0x3: Reserved 0x2: YCbCr 8bit	RW	0x2
11	OVF	ISIF module write port overflow status bit If the write port of the ISIF module overflows when writing data to SDRAM, this bit will toggle. 0x0: No overflow pending (r) No action (w) 0x1: Overflow pending (r) Clear overflow (w)	RW	0
10:8	CCDW	This bit enables to shift right (divide) the up-to-12-bit RAW data value when writing out to SDRAM. The effect is that the dynamic of the output signal is decreased. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x6: Reserved 0x1: 1-bit right shift out[15:0] = 00000 & data[11:1] 0x7: Reserved 0x0: No shift out[15:0] = 0000 & data[11:0] 0x2: 2-bit right shift out[15:0] = 000000 & data[11:2] 0x4: 4-bit right shift out[15:0] = 00000000 & data[11:4] 0x5: Reserved 0x3: 3-bit right shift out[15:0] = 0000000 & data[11:3]	RW	0x0
7	CCDMD	Field mode: This bit selects the type of image sensor: interlaced or progressive 0x0: Progressive image sensor 0x1: Interlaced image sensor	RW	0
6	DPOL	Image sensor input data polarity 0x0: No change 0x1: One's complement	RW	0
5	SWEN	External WEN selection In case this bit and SYNCEN.DWEN are set to 1, the external WEN signal is used to store image sensor data to memory. 0x0: WEN not used 0x1: Use external WEN	RW	0

Bits	Field Name	Description	Type	Reset
4	FIPOL	FLD Signal Polarity 0x0: Positive 0x1: Negative	RW	0
3	HDPOL	HD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0
2	VDPOL	VD Sync Signal Polarity 0x0: Positive 0x1: Negative	RW	0
1	FIDD	FLD Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output	RW	0
0	HDVDD	VD,HD Sync Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15	VLDC	On/off control of CPU registers resynchronize function by VSYNC. All the others are shadowed registers, where register values are updated at V-sync timing by default. If VDLC=1, ISIF register values are updated immediately after register write just like non-shadowed registers. 0x0: Enable 0x1: Disable	RW	0
14	RESERVED	Reserved. must always be set to 0.	RW	0
13	MSBINVI	MSB inverse of CIN port when the data are captured to SDRAM. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable	RW	0
12	BSWD	On/off control of Byte SWAP function when SDRAM capturing. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable (swap)	RW	0
11	Y8POS	Selects Y signal position when in 8bit input mode 0x0: even pixel 0x1: odd pixel	RW	0
10	EXTRG	Setting 1 to this register, the SDRAM address is initialized at the rising edge of FID input signal or DWEN register.	RW	0
9	TRGSEL	Select trigger source signal of SDRAM address initializing in case EXTRG=1. 0x0: DWEN register 0x1: FID input port	RW	0
8	WENLOG	Specifies the CCD valid area. 0x0: internal valid signal and WEN signal is ANDed logically. 0x1: internal valid signal and WEN signal is ORed logically.	RW	0
7:6	FIDMD	Specifies FID detection mode 0x0: latch the FID at the VSYNC timing 0x1: no latch the FID 0x3: Reserved 0x2: Reserved	RW	0x0
5	BT656	Selects bit width of CCIR656. This bit applies only if ISIF_REC656IF.R656ON = 1. 0x0: 8 bits 0x1: 10 bits	RW	0

Bits	Field Name	Description	Type	Reset
4	YCINSWP	The ISIF module has a 16-bit interface. When 16-bit YUV data are input, the luma data (YIN7-0) are expected to be on the 8 MS bits and the chroma (CIN7-0) data are expected to be on the LS bits. This bit enables to swap the 8 MS bits with the 8 LS bits of the interface in case the luma and chroma do not come in the correct order. See Section 8.3.3.6.2, *ISS ISP ISIF Top-Level Block Diagram*. 0x0: YIN7-0 = Y signal / CIN7-0 = C signal 0x1: YIN7-0 = C signal / CIN7-0 = Y signal	RW	0
3	RESERVED	Reserved. must always be set to 0.	RW	0
2	RESERVED	Reserved. must always be set to 0.	RW	0
1:0	SDRPACK	This bit field selects how the data are stored to SDRAM. There can be 8, 12 or 16 bits per pixel. The ISIF_MODESET.CCDW, ISIF_HSIZE.ADCR, ISIF_HSIZE.HSIZE, ISIF_CCDCFG.BSWD, ISIF_CCDCFG.MSBINV, ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: 16 bits / pixel 0x1: 12 bits / pixel 0x3: Reserved 0x2: 8 bits / pixel	RW	0x0

Description			
Type	RW		

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:4	RESERVED		R	0x000
3	SOF	Interrupt status for LSC SOF Indicates the start of the LSC valid region. LSC configuration registers can be updated after LSC SOF for the next frame. 0x0: Interrupt is masked 0x1: Interrupt is enabled	RW	0
2	PREFETCH_COMPLETED	Interrupt enable for Prefetch Complete Indicates current state of the prefetch buffer. Could be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. 0x0: Interrupt is masked 0x1: Interrupt is enabled	RW	0
1	PREFETCH_ERROR	Interrupt enable for Prefetch Error The prefetch error indicates when the gain table was read to slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after clearing this event. Until the next pre-fetch completion, the image will be multiplied with previous gain values, and output image is not correct. 0x0: Interrupt is masked 0x1: Interrupt is enabled	RW	0
0	DONE	Interrupt enable for LSC Done The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Interrupt is masked 0x1: Interrupt is enabled	RW	0

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0000 0000
1	SYNCOFF	VD output mask This register masks the VD output to the IPIPE module. This can be useful when one wants to read data from SDRAM which are stored in a double buffer. If the VD is not masked each time we start the module an new VD will be generated to the IPIPEIF module. Let's consider two buffers A and B of N lines each. *This bit field is latched by VD. 0x0: VD output mask is disabled. 0x1: VD output mask is enabled.	RW	0
0	ENABLE	IPIPE I/F Enable This register is used to start the operation of SDRAM buffer memory read and generates SYNC signals. This register is available when INPSRC1 or INPSCR2 = 1, 2 or 3. 0x0: disable 0x1: enable	RW	0

Bits	Field Name	Description	Type	Reset
31:8	RESERVED		R	0x000000
7	YUV8P	8-bit YUV data unpacking to 16 bits When IPIPEIF_CFG1.INPSRC2 = 0 and IPIPEIF_CFG2.YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the IPIPEIF_CFG2.YUV8P register. The upper 8 bits of the 16-bit output are set to 0. 0x0: Y output on even pixels C output on odd pixels 0x1: C output on even pixels Y output on odd pixels	RW	0
6	YUV8	YUV 8bit mode When ISIF_CFG1.INPSRC2 = 0 and YUV16 = 1, setting this bit to 1 enables the conversion from 8-bit YUV input to 16-bit YUV. This register is used when the input data from the ISIF module is 8-bit YUV data. 0x0: YUV16 0x1: YUV8 to 16	RW	0
5	DFSDIR	DFS direction Selects the direction of dark frame subtraction. 0x0: VPORT IF(capture frame) - SDRAM (dark frame) 0x1: SDRAM (capture frame) - VPORT IF(dark frame)	RW	0
4	RESERVED	Read returns reset value	RW	0

3	YUV16	Data type selection. The behavior of this bit field depends upon other register settings. The functionality is best explained with the following pseudo code:
		if ((CFG1.INPSRC2==0 && CFG2.YUV16) ||
		CFG1.INPSRC2==3) {
		data_out[15:0] = yuv[15:0]
		}
		else if (CFG1.INPSRC2==1 && CFG2.YUV16 &&
		CFG1.UNPACK=1) {
		data_out[15:8] = gain_clip[7:0];
		data_out[7:0] = 0;
		}
		else {
		data_out[15:12] = 0;
		data_out[11: 0] = gain_clip[11:0];
		}
		where:
		o data_out[15:0] = 16-bit YUV or 12-bit RAW data to ipipe
		o yuv[15:0] = 16-bit YUV data from "horizontal pixel decimator" block.
		o gain_clip[11:0] = 12-bit RAW data from "gain" block.
		0x0: 12-bit RAW data
		0x1: 16-bit YUV data
			RW	0

Bits	Field Name	Description	Type	Reset

Physical Address	0x5201 123C	**Instance**	ISS_IPIPEIF
Description	IPIPEIF data underflow detection		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED								FIFOWMRKLVL						ENM2MSTALL	DTUDF

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0000
15:6	RESERVED		R	0x0000
5:2	FIFOWMRKLVL	To guarantee that the FIFO does not overflow, the stall request is deasserted only when a certain number of locations in the FIFO are free. The number of free locations is configurable. A safe number of mandatory free locations can be configured by taking into consideration the pixel clock frequency (PCLK) with respect to that of the functional clock (ISP_FCLK). The worst case occurs when PCLK = ISP_FCLK. In that case, value should be configured to 0 (i.e. 16 free locations), so that the stall will be deasserted only when the 16-deep FIFO is completely empty. 0: Stall deassertion when FIFO is empty (16 free locations) and SDRAM data available; 1: Stall deassertion when FIFO has not more than 1 valid entry and SDRAM data available; … 15: Stall deassertion when FIFO has not more than 15 valid entries and SDRAM data available;	RW	0x0
1	ENM2MSTAL	Enable memory-to-memory stall mechanism: 0: disable (no special stall mechanism for memory-to-memory use cases); 1: enable (stall mechanism for memory-to-memory use cases);	RW	0
0	DTUDF	Data under flow error status register. Reading 1 shows there is data under flow and at least one data is corrupted while reading from SDRAM. Writing 1 to this register clears (=0) the error (=1) status. Underflow errors are non recoverable at ISP level, need to do a soft reset at ISS level. The IPIPEIF_UDF interrupt is generated when an underflow happens. The interrupt avoids polling this register for errors. If bit [1] ENM2MSTAL = 1, then programmers need to ensure that the SW does not clear bit [0] DTUDF, as this would reset the MTC read interface. Bit DTUDF can be cleared only in the on-the-fly operation where the stall mechanism will not work.	RW	0

RESERVED								AFINCH								AFINCV								PAXVC							
PAXHC																															

Bits	Field Name	Description	Type	Reset
31:21	RESERVED		R	0x000
20:17	AFINCH	AF Engine Column Increments Number of columns to increment in a paxel plus 1 multiplied by 2. Thus, the number of columns that can be skipped between two processed line pairs is 2-32 (even). The starting two columns in a paxel are first processed before this field is applied. This must be set so that there are at least 4 samples on a line when combined with the number of horizontal paxels. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0
16:13	AFINCV	AF Engine Line Increments Number of lines to increment in a Paxel plus 1 multiplied by 2. Incrementing the line in a paxel is always done on a line pair due to the fact that the RGB pattern falls in two lines. If all the lines are to be processed, this field should be set to zero, and thus line count is incremented by 2 following a line pair. Thus, the number of lines that can be skipped between two processed line pairs is 0-30 (even). The starting two lines in a paxel are first processed before this field is applied. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x0

Bits	Field Name	Description	Type	Reset
12:6	PAXVC	AF Engine Vertical Paxel Count The number of paxels in the vertical direction plus 1. The maximum number of vertical paxels in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded. * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00
5:0	PAXHC	AF Engine Horizontal Paxel Count The number of paxels in the horizontal direction plus 1. It is illegal to set a number that is greater than 35 (total of 36 paxels in the horizontal direction). The minimum number of paxels should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC.	RW	0x00

8.4 ISS Still Image Coprocessor

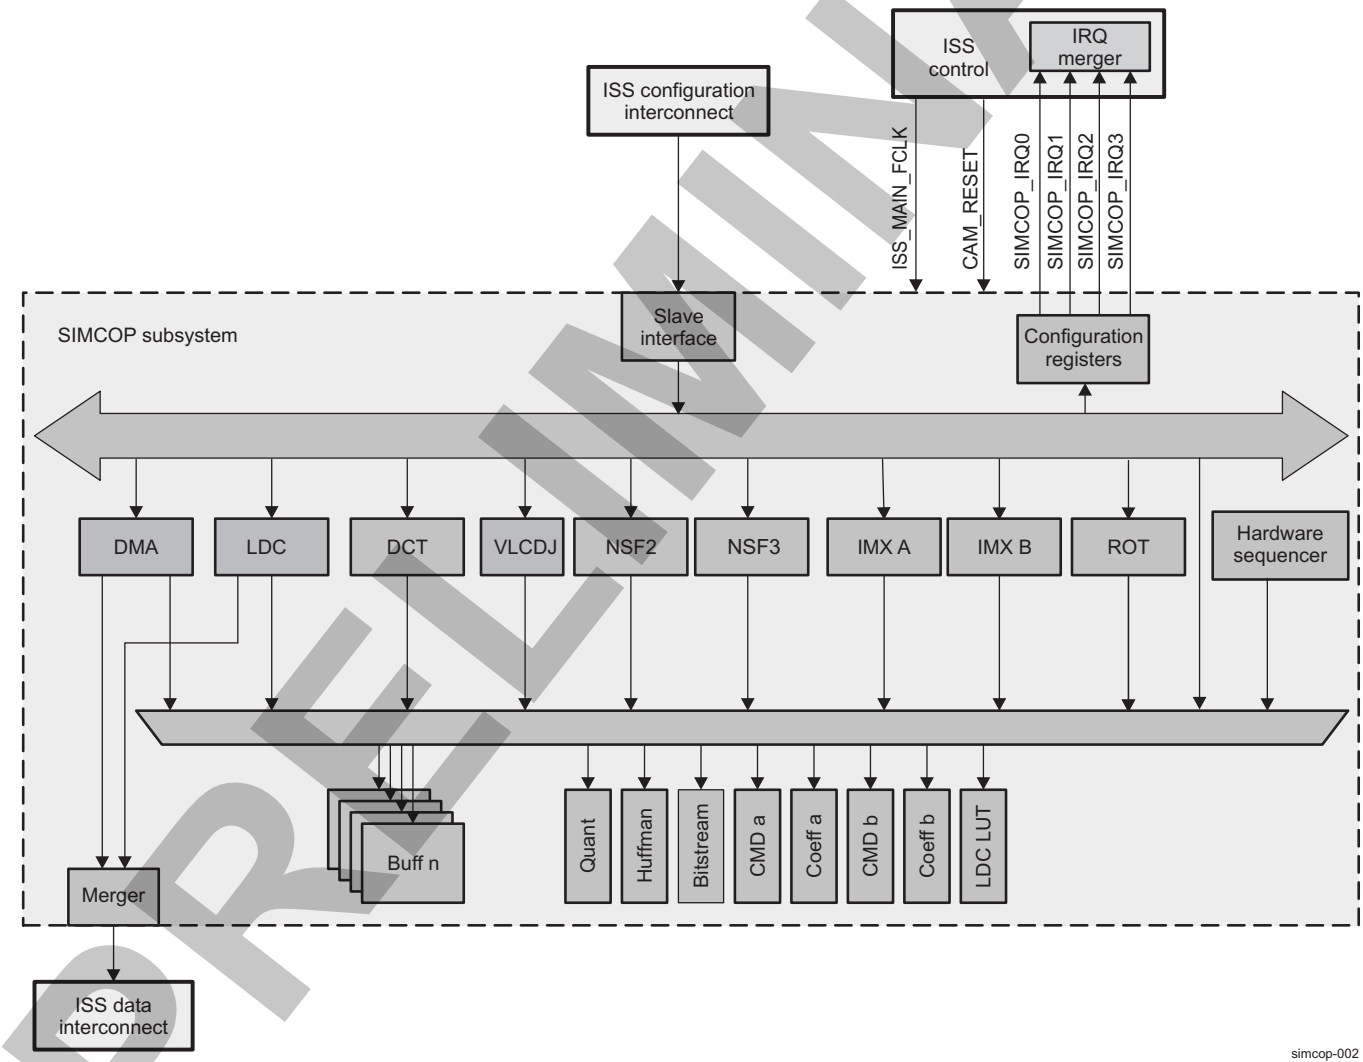
This section gives a high-level description of the ISS still iMage coprocessor (SIMCOP) in the device. For a high-level description of ISS level, see Section 8.1, *ISS:Overview*.

8.4.1 ISS SIMCOP Overview

The SIMCOP subsystem is designed to encode, decode, and process image data. SIMCOP is a macroblock-based memory-to-memory processing engine. It fetches macroblocks from system memory and stores them into local memories. Different accelerators take the fetched data, perform processing, and send the processing outcome back to local memories. From there the data could be further processed by other accelerators or sent back to system memory. The SIMCOP needs an external central processing unit (CPU) to perform high-level control tasks and configurations. SIMCOP is closely coupled to a CPU for that purpose.

Figure 8-256 shows a block diagram of the SIMCOP subsystem.

Figure 8-256. SIMCOP Subsystem Overview



The ISS SIMCOP subsystem consists of:

- Noise filter (NSF2 and NSF3) – For advanced noise filtering and an edge-enhancement
- Two image and video processing engines (IMXs) – Supplement various fixed-function processing blocks
- Variable-length coder/decoder for JPEG (VLCDJ) module – Handles quantization and variable length

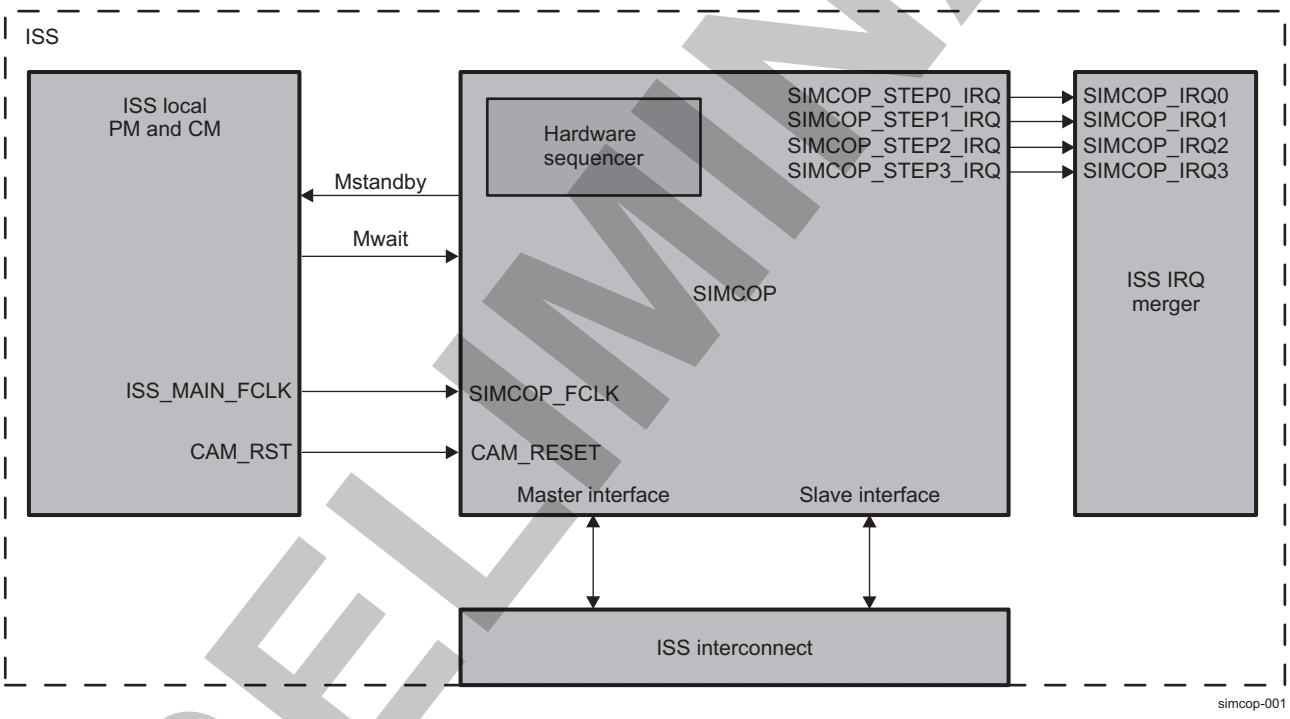
coding, decoding, and inverse quantization

- Discrete cosine transform (DCT) module – Implements method for transforming blocks of image during the compression flow.
- Lens distortion correction (LDC) module – Deals with lens geometric distortion issues in the camera subsystem
- Rotation accelerator (ROT) engine – Blocks data rotation and shifting from a SIMCOP local memory to another SIMCOP local memory
- Hardware sequencer and buffers – Controls SIMCOP modules and buffers to offload an external processor to perform low-level sequencing tasks
- Direct memory access (DMA) controller – Data transfers from SIMCOP memories to system memory or from system memory to SIMCOP memories

8.4.1.1 ISS SIMCOP Integration

The SIMCOP subsystem is connected to the rest of the system through the ISS local interconnect. Figure 8-257 shows the integration of the SIMCOP subsystem in the ISS.

Figure 8-257. SIMCOP Integration



NOTE: For more information about the IDLE hardware handshake and the wake-up request, see Section 3.1.1.1, *Clock Management* in Section 3.1.1 , *Power, Reset, and Clock Management*.

This section gives an overview of typical uses of the module. See Section 3.1.1, *Power, Reset, and Clock Management* for more information and settings of the PRCM relationship to ISS clocks and resets.

Table 8-1344 lists the Integration Attributes.

Table 8-1344. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
SIMCOP	PD_CAM	

Table 8-1345 lists the Clocks and Resets values.

Table 8-1345. Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SIMCOP	SIMCOP_FCLK	ISS_MAIN_FCLK	PRCM	Functional clock provided by CORE_ISS_MAIN_CLK from the PRCM. It is used by all ISS submodules and ISS top-level resources.
Resets				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
SIMCOP	CAM_RESET	CAM_RST	PRCM	ISS and SIMCOP global reset

Table 8-1346 lists the hardware resets.

Table 8-1346. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
SIMCOP	SIMCOP_STEP0_IRQ	SIMCOP_IRQ0	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP1_IRQ	SIMCOP_IRQ1	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP2_IRQ	SIMCOP_IRQ2	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
SIMCOP	SIMCOP_STEP3_IRQ	SIMCOP_IRQ3	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer

For more information about interrupt requests, see Section 8.1.2.1.1*Interrupt Merger*.

8.4.1.2 ISS SIMCOP Functional Description

8.4.1.2.1 ISS SIMCOP Local Power and Clock Management

8.4.1.2.1.1 ISS SIMCOP Local Clock Management

The ISS has five asynchronous clock domains. The SIMCOP belongs to the ISS_PCLK clock domain.

A clock-enable signal provided externally is used. Multiple subdomains exist internally to reduce dynamic power consumption. This feature does not require intervention by the PRCM module. For high-level description of the SIMCOP clock domain and configuration inside ISS, see Section 8.1.1.1.1, *ISS Clock Domains* and , *ISS Clocks*.

Moreover, at high level the functional clock of ISS SIMCOP submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the SIMCOP_CLKCTRL register (see Table 8-1347).

For software to enable a submodule:

- Software sets the appropriate bit in the SIMCOP_CLKCTRL register.
- Hardware enables the submodule functional and interface clocks.
- Hardware connects the configuration port of the submodule to the coprocessor bus.

- Hardware sets the appropriate bit in the SIMCOP_CLKCTRL register. Software must check if this bit is set before accessing the submodule.

Table 8-1347 shows the ISS SIMCOP clock control register settings.

Table 8-1347. ISS SIMCOP Clock Control Register Settings

Module Name	Bit Field Name	Description
NSF3	SIMCOP_CLKCTRL[9] NSF3	Writing 0x1 enables the module
ROT	SIMCOP_CLKCTRL[7] ROT_A	Writing 0x1 enables the module
IMX_B	SIMCOP_CLKCTRL[6] IMX_B	Writing 0x1 enables the module
IMX_A	SIMCOP_CLKCTRL[5] IMX_A	Writing 0x1 enables the module
NSF2	SIMCOP_CLKCTRL[4] NSF2	Writing 0x1 enables the module
VLCDJ	SIMCOP_CLKCTRL[3] VLCDJ	Writing 0x1 enables the module
DCT	SIMCOP_CLKCTRL[2] DCT	Writing 0x1 enables the module
LDC	SIMCOP_CLKCTRL[1] LDC	Writing 0x1 enables the module
DMA	SIMCOP_CLKCTRL[0] DMA	Writing 0x1 enables the module

For software to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
  - The submodule must not generate new events.
  - The submodule must not have any pending events.
  - For initiators, the submodule must stop interconnect transaction generation.
- Software clears the appropriate bit in the SIMCOP_CLKCTRL register.
- Hardware disconnects the configuration port of the module from the coprocessor bus, no more accesses are routed to the submodule. Ongoing transactions are finished (hardware stays in this state as long as required).
- For initiators, hardware waits until there are no more outstanding transactions:
  - The SIMCOP DMA provides an MStandBy signal used for that purpose.
  - The LDC does not provide this information. Software must ensure that LDC is idle. SIMCOP hardware ensures that the internal MTC2OCP bridges have no outstanding transactions.
- Hardware cuts the submodules clock.
- Hardware clears the appropriate SIMCOP_CLKCTRL registers.

SIMCOP submodules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled for debug or power consumption measurement purposes.

8.4.1.2.1.2 Local Clock Autogating

The SIMCOP subsystem modules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled. Table 8-1348 summarizes what modules support autogating control and which control bit is used.

Table 8-1348. Autoclock Gating Bit Control

SIMCOP resource	Autogating override
SIMCOP top-level resources	NA
SIMCOP DMA	NA
LDC	NA
DCT	DCT_CFG[5] AUTOGATING
VLCDJ	VLCDJ_CTRL[3] AUTOGATING
NSF2	NA
NSF3	NA

Table 8-1348. Autoclock Gating Bit Control (continued)

SIMCOP resource	Autogating override
IMX A	IMXa.IMX_CLKCNTRL[0] CLKCNTRL
IMX B	IMXb.IMX_CLKCNTRL[0] CLKCNTRL
ROT	ROT_CFG[9] AUTOGATING

8.4.1.2.1.3 ISS SIMCOP Power Management

The SIMCOP supports the STANDBY power management protocol. It is used by the SIMCOP to indicate when it has no more interconnect transactions to perform. This information is used at the ISS level to control the SIMCOP and ISS shut-down sequence. The SIMCOP does not have any internal wake-up events. DISCONNECT and IDLE protocols are not supported.

The typical SIMCOP shut-down sequence is:

- Software disables all SIMCOP submodules. This ensures the SIMCOP does not:
  - Generate any traffic on its master port; SIMCOP asserts the MStandby signal.
  - Generate new events (IRQs).
- Software clears all pending events at the SIMCOP level; all interrupt lines become inactive.
- Software initiates the SIMCOP shut-down sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
  - Disconnects the SIMCOP configuration port. Any access attempts to the SIMCOP are blocked at the ISS level. The DISCONNECT protocol is handled at the ISS level; the SIMCOP does not provide any handshake signals to support it.
  - Waits until MStandby from SIMCOP is asserted (always true in a normal case because SIMCOP submodules are inactive)
  - Asserts the SWait input of SIMCOP
  - Cuts the SIMCOP clock

The typical SIMCOP enable sequence is:

- Software initiates the SIMCOP enable sequence by writing the appropriate bit at the ISS level.
- ISS hardware:
  - Enables the SIMCOP clock
  - Deasserts the SWait input of SIMCOP
  - Connects the SIMCOP configuration port

Three modes for MStandBy control are supported. The mode is selected using the SIMCOP_HL_SYSCONFIG[5:4] STANDBYMODE register.

- Smart-standby: This is the normal mode to be used. When in this mode, SIMCOP asserts the MStandBy signal when the MStandBy output of SIMCOP DMA is asserted, the LDC module is effectively disabled (SIMCOP_CLKCTRL[1] LDC = 0), and the MTCR2OCP bridge and the merger have no more outstanding transactions.
- Force-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, SIMCOP asserts MStandBy unconditionally. Software must ensure that the SIMCOP is in a correct quiet state before programming this mode.
- No-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, SIMCOP never asserts the MStandBy signal.

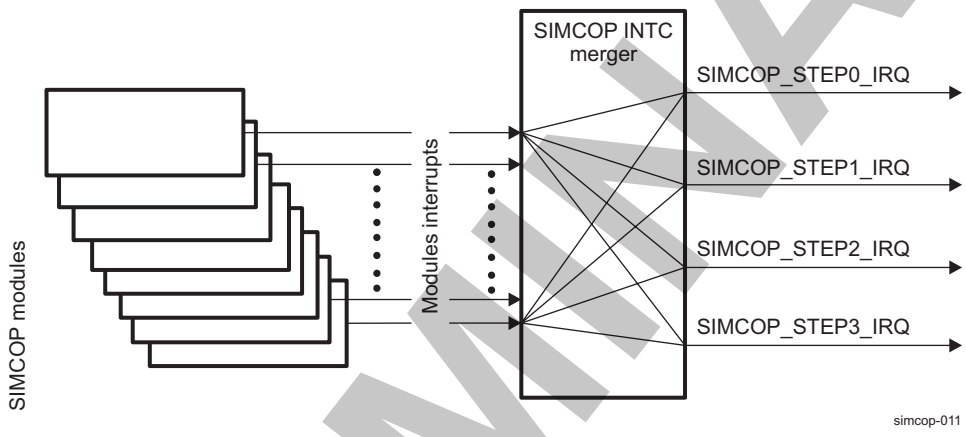
8.4.1.2.2 Software Reset

Software reset is intended to return the SIMCOP into a known state without requiring a complete device reset. A software reset at the SIMCOP level is seen as a hardware reset for SIMCOP submodules. To perform a software reset, set the SIMCOP_HL_SYSCONFIG[0] SOFTRESET bit to 1. The SIMCOP_HL_SYSCONFIG[0] SOFTRESET bit indicates that the software reset is ongoing when its value is 1. When the software reset completes, the SIMCOP_HL_SYSCONFIG[1] SOFTRESET bit is automatically reset. The software must ensure that the software reset completes before configuring hardware sequencer or buffers.

8.4.1.2.3 Interrupt Merger

SIMCOP interrupts are merged at the SIMCOP subsystem level into four interrupts as shown in Figure 8-258.

Figure 8-258. SIMCOP Interrupt Merger Overview



These four outputs interrupts can be configured using the SIMCOP_HL_IRQENABLE_SET_i and SIMCOP_HL_IRQENABLE_CLR_i (i = 0 to 3, corresponding to output interrupt) to enable or disable interrupt mask for each interrupt output. Software can poll the value of interrupt before masking SIMCOP_HL_IRQSTATUS_RAW_i and after masking SIMCOP_HL_IRQSTATUS_i.

Software can configure how outputs interrupts are generated by using the SIMCOP_CTRL[i] IRQi_MODE (i = 0 to 3) bit field(s):

- 0x0: OR – The interrupt is asserted when one of the selected events has occurred
- 0x1: AND – The interrupt is asserted when all selected events have occurred

Table 8-1349 shows how interrupts are mapped on the SIMCOP_HL_IRQSTATUS_RAW_i, SIMCOP_HL_IRQSTATUS_i, SIMCOP_HL_IRQENABLE_SET_i and SIMCOP_HL_IRQENABLE_CLR_i registers.

Table 8-1349. SIMCOP Interrupts

Bit	Name	Description
0	SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA
1	LDC_FRAME_IRQ	A full frame has been processed by LDC2 module
2	DCT_IRQ	DCT operation has been completed (configured number of MCUs for YUV4:2:0/YUV4:2:2 mode, or number of blocks for sequential block mode)
3	VLCDJ_BLOCK_IRQ	A macroblock has been processed (encode/decode)
4	NSF_IRQ	Event triggered by the NSF2 imaging accelerator when processing of a block is done.
5	IMX_A_IRQ	Event triggered when IMX has executed a SLEEP instruction.
6	IMX_B_IRQ	
7	ROT_A_IRQ	Event triggered by the ROT engine.
8	NSF3_IRQ	Event triggered by the NSF3 imaging accelerator when processing of a block is done.
9	LDC_BLOCK_IRQ	A macroblock has been processed by LDC2 module

Table 8-1349. SIMCOP Interrupts (continued)

Bit	Name	Description
10	SIMCOP_STEP0_IRQ	Event triggered when a SIMCOP context is activated by the HW sequencer
11	SIMCOP_STEP1_IRQ	
12	SIMCOP_STEP2_IRQ	
13	SIMCOP_STEP3_IRQ	
14	DONE_IRQ	Event triggered when the HW sequencer finishes the sequence: - the sequence step counter has reached the limit - All accelerator and DMA events for the last sequence step have been received.
15	VLCDJ_DECODE_ERR_IRQ	A decode error has been signaled by the VLCDJ module
16	ICNT_ERR_IRQ	An error has been received on the SIMCOP master port on L3 interconnect.
17	LDC2BRIDGE_ERR_IRQ	The LDC2 bridge has generated an error. This event shall not trigger in a normal use case.
18	SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
19	CPU_PROC_START_IRQ	This interrupt is used when CPU data processing is used in a macroblock processing pipeline. When CPU receives this IRQ, data for ready to be processed. When CPU is done with processing it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit. The interrupt is cleared as usual.

8.4.1.2.4 ISS SIMCOP Modules Description

This section provides links to each subchapter for each submodule in the ISS SIMCOP module.

The ISS module provides a unique ISS_MAIN_FCLK for all the submodules inside the SIMCOP, see Section 8.4.1.2.1.1.

For information about hardware and software resets for each module, see Table 8-1349.

For interrupt request information for each module, see Table 8-1346.

The ISS SIMCOP consists of the following submodules:

- Hardware Sequencer and buffers, for more information, see Section 8.4.2.
- DMA, for more information, see Section 8.4.3.
- ROT, for more information, see Section 8.4.7.
- IMX, for detailed information about the IMX modules, contact your TI representative.
- NSF2, for detailed information about the NSF2 modules, contact your TI representative.
- NSF3, for detailed information about the NSF3 modules, contact your TI representative.
- VLCDJ, for more information please see Section 8.4.6
- DCT, for more information, see Section 8.4.5
- LDC, for more information, see Section 8.4.4

8.4.1.3 ISS SIMCOP Programming Models

8.4.1.3.1 Global Initialization

8.4.1.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the ISS SIMCOP module is to be used for the first time after a device reset. This initialization of the surrounding modules is based on the integration of the ISS SIMCOP.

Table 8-1350. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
ISS local PM and CM	Module interface and functional clocks must be enabled. For more information, see Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management*.

8.4.1.3.1.2 ISS SIMCOP Module Global Initialization

This procedure initializes the ISS SIMCOP module after a power-on or software reset.

Table 8-1351. ISS SIMCOP Global Initialization

Step	Register/ Bitfield / Programming Model	Value
Execute software reset	SIMCOP_HL_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset completed?	SIMCOP_HL_SYSCONFIG[0] SOFTRESET	0x0
Configure standby mode	SIMCOP_HL_SYSCONFIG[5:4] STANDBYMODE	0x2

Set interrupt enable bit for the submodules	SIMCOP_HL_IRQENABLE_SET_i[7:0]	xxx

8.4.1.3.2 ISS SIMCOP Operational Modes Configuration

8.4.1.3.2.1 Interrupts

To unmask an interrupt for generation of the SIMCOP_IRQi output interrupts, software must set the corresponding bit of the SIMCOP_HL_IRQENABLE_SET_i (i = 0 to 3) register to 1.

Example 1:

SIMCOP_IRQ1 is generated when DCT_IRQ or VLCDJ_BLOCK_IRQ are generated:

- SIMCOP_HL_IRQENABLE_SET_i[2] DCT_IRQ = 0x1 (i = 1)
- SIMCOP_HL_IRQENABLE_SET_i[3] VLCDJ_BLOCK_IRQ = 0x1 (i = 1)
- SIMCOP_CTRL[1] IRQ1_MODE = 0x0

Example 2:

SIMCOP_IRQ3 is generated when IMX_A_IRQ and LDC_BLOCK_IRQ are generated:

- SIMCOP_HL_IRQENABLE_SET_i[5] IMX_A_IRQ = 0x1 (i = 3)
- SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ = 0x1 (i = 3)
- SIMCOP_CTRL[3] IRQ3_MODE = 0x1

To mask an interrupt for generation of the SIMCOP_IRQi output interrupts, software must clear the corresponding bit of the SIMCOP_HL_IRQENABLE_CLEAR_i (i = 0 to 3) register by setting it to 0.

When an event occurs, the corresponding bit in the SIMCOP_HL_IRQSTATUS_RAW_i (i = 0 to 3) register is set regardless of whether or not the event has been enabled. Bits in the SIMCOP_HL_IRQSTATUS_i (i = 0 to 3) registers are only set when an enabled event occurs. Software can clear a pending event by setting the appropriate bit in the SIMCOP_HL_IRQSTATUS_i (i = 0 to 3) register.

8.4.1.3.2.2 JPEG Encode Operational Mode Configuration

Figure 8-259 shows a typical JPEG encode macroblock pipeline.

Figure 8-259. JPEG Encode Pipeline

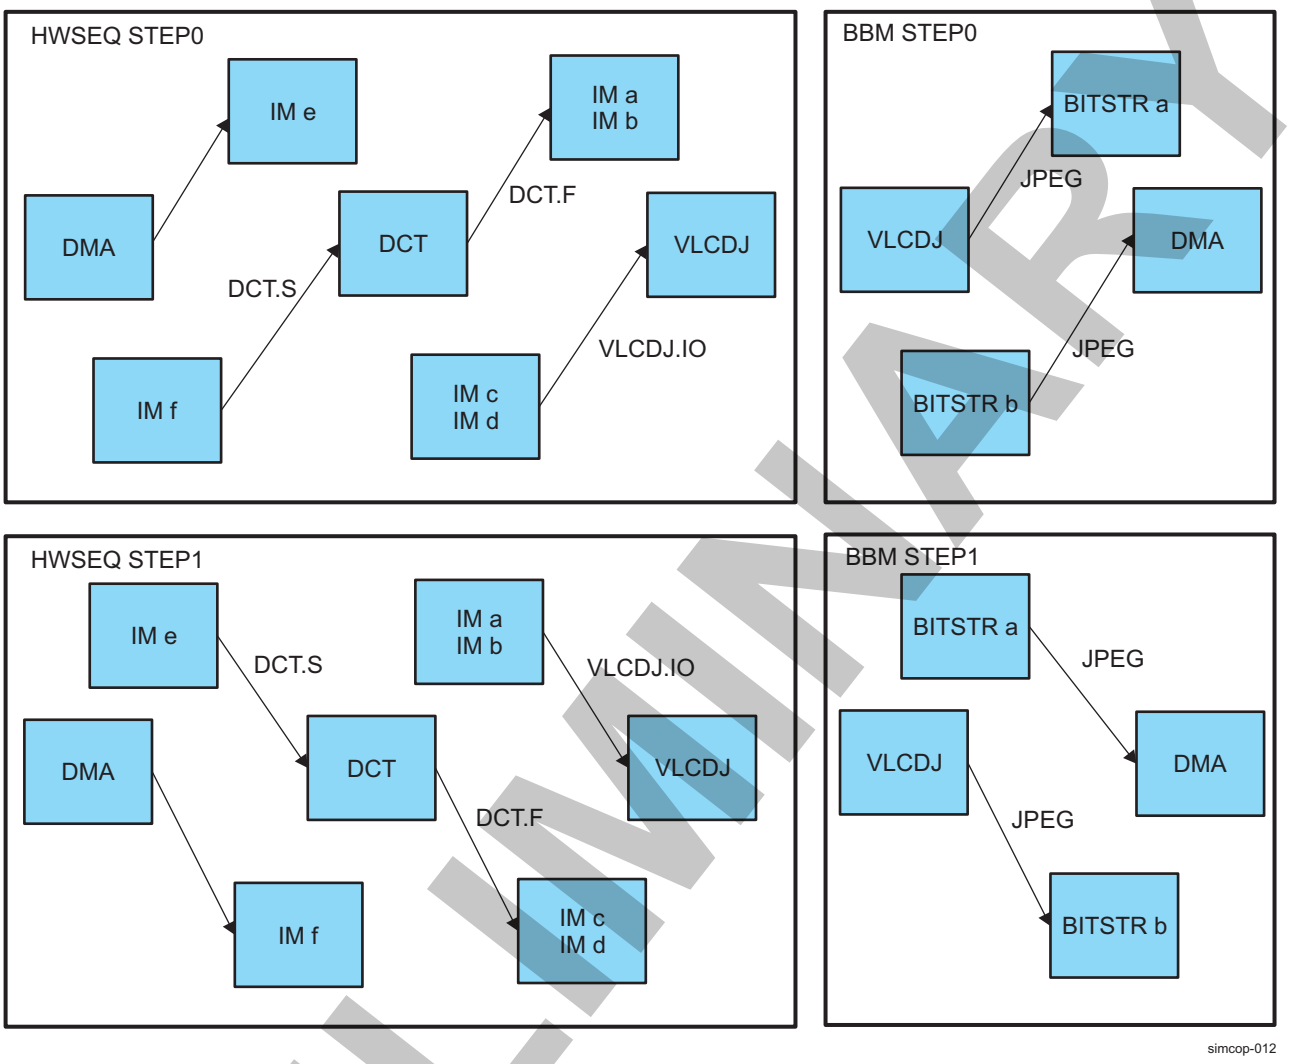

Table 8-1352. JPEG encode pipeline

Step	Register/ Bitfield / Programming Model	Value
Set SIMCOP DMA to fetch data from SDRAM and stored into an image buffer (IM e or IM f)	See DMA programming model, Section 8.4.3.4	xxx
Set DCT to reads data from an image buffer (IM E or IM F)	DCT_SPTR[12:5] ADDR	xxx
Set DCT to store data into sets of two image buffers (IM a + IM b or IM c+ IM d)	DCT_FPTR[12:4] ADDR	xxx
Set VLCDJ to read data from image buffers	See VLCDJ programming model, Section 8.4.6.4	xxx
Set VLCDJ to write the data to the BITSTREAM buffer	See VLCDJ programming model, Section 8.4.6.4	xxx
Set the SIMCOP DMA to send the data to SDRAM	See DMA programming model, Section 8.4.3.4	xxx

8.4.1.4 ISS SIMCOP Registers Manual

8.4.1.4.1 SIMCOP Instance Summary

Table 8-1353 summarizes the SIMCOP instance.

Table 8-1353. SIMCOP Instance Summary

Module Name	L3_MAIN Base Address	IPU Base Address	Size
SIMCOP	0x5202 0000	0x5506 0000	256Bytes

8.4.1.4.2 SIMCOP Registers

8.4.1.4.2.1 SIMCOP Register Summary

Table 8-1354 is the SIMCOP register mapping summary. through describe the registers in detail.

Bits	Field Name	Description	Type	Reset
31:30	NSF3_WMEM	Selects working memory for NSF3. Memories attached to NSF3 as working memories cannot be used by any other accelerators. HWSEQ or HWSEQ SW override settings are ignored for those memories. 0x0: No working memory attached to NSF3. NSF3 cannot be used. 0x1: IMX A + B coefficient memories used. 0x2: Image buffers a, b, c, and d used. Those image buffers cannot be used for other purposes. This setting has higher priority than the context configuration	RW	0x0
29	RESERVED		R	0x0
28	LDC_R_BURST_BREAK	Controls if bursts issued by the LDC2 bridge could cross burst length boundaries. When this register is set, the LDC2 bridge only issues aligned bursts. Register can only be used when LDC_R_MAX_BURST_LENGHT is 32, 64 or 128 bytes. 0x0: Yes. 0x1: No. OCP transactions must be split	RW	0
27:26	LDC_R_MAX_BURST_LENGHT	Limits the maximum burst length that could be used by the LDC2 bridge 0x0: 8x128 0x1: 6x128 0x2: 4x128 0x3: 2x128	RW	0x0
25	RESERVED	Read returns 0.	R	0
24:21	LDC_R_TAG_CNT	Limits the maximum number of outstanding requests to LDC_R_TAG_CNT+1	RW	0x3
20	RESERVED	Read returns 0.	R	0
19:16	LDC_R_TAG_OFST	First OCP tag ID that can be used by LDC reads. It is SW's responsibility to prevent overlap with tags generated by the SIMCOP DMA Typically this value should be equal to SIMCP_DMA_CTRL.TAG_CNT+1	RW	0xC
15	RESERVED	Read returns 0.	R	0
14	IMX_B_CMD	Switch for IMX # command memory 0x0: Coprocessor bus 0x1: IMX B instruction read / write	RW	0
13:12	IMX_A_CMD	Switch for IMX A command memory 0x0: Coprocessor bus 0x1: IMX A instruction read / write 0x2: IMX B instruction read / write	RW	0x0
11	HUFF	Switch for Huffman table 0x0: Coprocessor 0x1: VLCDJ Huffman table read	RW	0
10	QUANT	Switch for quantization table 0x0: Coprocessor bus 0x1: VLCDJ quantization table read	RW	0
9	RESERVED	Read returns 0.	R	0
8	LDC_LUT	Switch for LDC LUT 0x0: Coprocessor bus 0x1: The LDC module could access the LDC LUT.	RW	0

Bits	Field Name	Description	Type	Reset
7:6	LDC_INPUT	Selects input data buffer for LDC. Memories attached to LDC as working memories cannot be used by any other accelerators. HWSEQ or HWSEQ SW override settings are ignored for those memories. 0x0: No input memory attached 0x1: use image buffers a and b 0x2: use image buffers a, b, c, and d 0x3: Use LDC private input memory.	RW	0x0
5:4	NSF_WMEM	Selects working memory for NSF. Memories attached to NSF as working memories cannot be used by any other accelerators. HWSEQ or HWSEQ SW override settings are ignored for those memories. 0x0: No working memory attached to NSF2. NSF2 cannot be used. 0x1: IMX A coefficient memory used. 0x2: Image buffers a and b used. Those image buffers cannot be used for other purposes. This setting has higher priority than the context configuration 0x3: Image buffers a, b, c, d used. Those image buffers cannot be used for other purposes. This setting has higher priority than the context configuration	RW	0x0
3	IRQ3_MODE	Interrupt generation method 0x0: The interrupt line is asserted when one of the events enabled in SIMCOP_IRQENABLE_3 is pending 0x1: The interrupt line is asserted when all events enabled in SIMCOP_IRQENABLE_3 are pending	RW	0
2	IRQ2_MODE	Interrupt generation method 0x0: The interrupt line is asserted when one of the events enabled in SIMCOP_IRQENABLE_2 is pending 0x1: The interrupt line is asserted when all events enabled in SIMCOP_IRQENABLE_2 are pending	RW	0
1	IRQ1_MODE	Interrupt generation method 0x0: The interrupt line is asserted when one of the events enabled in SIMCOP_IRQENABLE_1 is pending 0x1: The interrupt line is asserted when all events enabled in SIMCOP_IRQENABLE_1 are pending	RW	0
0	IRQ0_MODE	Interrupt generation method 0x0: The interrupt line is asserted when one of the events enabled in SIMCOP_IRQENABLE_0 is pending 0x1: The interrupt line is asserted when all events enabled in SIMCOP_IRQENABLE_0 are pending	RW	0

8.4.2 ISS SIMCOP Hardware Sequencer and Buffers Module

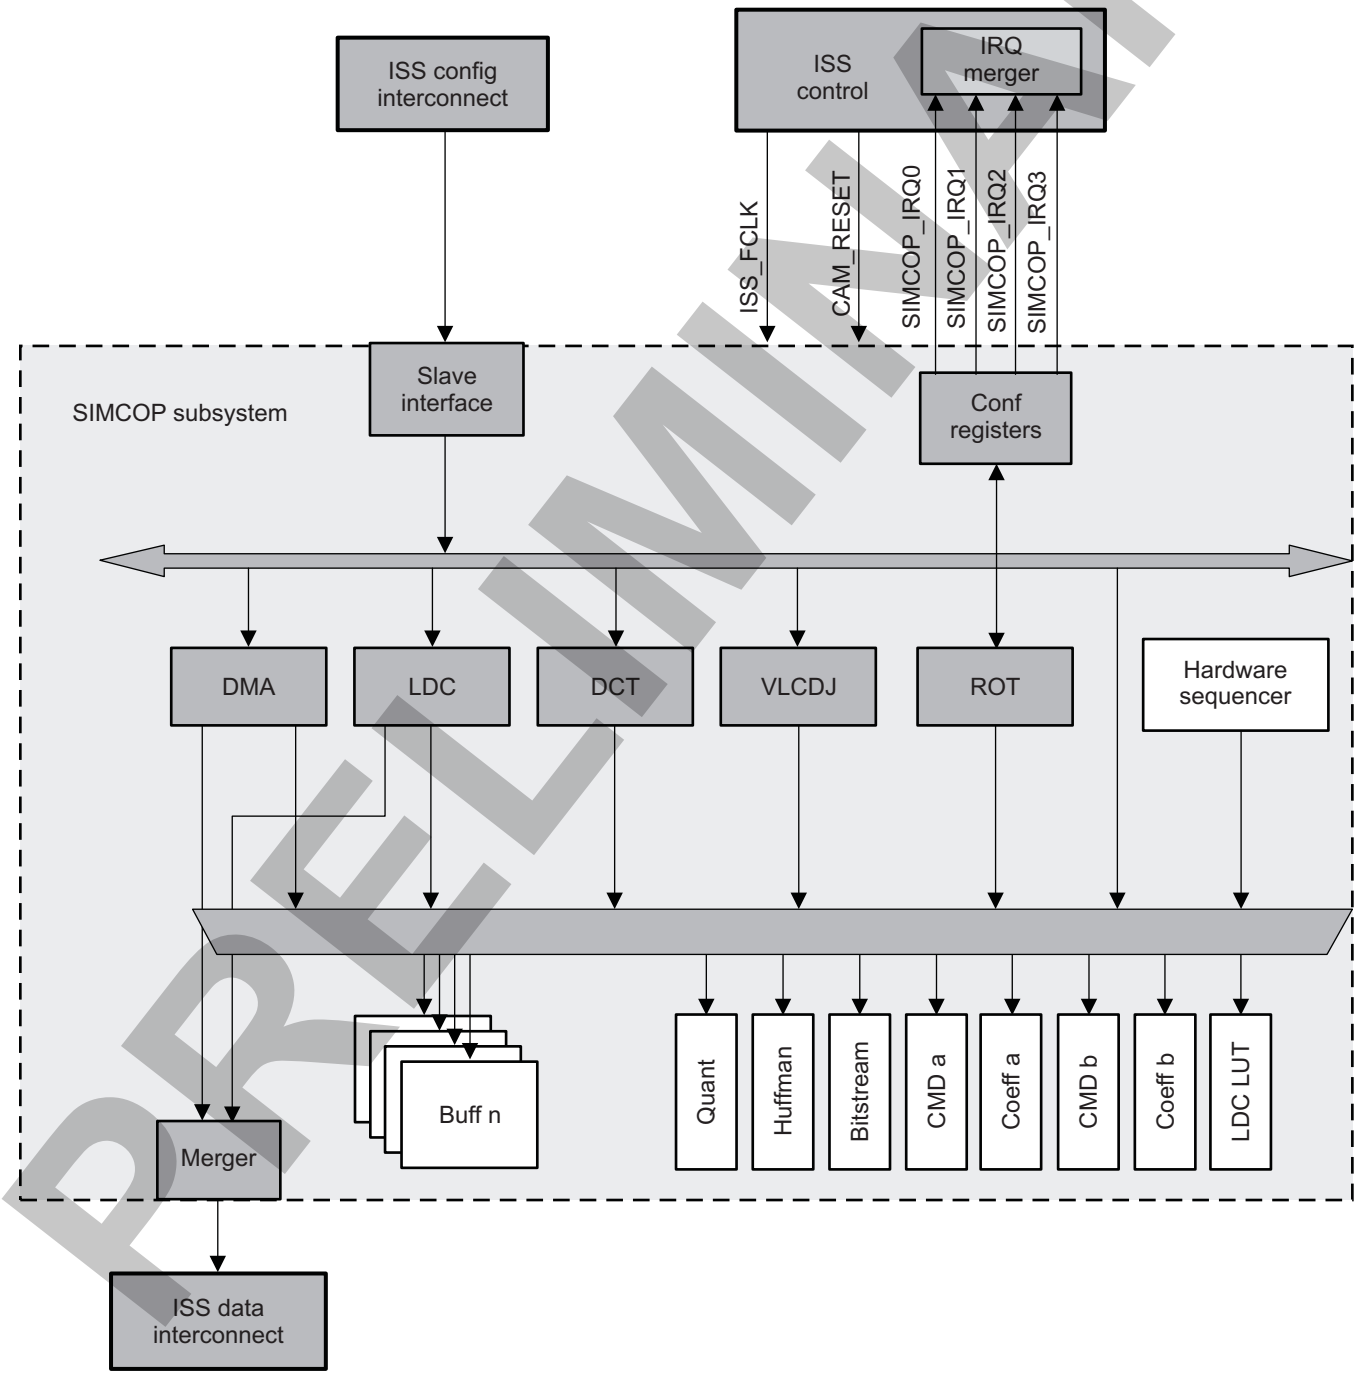
This section describes the hardware sequencer and buffers in the still image coprocessor (SIMCOP) subsystem.

8.4.2.1 ISS SIMCOP Hardware Sequencer and Buffers Overview

The SIMCOP hardware sequencer control all the modules included in the SIMCOP subsystem with their memories.

Figure 8-260 shows an overview of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 8-260. Hardware Sequencer and Buffers in the SIMCOP Subsystem



- Hadrware acceleration for low-level sequencing tasks:
  - Synchronizes with DMA, DCT, VLCD, ROT, LDC
  - Supports 4 memory crossbar contexts
- On chip memories (RAM):
  - 8 image buffers, 4 KiB each
  - Quantization table storage: 512 bytes
  - Huffman table storage: 4 KiB
  - Bitstream buffer: 4 KiB
  - LDC look-up table storage: 256 entries
- Power management support

8.4.2.2 ISS SIMCOP Hardware Sequencer and Buffer Integration

The hardware sequencer and buffers module is part of the SIMCOP subsystem in the ISS.

Figure 8-261 shows the integration of the hardware sequencer and buffers in the SIMCOP subsystem.

Figure 8-261. Hardware Sequencer and Buffer Integration

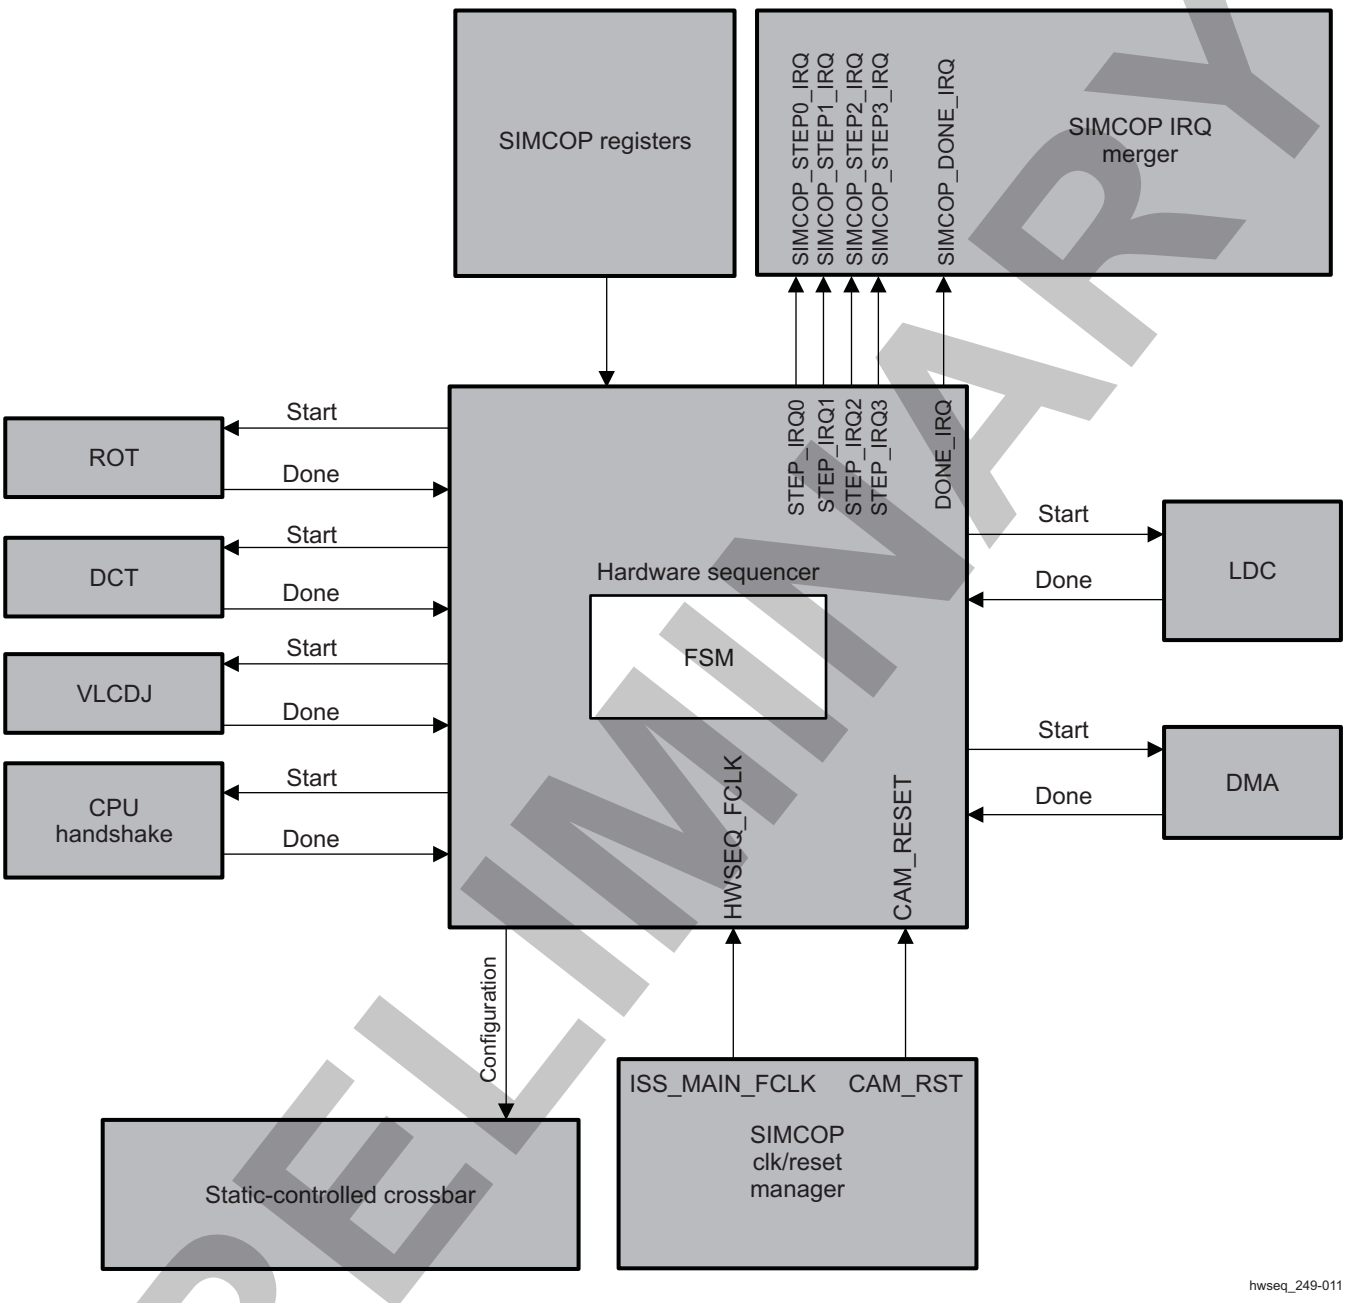


Table 8-1376 lists the integration attributes, Table 8-1377 lists the clocks and resets, and Table 8-1378 lists the hardware requests.

Table 8-1376. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
Hardware sequencer and buffers	PD_CAM	

Table 8-1377. Clocks and Resets

For information about clock and reset management, see Section 8.4.1.2.1, *ISS SIMCOP Local Power and Clock Management*.

Table 8-1378. Hardware Requests

Interrupt Requests				
Module Instance	**Source Signal Name**	**Destination Signal Name**	**Destination**	**Description**
Hardware sequencer and buffers	STEP_IRQ0	SIMCOP_STEP0_IRQ	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
Hardware sequencer and buffers	STEP_IRQ1	SIMCOP_STEP1_IRQ	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
Hardware sequencer and buffers	STEP_IRQ2	SIMCOP_STEP2_IRQ	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
Hardware sequencer and buffers	STEP_IRQ3	SIMCOP_STEP3_IRQ	SIMCOP IRQ merger	Event triggered when a SIMCOP context is activated by the hardware sequencer
Hardware sequencer and buffers	DONE_IRQ	SIMCOP_DONE_IRQ	SIMCOP IRQ merger	Event triggered when the hardware sequencer finishes the sequence

For more information about interrupt requests, see Section 8.4.1.2.3, *Interrupt Merger*

8.4.2.3 ISS SIMCOP Hardware Sequencer and Buffers Functional Description

8.4.2.3.1 ISS SIMCOP Hardware Sequencer and Buffers Software Reset

For information about how to perform a software reset, see Section 8.4.1.2.2, *Software Reset*.

8.4.2.3.2 ISS SIMCOP Hardware Sequencer and Buffers Power Management

For more information about power management, see Section 8.4.1.2.1.3, *ISS SIMCOP Power Management*.

8.4.2.3.3 ISS SIMCOP Hardware Sequencer and Buffer Interrupt Requests

This module sends four interrupts to the ISS top level. For more information about interrupt management, see Section 8.4.1.2.3, *Interrupt Merger*.

8.4.2.3.4 ISS SIMCOP Hardware Sequencer Buffer Description

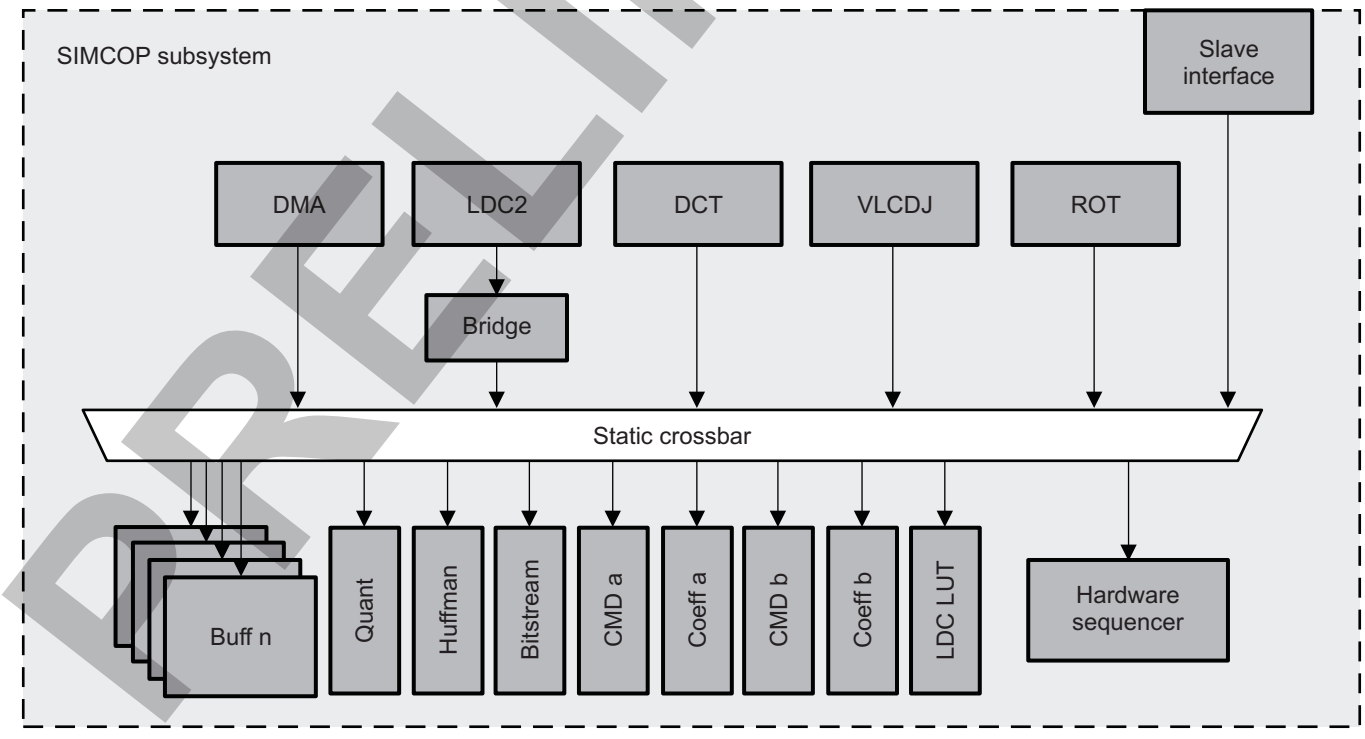
The SIMCOP subsystem includes the following memories:

- Eight image buffers: 4 KiB each
- Quantization table storage: 512 bytes
- Huffman table storage: 4 KiB
- Bitstream buffer: 4 KiB
- LDC lookup tables storage: 256 entries
- LDC private working memory

8.4.2.3.4.1 Static Crossbar

The static crossbar connect SIMCOP modules to the SIMCOP memories as shown in Figure 8-262.

Figure 8-262. SIMCOP Static Crossbar Overview



hwseq_249-002

The buses for QUANT, HUFF, LDC LUT, CMD a, and CMD b are controlled by the CPU. Typically, those memories are initialized before the SIMCOP starts processing and the content remains unchanged until the full frame is processed. The amount of data transferred to those memories is low and transfer is not timing critical. Table 8-1379 shows how to connect these memories to the SIMCOP modules.

NOTE: The transfer can only be done through the slave interface (that is, the CPU or system DMA). The SIMCOP DMA can not access those memories.

Table 8-1379. Static Crossbar Control Summary

Memory	Register SIMCOP_CTRL	Value				
		Bus	VLCDJ HUFF	VLCDJ QUANT	LDC LUT	LDC INPUT
Quantization	[10] QUANT	0		1		
Huffman	[11] HUFF	0	1			
LDC LUT	[8] LDC_LUT	0			1	
LDC Priv	[7:6] LDC_INPUT					3

Image buffers and coefficient memories are used to store the data to be processed and processing results. Those memories can be accessed by the SIMCOP DMA, SIMCOP bus, and SIMCOP modules. Table 8-1380 shows possible connections in the SIMCOP static crossbar. For example, the DCT Freq port could access image buffer a when SIMCOP_HWSEQ_SWITCH_i[2:0] IMBUFF_A = 5 (i = 0, 1, 2, or 3 corresponds to the active context).

The SIMCOP supports multiple contexts for the configuration of those memories. Software or the hardware sequencer can activate different contexts.

The BITSTREAM data flow is asynchronous from the macroblock pipeline, therefore, it supports dynamic buffer switching logic.

Table 8-1380. Static Crossbar Control Summary (2/2)

Memory	Register (SIMCOP_HWSEQ_STEP_SWITCH_i and SIMCOP_HWSEQ_STEP_CTRL2_i)	Value									
		Bus	DMA	VLCDJ IO	VLCDJ BS	DCT Spatial	DCT Freq	LDC 0	LDC WMEM	ROT In	ROT Out

8.4.2.3.4.2 Image Buffers

Image buffers are 4 banks × 256 × 32 bits (4K bytes) working memories used by the SIMCOP modules to perform image processing operations. Image buffers are shared between the DCT, LDC, VLCDJ, ROT, DMA, and SIMCOP bus accesses. All initiators cannot access the image buffers simultaneously.

Switches are controlled by the hardware sequencer or an external initiator through register configuration. Data is always organized in little endian form.

One or multiple image buffers can be attached to a given accelerator port by configuring the appropriate bits in the SIMCOP_HWSEQ_STEP_SWITCH_i registers.

The image buffer address mapping to different busses shown in Table 8-1381 is controlled using the appropriate SIMCOP_HWSEQ_STEP_CTRL_i register bit fields.

Table 8-1381. Image Buffer Address Map

Port	OFST	0x0000	0x1000	0x2000	0x3000	0x4000	0x5000	0x6000	0x7000

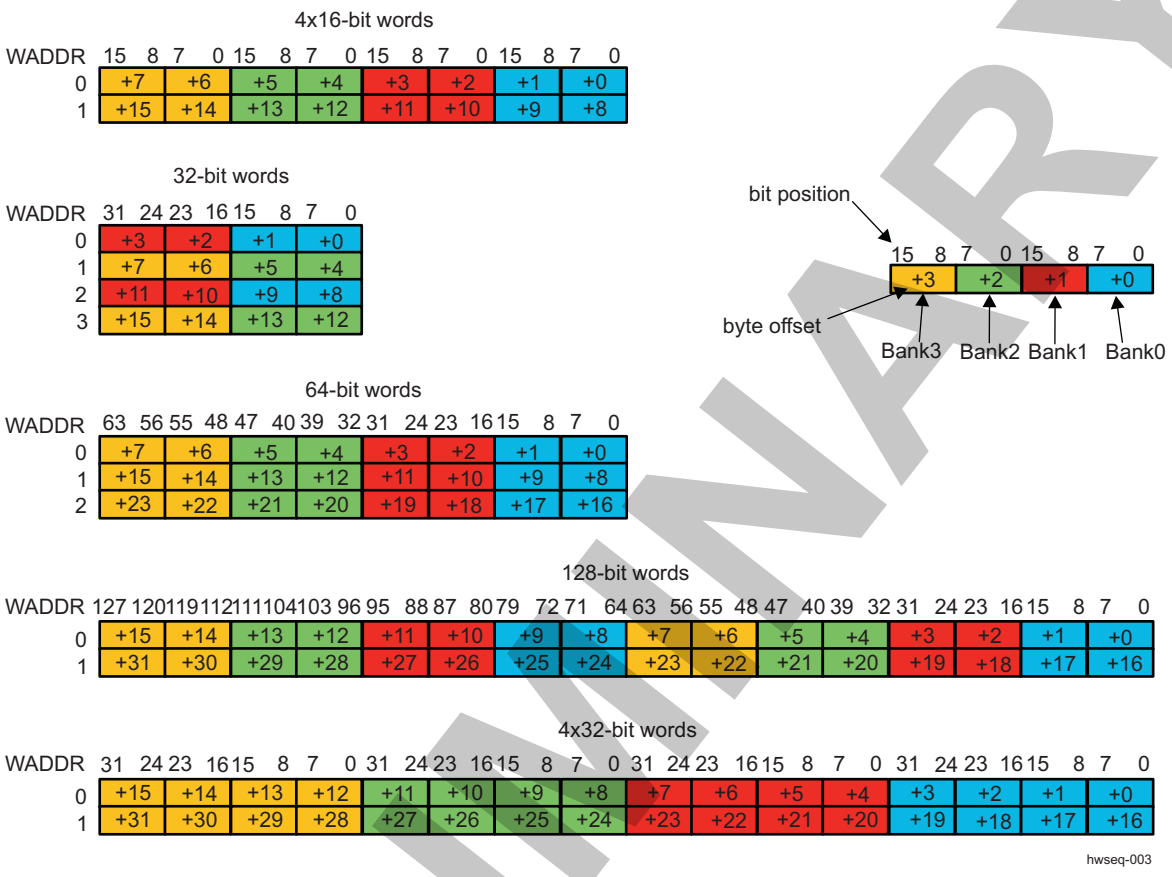
Figure 8-263 shows how width conversion and bank interleaving is performed, each colors correspond to a different physical bank.

Figure 8-263. Image Buffer Width Translation



8.4.2.3.4.3 Quantization Memories

The QUANT memory is used to store the quantization and dequantization tables for the VLCDJ module.

Coefficients are coded as 16-bit values. Every color component requires 8 × 8 quantization entries, therefore the QUANT memory of SIMCOP can hold up to four tables as shown in Table 8-1382.

Table 8-1382. Quantization Table Storage in QUANT Memory

Table	0	1	2	3
ADDR	0x000	0x0080	0x0100	0x0180
Encode only	Y quantization	UV quantization	Unused	Unused
Decode only	Unused	Unused	Y dequantization	UV dequantization
Encode and decode	Y quantization	UV quantization	Y dequantization	UV dequantization

The QUANT memory is shared between the VLCDJ and SIMCOP bus accesses. All initiators cannot access QUANT simultaneously.

The initiators access types to the QUANT memory are summarized in Table 8-1383. QUANT memory configuration depends on the initiators.

Table 8-1383. QUANT Memory Organization

VLCDJ	Coprocessor bus
128 words x 32 bit	128 words x 32 bits

8.4.2.3.4.4 Huffman Tables

The HUFF memory is used to store the Huffman table for the VLCDJ module. Details about the Huffman table organization can be found in the VLCDJ module description, see Section 8.4.6, *VLCDJ* .

The HUFF memory is shared between the VLCDJ and SIMCOP bus accesses. All initiators cannot access the HUFF memory simultaneously.

The initiators access types to the HUFF memory are summarized in Table 8-1384. The HUFF memory configuration depends on the initiators.

Table 8-1384. HUFF Memory Organization

VLCDJ	Coprocessor bus
1024 words x 32 bits	1024 words x 32 bits

8.4.2.3.4.5 BITSTREAM Buffer

8.4.2.3.4.5.1 Overview

The BITSTREAM buffer is used to store the VLCDJ bit stream. The BITSTREAM buffer is shared between the VLCDJ, DMA, and SIMCOP bus accesses.

The BITSTREAM buffer can be used in manual or automatic mode.

In manual mode, software selects if the SIMCOP DMA, VLCDJ Bit Stream port, or SIMCOP bus can access the BITSTREAM buffer. Manual mode is typically used to interleave JPEG encode and decode, for example to support JPEG transcoding. .

In automatic mode (SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = ENCODE or DECODE) the BITSTREAM buffer is handled as two banks to prevent access collision between the VLCDJ and SIMCOP DMA. A dedicated hardware engine (BBM) is used to guarantee that the VLCDJ and SIMCOP DMA access separate banks.

Automatic mode is disabled by writing SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = COPR.

The BITSTREAM buffer mapping into the SIMCOP DMA address map depends on the SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM, SIMCOP_HWSEQ_CTRL[3:2] BITSTR_XFER_SIZE registers and the internal state of the BBM. Table 8-1385 shows the mapping of bitstream buffer for the SIMCOP DMA.

Table 8-1385. BITSTREAM Buffer Mapping to SIMCOP DMA

SIMCOP_HWSEQ_CTRL		Address Map		BBM count	Bitstream buffer	
BITSTREAM	XFER_SIZE					
0: COPR	N/A	0x1000	0x1FFF	N/A	0x000	0xFFF

SIMCOP_HWSEQ_CTRL		Address Map		BBM count	Bitstream buffer	
BITSTREAM	XFER_SIZE					
		0x1000	0x10FF	3	0x300	0x3FF
				4	0x400	0x4FF
				5	0x500	0x5FF
				6	0x600	0x6FF
				7	0x700	0x7FF
		0x1100	0x1FFF	N/A	N/A	N/A

8.4.2.3.4.5.2 Automatic BITSTREAM Buffer Management

To enter automatic mode, software must write the following values into the BITSTREAM configuration register:

- SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = COPR (required to reset BBM)
- SIMCOP_HWSEQ_CTRL[6:4] BITSTREAM = JPEG_ENCODE or JPEG_DECODE

8.4.2.3.4.6 LDC Lookup Table

The LDC_LUT memory is used to store lookup tables for the LDC module. The LDC_LUT is shared between the LDC and SIMCOP bus accesses. All initiators cannot access LDC_LUT simultaneously.

The initiators access types to the QUANT memory are summarized in Table 8-1386. QUANT memory configuration depends on the initiators.

Table 8-1386. LDC_LUT Memory Organization

LDC	Coprocessor bus
256 words x 14 bit	128 words x 32 bit (see Table 8-1387)

RESERVED								LDC_LUT [2a+1]								RESERVED								LDC_LUT [2a+0]							

8.4.2.3.4.7 LDC Private Input Memory

The LDC has a private input memory that can be used when the LDC operates in YUV4:2:0 mode. For YUV4:2:2 and RAW operation, the LDC must use image buffers as input memories.

The LDC input memory is dedicated for LDC operation. It cannot be accessed from the SIMCOP bus or by any other SIMCOP module.

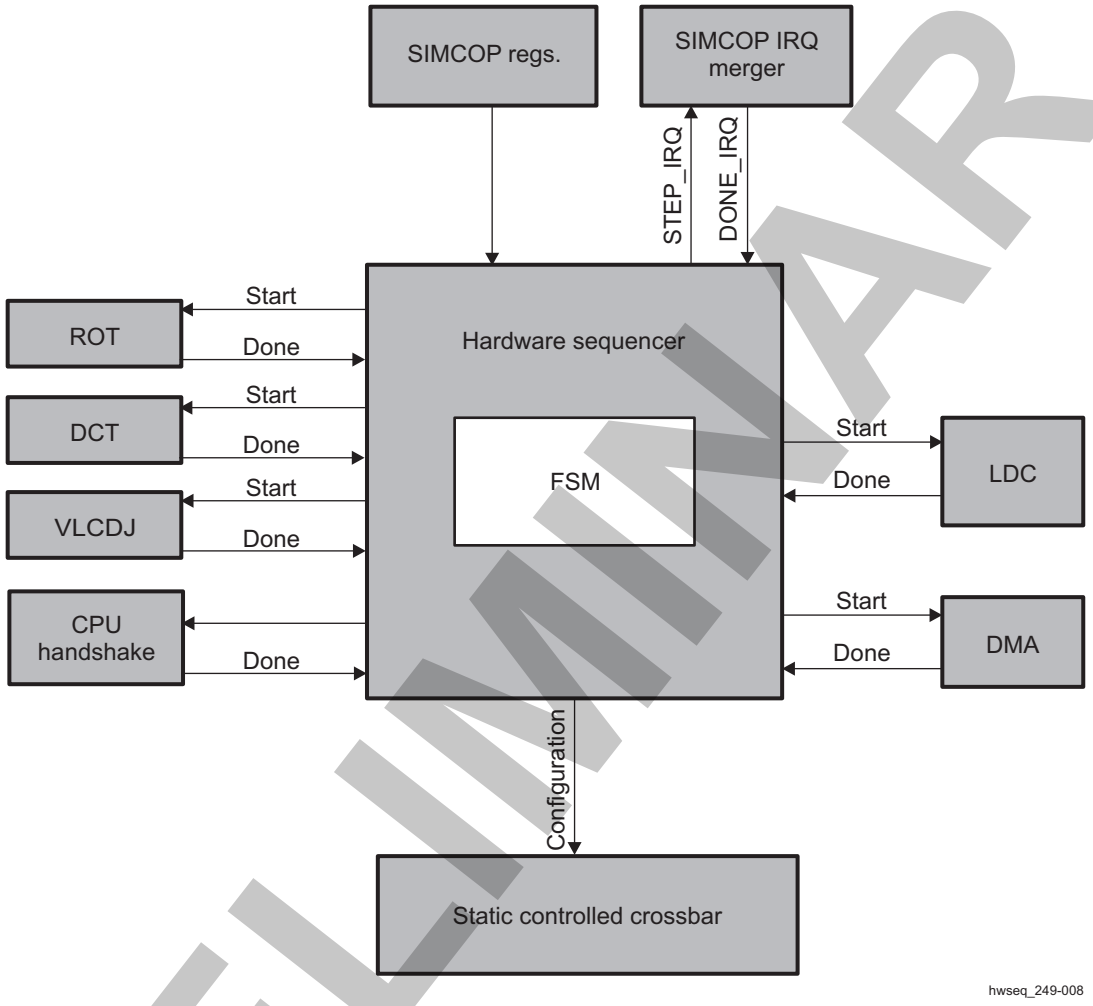
8.4.2.3.5 ISS SIMCOP Hardware Sequencer

The SIMCOP typically processes a full frame on a macroblock-by-macroblock basis. The SIMCOP modules and the DMA controller trigger an interrupt when they have completed a macroblock. This event can either trigger an interrupt to an external initiator (CPU) (manual mode) or trigger a context switch and resume DMA/SIMCOP module processing. Typically, initiator intervention is needed to fill the macroblock pipeline (called pipe-up, that is, the first n macroblocks of an image) and to flush the macroblock pipeline (called pipe-down, that is, the last n macro-blocks of an image). Automatic sequencing mode is typically used for the rest of the image.

The hardware sequencer is particularly useful to offload the initiator during JPEG encoding/decoding, ROT or LDC processing.

Figure 8-264 depicts the SIMCOP hardware sequencer overview.

Figure 8-264. SIMCOP Hardware Sequencer Overview

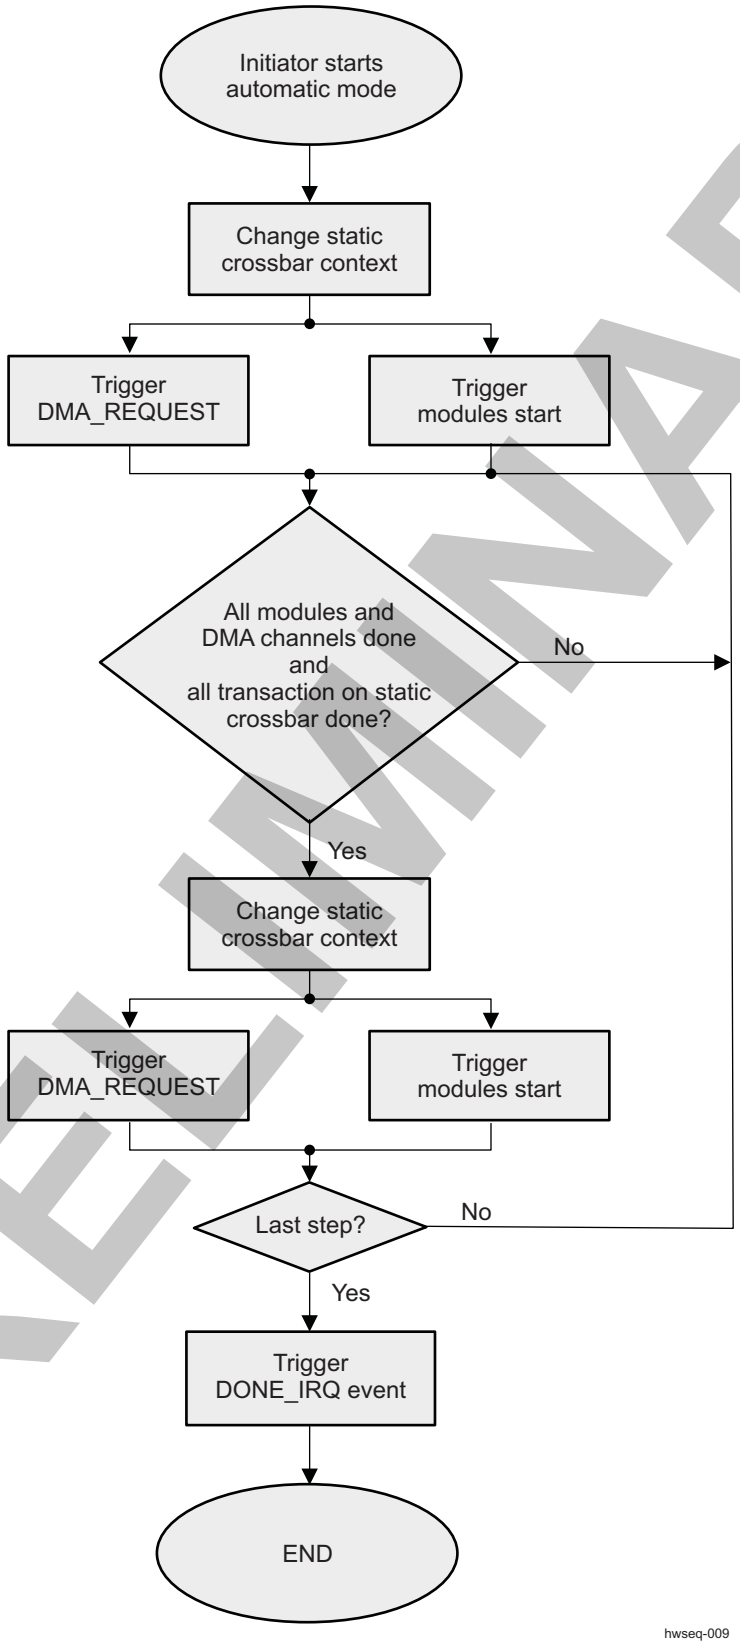


The hardware sequencer can automatically execute a predefined number of sequencing steps without software intervention. This is called automatic operation. Automatic operation can also be used for pipeline filling and flushing with some limited software intervention. During automatic operation, the hardware sequencer controls the generation of START/DONE pulses and the connections in the static controlled crossbar. Software can take control over some resources while the hardware sequencer is running. This is called hardware sequencer override.

8.4.2.3.5.1 Automatic Operation

Figure 8-265 shows the flow diagram executed by the hardware sequencer.

Figure 8-265. Hardware Sequencing Example



The external initiator configures the different SIMCOP modules and DMA channels. When this is complete, it enables the hardware sequencer. This resets the internal state of the hardware sequencer (pending events and context switch counter).

It starts by running sequence step SIMCOP_HWSEQ_CTRL[12:11] STEP:

- Clear all pending completion events that have been selected for Step 0 in the hardware sequencer. Note: This does not affect the SIMCOP_IRQSTATUS register.
- Apply step SIMCOP_HWSEQ_CTRL[12:11] STEP configuration to the static crossbar
- Start DMA transfers. Multiple channels can be enabled sequentially (that is, YUV4:2:0 data transfers or SIMCOP-SDRAM followed by SDRAM-SIMCOP) by using the SIMCOP DMA linking feature.
- Start hardware accelerators. The list of accelerators to start can be selected by software using the SIMCOP_HWSEQ_STEP_CTRL_i[7:0] *_SYNC register

The hardware sequencer then waits for completion of events from the selected SIMCOP modules and SIMCOP DMA channels.

The hardware sequencer also ensures that all SIMCOP memory accesses requested by the accelerators and DMA channels enabled for the synchronization step have completed. This condition prevents data corruption due to early switching.

Steps can be chained to define the sequence to execute. Steps are started until the step counter reaches the limit defined by software. When the last step has completed, a DONE_IRQ event is triggered.

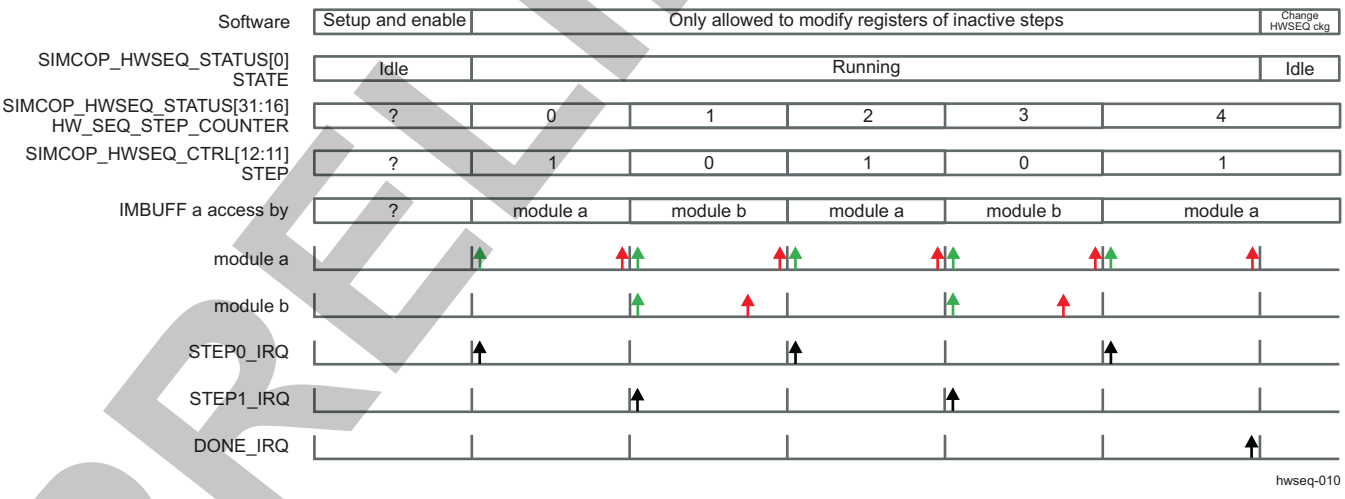
The SIMCOP can execute one hardware sequence at the time. However, software can be used to execute multiple independent sequences in parallel (that is, two unrelated macroblock pipelines) using the override feature.

The hardware sequencer has no specific support for macroblock pipeline filling (pipe-up) or flushing (pipe-down). It needs some software intervention.

The hardware sequencer supports sequences composed of up to four steps. Longer sequences require software intervention.

Figure 8-265 illustrates the hardware sequencer operation.

Figure 8-266. Hardware Sequencer Operation Example



The example involves utilization of two SIMCOP modules (or DMA channels) that are synchronized using the hardware sequencer. A total of five sequencing steps are executed (SIMCOP_HWSEQ_CTRL[31:6] HW_SEQ_STEP_COUNTER=5). The sequence is 2 steps long and starts with Step 1. Those two steps are configured using the SIMCOP_HWSEQ_STEP_*_i registers(where i = 0 and 1).

The SIMCOP modules processing is started using START pulses (green). When the SIMCOP modules are done, they return a DONE pulse (red). Software can choose which accelerators to run for a given step using the SIMCOP_HWSEQ_STEP_CTRL_i[7:0] *_SYNC registers. They do not need to finish at the same time because the hardware sequencer waits for reception of all DONE pulses of used accelerators before moving to the next step.

The hardware sequencer also triggers a series of interrupts that can be used by software. It is possible, for example, for software to change the configuration of inactive sequencing steps. This can be particularly useful to run longer sequences than what is supported by hardware.

For example, software can setup a 4-step long looping sequence: Step 0 → 1 → 2 → 3 → 0 → 1 → .... When the STEP1_IRQ event is triggered, software can load the configuration to be used next time Step 0 becomes active in the SIMCOP_HWSEQ_STEP_*_i registers.

8.4.2.3.5.2 Hardware Sequencer Override

By default, the hardware sequencer controls START/DONE pulses of all SIMCOP modules as well as the static controlled crossbar. Software can take the control over some resources by setting the appropriate bits in the SIMCOP_HWSEQ_OVERRIDE register. Sequencing resources under software control are managed using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers.

Changes done to the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[27:11] *_OFST and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers have immediate effect. It is the responsibility of software to ensure there is no active traffic on the impacted connection in the static controlled crossbar.

For example, when software wants to alternatively attach image buffers a and b to SIMCOP_DMA while preserving the buffer start address in the SIMCOP DMA address map constant it sets:

- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[2:0] IMBUFF_A = 1
- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[6:4] IMBUFF_B = 1

for the full application duration. It then changes the SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[2:0] IMBUFF_A and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[6:4] IMBUFF_B registers to attach the image buffers to the correct SIMCOP submodule.

The settings in the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers for resources controlled by the hardware sequencer have no effect.

Synchronization with SIMCOP submodules is controlled using the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:0] *_TRIGGER bit fields. For the ROT, VLCDJ, DCT, and LDC, a START pulse is sent to the module when a 1 is written into the appropriate bit field. Software can trigger one or multiple start pulses at the time. The *_TRIGGER bit field is cleared by writing 1. It is automatically set by hardware when a DONE pulse is received from the relevant SIMCOP submodule.

Software can poll the status of the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:0] *_TRIGGER bit fields to detect when a SIMCOP module has completed its processing task. Alternatively, software can also use an interrupt. SIMCOP has the capability to merge one or multiple internal events into SIMCOP outgoing interrupts. Software can choose between two modes for each interrupt output (SIMCOP_CTRL[3:0] IRQx_MODE):

- 0x0 : OR, the interrupt is asserted when one of the selected events has occurred
- 0x1 : AND, the interrupt is asserted when all selected events have occurred

The AND mode leads to a lower initiator load. In fact, the initiator is only interrupted once per sequencing step even when events from multiple SIMCOP submodules are expected. Also, it does not need to poll the SIMCOP_HL_IRQSTATUS_i register to detect which events have occurred, it simply needs to write 0xFFFFFFF into the SIMCOP_HL_IRQSTATUS_i register to clear all pending events.

The SIMCOP DMA START/DONE control is slightly different. Software can trigger one or multiple DMA channels by writing into the SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE[7:5] DMA_TRIGGER bit field. The DMA_TRIGGER bit field returns the written value when all expected DONE pulses have been received from SIMCOP DMA.

Alternatively, SIMCOP modules (except the LDC) may be triggered by direct writes into their configuration registers. However, this approach lead to higher initiator load because multiple writes must be done.

8.4.2.4 ISS SIMCOP Hardware Sequencer and Buffers Basic Programming Model

8.4.2.4.1 ISS SIMCOP Hardware Sequencer and Buffers Application Programming Principle

Software must first configure the SIMCOP access tag handling (SIMCOP_CTRL[24:21] LDC_R_TAG_CNT, SIMCOP_CTRL[19:16] LDC_R_TAG_OFST, and SIMCOP_DMA_CTRL[7:4] TAG_CNT). Software must ensure there is no active traffic on the SIMCOP master port before changing those registers.

Then it initializes the Huffman, Quantization, and LDC LUT if they are used. Those memories must first be attached to the SIMCOP bus so that they can be accessed from the slave port (SIMCOP_CTRL[11] HUFF, SIMCOP_CTRL[10] QUANT, and SIMCOP_CTRL[7:6] LDC_LUT). Then they can be preloaded using either an external CPU or an external DMA engine. SIMCOP DMA cannot preload those tables.

Similarly, software can also preload data like filter coefficients into image buffers. This can be handled by the SIMCOP DMA:

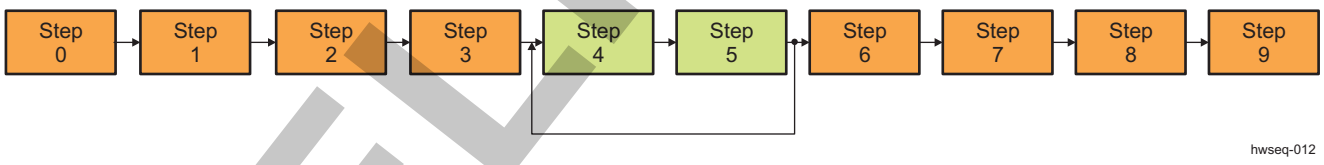
- The buffers must first be attached to the SIMCOP DMA using the SIMCOP_HWSEQ_OVERRIDE and SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE registers.
- Alternatively, software can use the SIMCOP_HWSEQ_STEP_*_0 registers instead of the override feature. The hardware sequencer ensures that the configuration of Step 0 is applied when the hardware sequencer is disabled.
- Software then configures and starts one or multiple data transfers using the SIMCOP DMA.
- Software monitors SIMCOP DMA events to know when DMA transfers are complete. Other configuration tasks may happen concurrently, but software must ensure that transfers have completed before attaching the memories to another module.

It must then enable the modules going to be used.

Typically, the first and last steps of the macroblock pipeline are different from those in the middle of the pipeline. The hardware sequencer has no specific support for pipe-up and pipe-down. However, software cancut the sequence into smaller ones to still benefit from the hardware sequencing and to avoid software sequencing.

Figure 8-267 shows an example of a 10-step sequence involving two DMA transfers and three modules.

Figure 8-267. Typical Hardware Sequencer Controlled Sequencer With Pipe-Up and Pipe-Down



The macroblock pipeline is composed of a chain of three accelerators. Data between modules is exchanged using ping-pong buffering.

Pipe-up and pipe-down require four sequencing steps each. The main processing can be done with two steps.

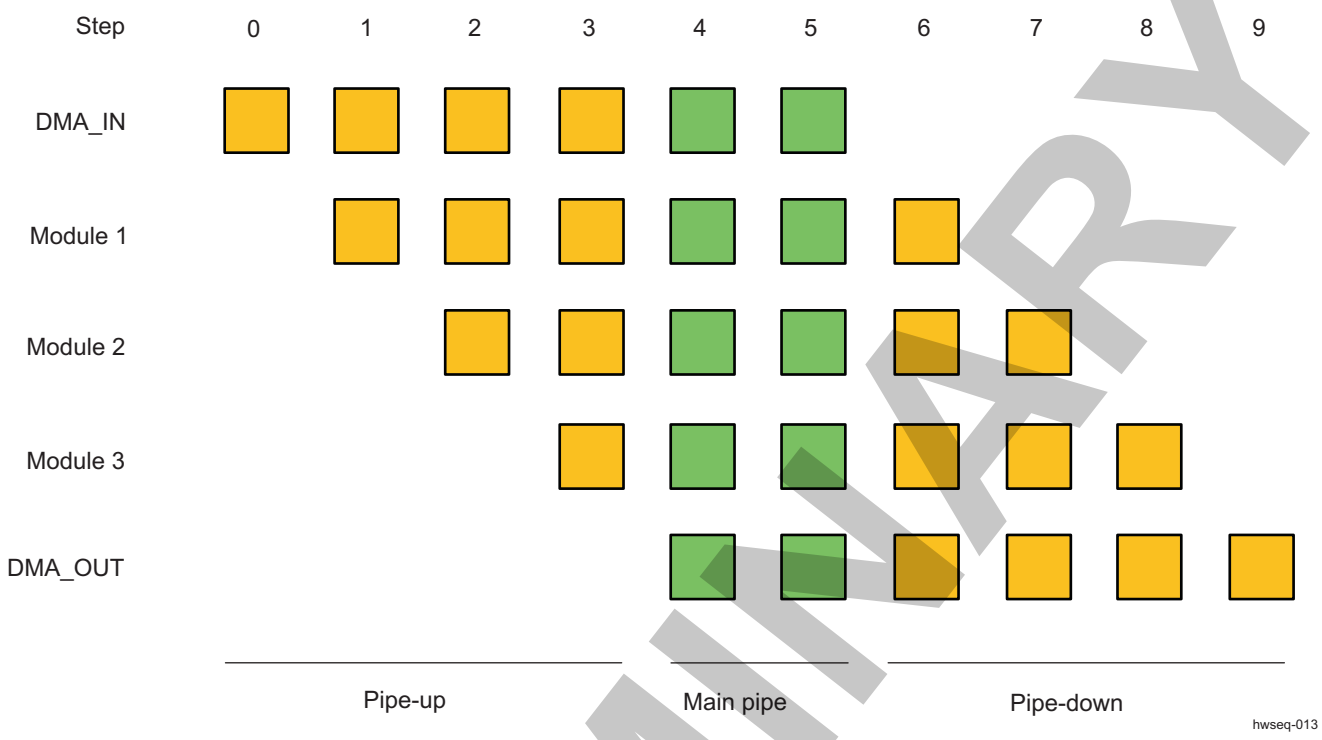
Software configures the hardware sequencer with the four step pipe-up sequence. Each step is executed once. When pipe-up is done, the SIMCOP triggers the DONE_IRQ event.

Software then reconfigures the hardware sequencer for the two step main sequence. The number of steps is defined by the amount of data to process. When the main pipe is done, the SIMCOP triggers the DONE_IRQ event.

Software finally reconfigures the hardware sequencer with the four step pipe-down sequence. Each step is executed once. When pipe-down is done, the SIMCOP triggers the DONE_IRQ event.

Figure 8-268 shows an example of pipe-up and pipe-done.

Figure 8-268. Pipe-Up and Pipe-Down



The hardware sequencer configuration determines which module can access a given SIMCOP memory for a sequence step.

8.4.2.4.2 External CPU Use for Data Processing

An external CPU can be used to perform some data processing as the SIMCOP hardware accelerators do. A similar mechanism to the START/DONE pulse interaction with the SIMCOP hardware accelerators is implemented.

The external CPU receives the request to start processing by the CPU_PROC_START_IRQ interrupt merged at the SIMCOP subsystem level. This interrupt is enabled and acknowledged as usual.

When processing has completed, the CPU generates the DONE pulse to the hardware sequencer by writing 1 into the SIMCOP_HWSEQ_CTRL[10] CPU_PROC_DONE register.

8.4.2.4.3 Rotation Operational Mode Configuration

The macroblock pipeline is controlled by a two step hardware sequence:

Figure 8-269. Rotation Macroblock Pipeline

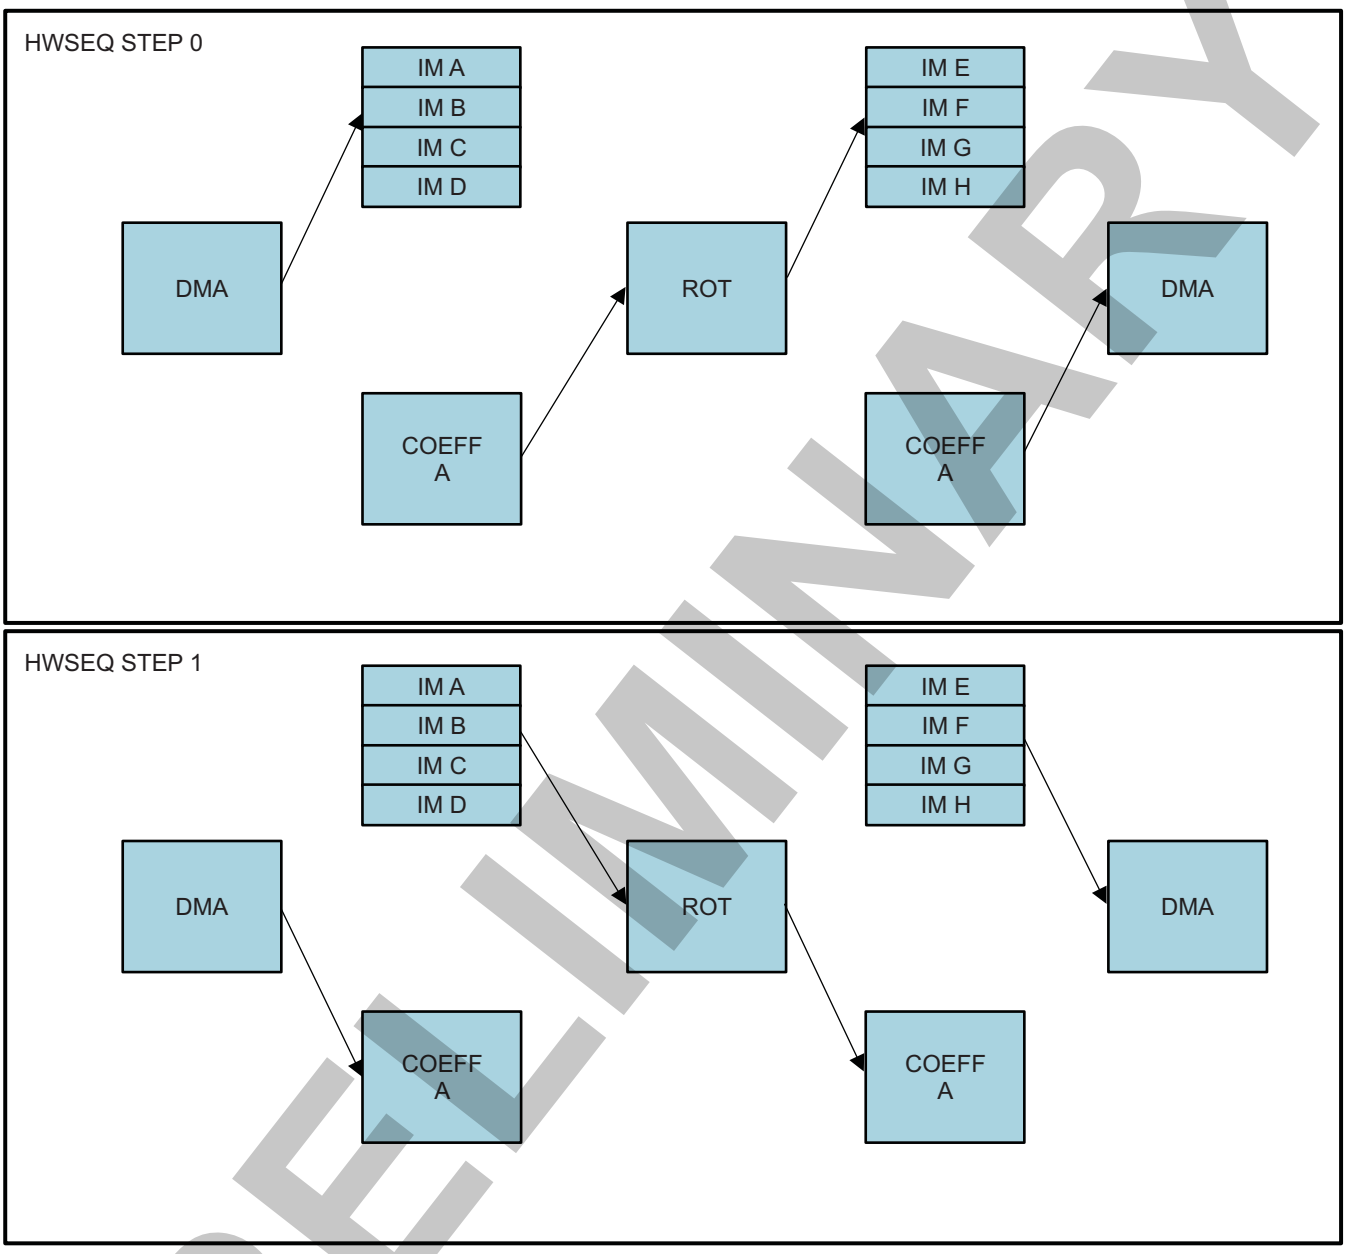


Table 8-1388. Rotation Macro-Block Pipeline

Step	Register/ Bitfield / Programming Model	Value
Set DMA to access IMBUFF_A	SIMCOP_HWSEQ_STEP_SWITCH_i[2:0] IMBUFF_A (i = 0)	0x1
Set ROT_A_O to access IMBUFF_E	SIMCOP_HWSEQ_STEP_SWITCH_i[18:16] IMBUFF_E (i = 0)	0x7
Set ROT_A_I to access COEFF_A	SIMCOP_HWSEQ_STEP_CTRL2_i[2:0] = COEFF_A (i = 0)	0x6
Set DMA to access COEFF_B	SIMCOP_HWSEQ_STEP_CTRL2_i[6:4] COEFF_B (i = 0)	0x1
Set ROT_A_I to access IMBUFF_A	SIMCOP_HWSEQ_STEP_SWITCH_i[2:0] IMBUFF_A (i = 1)	0x6

Table 8-1388. Rotation Macro-Block Pipeline (continued)

Step	Register/ Bitfield / Programming Model	Value
Set DMA to access IMBUFF_E	SIMCOP_HWSEQ_STEP_SWITCH_i[18:16] IMBUFF_E (i = 1)	0x1
Set DMA to access COEFF_A	SIMCOP_HWSEQ_STEP_CTRL2_i[2:0] COEFF_A (i = 1)	0x1
Set ROT_A_O to access COEFF_B	SIMCOP_HWSEQ_STEP_CTRL2_i[6:4] COEFF_B (i = 1)	0x6

8.4.2.4.4 LDC Operational Mode Configuration

The LDC module fetches data from system memory, performs the transformation, and stores results into image buffers. The DCT and VLCDJ modules are used to JPEG compress this data and store the results to the BITSTREAM buffer. The SIMCOP DMA is used to transfer compressed data from the BITSTREAM buffer to system memory.

Figure 8-270. LDC Transformation Pipeline

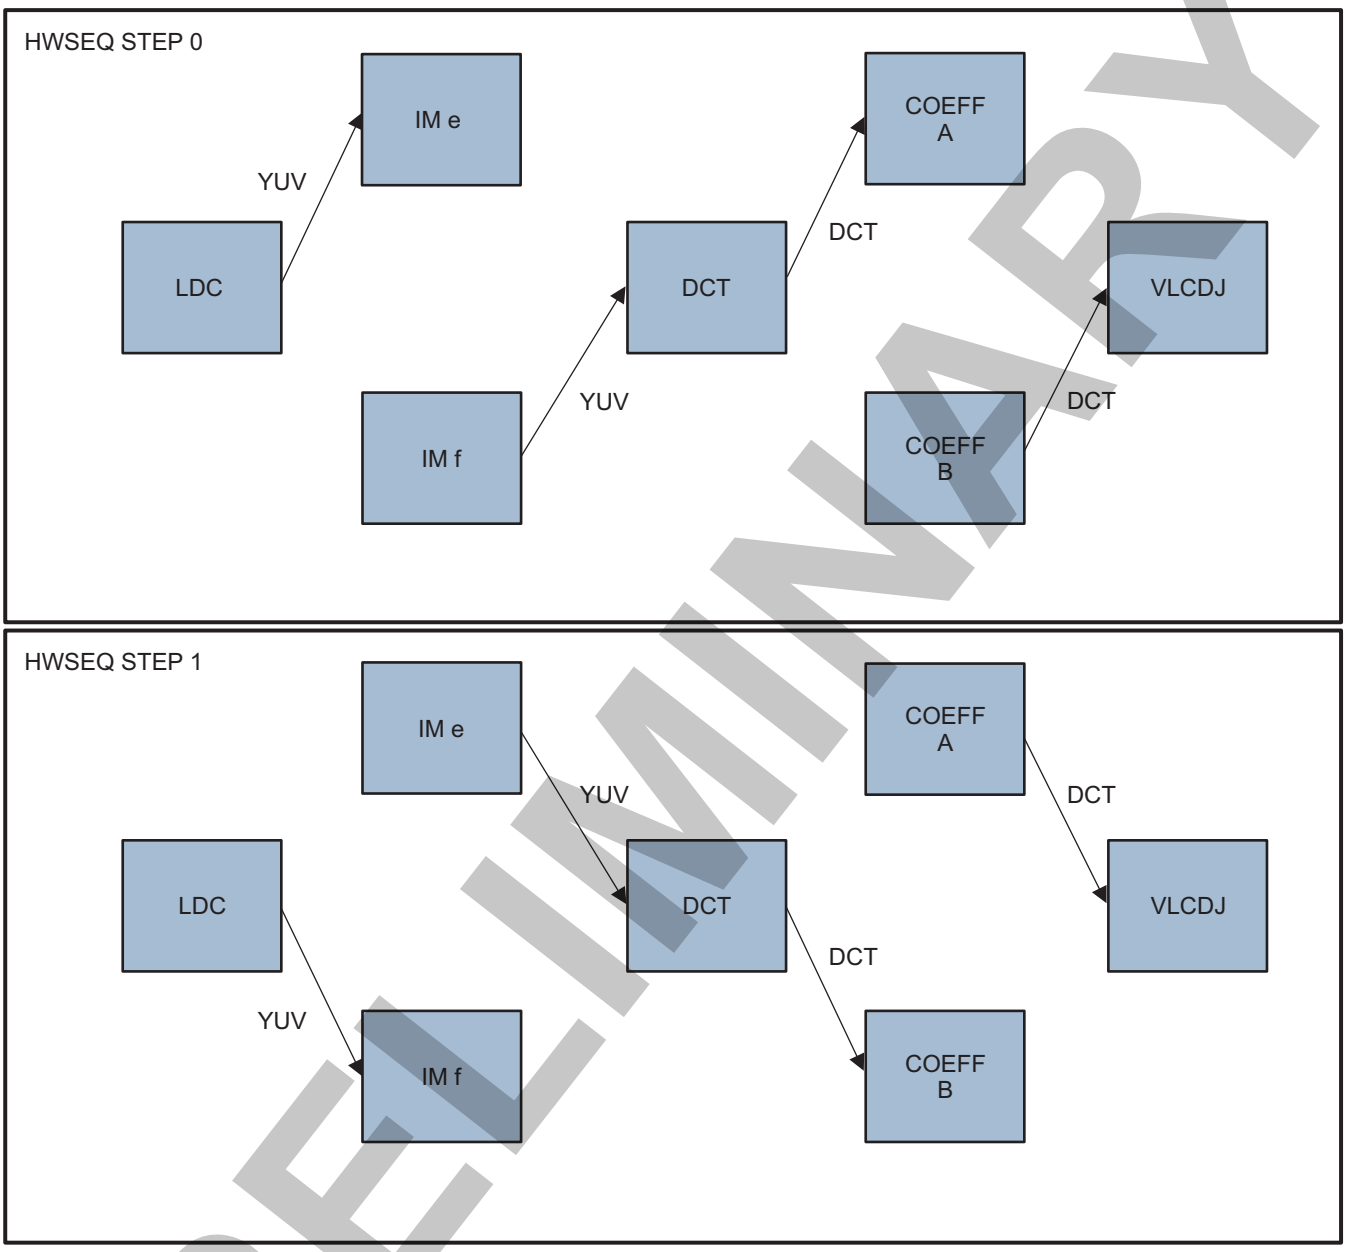

Table 8-1389. LDC Transformation

Step	Register/ Bitfield / Programming Model	Value
Set image buffers a and b as input buffer	SIMCOP_CTRL[7:6] LDC_INPUT	0x1
Set LDC to access the image buffer e	SIMCOP_HWSEQ_STEP_SWITCH_i[18:16] IMBUFF_E	0x6
Set DCT to access coefficient buffer a	SIMCOP_HWSEQ_STEP_CTRL2_i[2:0] COEFF_A	0x5
Set VLCDJ_IO to access coefficient buffer b	SIMCOP_HWSEQ_STEP_CTRL2_i[6:4] COEFF_B	0x4
Set DCT to access the image buffer e	SIMCOP_HWSEQ_STEP_SWITCH_i[18:16] IMBUFF_E	0x4
Set LDC to access the image buffer f	SIMCOP_HWSEQ_STEP_SWITCH_i[18:16] IMBUFF_F	0x6
Set VLCDJ_IO to access coefficient buffer a	SIMCOP_HWSEQ_STEP_CTRL2_i[2:0] COEFF_A	0x4

Table 8-1389. LDC Transformation (continued)

Step	Register/ Bitfield / Programming Model	Value
Set DCT to access coefficient buffer b	SIMCOP_HWSEQ_STEP_CTRL2_i[6:4] COEFF_B	0x5

8.4.2.4.5 Concurrent Software and Hardware Sequencing

Software can perform sequencing tasks concurrently to hardware sequencing. This is supported through the hardware sequencer override registers:

- SIMCOP_HWSEQ_OVERRIDE
- SIMCOP_HWSEQ_STEP_CTRL_OVERRIDE
- SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE
- SIMCOP_HWSEQ_STEP_CTRL2_OVERRIDE

  Software can select which hardware resources are controlled by the hardware sequencer and what resources are controlled by software. Configuration parameters for software-controlled resources are provided using those registers as well.

Table 8-1390. Concurrent Software and Hardware Sequencing

Step	Register/ Bitfield / Programming Model	Value
Set software to control IMBUFF_E	SIMCOP_HWSEQ_OVERRIDE[13] IMBUFF_E	0x1
Set DMA to access the image buffer e	SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[18:16] IMBUFF_E	0x1
Set software to control IMBUFF_F	SIMCOP_HWSEQ_OVERRIDE[14] IMBUFF_F	0x1
Set DCT_S to access the image buffer f	SIMCOP_HWSEQ_STEP_SWITCH_OVERRIDE[22:20] IMBUFF_F	0x4
Set software to control COEFF_A	SIMCOP_HWSEQ_OVERRIDE[17] COEFF_A	0x1
Set hardware sequencer to control COEFF_B	SIMCOP_HWSEQ_OVERRIDE[18] COEFF_B	0x0

8.4.2.5.2.2 Hardware Sequencer Register Description

through describe the registers in detail.

Table 8-1393. SIMCOP_HWSEQ_CTRL

Address Offset	0x0000 0068		
Physical Address	0x5202 0068 0x5506 0068	**Instance**	HWSEQ_MAIN_L3 HWSEQ_IPU
Description	SIMCOP HW sequencer control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HW_SEQ_STEP_COUNTER																RESERVED			STEP		CPU_PROC_DONE		BBM_SYNC_CHAN	BBM_STATUS			BITSTREAM				BITSTR_XFER_SIZE		HW_SEQ_STOP	HW_SEQ_START

Bits	Field Name	Description	Type	Reset
31:16	HW_SEQ_STEP_COUNTER	Number of steps executed by the HW sequencer. HW_SEQ_STEP_COUNTER=0 corresponds to manual sequencing.	RW	0x0000
15:13	RESERVED	Read returns 0.	R	0x0
12:11	STEP	This register is automatically updated by the HW sequencer when it is active. Otherwise, SW could use it to activate the content of a given set of step registers (SIMCOP_HWSEQ_STEP_i).	RW	0x0
10	CPU_PROC_DONE	Used by the CPU to tell that it has completed data processing. This feature should be used together with the CPU_PROC_START_IRQ event Read's always return 0. Write 0x0: No effect. Write 0x1: CPU processing completed.	W	0
9:8	BBM_SYNC_CHAN	Defines the SIMCOP DMA HW synchronization channel to be used for BBM. This register is only used when BITSTREAM=ENCODE or DECODE. SW must ensure that the same DMA HW synchronization channel isn't used by the HW sequencer.	RW	0x0
7	BBM_STATUS	Status of the Bitstream buffer management HW. Used only during automatic mode [BITSTREAM=5 or 6] Equals 0 (IDLE) in manual mode [BITSTREAM=0..4]. Set when automatic mode is entered. Automatic encode mode: used to detect when all banks have been flushed after the processing has completed (i.e. but request bank signals have been de-asserted by BBM). Automatic decode mode (BITSTREAM=DECODE): returns to 0 (IDLE) when automatic mode is left (BITSTREAM=COPR). Read 0x1: BBM is busy. Read 0x0: BBM is idle	R	0
6:4	BITSTREAM	BITSTREAM buffer access control 0x0: Bank 0: coprocessor bus (0x1000-0x17FF) Bank 1: coprocessor bus (0x1800-0x1FFF) 0x1: Bank 0: DMA (0x1000-0x17FF) Bank 1: DMA (0x1800-0x1FFF) 0x2: Bank 0: VLCDJ.B (0x000-0x7FF) Bank 1: VLCDJ.B (0x800-0xFFF) 0x3: Bank 0: DMA (0x1000-0x17FF) Bank 1: VLCDJ.B (0x800-0xFFF) 0x4: Bank 0: VLCDJ.B (0x000-0x7FF) Bank 1: DMA (0x1800-0x1FFF) 0x5: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG encode use case. It could be accessed by the SIMCOP DMA or the VLCDJ module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA. 0x6: The BITSTREAM buffer is managed by HW as a PING/PONG buffer to support JPEG decode use case. It could be accessed by the SIMCOP DMA or the VLCDJ module. The BITSTREAM HW sequence is reset when the mode is changed to COPR, VLCDJ or DMA.	RW	0x0

Bits	Field Name	Description	Type	Reset
3:2	BITSTR_XFER_SIZE	Defines the amount of data to be transferred per HW request to the SIMCOP DMA. Bigger sizes lead to better SDRAM efficiency but prevents fine grained DMA transfer arbitration. This register is only used by HW when BITSTREAM=ENCODE or BITSTREAM=DECODE. 0x0: 2048 bytes 0x1: 1024 bytes 0x2: 512 bytes 0x3: 256 bytes	RW	0x0
1	HW_SEQ_STOP	Stop the HW sequencer. This feature is typically used to recover from an error condition. Read's always return 0. Write 0x0: No effect. Write 0x1: Stop the HW sequence immediately (don't wait for expected DONE events). Setting this bit while the sequencer is idle has no effect.	W	0
0	HW_SEQ_START	Start the HW sequencer. Read's always return 0. Write 0x0: No effect. Write 0x1: Start STEP0 of the HW sequence. Setting this bit while the sequencer is running has no effect.	W	0

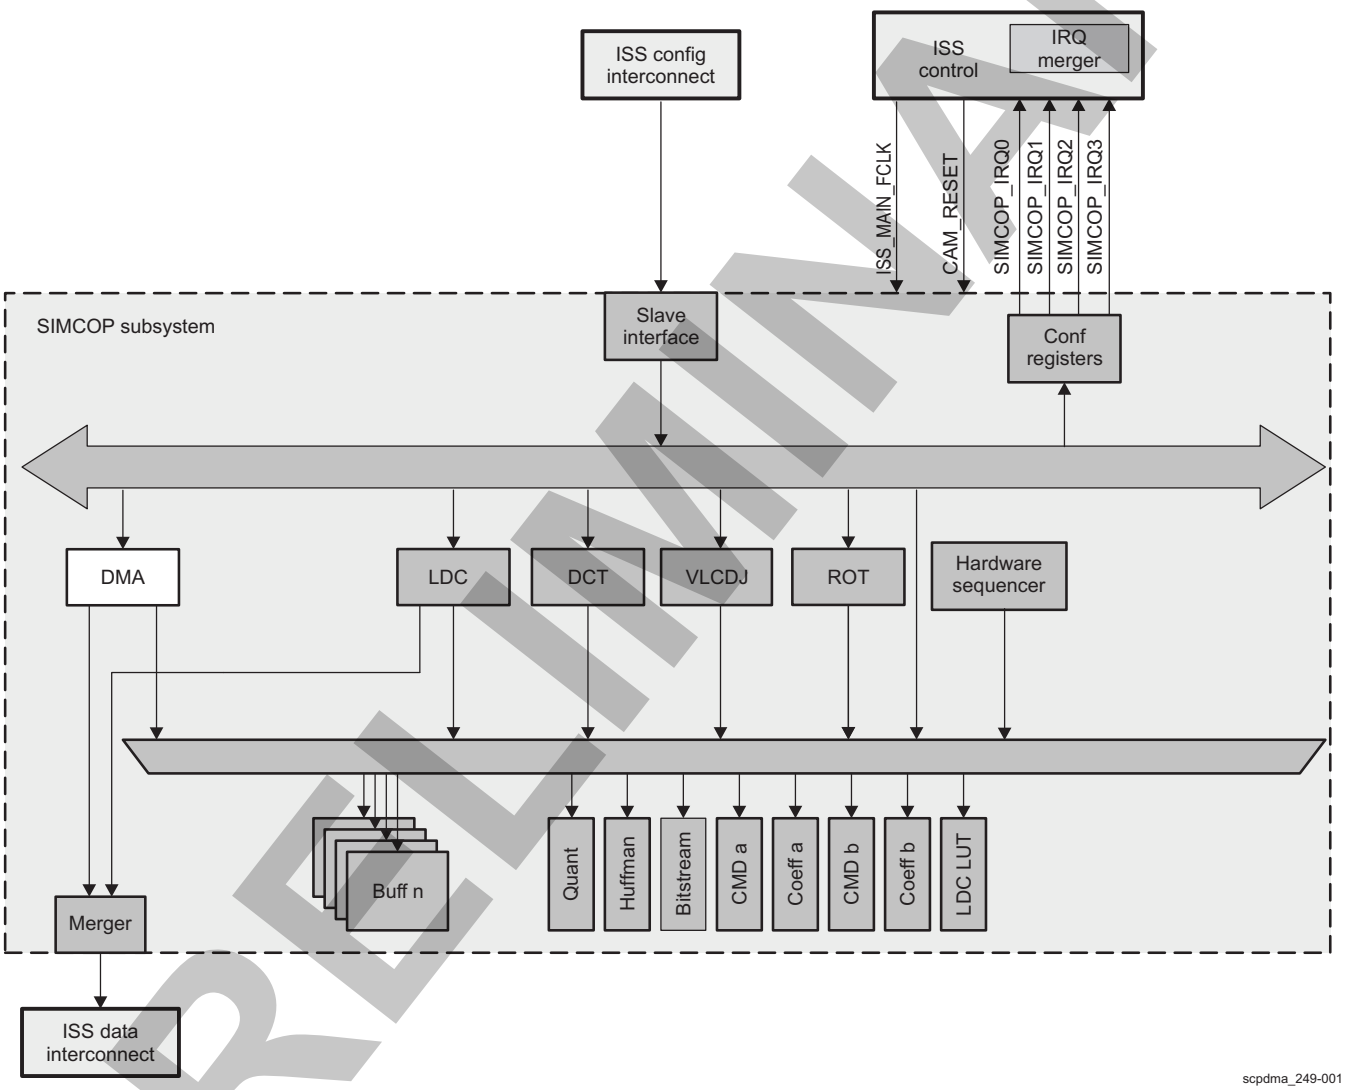
8.4.3 ISS SIMCOP DMA Module

This section describes the direct memory access (DMA) module in the still image coprocessor (SIMCOP) subsystem.

8.4.3.1 ISS SIMCOP DMA Overview

The direct memory access (DMA) module transfers data from system memory to the still image coprocessor (SIMCOP) memories and from SIMCOP memories. Figure 8-271 is an overview of the DMA module in the SIMCOP subsystem.

Figure 8-271. DMA in the SIMCOP Subsystem



The SIMCOP DMA supports the following features:

- Configuration interface, for register access
- Image subsystem (ISS) data interconnect master interface, for system memory access
  - Supports 1-dimensional (1D) and 2-dimensional (2D) burst
- SIMCOP crossbar master interface, for SIMCOP memories access
- Eight logical channels supported
- Hardware synchronization support
- 2-dimensional (2D) addressing transfers

- 2D data block transfer (base address, stride, height, width)
- Array of 2D block transfer support
- Performance: Software-controllable bandwidth limiter

The SIMCOP DMA is not a general-purpose DMA. It can perform only 16-byte aligned transfers and does not have access to the ISS configuration interconnect. SDMA must be used instead.

8.4.3.2 ISS SIMCOP DMA Integration

The DMA module is part of the SIMCOP subsystem in the ISS. Figure 8-272 shows the integration of the DMA in the SIMCOP sybsystem.

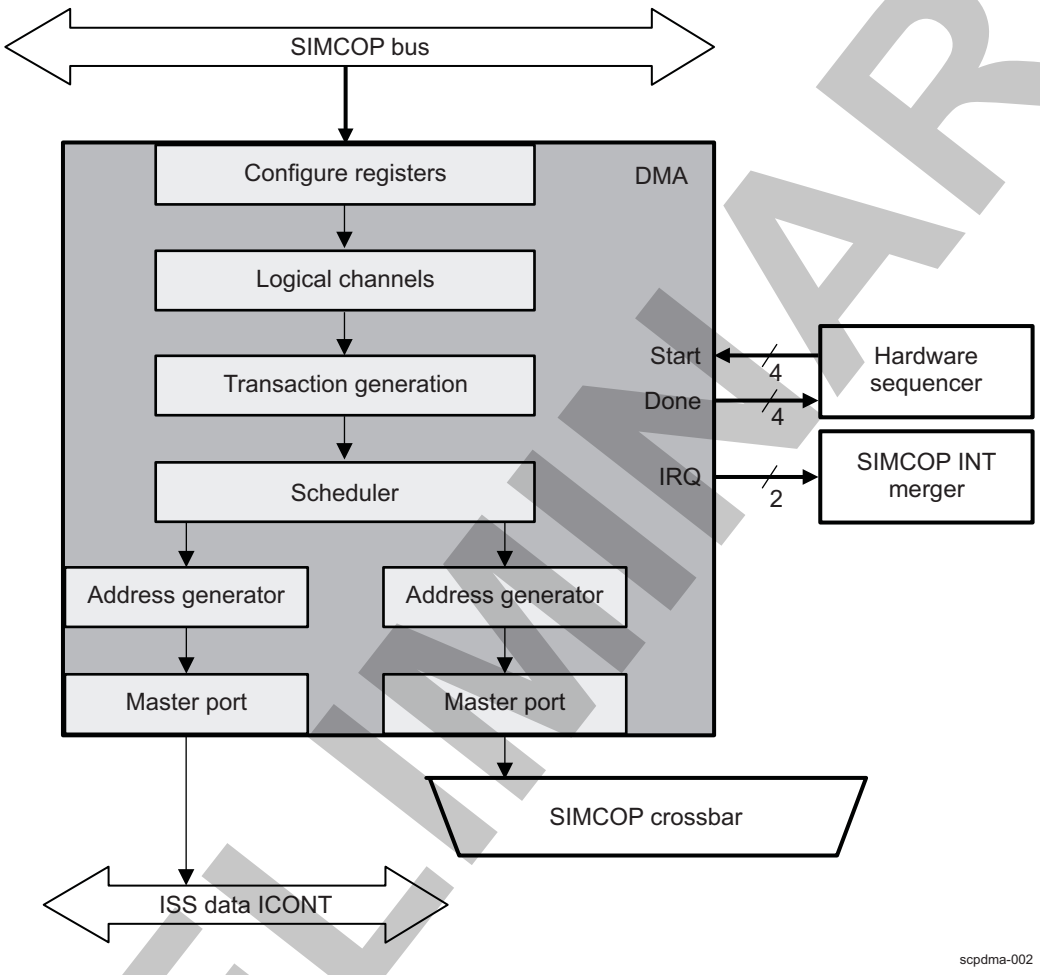
8.4.3.3 ISS SIMCOP DMA Functional Description

8.4.3.3.1 ISS SIMCOP DMA Block Diagram

Figure 8-273 is a block diagram of the SIMCOP DMA.

Figure 8-273. DMA Block Diagram



An external initiator sets up logical channels using the configuration interface.

When a logical channel becomes active, a transfer must be executed. A transfer corresponds to a 2D block of data copied from system memory to SIMCOP memory and vice versa.

A transfer is decomposed into one or multiple transactions by the transaction generation unit.

The scheduler issues transactions when tags are available. There can be one outstanding command per tag on the ISS data interconnect.

8.4.3.3.2 ISS SIMCOP DMA Power Management

Table 8-1414 lists the power-management features available in the DMA module.

Table 8-1414. Local Power-Management Features

Feature	Registers	Description
Master standby modes	SIMCOP_DMA_SYSCONFIG[5:4] STANDBYMODE	Force-standby, no-standby, and smart-standby modes are available.

8.4.3.3.3 ISS SIMCOP DMA Interrupt Requests

The SIMCOP DMA module can generate two interrupts, SIMCOP_DMA_IRQ0 and SIMCOP_DMA_IRQ1. These two interrupts are controlled by four registers:

- SIMCOP_DMA_IRQSTATUS_RAW_j: The status of the interrupt before masking
- SIMCOP_DMA_IRQSTATUS_j: The status of the interrupt after masking
- SIMCOP_DMA_IRQENABLE_SET_j: Enable an interrupt to propagate to SIMCOP_DMA_IRQi signal (unmask)
- SIMCOP_DMA_IRQENABLE_CLR_j: Disable an interrupt to propagate to SIMCOP_DMA_IRQi signal (mask)

To clear an interrupt, software must write 1 in the corresponding bit of the SIMCOP_DMA_IRQSTATUS_j register even if the event is not enabled (SIMCOP_DMA_IRQSTATUS_RAW_j is also cleared).

Table 8-1415 list all the SIMCOP DMA events that can lead to an interrupt generation.

Table 8-1415. SIMCOP DMA Events List

Bit Name	Bit	Event
BUS_ERR	0	Error occurred on bus
CHAN0_BLOCK_DONE_IRQ	16	Channel 0 has completed transfer of one 2D block.
CHAN1_BLOCK_DONE_IRQ	17	Channel 1 has completed transfer of one 2D block.
CHAN2_BLOCK_DONE_IRQ	18	Channel 2 has completed transfer of one 2D block.
CHAN3_BLOCK_DONE_IRQ	19	Channel 3 has completed transfer of one 2D block.
CHAN4_BLOCK_DONE_IRQ	20	Channel 4 has completed transfer of one 2D block.
CHAN5_BLOCK_DONE_IRQ	21	Channel 5 has completed transfer of one 2D block.
CHAN6_BLOCK_DONE_IRQ	22	Channel 6 has completed transfer of one 2D block.
CHAN7_BLOCK_DONE_IRQ	23	Channel 7 has completed transfer of one 2D block.
CHAN0_FRAME_DONE_IRQ	24	Channel 0 has completed transfer of the full frame.
CHAN1_FRAME_DONE_IRQ	25	Channel 1 has completed transfer of the full frame.
CHAN2_FRAME_DONE_IRQ	26	Channel 2 has completed transfer of the full frame.
CHAN3_FRAME_DONE_IRQ	27	Channel 3 has completed transfer of the full frame.
CHAN4_FRAME_DONE_IRQ	28	Channel 4 has completed transfer of the full frame.
CHAN5_FRAME_DONE_IRQ	29	Channel 5 has completed transfer of the full frame.
CHAN6_FRAME_DONE_IRQ	30	Channel 6 has completed transfer of the full frame.
CHAN7_FRAME_DONE_IRQ	31	Channel 7 has completed transfer of the full frame.

8.4.3.3.4 ISS SIMCOP DMA Logical Channels

In the context of the SIMCOP, multiple logical channels are required to offload the external initiator. Typical uses of multiple contexts are:

- Run a read transfer followed by a write transfer. When this transfer is complete, new input data is fetched from system memory and stored in the image buffers.
- Read or write YUV4:2:0 data from system memory; YUV4:2:0 data is stored in two different system memory buffers.

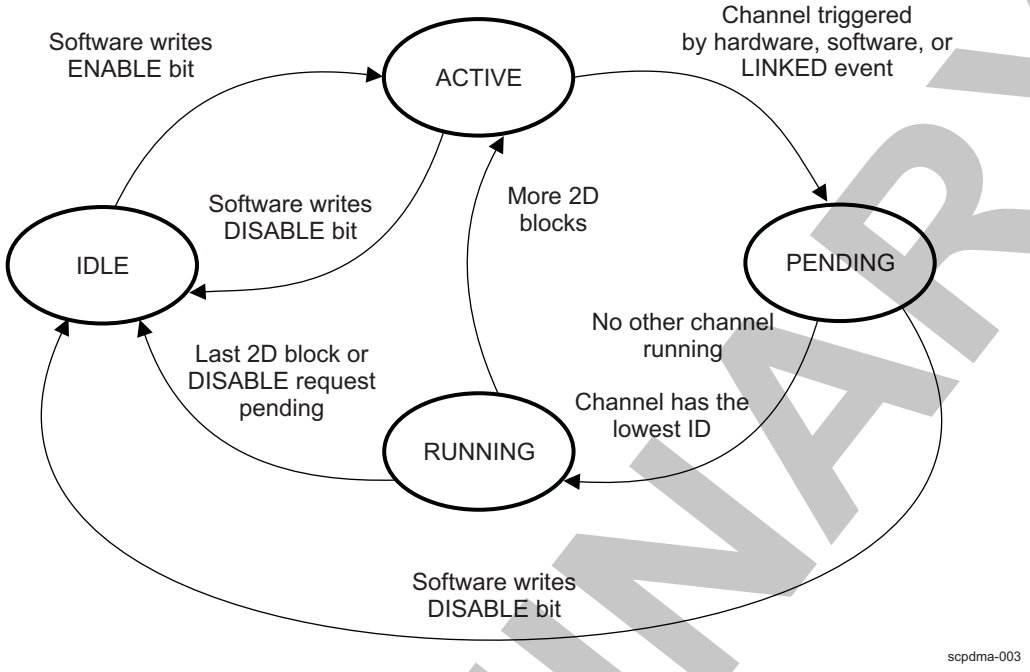
8.4.3.3.4.1 Logical Channel States

The SIMCOP DMA supports up to eight ((SIMCOP_DMA_HWINFO[2] CHAN+1) × 4) logical channels. Each logical channel can be configured and triggered separately.

Idle logical channels must be configured and enabled (SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1) to be used.

Figure 8-274 shows the different states of a logical channel. Software can poll the current state from the SIMCOP_DMA_CHAN_CTRL_i[4:3] STATUS bit field.

Figure 8-274. DMA Logical Channel States



When a trigger event is received by a channel in the ACTIVE state, it moves to the PENDING state. Trigger events received when the channel is in the IDLE, PENDING, or RUNNING state are discarded.

A logical channel is automatically disabled by hardware when a complete frame (all 2D blocks) is transferred. It can be disabled earlier by software by writing the SIMCOP_DMA_CHAN_CTRL_i[1] DISABLE bit. When a disable request occurs in the RUNNING state, it is memorized and executed when the channel leaves the RUNNING state. Pending disable requests have higher priority than channel trigger events.

When multiple logical channels are pending simultaneously, the following rules apply:

- An ongoing transfer of a 2D block is never stopped. It must complete before the next one starts.
- The logical channel with the lowest ID wins the arbitration (that is, CHAN0 has higher priority than CHAN1). Software can give higher priority to a channel by choosing a lower ID.

This situation can, for example, occur when software triggers a channel while a transfer is ongoing for another one. Two types of interrupts can be generated:

- CHANx_BLOCK_DONE_IRQ (where x = channel number): It is generated when the channel leaves the RUNNING state (RUNNING -> ACTIVE or RUNNING -> IDLE).
- CHANx_FRAME_DONE_IRQ (where x = channel number): It is generated when the channel enters the IDLE state.

8.4.3.3.4.2 Logical Channel Chaining, Trigger, and Hardware Synchronization

Active logical channels can be triggered:

- By software. Writes the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit
- By a hardware DMA request. A channel can be made sensitive to a pulse on the START[y] input when SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART = y has been configured by software.
- When the previous channel in the linked list finishes. This feature is enabled through the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field of the preceding channel in the chain.

When a channel completes, it can optionally send a pulse to the DONE[y] output. Software enables this feature by configuring SIMCOP_DMA_CHAN_CTRL_i[22:20] HWDONE = y.

Typically, the START + DONE synchronization mechanism is used together with the SIMCOP hardware sequencer. The hardware sequencer sends a pulse to START[y] a data transfer and the SIMCOP DMA responds with a DONE[y] pulse when the transfer completes. A transfer can be composed of one or multiple logical channels. For example, a YUV4:2:0-NV12 block copy from system memory to SIMCOP local memories requires two chained logical channels.

CAUTION

Software must ensure that only one trigger event source is selected at a given time for a logical channel; otherwise, unpredictable behavior may occur.

Typically, the following combinations can be used:

- Single channel triggered by software: Hardware synchronization and linking are disabled. Software writes the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit to start the transfer of one 2D block. Software must not trigger the channel again before the CHANx_BLOCK_DONE_IRQ (where x = channel number) event is generated by the DMA.
- Channels chain-triggered by software: Multiple channels are linked together using the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field. Software triggers the first one in the chain and monitors the CHANx_BLOCK_DONE_IRQ (where x = channel number) event to know when the chain can be triggered again.
- Single channel triggered by hardware synchronization: Sensitivity on START pulses is activated through the SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART bit field. DONE pulse generation is activated using the SIMCOP_DMA_CHAN_CTRL_i[22:20] HWSTOP bit field.
- Channels chain-triggered by hardware: Multiple channels are linked together using the SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED bit field. Sensitivity on START pulses is activated for the first channel in the chain through the SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART bit field. DONE pulse generation for the last channel in the chain is activated using the SIMCOP_DMA_CHAN_CTRL_i[22:20] HWDONE bit field.

8.4.3.3.4.3 Logical Channel Data Transfer

Each logical channel can handle 4D transfers from system memory to SIMCOP memory and vice versa.

A frame is composed of SIMCOP_DMA_CHAN_FRAME_i[9:0] XCNT * SIMCOP_DMA_CHAN_FRAME_i[25:16] YCNT 2D blocks of data. A single 2D block of data is transferred each time a logical channel is in the RUNNING state.

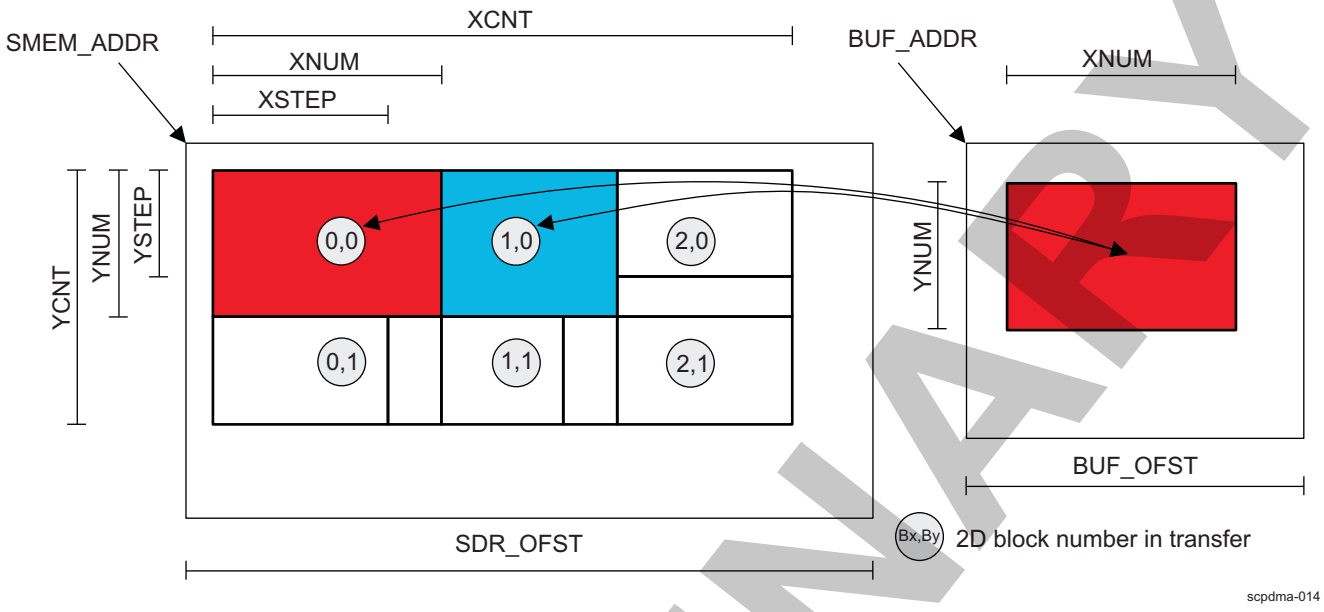
The size of a 2D block is SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM * SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM words of 128 bits. The SIMCOP DMA can transfer only full 128-bit words.

2D blocks may overlap in system memory. This feature is typically used for source data fetches from system memory to handle filter dependencies. If this feature is not used, software must set:

- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM = SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP
- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[28:16] YNUM = SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP

Figure 8-275 shows DMA addressing.

Figure 8-275. DMA Addressing



The base position of 2D blocks in system memory is automatically computed by the SIMCOP DMA. The base address is computed using the following formula:

SMEM_BASE = SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR +
Bx × SIMCOP_DMA_CHAN_BLOCK_STEP_i[14:4] XSTEP +
By × SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP ×
SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST

All 2D blocks of a logical channel have the same location in SIMCOP local memories:

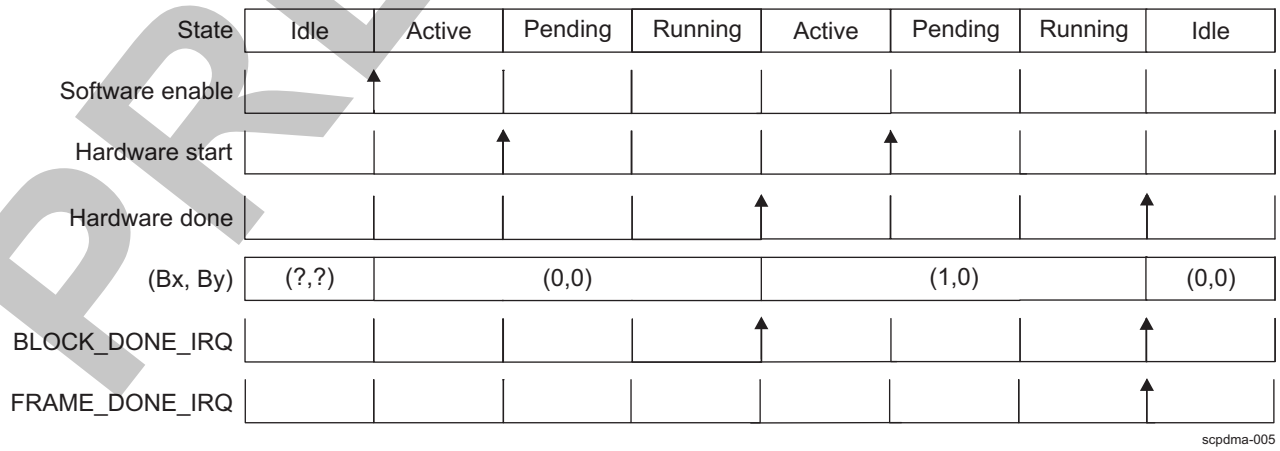
BUF_BASE = SIMCOP_DMA_CHAN_BUF_ADDR_i[23:4] ADDR

The same functionality can also be used to read or write sparse data from SDRAM. Typically, that is useful to split processing between two SIMCOP accelerators .

Software can poll the status of a channel using the SIMCOP_DMA_CHAN_CURRENT_BLOCK_i register. It holds the Bx, By values of the last-transferred 2D block. The Bx, By values are reset when a channel is enabled (set the SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE bit) and they are updated when a channel enters the RUNNING state.

Figure 8-276 shows an example of a 2-block large transfer.

Figure 8-276. 2-Block Large Transfer Example



8.4.3.3.5 Transaction Generation

Each transfer is decomposed into one or multiple transactions by the DMA engine. The firmware can define:

- Burst generation for regular or tiled accesses (SIMCOP_DMA_CHAN_CTRL_i[6] TILERMODE). Additional parameters must be defined for tiled accesses. See Section 8.4.3.3.5.2, *Block Bursts for Tiled Transfers*.
- The maximum burst size (SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE). It must be aligned with the interconnect configuration.
- Use of posted or nonposted writes (SIMCOP_DMA_CTRL[3] POSTED_WRITES). It must be aligned with the interconnect configuration. Mainly, in a multichannel system memory, system bursts must be issued nonposted.

8.4.3.3.5.1 Incrementing Bursts for Regular Transfers

Lines of 2D blocks are processed sequentially. The following transaction process is used for a given line:

1. Perform a single nonaligned burst from the start address to the next SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE boundary (or less if the transfer is smaller).
2. Perform "n" aligned bursts (n can be 0).
3. Perform a single nonaligned burst up to the end address (if needed).

A transaction is aligned when the start address modulo burst length is 0.

8.4.3.3.5.2 Block Bursts for Tiled Transfers

The line stride is configured using the SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST bit field. The full register content is used for internal address computation. The SIMCOP_DMA_CHAN_SMEM_OFST_i[19:4] OFST bit field must be a multiple of the SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE bit field.

The SIMCOP DMA has the following alignment constraints:

- SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR is 128 bit-aligned.
- SIMCOP_DMA_CHAN_BLOCK_SIZE_i[13:4] XNUM is 128 bit-aligned.

Only the values in Table 8-1416 are allowed for the SIMCOP_DMA_CTRL[1:0] MAX_BURST_SIZE bit field. Other values lead to undefined behavior.

Table 8-1416. Allowed Max Burst Size

Minimum Burst Height	MAX_BURST_SIZE
2	2, 4, or 8 x 128 bits
4	4 or 8 x 128 bits

8.4.3.4 ISS SIMCOP DMA Basic Programming Model

8.4.3.4.1 Initialization of Surrounding Modules

To initialize the DMA, the surrounding modules must be initialized. Table 8-1417 lists these modules.

Table 8-1417. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable SIMCOP clock	
Buffers	Configure DMA access to image buffer	
SIMCOP CTRL		Configure SIMCOP CTRL to handle DMA interrupts

8.4.3.4.2 ISS SIMCOP DMA Channel Configuration and Hardware Synchronization

Software must fully configure a DMA channel before enabling it. It then configures channel linking and the used synchronization method.

The following example shows four logical channels chained with hardware synchronization used to copy YUV4:2:0-NV12 data from SIMCOP local memories to system memory, and then to copy YUV4:2:0-NV12 data from system memory to SIMCOP local memories.

YUV4:2:0-NV12 data is stored in two separate buffers in SDRAM. Therefore, two channels are used for the SIMCOP -> system copy, and two channels are used for the system -> SIMCOP copy.

In this example, the intent is to transfer a 2 x 2 array of 64 x 32 pixel blocks. It is assumed that input data is stored contiguously in system memory and that the output buffer size in system memory is 256 x 32 pixels. In SIMCOP local memories, data is contiguously stored starting at address 0

The following configuration is used:

- Channel i = 0, input Y buffer:
  - SIMCOP_DMA_CHAN_SMEM_ADDR_i[31:4] ADDR = Start address of Y input buffer

  - SIMCOP_DMA_CHAN_BLOCK_STEP_i[29:16] YSTEP = 16

Figure 8-277 shows the channel linking chain used. All four channels are executed sequentially. Doing so prevents access collision in SIMCOP local memories or system memories. Channel 0 is started by a START[0] pulse from SIMCOP. When Channel 3 completes the last transfer, a pulse to DONE[0] is sent back to SIMCOP.

Figure 8-278 shows the temporal channel sequence.

Figure 8-277. YUV4:2:0-NV12 Read/Write Chain

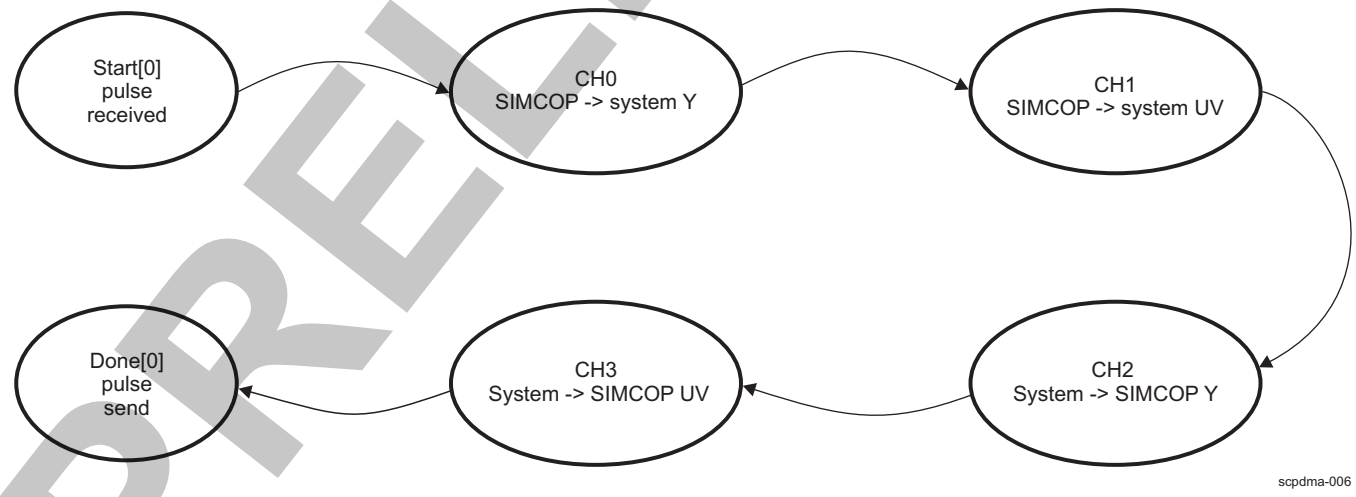

Figure 8-278. Temporal Channel Sequence

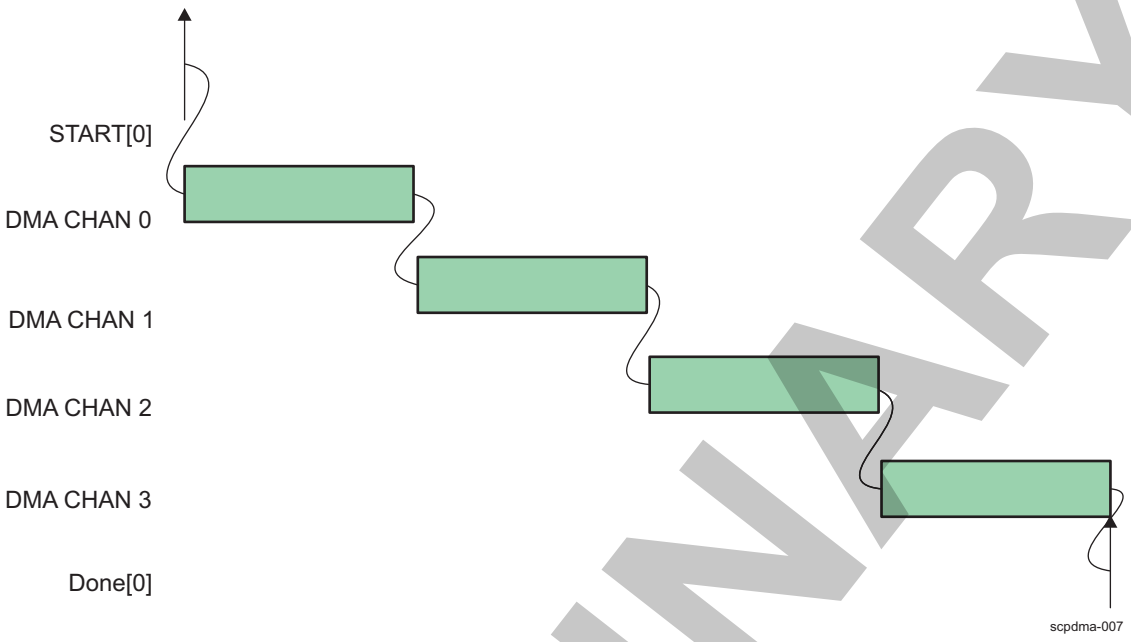

The following configuration is used for each channel:

- Channel i = 0, input Y buffer, first in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x11 (= CHAN 1)
  - SIMCOP_DMA_CHAN_CTRL_i[19:17] HWSTART = 0x4 (= CHAN 0)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 1 (= SIMCOP buffers -> system memory)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 1, input UV buffer, second in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x12 (= CHAN 2)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 1 (= SIMCOP buffers -> system memory)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 2, output Y buffer, third in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = 0x13 (= CHAN 3)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 0 (= system memory -> SIMCOP buffers)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1
- Channel i = 3, output UV buffer, last in sequence:
  - SIMCOP_DMA_CHAN_CTRL_i[16:12] LINKED = CHAN 1
  - SIMCOP_DMA_CHAN_CTRL_i[22:20] HWSTOP = 0x4 (= CHAN 0)
  - SIMCOP_DMA_CHAN_CTRL_i[5] DIR = 0 (= system memory -> SIMCOP buffers)
  - SIMCOP_DMA_CHAN_CTRL_i[0] ENABLE = 1

Software can read the status of a logical channel at any time. However, logical channel configuration registers can be changed only when the channel is in the IDLE state.

Software can disable a logical channel by writing the SIMCOP_DMA_CHAN_CTRL_i[1] DISABLE bit. A channel is effectively disabled when SIMCOP_DMA_CHAN_CTRL_i[4:3] STATUS = IDLE. In case of linked channels, software must disable all channels in the chain and wait until all of them are back in the IDLE state before channels can be reprogrammed.

8.4.3.4.3 Software Synchronization

Software performs the following sequence:

1. Configures the channel
2. Enables the channel
3. Triggers the channel by writing the SIMCOP_DMA_CHAN_CTRL_i[2] SWTRIGGER bit
4. Waits for BLOCK_DONE_IRQ

Step 2 and Step 4 are repeated until all 2D blocks have been transferred.

BW_LIMITER																RESERVED								TAG_CNT				POSTED_WRITES	RESERVED	MAX_BURST_SIZE	

Bits	Field Name	Description	Type	Reset
31:16	BW_LIMITER	SIMCOP DMA guarantees that there are at least BW_LIMITER functional clock cycles between two OCP requests. No IDLE cycles are inserted during an OCP transaction. This parameter could be used to reduce traffic generated by the SIMCOP DMA for non timing critical applications. Doing so leaves more BW for other system initiators. Default value corresponds to maximum performance.	RW	0x0000
15:8	RESERVED		R	0x00
7:4	TAG_CNT	Limits the outstanding transactions count. Only tags 0 - TAG_CNT will be used by SIMCOP DMA The maximum allowed value is $2^{(SIMCOCP\_DMA\_GNC.CONTEXT+2)-1}$	RW	0x3
3	POSTED_WRITES	Select write type. Setting depend on the used interconnect 0x0: Only non posted writes are generated 0x1: Only posted writes are generated	RW	0
2	RESERVED		R	0
1:0	MAX_BURST_SIZE	Defines the maximum burst length for INCR bursts. In case of 2D bursts, length x height is less or equal to this value. 0x0: Single requests only 0x1: less or equal to 2 0x2: less or equal to 4 0x3: less or equal to 8	RW	0x0

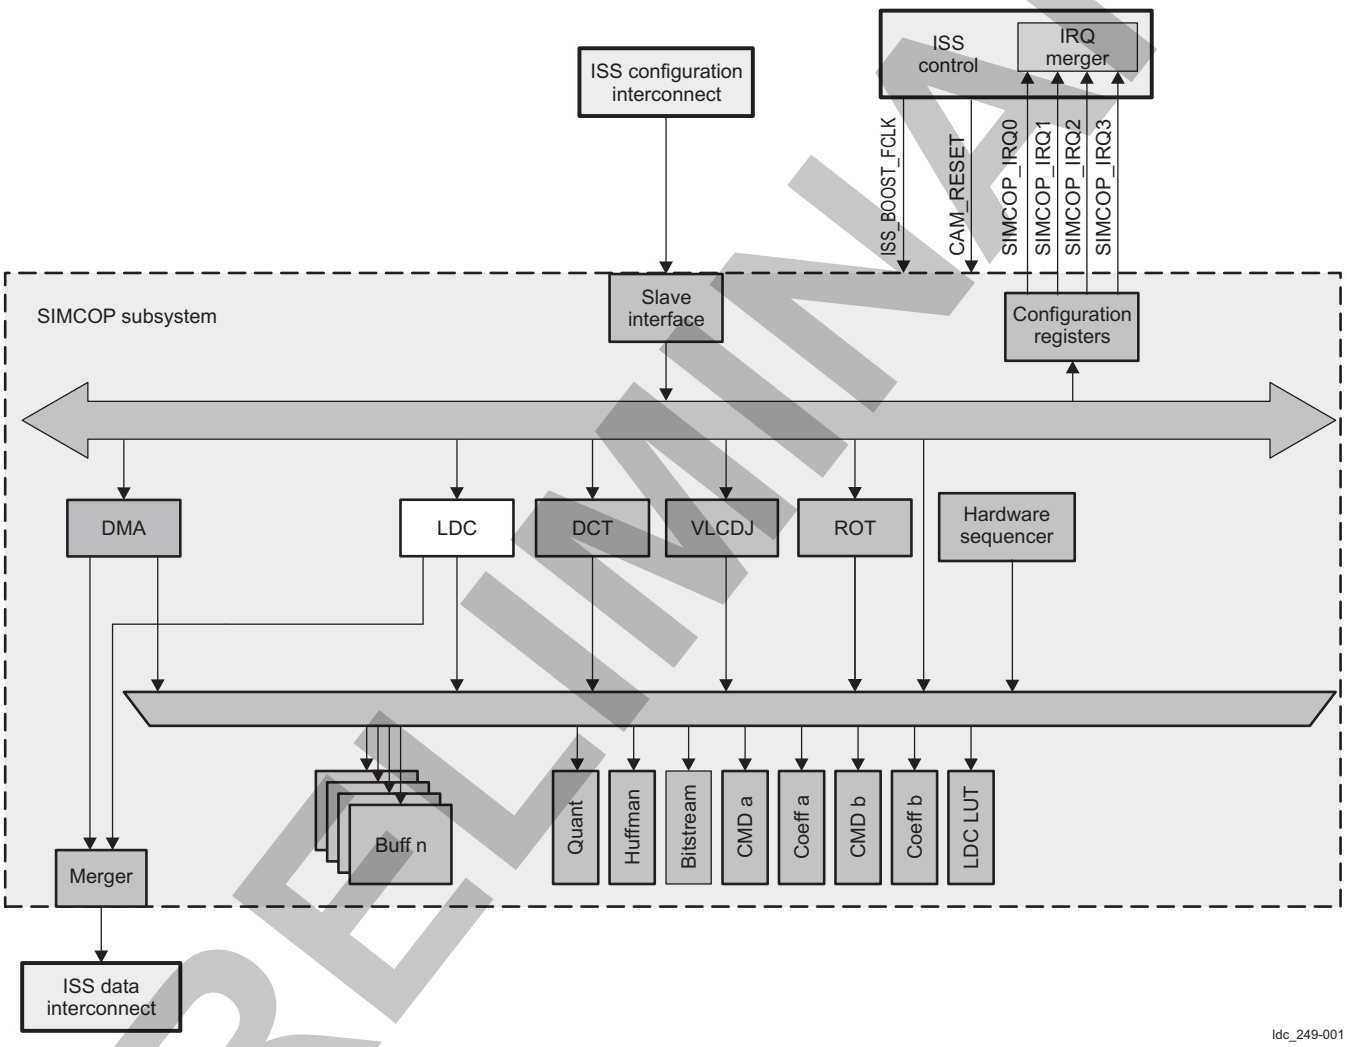
8.4.4 ISS SIMCOP LDC Module

This chapter describes the lens distortion correction (LDC) module in the still image coprocessor (SIMCOP) subsystem.

8.4.4.1 ISS SIMCOP LDC Overview

The lens distortion correction (LDC) module deals with lens geometric distortion issues, chromatic aberration, and affine transformation for camera images. Figure 8-279 is an overview of the LDC in the SIMCOP subsystem.

Figure 8-279. LDC in the SIMCOP Subsystem



For still image or video applications the LDC supports:

- Lens distortion correction:
  - YCbCr4:2:2/YCbCr4:2:0 data format input/output for post-image-pipe correction
  - Correct barrel distortion and pin-cushion distortion
  - Radius-to-magnification-factor table to accommodate various distortion functions through programming
  - Configurable center point and horizontal/vertical adjustment
  - One 256-entry lookup table for Y, Cb, and Cr
  - 8 bits for YCbCr

  - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode for Y to offer faster processing
  - Up to 16,383 x 16,383 image dimension
  - Format restriction:
    - YCbCr4:2:2 format: Tile width must be a multiple of 16.
    - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Image warping, scaling, and rotation:
  - Affine transformation for image warping, scaling, and rotation
  - 8 bits for YCbCr
  - Bicubic interpolation for Y and bilinear interpolation for Cb/Cr
  - Bilinear interpolation mode for Y to offer double throughput
  - Format restriction:
    - YCbCr4:2:2 format: Tile width must be a multiple of 16.
    - YCbCr4:2:0 format: Tile width must be a multiple of 32.
- Chromatic aberration correction:
  - Supports Bayer data in unpacked 12-bit per pixel, 8-bit per pixel A-Law, 8-bit per pixel unpacked, and 12-bit per pixel packed formats
  - Radius-to-magnification-factor table to accommodate various distortion functions through programming
  - Configurable center point and horizontal/vertical adjustment
  - Red and blue distortion only. Green pixels are copied to output.
  - Independent 128-entry lookup tables for red and blue
  - Bilinear interpolation
  - Up to 16,383 x 16,383 image dimension
  - Format restriction:
    - Unpacked 12-bit format: Tile width must be a multiple of 16.
    - A-Law 8-bit format: Tile width must be a multiple of 32.
    - Unpacked 8-bit format: Tile width must be a multiple of 32.
    - Packed 12-bit format: Tile width must be a multiple of 64.

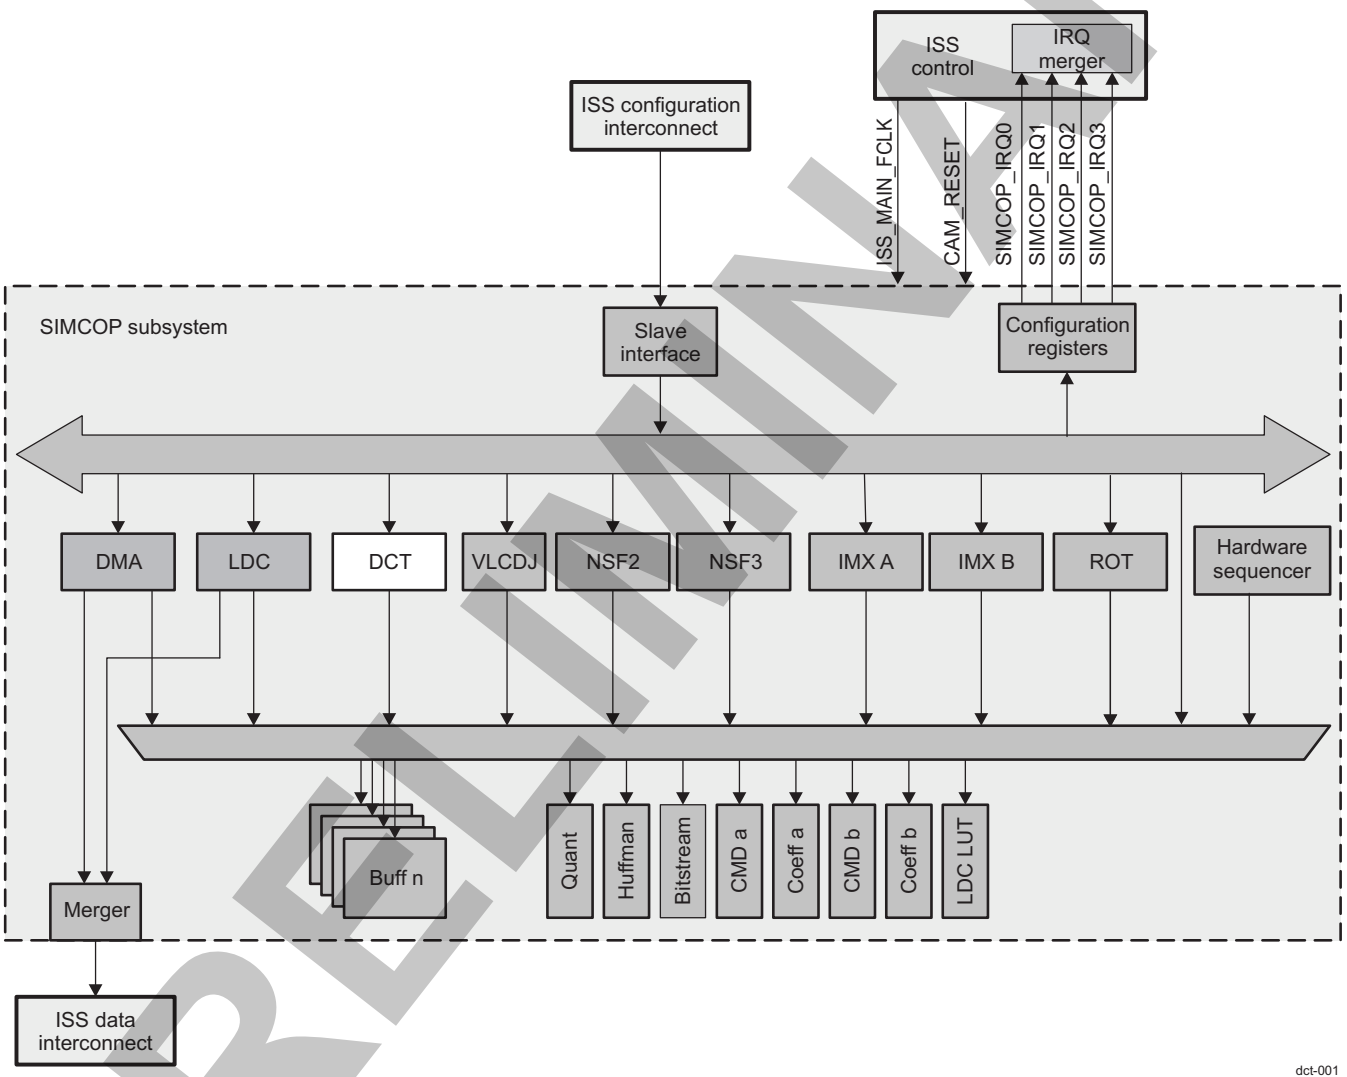
8.4.5 ISS SIMCOP Discrete Cosine Transform (DCT) Module

This section describes the discrete cosine transform (DCT) module in the still-image coprocessor (SIMCOP) subsystem.

8.4.5.1 ISS SIMCOP DCT Overview

The discrete cosine transform (DCT) module performs DCT and inverse DCT (IDCT) operations required for still-image coder/decoder (codec) applications. Figure 8-280 is an overview of the DCT in the still-image coprocessor (SIMCOP) subsystem.

Figure 8-280. DCT in the SIMCOP Subsystem



For still-image or video applications, the DCT supports:

- 8-bit data in the spatial domain (input to DCT or output of IDCT) with –128 offset on color components
- 16-bit data in the frequency domain
- Exact input/output (I/O) range:
  - DCT expected input range [0, 255], subtracting 128 offset before transform, output saturated to [–1024, 1023]
  - IDCT expected input range [–1280, 1079], adding 128 to inverse transform outcome and saturating to [0, 255]
  - IDCT input range is from DCT output range plus [–256, 256] worst-case quantization error

- Configurable to process up to 32 microcontroller units (MCUs) at a time (21 MCUs for YUV4:2:0, and 32 MCUs for YUV4:2:2, because of memory size limitations
- The following formats are supported by the DCT:
  - 16 x 16-pixel block MCU for YUV4:2:0 format, spatial data storage follows NV12
  - 16 x 8-pixel block MCU for YUV4:2:2 format, spatial data storage follows UYVY
  - Sequential 8 x 8 block mode, other than YUV4:2:0 and YUV4:2:2, a color-neutral format to allow flexibility in color component configuration in MCU, processes up to 64 blocks per task
- JPEG baseline sequential is supported by sequential 8 x 8 block mode. Some post-processing to reorder data and color space conversion may be required.
- All frequency domain data are stored sequentially for each 8 x 8 block, 16 bits per data point.

8.4.5.2 ISS SIMCOP DCT Integration

The DCT is part of the SIMCOP subsystem in the imaging subsystem (ISS). Figure 8-281 shows the integration of the DCT in the SIMCOP subsystem.

Figure 8-281. DCT Engine Integration

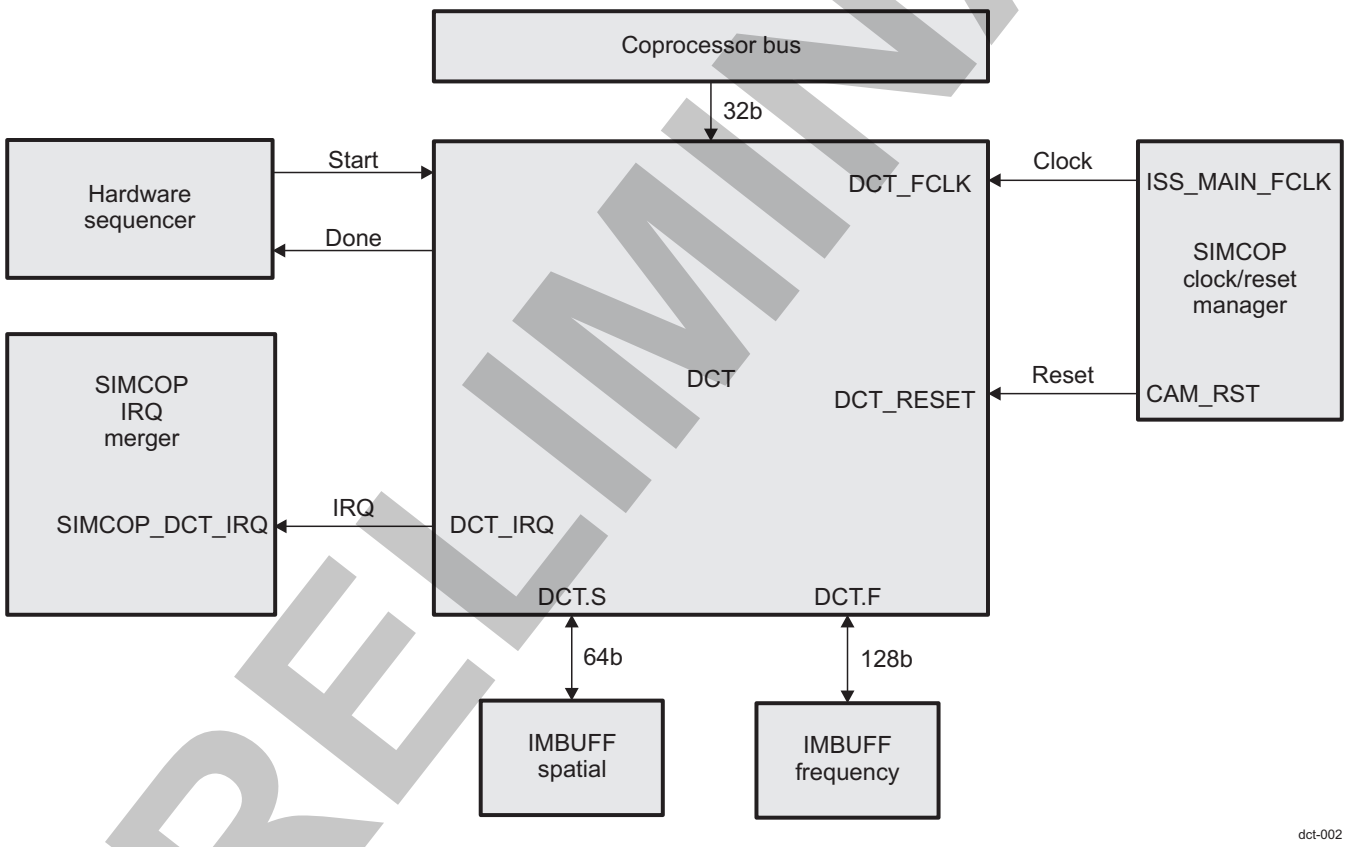


Table 8-1454 through Table 8-1456 list the integration attributes, clocks and resets, and hardware requests, respectively, for the DCT.

Table 8-1454. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect

For more information about interrupt requests, see Section 8.4.1.2.3, *Interrupt Merger*.

8.4.5.3 ISS SIMCOP DCT Functional Description

8.4.5.3.1 ISS SIMCOP DCT Block Diagram

The DCT implements 8 × 8 2-dimensional (2D) DCT and IDCT specified in JPEG image coding standards:

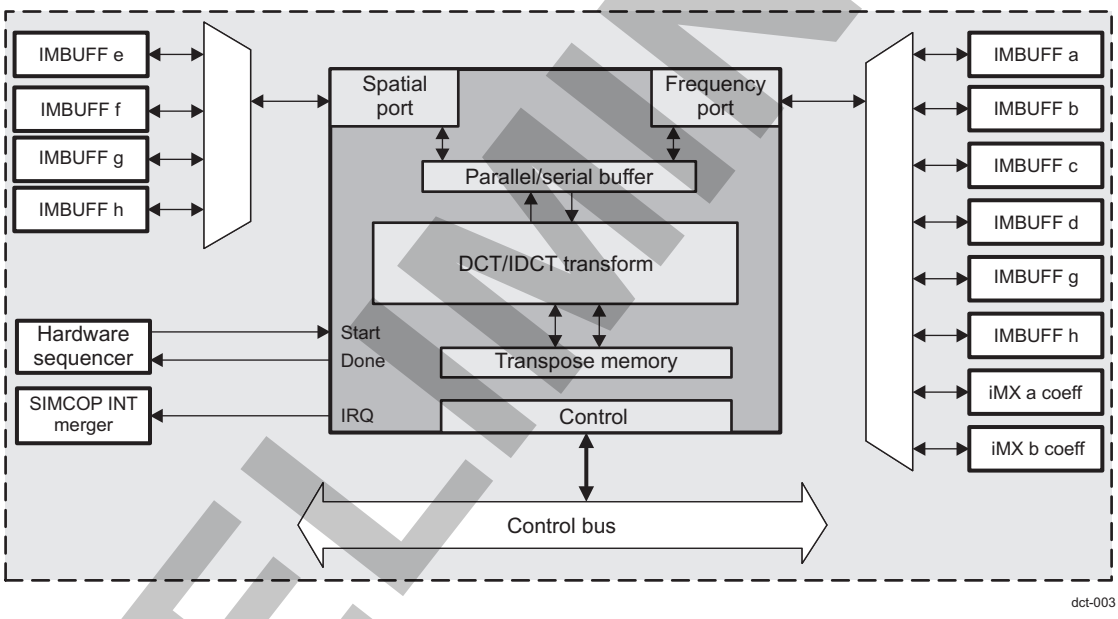
- In 4:2:0 mode, spatial domain data is organized in NV12 format. The frequency domain is organized as six blocks of 8 × 8.
- In 4:2:2 mode, spatial domain data is organized in UYVY format. The frequency domain is organized as four blocks of 8 × 8.
- In sequential 8 × 8 block mode, spatial and frequency domain data are organized as N blocks of 8 × 8 blocks.

NOTE:

- The spatial domain is the DCT input and IDCT output.
- The frequency domain is the DCT output and IDCT input.

Figure 8-282 is a block diagram of the DCT.

Figure 8-282. DCT Block Diagram



8.4.5.3.2 ISS SIMCOP DCT Power Management

Table 8-1457 describes the power-management features available for the DCT.

Table 8-1457. Local Power Management features

Feature	Registers	Description
Clock autogating	DCT_CFG[5] AUTOGATING	Free-running or autogating modes are available.

8.4.5.3.3 ISS SIMCOP DCT Interrupt Requests

Table 8-1458 lists the event flags, and their mask, that can cause module interrupts.

Table 8-1458. Events

Event Flag	Event Mask	Map to	Description
N/A	DCT_CFG[3] INTEN	DCT_IRQ	End of processing

8.4.5.3.4 Control and Status

The DCT is controlled through the control registers accessed through the coprocessor bus by an external initiator. Before starting the DCT, the buffer memory must be configured for DCT access and initialized, and the control register must be set (for more information about DCT/IDCT processing, see Section 8.4.5.3.4.1, *DCT Configuration*).

The DCT_CFG[4] TRIG_SRC bit is used to select the DCT start source:

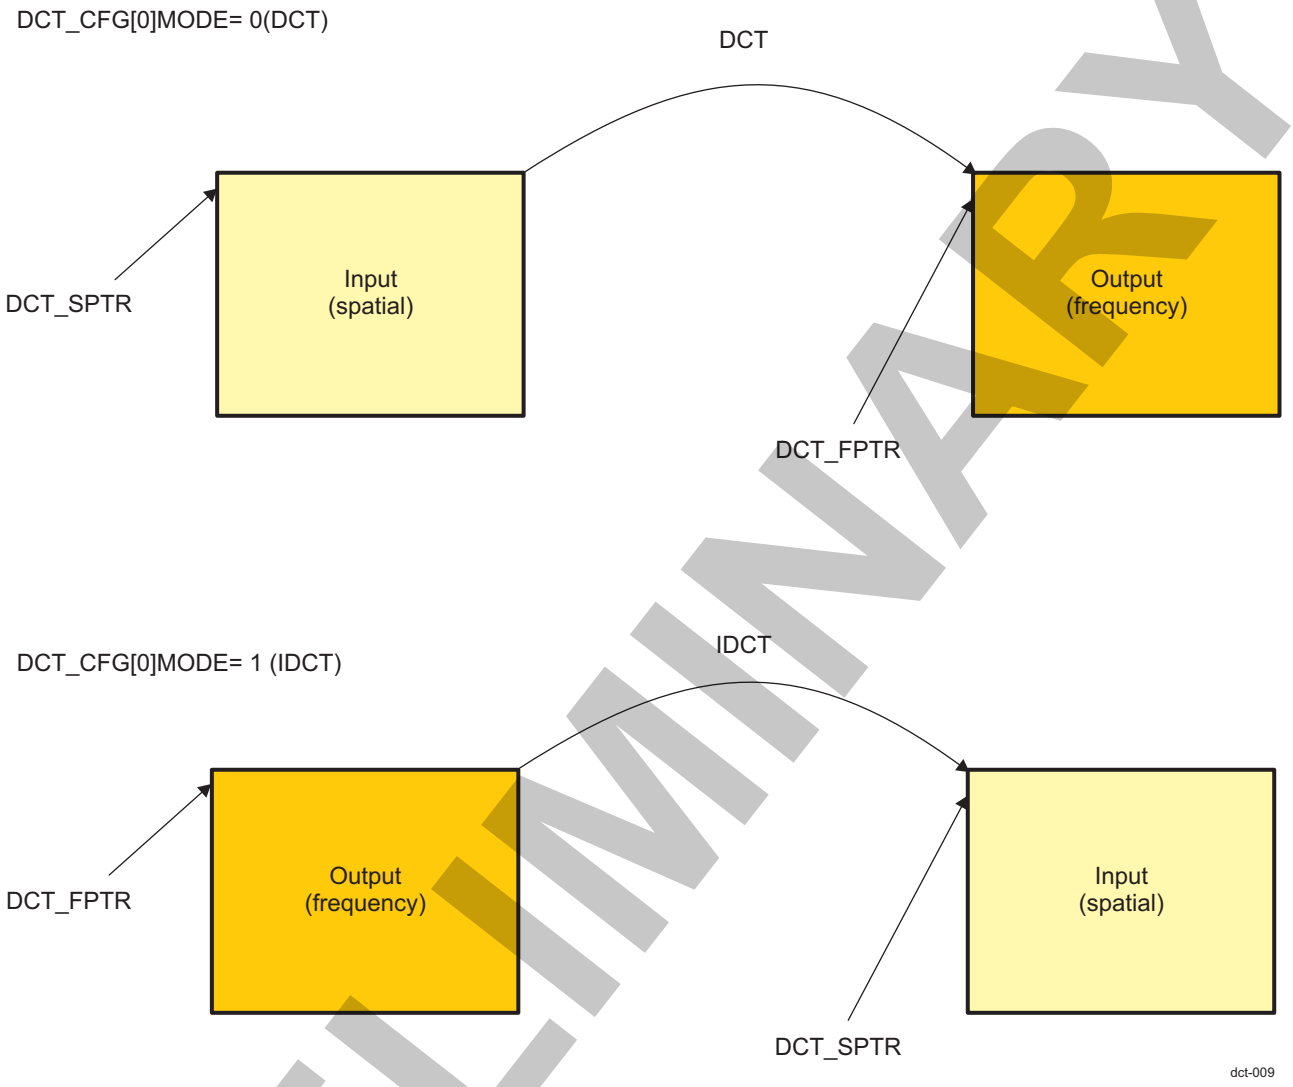
- If TRIG_SRC = 0, the DCT is started through the DCT_CTRL[0] EN bit.
- If TRIG_SRC = 1, the DCT is started by a hardware-start signal generated by the SIMCOP hardware sequencer.

When the DCT is configured for one trigger, the other trigger has no effect on the DCT.

An external initiator can read the state of the DCT (running or not running) by reading the DCT_CTRL[15] BUSY bit. When the BUSY bit goes back to 0, processing is complete (TRIG_SRC = 0 or 1).

Before starting the DCT, the DCT_SPTR and DCT_FPTR registers must be configured with spatial and frequency addresses. Figure 8-283 shows the use of spatial and frequency addresses.

Figure 8-283. DCT I/O Address Configuration



An interrupt can be generated when DCT operation completes (the configured number of MCUs for YUV4:2:0/4:2:2 mode, or the number of blocks for sequential block mode). To enable interrupt generation, set the DCT_CFG[3] INTEN bit to 1.

When the DCT_CFG[3] INTEN bit is set to 0, no interrupt generation is performed.

8.4.5.3.4.1 DCT Configuration

The following features can be configured in the DCT register:

- DCT module operation: The DCT_CFG[0] MODE bit configures the processing:
  - MODE = 0: DCT processing
  - MODE = 1: IDCT processing
- Number of MCUs to process: The number of MCUs to process –1 is configured in the DCT_CFG[13:8] NMCUS bit field:
  - YUV4:2:0 maximum MCUs = 21 (memory limitation, 126 blocks)
  - YUV4:2:2 maximum MCUs = 32 (128 blocks)
  - Sequential maximum MCUs = 64 (64 blocks)

8.4.5.3.5 Data Format

The DCT reads and writes data from and to image buffers. I/O format can be configured in the DCT_CFG[2:1] FMT bit field. The following formats can be configured:

- YUV4:2:0
- YUV4:2:2
- Sequential

8.4.5.3.5.1 YUV4:2:0 Format

In JPEG YUV4:2:0 format, each MCU is 16 × 16 pixels, and has 16 × 16 Y data points, 8 × 8 U data points, and 8 × 8 V data points. Each square array of 8 × 8 data points is called a block. Thus, an MCU with a YUV4:2:0 format has four Y blocks, one U block, and one V block.

This module follows the NV12 data storage format for YUV4:2:0 spatial data. For YUV4:2:0 format:

- line_offset_in_bytes = (DCT_CFG[13:8] NMCUS + 1) × 16
- starting_addr_uv = DCT_SPTR + (DCT_CFG[13:8] NMCUS + 1) × 256

Figure 8-284 shows the organization of the data for two MCUs in the spatial domain, when the DCT is configured to process two MCUs. To select the YUV4:2:0 format, write 0 x 0 in the DCT_CFG[2:1] FMT bit field. YUV4:2:0 processes six blocks (four Y, one U, and one V) during each MCU DCT processing.

Figure 8-284. YUV4:2:0 Format Data Order

Byte offset	0	1	2	3	...	15	16	17	...	31
0	Y(0,0)	Y(1,0)	Y(2,0)	Y(3,0)	...	Y(15,0)	Y(16,0)	Y(17,0)	...	Y(31,0)
32	Y(0,1)	Y(1,1)	Y(2,1)	Y(3,1)	...	Y(15,1)	Y(16,1)	Y(17,1)	...	Y(31,1)
64	Y(0,2)	Y(1,2)	Y(2,2)	Y(3,2)	...	Y(15,2)	Y(16,2)	Y(17,2)	...	Y(31,2)
	:									
480	Y(0,15)	Y(1,15)	Y(2,15)	Y(3,15)	...	Y(15,15)	Y(16,15)	Y(17,15)	...	Y(31,15)
512	U(0,0)	V(0,0)	U(2,0)	V(2,0)	...	V(14,0)	U(16,0)	V(16,0)	...	V(30,0)
544	U(0,2)	V(0,2)	U(2,2)	V(2,2)	...	V(14,2)	U(16,2)	V(16,2)	...	V(30,2)
	:									
736	U(0,14)	V(0,14)	U(2,14)	V(2,14)	...	V(14,14)	U(16,14)	V(16,14)	...	V(30,14)

dct-005

Each YUV4:2:0 has four Y blocks, one U block, and one V block. For the first MCU in Figure 8-284, the blocks are:

- Y_Block 0:
  - Y(0, 0), Y(1, 0), ..., Y(7, 0)
  - Y(0, 1), Y(1, 1), ..., Y(7, 1)
  - ....
  - Y(0, 7), Y(1, 7), ..., Y(7, 7)
- Y_Block 1:
  - Y(8, 0), Y(9, 0), ..., Y(15, 0)
  - Y(8, 1), Y(9, 1), ..., Y(15, 1)
  - ....
  - Y(8, 7), Y(9, 7), ..., Y(15, 7)
- Y_Block 2:
  - Y(0, 8), Y(1, 8), ..., Y(7, 8)
  - Y(0, 9), Y(1, 9), ..., Y(7, 9)
  - ....
  - Y(0, 15), Y(1, 15), ..., Y(7, 15)
- Y_Block 3:
  - Y(8, 8), Y(9, 8), ..., Y(15, 8)

  - Y(8, 9), Y(9, 9), ..., Y(15, 9)
  - ....
  - Y(8, 15), Y(9, 15), ..., Y(15, 15)
- U_Block:
  - U(0, 0), U(2, 0), ..., U(14, 0)
  - U(0, 2), U(2, 2), ..., U(14, 2)
  - ....
  - U(0, 14), U(2, 14), ..., U(14, 14)
- V_Block:
  - V(0, 0), V(2, 0), ..., V(14, 0)
  - V(0, 2), V(2, 2), ..., V(14, 2)
  - ....
  - V(0, 14), V(2, 14), ..., V(14, 14)

8.4.5.3.5.2 YUV4:2:2 Format

In JPEG YUV4:2:2 format, each MCU is 16 x 8 pixels and has 16 x 8 Y data points, 8 x 8 U data points, and 8 x 8 V data points. Thus, an MCU with a 4:2:2 format has two Y blocks, one U block, and one V block.

This module follows the UYVY data storage format for YUV4:2:2 spatial data. For YUV4:2:2 format:

line_offset_in_bytes = (DCT_CFG[13:8] NMCUS + 1) × 16

starting_addr_uv=DCT_SPTR + (DCT_CFG[13:8] NMCUS+1) * 256

Figure 8-285 shows the organization of the data for two MCUs in the spatial domain, when the DCT is configured to process two MCUs. To select the YUV4:2:2 format, write 0 x 1 in the DCT_CFG[2:1] FMT bit field. YUV4:2:2 processes four blocks (two Y, one U, and one V) during each MCU DCT processing.

Figure 8-285. YUV4:2:2 Format Data Order

Byte Offset																
	0	1	2	3	4	5	6	7	...	31	32	33	34	35	...	63
0	U(0,0)	Y(0,0)	V(0,0)	Y(1,0)	U(2,0)	Y(2,0)	V(2,0)	Y(3,0)	...	Y(15,0)	U(16,0)	Y(16,0)	V(16,0)	Y(17,0)	...	Y(31,0)
64	U(0,1)	Y(0,1)	V(0,1)	Y(1,1)	U(2,1)	Y(2,1)	V(2,1)	Y(3,1)	...	Y(15,1)	U(16,1)	Y(16,1)	V(16,1)	Y(17,1)	...	Y(31,1)
128	U(0,2)	Y(0,2)	V(0,2)	Y(1,2)	U(2,2)	Y(2,2)	V(2,2)	Y(3,2)	...	Y(15,2)	U(16,2)	Y(16,2)	V(16,2)	Y(17,2)	...	Y(31,2)
	:															
448	U(0,7)	Y(0,7)	V(0,7)	Y(1,7)	U(2,7)	Y(2,7)	V(2,7)	Y(3,7)	...	Y(15,7)	U(16,7)	Y(16,7)	V(16,7)	Y(17,7)	...	Y(31,7)

dct-011

Each YUV4:2:2 has two Y blocks, one U block, and one V block. The four blocks of the first MCU are:

- Y_Block 0:
  - Y(0, 0), Y(1, 0), ..., Y(7, 0)
  - Y(0, 1), Y(1, 1), ..., Y(7, 1)
  - ....
  - Y(0, 7), Y(1, 7), ..., Y(7, 7)
- Y_Block 1:
  - Y(8, 0), Y(9, 0), ..., Y(15, 0)
  - Y(8, 1), Y(9, 1), ..., Y(15, 1)
  - ....
  - Y(8, 7), Y(9, 7), ..., Y(15, 7)

8.4.5.3.5.3 Sequential Block Format

The sequential block format supports any color format other than YUV4:2:0 or YUV4:2:2. There is no notion of colors, and each 8 x 8 block is ordered sequentially. The DCT can be configured to process N blocks (versus N MCUs for YUV4:2:0 and YUV4:2:2, N is up to 64). In this format:

- Block i =
  - X(8*i, 0), X(8*i+1, 0), ..., X(8*i+7, 0)
  - X(8*i, 1), X(8*i+1, 1), ..., X(8*i+7, 1)
  - ....
  - X(8*i, 7), X(8*i+1, 7), ..., X(8*i+7, 7)

To select sequential block format, write 0 x 2 in the DCT_CFG[2:1] FMT bit field.

8.4.5.4 ISS SIMCOP DCT Basic Programming Model

8.4.5.4.1 Initialization of Surrounding Modules

To initialize the DCT, the surrounding modules must be initialized. Table 8-1459 lists these modules.

Table 8-1459. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable the SIMCOP clock.	
Buffers	Configure DCT access to the image buffer.	
SIMCOP CTRL		Configure SIMCOP CTRL to handle DCT interrupts.

8.4.5.4.2 Using the DCT for DCT Processing

To configure the DCT for DCT processing, software must follow the procedure listed in Table 8-1460.

Table 8-1460. DCT Processing Procedure

Step	Register/Bit Field	Value
Prepare data in buffer memory.	SIMCOP buffers	
Switch buffer access to the DCT.	SIMCOP buffers	
Configure the start of the DCT input address (address must be in the memory buffer).	DCT_SPTR[12:5] ADDR	Start address (spatial domain)
Configure the start of the DCT output address (address must be in the memory buffer).	DCT_FPTR[13:4] ADDR	Start address (frequency domain)
Set the DCT_CFG register.	DCT_CFG[0] MODE	0 (DCT mode)
	DCT_CFG[2:1] FMT	Depends on data format
	DCT_CFG[3] INTEN	0: No interrupt 1: Interrupt at end of processing
	DCT_CFG[4] TRIG_SRC	1: Start controlled by hardware signal 0: Start controlled by a register
	DCT_CFG[13:8] NMCUS	Number of MCUs to process
IF: DCT_CFG[4] TRIG_SRC = 0		
Start DCT through the register.	DCT_CTRL[0] EN	1
ELSE		
Start the DCT using the hardware sequencer.	SIMCOP hardware sequencer	
ENDIF		

The DCT is now processing the blocks. To detect the end of DCT processing:

- If DCT_CFG[3] INTEN = 1, wait for the interrupt signal.
- If DCT_CFG[3] INTEN = 0, the processor must poll the DCT_CTRL[15] BUSY bit. When the BUSY bit is 0, processing is complete.

When DCT processing completes, the frequency output result is stored in the memory buffer at the address given by the DCT_FPTR[13:4] ADDR bit field.

8.4.5.4.3 Using the DCT for IDCT Processing

To configure the DCT for IDCT processing, software must follow the procedure listed in Table 8-1461.

Table 8-1461. IDCT Processing Procedure

Step	Register/Bit Field	Value
Prepare data in buffer memory.	SIMCOP buffers	
Switch buffer access to the DCT.	SIMCOP buffers	

Table 8-1461. IDCT Processing Procedure (continued)

Step	Register/Bit Field	Value
Configure the start of the DCT output address (address must be in the memory buffer).	DCT_SPTR[12:5] ADDR	Start address (spatial domain)
Configure the start of the DCT input address (address must be in the memory buffer).	DCT_FPTR[13:4] ADDR	Start address (frequency domain)
Set the DCT_CFG register.	DCT_CFG[0] MODE	1 (IDCT mode)
	DCT_CFG[2:1] FMT	Depends on data format
	DCT_CFG[3] INTEN	0: No interrupt 1: Interrupt at end of processing
	DCT_CFG[4] TRIG_SRC	1: Start controlled by a hardware signal 0: Start controlled by a register
	DCT_CFG[13:8] NMCUS	Number of MCUs to process
IF: DCT_CFG[4] TRIG_SRC = 0		
Start the DCT through a register.	DCT_CTRL[0] EN	1
ELSE		
Start the DCT using hardware sequencer.	SIMCOP hardware sequencer	
ENDIF		

The DCT is now processing the blocks. To detect the end of DCT processing:

- If DCT_CFG[3] INTEN = 1, wait for the interrupt signal.
- If DCT_CFG[3] INTEN = 0, the processor must poll the DCT_CTRL[15] BUSY bit. When the BUSY bit is 0, processing is complete.

When IDCT processing completes, the spatial output result is stored in the memory buffer at the address given by the DCT_SPTR[12:5] ADDR bit field.

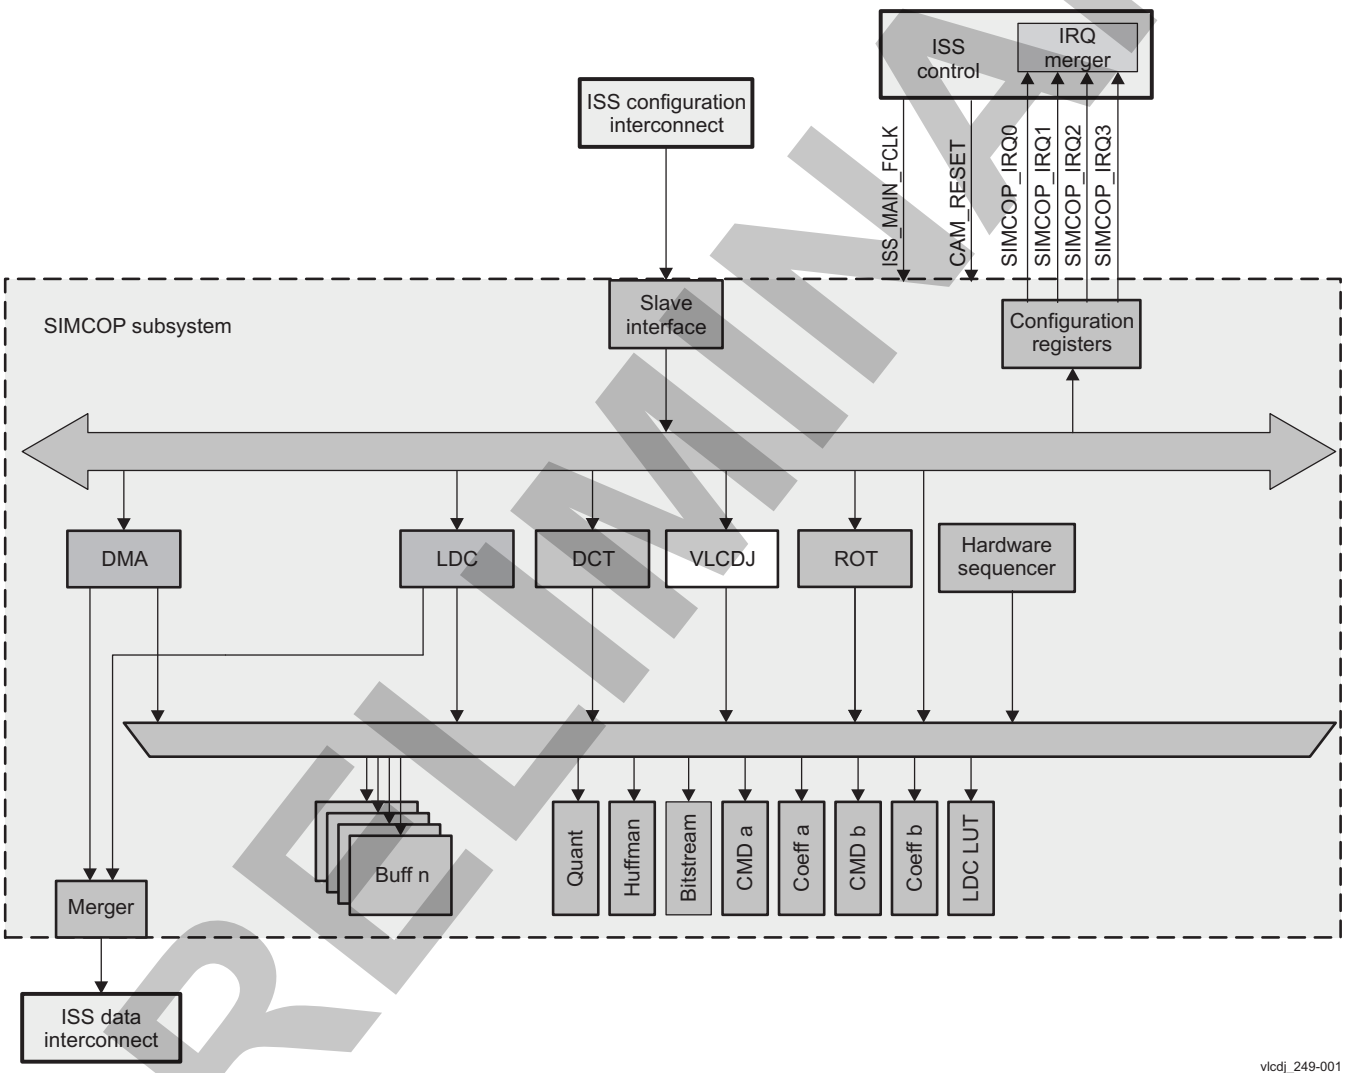
8.4.6 ISS SIMCOP Variable Length Coder/Decoder for JPEG (VLCDJ) Module

This section describes the variable-length coder/decoder for JPEG (VLCDJ) module in the still-image coprocessor (SIMCOP) subsystem.

8.4.6.1 ISS SIMCOP VLCDJ Overview

The variable-length coder/decoder for JPEG (VLCDJ) module handles quantization (Q) and variable-length coding (VLC) in JPEG encoding, and variable-length decoding (VLD) and inverse quantization (IQ) in JPEG decoding. These operations are required for JPEG image compression and decompression. Figure 8-286 is an overview of the VLCDJ in the still-image coprocessor (SIMCOP) subsystem.

Figure 8-286. VLCDJ in the SIMCOP Subsystem



The VLCDJ supports the following operations:

- Q and VLC for JPEG encoding
- VLD and IQ for JPEG decoding
- Data formats:
  - YUV4:2:0 format in 16 × 16-pixel microcontroller unit (MCU)
  - YUV4:2:2 format in 16 × 8-pixel MCU
  - Sequential block mode to support arbitrary color component configuration within JPEG baseline sequential (software intervention required to context-switch among color components)

- Configurable for number of MCUs per initiation (up to 21 MCUs for YUV4:2:0, 32 MCUs for YUV4:2:2, 64 8 × 8 blocks for sequential block mode)
- Discrete cosine transform (DCT) coefficients are stored sequentially for each 8 × 8 block, 16 bits per data point
- Stall processing for interface with bitstream data overrun/underrun protection
- Insertion of restart markers during encoding (YUV4:2:0, YUV4:2:2, sequential block modes)
- Record of restart marker locations during encoding (YUV4:2:0, YUV4:2:2 only)
- Processing of restart markers on the MCU boundary during decoding, reset of direct coefficient (DC) predictors as required by the JPEG standard (YUV4:2:0, YUV4:2:2, sequential block modes)

8.4.6.2 ISS SIMCOP VLCDJ Integration

The VLCDJ is part of the SIMCOP subsystem in the imaging subsystem (ISS). Figure 8-287 shows the integration of the VLCDJ in the SIMCOP subsystem.

Figure 8-287. VLCDJ Engine Integration

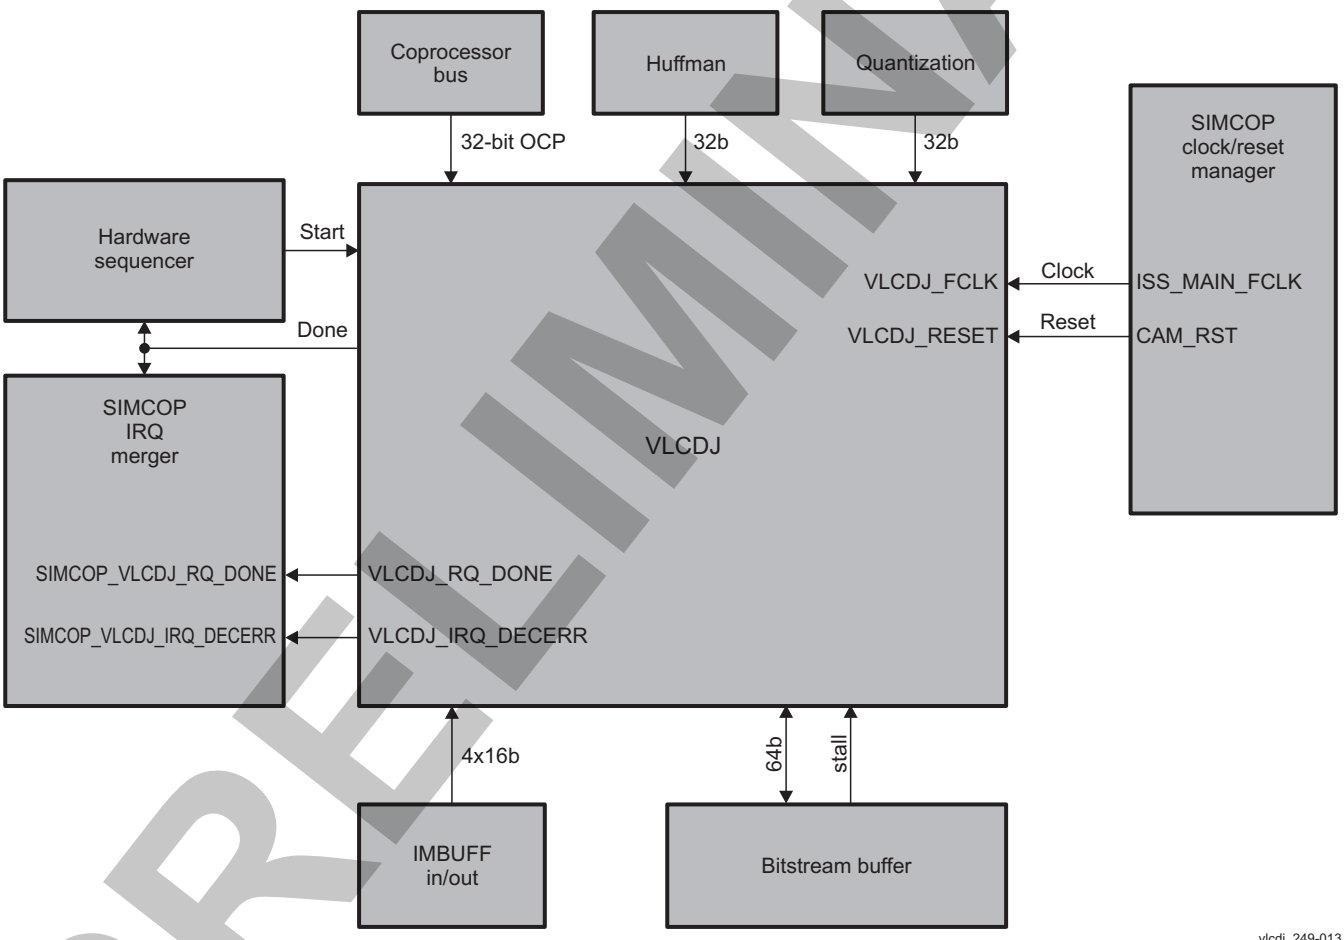


Table 8-1474 through Table 8-1476 list the integration attributes, clocks and resets, and hardware requests, respectively, for the VLCDJ.

Table 8-1474. Integration Attributes

Module Instance	Attributes

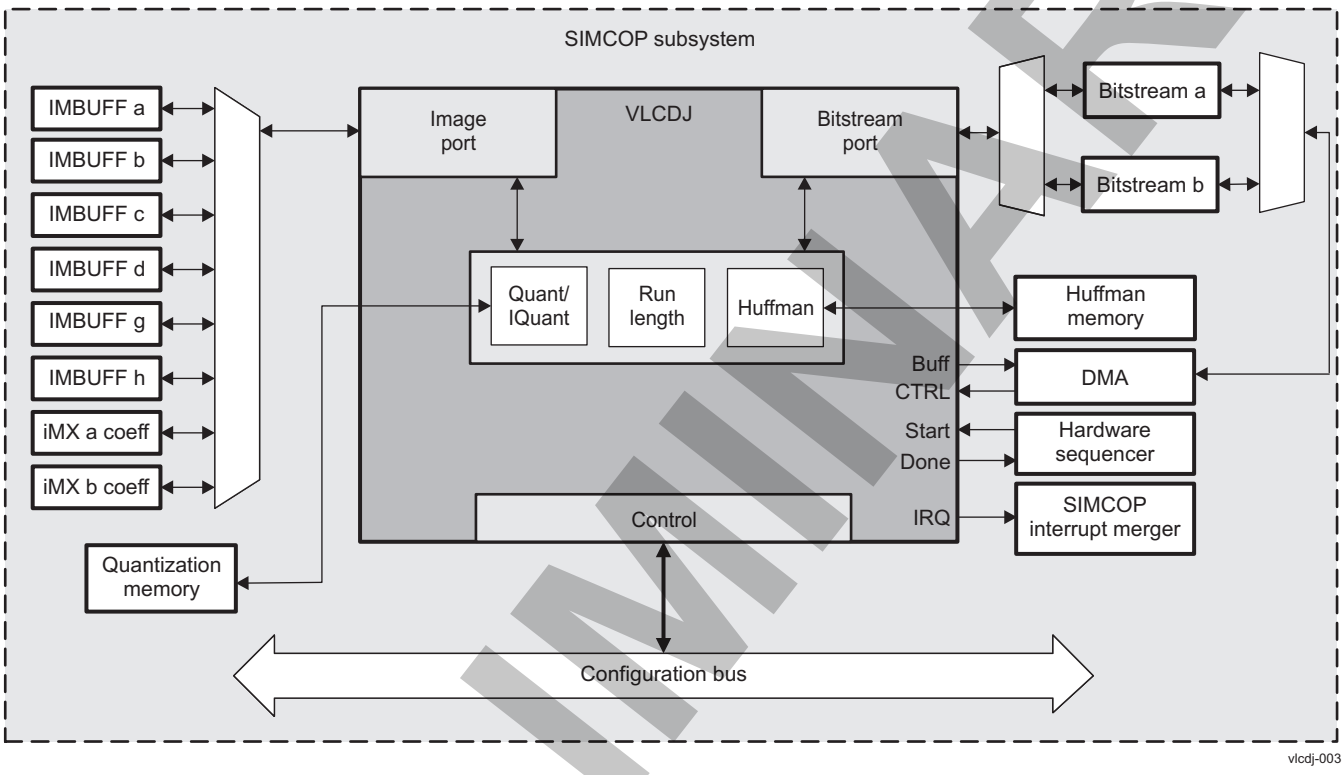
For more information about interrupt requests, see Section 8.4.1.2.3, *Interrupt Merger*.

8.4.6.3 ISS SIMCOP VLCDJ Functional Description

8.4.6.3.1 ISS SIMCOP VLCDJ Block Diagram

The VLCDJ implements quantization, run-length encode, and Huffman encode stages of JPEG compression, and Huffman decode, run-length expansion, and dequantization stages of JPEG decompression. Figure 8-288 is a block diagram of the VLCDJ with connected memories and modules.

Figure 8-288. VLCDJ Block Diagram



8.4.6.3.2 ISS SIMCOP VLCDJ Power Management

The VLCDJ uses clock autogating to conserve power. When any substantial subblocks are not in use, the corresponding clock trees are gated off. Table 8-1477 describes the power-management feature available for the VLCDJ.

Table 8-1477. Local Power-Management Feature

Feature	Registers	Description
Clock autogating	VLCDJ_CTRL[3] AUTOGATING	Free-running or autogating modes are available.

8.4.6.3.3 ISS SIMCOP VLCDJ Interrupt Requests

Table 8-1478 lists the event flags and their masks that can cause module interrupts.

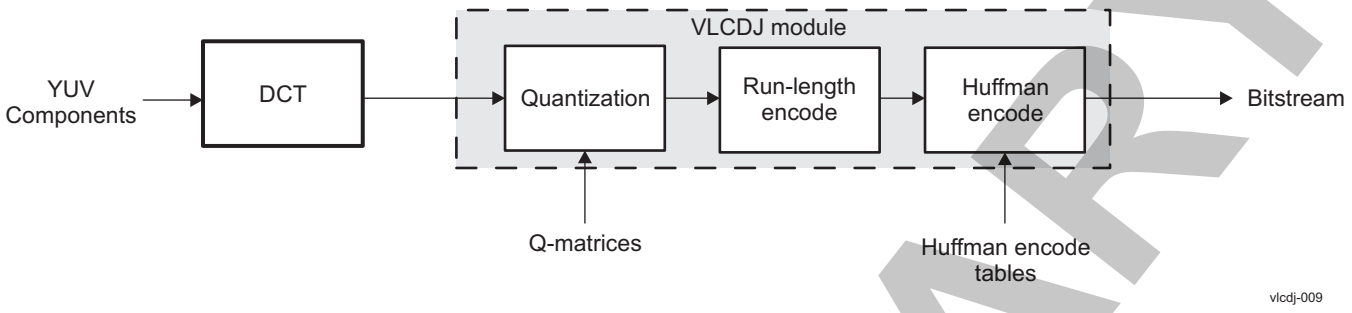
Table 8-1478. Events

Event Flag	Event Mask	Map to	Description
N/A	VLCDJ_CTRL[4] INTEN_DONE	VLCDJ_RQ_DONE	VLCDJ operation completed
N/A	VLCDJ_CTRL[5] INTEN_ERR	VLCDJ_IRQ_DECERR	Error occurred

8.4.6.3.4 ISS SIMCOP VLCDJ in JPEG Encoding Flow

Figure 8-289 shows the JPEG compression or encoding flow.

Figure 8-289. JPEG Encoding Flow



The DCT coefficients are quantized by dividing each data point with a quantizer. The quantizers form an 8 × 8 matrix for Luma Y, and another 8 × 8 matrix for U and V, and the matrices are fixed in each image. The quantizer matrices can vary between images, and are sometimes fine-tuned in a multiple-pass process to regulate the compressed JPEG file size.

For quantization, VLCDJ reads a reciprocal of the quantizer values (16 bits per entry carrying 2^{15}/quant) so that hardware performs multiplications rather than divisions. The result is rounded to the nearest integer.

After quantization, the DC terms (the first term in each 8 × 8 block of DCT coefficients) are differentially coded within each color. Thus, three predictors are used for the common formats.

Next, the coefficients are scanned in a zigzag order (the same order for all colors) to form DC term + zero-run and nonzero level pairs for the alternative coefficient (AC) terms. The run-level pairs are then coded with a Huffman table.

The DC level is first categorized into size groups, basically the number of bits that represents the absolute value of the level. This size is translated to a bit segment using the Huffman table. Then, additional bits are appended to represent the exact DC level.

For AC run-level pairs, the process is similar. Each AC level is first categorized into size groups, basically the number of bits that represents the absolute value of the level. Then the size and the run are combined and translated to a bit segment using the Huffman table. Then, additional bits are appended to represent the exact AC level.

The number of additional bits to encode after the Huffman-coded segment, for DC or AC level, equals the size value. For example, coefficient values –3, –2, and 3 are of size 2, because 2 bits are required to represent the absolute values 2 and 3. There are four coefficient values in the size –2 category, so 2 additional bits are required to uniquely identify each value.

Some special symbols go with the AC run/size pairs. The ZRL symbol represents a run of 15 zeros, and is used to code unusually long zero runs. The EOB symbol represents end of block, meaning that there are only 0 AC coefficients at the end.

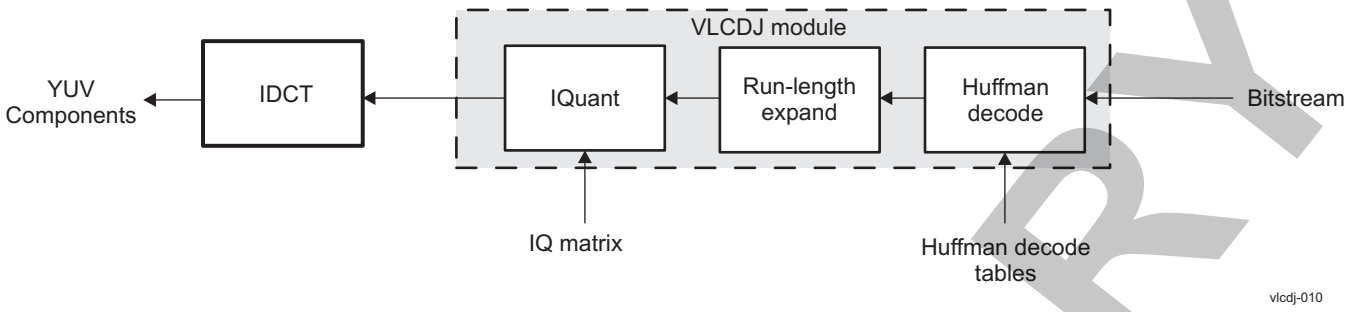
In the bitstream management level, after each byte of 0xFF, a byte of 0 is inserted to prevent the decoder from detecting special markers in the bitstream.

Because the VLCDJ handles multiple MCUs and allows restart marker insertion in MCU boundaries inside a task, the inserted flags are flagged to prevent the insertion of a 0 byte after 0xFF.

8.4.6.3.5 ISS SIMCOP VLCDJ in JPEG Decoding Flow

Decoding or decompression operates in the reverse order, as shown in Figure 8-290.

Figure 8-290. JPEG Decoding Flow



1. In decoding, in the MCU data section, when the VLCDJ recognizes the 0xFF byte in the bitstream, it detects whether the next byte is a 0 byte. If it is, the 0 byte is removed and decoding continues as if the 0 byte is not there (the 0xFF byte is kept). If the next byte is not a 0 byte, the VLCDJ flags this as a JPEG data error. This can be caused by an earlier bitstream error that causes the module to parse outside the MCU entropy data and into markers that are not supported by the module.
2. Because the VLCDJ decodes for multiple MCUs, restart markers can occur in MCU boundaries. Restart marker detection and processing work with the 0 byte removal logic to ensure that restart markers are detected and removed correctly. When the VLCDJ detects a restart marker, it resets the DC predictors in the IQ stage.
3. The VLCDJ looks up the Huffman table to convert a variable-length bit segment into a DC size or an AC run/size pair. The number of additional bits equal to the size is extracted and the DC/AC coefficient is reconstructed. Then, zero runs are expanded.
4. IQ is performed, which is simply multiplication of the coefficients with values in the quantizer matrices.

8.4.6.3.6 Memory Interfaces

The VLCDJ has four memory interfaces (all memories are inside the SIMCOP subsystem):

- Image buffer (input DCT coefficients for encoding and output DCT coefficients for decoding)
- Quantizer memory
- Huffman memory
- Bitstream memory (output for encoding and input for decoding)

8.4.6.3.6.1 Image Buffer

An image buffer stores DCT data in the context of the VLCDJ. This is an input in encode mode and an output in decode mode.

When multiple MCUs are configured, DCT coefficients for the MCUs are stored sequentially (MCU 0 is stored first, followed by MCU 1, and so on).

Blocks in an MCU are stored sequentially; that is, block 0 first, block 1 next, and so on. There are six blocks per MCU in YUV4:2:0 format, {Y0, Y1, Y2, Y3, U, V}, and four blocks per MCU in YUV4:2:2 format, {Y0, Y1, U, V}.

The 64 DCT coefficients for each block are stored in an 8 × 8 transposed format (the companion DCT module handles the transposed format). Each coefficient, up to [–2047, 2047] in range is stored on a 16-bit word. Table 8-1479 lists the data format in each 8 × 8 block of coefficients.

Table 8-1479. Image Buffer Block Format

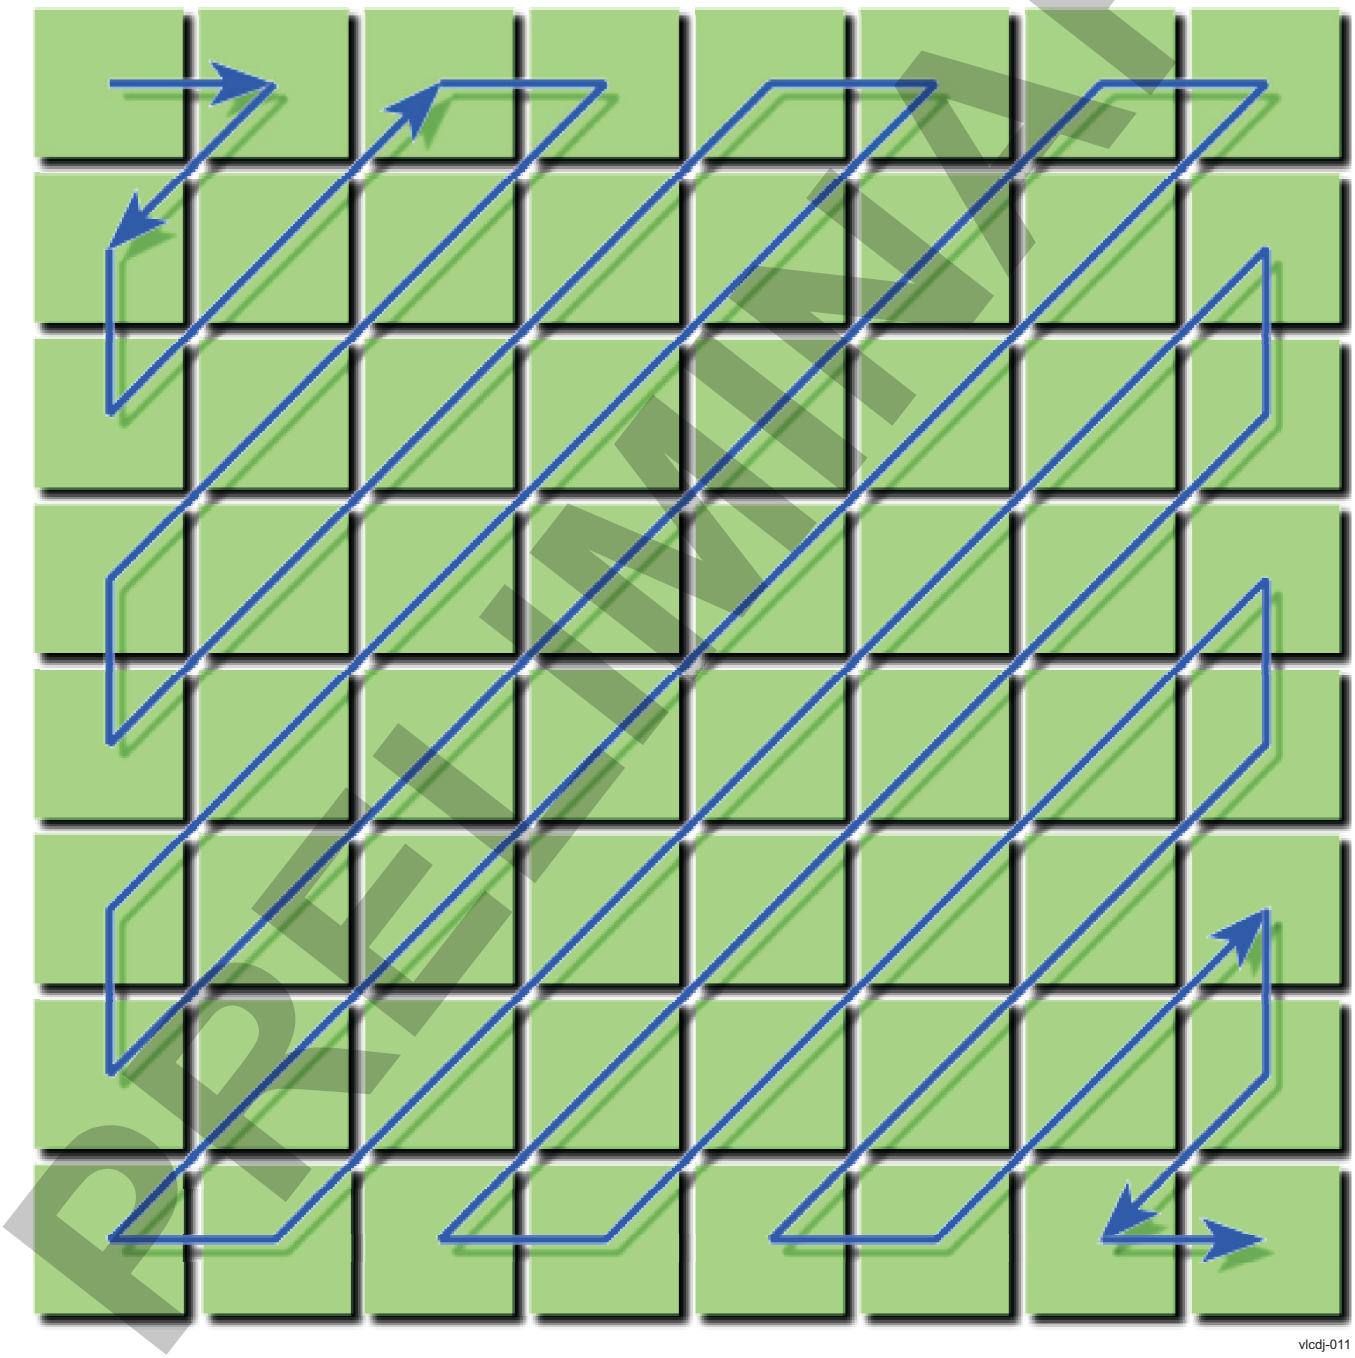
Byte Offset								
0	1	2	3	4	5	...	14	15
c(0, 0)		c(0, 1)		c(0, 2)		...	c(0, 7)	
c(1, 0)		c(1, 1)		c(1, 2)		...	c(1, 7)	
c(2, 0)		c(2, 1)		c(2, 2)		...	c(2, 7)	

Table 8-1479. Image Buffer Block Format (continued)

Byte Offset								
0	1	2	3	4	5	...	14	15
:								
c(7, 0)		c(7, 1)		c(7, 2)		...	c(7, 7)	

The DCT coefficients are processed in zigzag order, as required by JPEG and shown in Figure 8-291.

Figure 8-291. JPEG Zigzag Order



8.4.6.3.6.2 Quantizer Memory

The quantization memory stores the reciprocal of quantizers, 2^{15}/qmat[i][j] so that hardware performs multiplications rather than divisions. Each data point is stored in 16 bits.

The quantizer matrices have a fixed size, 64 16-bit elements each. The quantizer memory (QMEM) is sized to hold up to four matrices (for the recommended allocation for YUV4:2:0 and YUV4:2:2, see Table 8-1480).

Table 8-1480. Recommended QMEM Allocation for YUV4:2:0 and YUV4:2:2

Quadrant of QMEM	Address Offset (Bytes)	Contents
00	0x000	(Encode) Quantizer reciprocal for Y (2^{15}/qmat[i][j])
01	0x080	(Encode) Quantizer reciprocal for UV (2^{15}/qmat[i][j])
10	0x100	(Decode) Quantizer for Y (qmat[i][j])
11	0x180	(Decode) Quantizer for UV (qmat[i][j])

Each matrix is stored in zigzag order to make quantization and inverse quantization more efficient.

8.4.6.3.6.3 Huffman Memory

Huffman memories store Huffman encode tables and Huffman control/decode tables. For information about Huffman tables, see Section 8.4.6.3.7, *Huffman Table Organization*.

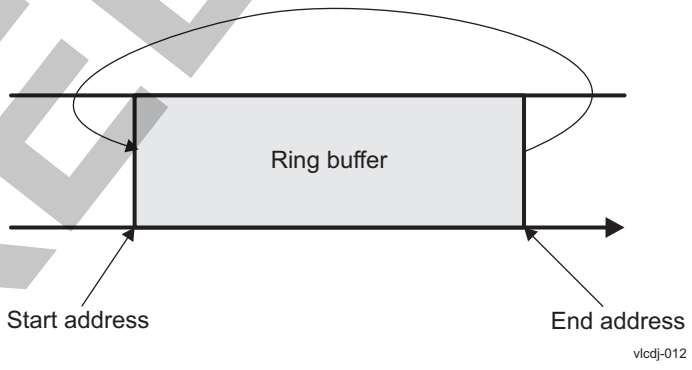
8.4.6.3.6.4 Bitstream Memory

Bitstream memory is for input/output (I/O) bitstream. Bitstream data is stored in little-endian format in the memory. Circular buffer start and end addresses are provided in registers to facilitate bitstream data management:

- VLCDJE_CBUF[11:10] START, start of ring buffer for encode mode (address must be 1 KiB aligned)
- VLCDJE_CBUF[27:26] END, end of ring buffer for encode mode (address must be 1 KiB aligned)
- VLCDJD_CBUF[11:10] START, start of ring buffer for decode mode (address must be 1 KiB aligned)
- VLCDJD_CBUF[27:26] END, end of ring buffer for decode mode (address must be 1 KiB aligned)

Figure 8-292 shows the start and end addresses of a ring buffer.

Figure 8-292. VLCDJ Ring Buffer



In encoding and decoding, a bit-level boundary defines bitstream data written (for encoding) or parsed (for decoding). To point to that boundary, bit and byte pointers are provided in the registers:

- VLCDJE_BSPTR[19:16] BITPTR (encoding)
- VLCDJE_BSPTR[11:0] BYTEPTR (encoding)
- VLCDJD_BSPTR[19:16] BITPTR (decoding)
- VLCDJD_BSPTR[11:0] BYTEPTR (decoding)

BYTEPTR (byte pointer) points to the byte where the boundary lies, and BITPTR (bit pointer) specifies the number of available vacant data bits (for encoding) or remaining data bits (for decoding). BITPTR is always within the range from 1 to 8, where 8 indicates that an entire byte is available for writing or reading.

For example, for encoding, if BYTEPTR = 0 and BITPTR = 8, after the hardware encodes a specified number of MCUs that together generate 30 bits, or 3 full bytes and 6 bits, BYTEPTR = 3 and BITPTR = 2. The JPEG standard requires that at the end of MCU data, any remaining bits of the last byte are padded with 1s. For example, if the last byte has 4 bits written 0101, the last byte of MCU data in the JPEG data is 0x5F.

8.4.6.3.7 Huffman Table Organization

8.4.6.3.7.1 Huffman Table for Encode Mode

Because the Huffman encode tables are compact, they are fixed relative to a common pointer:

- The Luma DC table starts at VLCDJE_VLCTBL[11:2] ADDR (12 entries × 4 = 48 bytes)
- The Luma AC table starts at VLCDJE_VLCTBL[11:2] ADDR + 48 bytes (11 × 16 x 4 = 704 bytes)
- The Chroma DC table starts at VLCDJE_VLCTBL[11:2] ADDR + 752 bytes (12 entries × 4 = 48 bytes)
- The Chroma AC table starts at VLCDJE_VLCTBL[11:2] ADDR + 800 bytes (11 × 16 × 4 = 704 bytes)

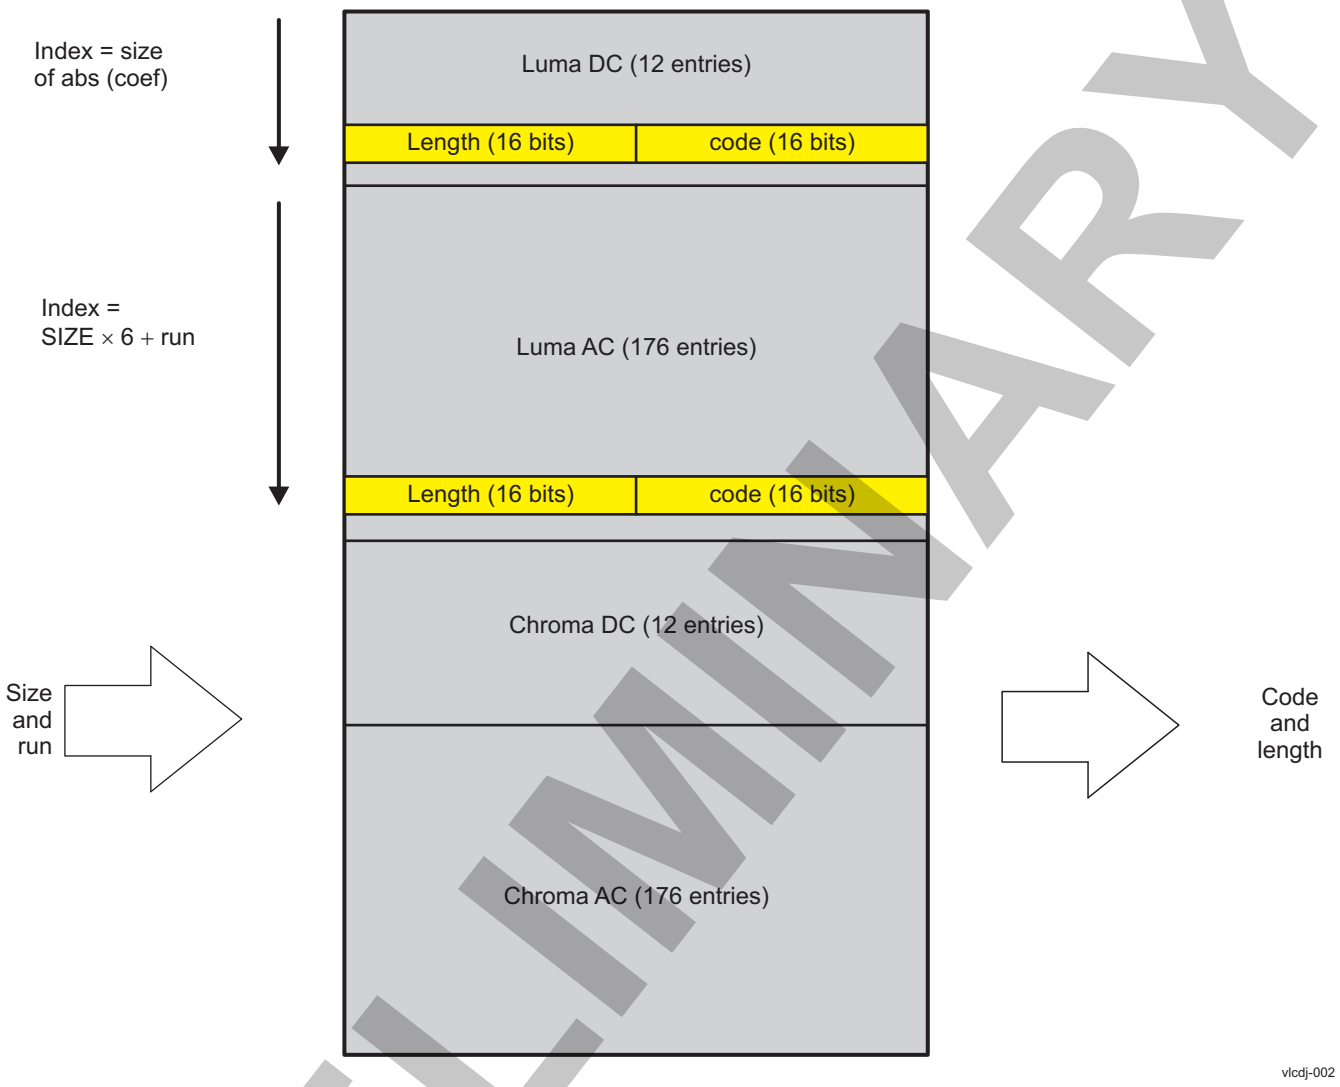
For DC tables, the index of each table corresponds to the size of the absolute value of the DC coefficient.

For AC tables, the index of each table corresponds to a formula including the size (of absolute value of nonzero AC coefficients) and the zero run: Index = SIZE × 16 + run. Because the size cannot be 0, the first 16 entries hold special symbols. EOB is at entry 0, and ZRL is at entry 15.

The size of a non-negative value is the number of bits required to represent the value (for example, a size of 4..7 = 3).

Figure 8-293 shows the organization of the Huffman encode table.

Figure 8-293. Huffman Encode Table Organization



8.4.6.3.8 Restart Marker

8.4.6.3.8.1 Restart Marker Insertion for Encode

As specified in the JPEG standard, the VLCDJ can insert a restart marker at a specified MCU interval (for information about restart markers, see Section 8.4.6.3.5, *VLDCJ in JPEG Decoding Flow*). Any remaining bits in the last partial byte are padded with 1s.

When enabled, the VLCDJ inserts a restart marker at the end of a group of MCUs. A partial byte is automatically padded with 1s.

8.4.6.3.8.2 Restart Marker Location Recording

To facilitate reordering of compressed JPEG data sections to achieve JPEG rotation, the VLCDJ also records the restart marker locations.

8.4.6.3.8.3 Restart Marker Handling for Decoding

Restart markers are handled automatically during MCU data decoding according to the JPEG standard. The DC predictors are reset at the MCU boundary where restart markers are present.

Because the handling of restart markers is complex, there is no check of the consistency of restart marker value or existence/nonexistence with the restart interval (which is not part of the decoder register setting). Correct JPEG files are decoded correctly. Incorrect JPEG files can escape error detection.

To decode correctly, in spite of the presence of restart markers, software must configure the VLCDJ with the correct byte pointer for the VLCDJ. To reset DC predictors to occur before an MCU, the byte pointer must point to the restart marker before the MCU data in the bitstream data. In other words, the VLCDJ does not search for the correct marker and resume MCU decoding after the marker. The VLCDJ detects the presence of the marker only at the MCU boundaries.

8.4.6.3.9 Encode/Decode Context Switching

The bitstream memory is organized as two banks of memory. When the VLCDJ performs only encoding or only decoding, the two banks are used to achieve VLCDJ and DMA concurrence, and automatic bitstream data DMA is supported.

When the VLCDJ performs one encode and one decode concurrently, both contexts can coexist in the configuration registers, because encode and decode configurations are in separate registers. The bitstream memory must be partitioned half-and-half between encode and decode. For example:

- VLCDJE_CBUF[11:10] START = 0x0
- VLCDJE_CBUF[27:26] END = 0x7FF
- VLCDJD_CBUF[11:10] START = 0x800
- VLCDJD_CBUF[27:26] END = 0xFFF

The byte pointers and the bitstream data DMA must be set up accordingly.

When the VLCDJ is encoding, the decode half of bitstream memory can be refilled by DMA. When the VLCDJ is decoding, the encode half of bitstream memory can be transferred out by DMA. Hardware does not support automatic triggering of DMA; software must submit DMA based on the byte pointer value of each context. For good SDRAM efficiency, the DMA block must be aligned correctly.

8.4.6.3.10 Using Sequential Block Mode for YUV4:4:4 Encoding/Decoding

In sequential block mode, because it deals with only one color component, the VLCDJ does the following:

- Uses DCPREDY for the DC predictor
- Uses the first quantizer matrix pointed by QM/QMR
- Starts from the first block pointed to by DCT
- Uses the first VLC/VLD table

Thus, to encode/decode YUV4:4:4 format using sequential block mode, software must switch context among Y, U, and V between initiations of the VLCDJ. Memory organization and registers are designed so that QM/QMR, DCT, and VLC/VLD tables can be swapped by changing the corresponding pointers in the registers. The DC predictor must be saved and restored.

For more information, see Section 8.4.6.4.6, *Example of YUV4:4:4 Encoding*.

8.4.6.3.11 Error Reporting

The VLCDJ can report the following decode errors:

- Invalid Huffman code
- Block exceeding 64 coefficients

NOTE: Decoding of an 0xFF byte followed by a nonzero byte is not reported as an error (for more information, see Section 8.4.6.3.5, *VLCDJ in JPEG Decoding Flow*).

When there is a decode error, VLCDJ operation is suspended immediately. Bit and byte pointers to the bitstream near where the error occurs are reflected in the VLCDJD_BSPTR[19:16] BITPTR and VLCDJD_BSPTR[11:0] BYTEPTR bit fields. The DCT coefficient index, in zigzag order of the task, near where the error occurs, is also reflected in a read-only bit field, VLCDJD_DCTERR[13:0] ERRPTR. For example, if decoding fails at the fifth coefficient of the third block of the VLCDJ task (which can be multiple MCUs), ERRPTR returns 2 × 64 + 4 = 195.

The IQ stage of the hardware does not stop and runs to completion. When there is a decode error, the DC predictor and decoded DCT coefficient outcomes are indeterminate.

Because the VLCDJ does not start in the middle of an MCU, software must recover from the error and configure the VLCDJ from an MCU boundary.

8.4.6.4 ISS SIMCOP VLCDJ Basic Programming Model

8.4.6.4.1 Initialization of Surrounding Modules

To initialize the VLCDJ, surrounding modules must be initialized. Table 8-1481 lists these modules.

Table 8-1481. Initialization of Surrounding Modules

Module	Minimum Required Setting	Optional Settings
CLKC	Enable the SIMCOP clock.	
Buffers	Configure VLCDJ access to the image buffer.	
SIMCOP CTRL		Configure SIMCOP CTRL to handle VLCDJ interrupts.

8.4.6.4.2 ISS SIMCOP VLCDJ Start and Register Modification During Processing

The module operation can be started with two mechanisms, depending on the status of the VLCDJ_CTRL[2] TRIG_SRC bit.

When the VLCDJ_CTRL[2] TRIG_SRC bit is set to 0 and the module is idle (the VLCDJ_CTRL[16] BUSY bit is set to 0), the module is started by setting the VLCDJ_CTRL[0] EN bit to 1. Any hardware start pulses are ignored. To simplify software control, in the same register write, changing the VLCDJ_CTRL[2] TRIG_SRC bit from 1 to 0 and setting the VLCDJ_CTRL[0] EN bit to 1 is recognized as a valid starting condition.

When the VLCDJ_CTRL[2] TRIG_SRC bit is set to 1, and the module is idle (the VLCDJ_CTRL[16] BUSY bit is set to 0), the module is started by the START_PULSE signal going active. Any software write to the VLCDJ_CTRL[0] EN bit is ignored.

During encoding, encode configuration registers must not be modified by software, while decode configuration registers can be freely modified.

During decoding, decode configuration registers must not be modified by software, while encode configuration registers can be freely modified.

8.4.6.4.3 JPEG Encoding

For JPEG encoding of a YUV4:2:0 image, eight MCUs per task, software first composes the JPEG header, which includes image dimension, YUV4:2:0 format, Huffman tables, quantizer matrices, and the start-of-scan marker and scan header, all before the MCU data. Software then sets up the encoding task, once per image, with the procedure listed in Table 8-1482.

Table 8-1482. JPEG Encoding Procedure

Step	Register/Bit Field	Value
Configure the encode configuration register.	VLCDJE_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJE_CFG[13:8] NMCUS	7 (eight MCUs)
	VLCDJE_CFG[2] RSTEN	0 (no restart marker)
Configure the DC predictor.	VLCDJE_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJE_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJE_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
Configure the input and output memories.	VLCDJE_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJE_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJE_CBUF[11:10] START	0 (bitstream starts from beginning of first quadrant of bitstream memory)
	VLCDJE_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)
	VLCDJE_DCTQM[13:4] DCT	0 (DCT coefficients at beginning of image buffer)

Table 8-1482. JPEG Encoding Procedure (continued)

Step	Register/Bit Field	Value
Configure Huffman and quantizer memory pointers.	VLCDJE_DCTQM[24:23] QMR	0 (quantizer matrix reciprocal at beginning of QMEM)
	VLCDJE_VLCTBL[11:2] ADDR	0 (VLC table at beginning of HUFMEM)
Start encode with automatic ring buffer management.	VLCDJ_CTRL[1] MODE	0 (encode mode)
	VLCDJ_CTRL[0] EN	1 (start VLCDJ operation)

For each group of eight MCUs (the VLCDJ does not care if these MCUs cross multiple MCU rows), software sets the VLCDJ_CTRL[0] EN bit to 1 (restart VLCDJ operation).

Alternately, the hardware sequencer can start the VLCDJ. Usually, DMA is also configured to bring in YUV4:2:0 image data as input to DCT, and DMA, DCT, and VLCDJ are all put under control of the hardware sequencer.

Bitstream data is managed automatically between the VLCDJ and DMA throughout JPEG encoding of MCUs.

NOTE: Many registers change during the encoding of a frame, but software is not required to access these registers, because the VLCDJ manages the status information between tasks.

The last hardware task may require a smaller number of MCUs (the VLCDJE_CFG[13:8] NMCUS bit field) to adjust for the number of MCUs in the last group.

After the last VLCDJ task for the image, software must disable the automatic bitstream buffer management and prepare for the next image by setting the following values (these can be issued as a single write):

- VLCDJ_CTRL[6] RBEN = 0 (disable automatic DMA interaction)
- VLCDJ_CTRL[7] CLRRB = 1

Finally, software must pad the last data byte with bit 1s, then place an end-of-image marker after the last data byte. The VLCDJE_BSPTR[11:0] BYTEPTR and VLCDJE_BSPTR[19:16] BITPTR bit fields indicate the locations of the last data byte and bit, respectively. Software must then set up DMA to transfer out the remaining data in bitstream memory.

The number of MCUs processed by hardware per task must be set according to image buffer allocation. For example, with 8 KiB available for DCT coefficient memory, and YUV4:2:0 format, it is possible to process 8K/(16 × 16× 1.5 × 2) = 10 MCUs. Because the bitstream DMA is automatic, bitstream data does not overflow bitstream memory for this many MCUs in densely coded JPEG.

8.4.6.4.4 JPEG Decoding

For JPEG decoding of an image, software first parses the JPEG header, which includes image dimension, YUV sampling, Huffman tables, quantizer matrices, and start-of-scan marker and scan header, before the MCU data. Software then sets up DMA to load bitstream data into the first half of bitstream memory.

The Huffman tables must be processed to generate hardware control tables and decode tables for a particular JPEG file, unless the Huffman tables match previously processed tables for which the hardware control and decode tables are known. The hardware control and decode tables must be transferred to HUFMEM.

If the JPEG file is YUV4:2:0, and image buffer memory is sufficient to process eight MCUs per hardware task, software must set up the decode task, once per image, with the procedure listed in Table 8-1483.

Table 8-1483. JPEG Decoding Procedure

Step	Register/Bit Field	Value
Configure the decode configuration register.	VLCDJD_CFG[1:0] FMT	0 (YUV4:2:0 mode)

Table 8-1483. JPEG Decoding Procedure (continued)

Step	Register/Bit Field	Value
	VLCDJD_CFG[13:8] NMCUS	7 (eight MCUs)
	VLCDJD_CFG[2] RSTEN	0 (no restart marker)
Configure the DC predictor.	VLCDJD_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJD_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJD_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
Configure the input and output memories.	VLCDJD_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJD_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJD_CBUF[11:10] START	0 (bitstream starts from beginning of first quadrant of bitstream memory)
	VLCDJD_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)
	VLCDJD_DCTQM[13:4] DCT	0 (DCT coefficients at the beginning of the image buffer)
Configure Huffman and quantizer memory pointers.	VLCDJD_DCTQM[24:23] QM	0 (quantizer matrix at beginning of QMEM)
	VLCDJD_CTRLTBL[11:2] ADDR	0 (typically, control table is placed at the beginning of HUFMEM)
	VLCDJD_DCDTBL01[11:2] TBL0	30 (typically, the first decode table follows the control table, 60 shorts = 120 bytes = 30 words)
	VLCDJD_DCDTBL01[27:18] TBL1	? (where the second decode table starts)
	VLCDJD_DCDTBL23[11:2] TBL2	? (where the third decode table starts)
	VLCDJD_DCDTBL23[27:18] TBL3	? (where the fourth decode table starts)
Start decode with automatic ring buffer management.	VLCDJ_CTRL[1] MODE	1 (decode mode)
	VLCDJ_CTRL[0] EN	1 (start VLCDJ operation)

For each group of eight MCUs (the VLCDJ does not care if these MCUs cross multiple MCU rows), software sets the VLCDJ_CTRL[0] EN bit to 1 (start VLCDJ operation).

Alternately, the hardware sequencer can start the VLCDJ, as well as control buffer switches and coordinate among the VLCDJ, DCT, and DMA.

Bitstream data is managed automatically between the VLCDJ and DMA throughout JPEG encoding of MCUs.

NOTE: Many registers change during the decoding of a frame, but software is not required to access these registers, because the VLCDJ manages the status information between tasks.

The last hardware task may require a smaller number of MCUs (the VLCDJD_CFG[13:8] NMCUS bit field) to adjust for the number of MCUs in the last group.

After the last VLCDJ task for the image, software must disable the automatic bitstream buffer management and prepare for the next image by setting the following values (these can be issued as a single write):

- VLCDJ_CTRL[6] RBEN = 0 (disable automatic DMA interaction)
- VLCDJ_CTRL[7] CLRRB = 1

Any remaining bitstream data in bitstream memory afterward is harmless, because before the VLCDJ processes the next image decode, new bitstream data must be brought in, thereby overwriting the old data, and bit/byte pointers must be reset to the beginning of bitstream memory.

The number of MCUs processed by hardware per task must be set according to image buffer allocation. For example, with 16 KiB available for DCT coefficient memory, and YUV4:2:0 format, it is possible to process 16K/(16 × 16 × 1.5 × 2) = 21 MCUs. Because the bitstream DMA is automatic, there is no bitstream data underrun for this many MCUs.

8.4.6.4.5 Concurrent JPEG Encoding and Decoding

For concurrent decoding and encoding, the two operations are configured separately but similarly.

Half of bitstream memory is used for encoding (for example, the first half), and the rest is used for decoding. Automatic bitstream DMA does not work in this case, so the number of MCUs must accommodate the worst-case bitstream size per MCU.

Theoretically, the worst case is 16 bits of Huffman code + 12 additional bits per coefficient, or 28 bits per coefficient. With natural images, there are typically about 8 bits per pixel when quantizers are minimal (that is, all 1s). With 16 bits per coefficient, or 768 bytes per MCU in YUV4:2:0 (this is 24 bits per pixel and three times the typical worst case), half of bitstream memory is 2 KiB, which can safely hold two MCUs.

In this case, half of QMEM is used for encoding and half is used for decoding. Encode and decode Huffman tables are placed so that they coexist in HUFFMEM.

The Huffman tables for encoding, decoding, and quantizer matrices must be placed accordingly in HUFMEM and QMEM. Bitstream data is filled at the second half of bitstream memory for decoding.

Register fields are configured as listed in Table 8-1484.

Table 8-1484. Concurrent JPEG Encoding and Decoding

Step	Register/Bit Field	Value
Configure the encode register.	VLCDJE_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJE_CFG[13:8] NMCUS	1 (two MCUs)
	VLCDJD_CFG[2] RSTEN	0 (no restart marker)
	VLCDJE_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJE_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJE_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
	VLCDJE_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJE_DCTQM[13:4] DCT	0 (DCT coefficients at beginning of image buffer)
Configure the decode register.	VLCDJD_CFG[1:0] FMT	0 (YUV4:2:0 mode)
	VLCDJD_CFG[13:8] NMCUS	1 (two MCUs)
	VLCDJD_CFG[2] RSTEN	0 (no restart marker)
	VLCDJD_DCPREDY[11:0] PREDY	0 (reset DC predictor for Y)
	VLCDJD_DCPREDUV[11:0] PREDU	0 (reset DC predictors for U)
	VLCDJD_DCPREDUV[27:16] PREDV	0 (reset DC predictors for V)
	VLCDJD_BSPTR[19:16] BITPTR	8 (initially empty byte, thus 8 free bits)
	VLCDJD_DCTQM[13:4] DCT	0 (DCT coefficients at the beginning of the image buffer)
Configure the byte pointer to bitstream memory.	VLCDJE_BSPTR[11:0] BYTEPTR	0 (beginning of bitstream memory)
	VLCDJD_BSPTR[11:0] BYTEPTR	0x800 (beginning of bitstream memory second half)
Configure the bitstream memory partition.	VLCDJE_CBUF[11:10] START	0 (bitstream starts at beginning of first quadrant of bitstream memory)
	VLCDJE_CBUF[27:26] END	1 (bitstream ends at end of second quadrant of bitstream memory)
	VLCDJD_CBUF[11:10] START	2 (bitstream starts at beginning of third quadrant of bitstream memory)
	VLCDJD_CBUF[27:26] END	3 (bitstream ends at end of fourth quadrant of bitstream memory)

Table 8-1484. Concurrent JPEG Encoding and Decoding (continued)

Step	Register/Bit Field	Value
Configure the quantizer matrix pointer.	VLCDJE_DCTQM[24:23] QMR	0 (quantizer matrix at beginning of QMEM)
	VLCDJD_DCTQM[24:23] QMR	2 (quantizer matrix at second half of QMEM)
Configure Huffman tables.	VLCDJE_VLCTBL[11:2] ADDR	0 (VLC table at beginning of HUFMEM)
	VLCDJD_CTRLTBL[11:2] ADDR	376 (after VLC table, 2 × (24 + 352) shorts = 376 words)
	VLCDJD_DCDTBL01[11:2] TBL0	406 (after control table of 30 words)
	VLCDJD_DCDTBL01[27:18] TBL1	? (where the second decode table starts)
	VLCDJD_DCDTBL23[11:2] TBL2	? (where the third decode table starts)
	VLCDJD_DCDTBL23[27:18] TBL3	? (where the fourth decode table starts)

Software sets the following values to start encoding:

- VLCDJ_CTRL[1] MODE = 0 (encode mode)
- VLCDJ_CTRL[0] EN = 1 (start VLCDJ operation)

When the VLCDJ completion interrupt is detected by software, encoding is complete and software must service the encoded bitstream data in the first half of bitstream memory, letting hardware access the second half of the bitstream for decoding. Software sets up bitstream writes to transfer the encoded bitstream from bitstream memory[0] to bitstream memory[128 × (VLCDJE_BSPTR[11:0] BYTEPTR/128)] (rounding down to 128-byte alignment improves SDRAM efficiency). Software must identify the bitstream data already transferred out, for the next round of servicing encoded bitstream data. Software must also service to-encode input data to the DCT.

After kicking off encode DMAs, without waiting for DMA completion, software must set the following values to start VLCDJ decoding in parallel with the DMA:

- VLCDJ_CTRL[1] MODE = 1 (decode mode)
- VLCDJ_CTRL[0] EN = 1 (start VLCDJ operation)

When the VLCDJ completion interrupt is detected by software, decoding is complete and software must service the decoded bitstream data in the second half of bitstream memory, letting hardware access the first half of the bitstream for encoding. Software sets up bitstream writes to transfer the bitstream to be decoded from bitstream memory[0] to bitstream memory[128 × (VLCDJD_BSPTR[11:0] BYTEPTR/128)] (rounding down to 128-byte alignment improves SDRAM efficiency). Software must identify the bitstream data already transferred in, for the next round of servicing bitstream data to be decoded. Software must also service decoded image data in the output image buffer of the DCT.

After kicking off decode DMAs, without waiting for DMA completion, software must start VLCDJ encoding in parallel with the DMA.

Software must continue to alternate between encoding and decoding until the image completes.

Figure 8-294 shows the concurrence schedule for JPEG encoding and decoding.

Figure 8-294. Concurrence Schedule for JPEG Encoding and Decoding

DMA	E[0]		E[1]		E[2]		E[3]					
in			D[0]		D[1]		D[2]		D[3]			
DCT		E[0]		E[1]	D[0]	E[2]	D[1]	E[3]	D[2]		D[3]	
VLCD			E[0]	D[0]	E[1]	D[1]	E[2]	D[2]	E[3]	D[3]		
DMA				E[0]		E[1]		E[2]		E[3]		
out						D[0]		D[1]		D[2]		D[3]

vlcdj-007

Management of bitstream I/O and image I/O is heavy in intervals of only two MCUs. It is better to run only encoding for many MCUs, switch context, and then run decoding for many MCUs.

When running JPEG transcoding, decoding a picture and re-encoding it, to adjust quantizers and/or remove/insert restart markers, it can be more efficient to run encode and decode concurrently in VLCDJ, skipping DCT and image I/O DMA altogether. In this case, software handles only bitstream data I/O, which is more manageable.

Figure 8-295 shows the concurrence schedule.

Figure 8-295. Concurrence Schedule for JPEG Transcoding

DMA in	D[0]		D[1]		D[2]		D[3]			
VLCD		D[0]	E[0]	D[1]	E[1]	D[2]	E[2]	D[3]	E[3]	
DMA out				E[0]		E[1]		E[2]		E[3]

vlcdj-008

8.4.6.4.5.1 DMA and Buffer Manual Management

When the VLCDJ performs one encode and one decode concurrently, both contexts can coexist in the configuration registers, because encode and decode configurations are in separate registers. The bitstream memory must be partitioned half-and-half between encode and decode:

- VLCDJE_CBUF[11:10] START = 0 (0x0)
- VLCDJE_CBUF[27:26] END = 1 (0x7FF)
- VLCDJD_CBUF[11:10] START = 2 (0x800)
- VLCDJD_CBUF[27:26] END = 3 (0xFFF)

The byte pointers and the bitstream data DMA must be set up accordingly.

When the VLCDJ is encoding, the decode half of the bitstream memory can be refilled by DMA. When the VLCDJ is decoding, the encode half of the bitstream memory can be transferred out by DMA. Hardware does not support automatic triggering of DMA; software must submit DMA based on the byte pointer value of each context. For greater SDRAM efficiency, the DMA block must be aligned correctly. For example, the pseudo code that sets up the DMA for an encode task may appear as:

```
new_dma_ptr = VLCDJ_BSPTR.BYTEPTR & ~0x3F; // align to 64-byte

if (new_dma_ptr > saved_dma_ptr)
{
 setup_dma(saved_dma_ptr, new_dma_ptr - saved_dma_ptr);
 // start DMA at saved_dma_ptr, length = new_dma_ptr - saved_dma_ptr
}
else // wraps around, need to DMA 2 blocks
{
 setup_dma(saved_dma_ptr, 0x800 - saved_dma_ptr);
 setup_dma(saved_dma_ptr, new_dma_ptr);
}

saved_dma_ptr = new_dma_ptr;
```

This DMA setup can be carried out concurrently with VLCDJ operation; thus, this code is executed with each encode or decode task. When the VLCDJ is encoding, software can access the decode bit/byte points to set up DMA for decoding, and vice versa.

Because hardware stalling does not work in this case, the number of MCUs must be configured so that in the worst case there is no bitstream data overrun or underrun.

The bitstream buffer can be allocated at a quarter of bitstream memory granularity, or 1 KiB. This allows at most four separate buffers to coexist in bitstream memory.

If multiple encode and/or decode threads are performed concurrently, software must save and restore the appropriate configuration registers. The register map has common registers in one group, encode registers in another group, and decode registers in a third group. Bitstream memory partitioning and corresponding DMA submission are left to software.

8.4.6.4.6 Example of YUV4:4:4 Encoding

The following pseudo code shows the general sequence involved in YUV4:4:4 encoding. Decoding can be similarly derived.

```
encode_yuv444()
{
 VLCDJ_CTRL[1] MODE = 0; /* encode */
 VLCDJE_CFG[1:0] FMT = 2; /* sequential block mode */
 VLCDJE_CFG[13:8] NMCUS = 0; /* 1 block at a time */
 pred_y = 0;
 pred_u = 0;
 pred_v = 0;

 for (i=0; i<num_mcus; i++)
 {
 VLCDJE_DCPREDY = pred_y; /* restore Y context */
 VLCDJE_DCT = DCT_Y;
 VLCDJE_QMR = QMR_Y;
 VLCDJE_VLCTBL = VLC_Y;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for Y */

 pred_y = VLCDJE_DCPREDY; /* save Y context */
 VLCDJE_DCPREDY = pred_u; /* restore U context */
 VLCDJE_DCT = DCT_U;
 VLCDJE_QMR = QMR_UV;
 VLCDJE_VLCTBL = VLC_UV;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for U */

 pred_u = VLCDJE_DCPREDY; /* save U context */
 VLCDJE_DCPREDY = pred_v; /* restore V context */
 VLCDJE_DCT = DCT_V;

 VLCDJ_CTRL[0] EN = 1; /* kick off VLCDJ for V */

 pred_v = VLCDJE_DCPREDY; /* save V context */
 }
}
```

8.4.6.4.7 Example of Huffman Encode and Decode Tables

8.4.6.4.7.1 Huffman Encode Table

Sample JPEG Luma DC encode table:

```
unsigned short jpeg_dc_y[24] =
{
 0x0000,0x0002,0x0002,0x0003,0x0003,0x0003,0x0004,0x0003,
 0x0005,0x0003,0x0006,0x0003,0x000e,0x0004,0x001e,0x0005,
 0x003e,0x0006,0x007e,0x0007,0x00fe,0x0008,0x01fe,0x0009
};
```

Table 8-1485 corresponds to Table 17 in the JPEG standard *ISO/IEC JTC1/SC29/WG10 Standard 10918-1 (JPEG), Information Technology – Digital Compression and Coding of Continuous-Tone Still Images – Requirements and Guidelines.*

Table 8-1485. Sample Luma DC Huffman Code Table

Category	Code Length	Code Word
0	2	00
1	3	010
2	3	011
3	3	100
4	3	101
5	3	110
6	4	1110
7	5	11110
8	6	111110
9	7	1111110
10	8	11111110
11	9	111111110

For example if we want to code a DC coefficient value of –5:

Use abs(–5) = 5 to select a size of 3. Look up the encode table to find:

- jpeg_dc_y[2 × 3] = 4 (code)
- jpeg_dc_y[2 × 3 + 1] = 3 (length)

Thus, the VLCDJ adds 100 to the bitstream as the Huffman code of the size.

The additional bits for negative coefficients are ones complement of the absolute value, so for –5, this is 010, or 2. After the Huffman code of the size, the VLCDJ adds 010 to the bitstream.

The AC coefficient table is the same, except that the VLCDJ uses 16 × size + run to index the encode table.

8.4.6.4.7.2 Huffman Decode Tables

Sample JPEG Luma DC control and decode tables:

```
unsigned short jpeg_dc_y_ctl_tbl[13]=
{
 0x0000,0x0000,0x0000,0x0000,0x1800,0x2001,0x2802,0x3003,
 0x3804,0x4005,0x4806,0x4806,0x4806
};

unsigned short jpeg_dc_y_dcd_tbl[14]=
{
 0x0000,0x480b,0x400a,0x3809,0x3008,0x2807,0x2006,0x1805,
 0x1804,0x1803,0x1802,0x1801,0x1000,0x1000
};
```

These tables contain the same information as Table 8-1485, which complies with the JPEG standard.

16	BUSY	Idle/busy status 0: Idle 1: Busy	R	0
15:8	RESERVED	Read returns 0.	R	0x00
7	CLRRB	Write only; read returns 0.	W	0
6	RBEN	Enable RB signaling.	RW	0
5	INTEN_ERR	Interrupt enable for decode error 0: No interrupt generated on decode error 1: Interrupt generated on decode error	RW	0
4	INTEN_DONE	Interrupt enable for task completion. DONE_VLCD is not gated by this and is always asserted at task completion. 0: No interrupt generated on task completion 1: Interrupt generated on task completion	RW	0

Bits	Field Name	Description	Type	Reset
3	AUTOGATING	Internal clock gating on OCP clock and functional clock 0: Clocks are free-running. 1: Clocks are gated off in sub-blocks that are not required for operation.	RW	1
2	TRIG_SRC	Which mechanism starts VLCDJ operation 0: MMR write to VLCDJ_CTRL.EN 1: Hardware start signal	RW	0
1	MODE	0: Encode 1: Decode	RW	0
0	EN	Module enable by software (write-only, read returns 0). When TRIG_SRC = 0 and BUSY = 0, set this field to 1 to start VLCDJ. When TRIG_SRC = 1, writes to this field are ignored. Setting TRIG_SRC = 0 and EN = 1 on the same register write is recognized.	W	0

Description	Decode Huffman tables 2 and 3		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DCDTBL3								RESERVED								DCDTBL2							RESERVED

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Read returns 0.	R	0x0
27:18	DCDTBL3	Starting byte address of decode table 3, 32-bit word. Software can write a byte address into the lower 16 bits of the register. This is for Chroma AC.	RW	0x000
17:12	RESERVED	Read returns 0.	R	0x00
11:2	DCDTBL2	Starting byte address of decode table 2, 32-bit word. Software can write a byte address into the lower 16 bits of the register. This is for Chroma DC.	RW	0x000
1:0	RESERVED	Read returns 0.	R	0x0

Table 8-1529. Register Call Summary for Register VLCDJD_DCDTBL23

ISS SIMCOP Variable Length Coder/Decoder for JPEG (VLCDJ) Module

- JPEG Decoding: [2] [3]
- Concurrent JPEG Encoding and Decoding: [4] [5]
- ISS SIMCOP VLCDJ Register Summary: [6]

Table 8-1530. VLCDJD_DCTERR

Address Offset	0x0000 0064		
Physical Address	0x5202 0664 0x5506 0664	**Instance**	VLCDJ_MAIN_L3 VLCDJ_IPU
Description			
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																								ERRPTR							

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Read returns 0.	R	0x00000
13:0	ERRPTR	Byte address pointer to DCT coefficients, near where decode error occurs (read-only)	R	0x0000

Table 8-1531. Register Call Summary for Register VLCDJD_DCTERR

ISS SIMCOP Variable Length Coder/Decoder for JPEG (VLCDJ) Module

- Error Reporting: [0]
- ISS SIMCOP VLCDJ Register Summary: [1]

8.4.7 ISS SIMCOP Rotation Accelerator (ROT) Module

This section describes the rotation accelerator (ROT) module in the still-image coprocessor (SIMCOP) subsystem.
